Preface

The American Psychological Association (APA) is proud to offer the second edition of its critically acclaimed and best-selling APA Dictionary of Psychology. The first edition, copyright 2007, included some 25,000 entries. That corpus was vetted by nearly 100 experts in the field of psychology and labored over for almost a decade by APA Reference staff and associated lexicographers. The first edition reflected current dimensions of the field as a whole, with entries ranging from the fundamental mainstays to those representative of the evolving language of a diversely oriented and porous field, including numerous topical overlaps in the other social, behavioral, and health sciences. This characterization of coverage remains true in the second edition.

APA collaborated intensively on the first edition with Market House Books Ltd (MHB), a British firm with, to date, 45 years' experience in creating reference books for both British and American markets. Broadly, APA Reference staff managed the dictionary's conceptual and editorial development, and MHB staff handled its administration, copyediting, and composition. (For an extensive history of the first edition process, the interested reader may consult its preface.) This professionally and personally rewarding collaboration continued with the preparation of the second edition.

As with the parent edition, the second edition is intended for psychologists, graduate and undergraduate psychology students, practitioners and researchers in allied mental health professions (e.g., psychiatrists, nurses, and social workers), and all thoughtful readers who are curious about mental health issues; psychological history and theories; and, perhaps most important, psychological assessment, diagnosis, and therapy. In order to engage such a broad audience and fulfill its varied expectations, every effort has been made to present the dictionary's entries in a clear, jargon-free style that should enable them to be understood not only by experts but also by readers who lack specialized knowledge.

Evolution of the Second Edition

If the process of vetting, compiling, reviewing, editing, and composing the parent edition seemed an almost Herculean task, some eight years later, the process of preparing the second edition was nearly as complex, although now, naturally, a large, established corpus of entries already existed as a solid basis from which to work. It is not an exaggeration to say that the second edition of the APA Dictionary of Psychology began prior to the release date of the first edition and initially evolved through work on several smaller, interim dictionaries for specific users.

For instance, an abridgment for general readers and a lightweight, portable collegiate version had been planned even before the first edition went to the printer. The results of those first efforts were, respectively, the APA Concise Dictionary of Psychology (2009; 10,000 entries) and the APA College Dictionary of Psychology (2009; 5,000 entries). Two subfield-focused collections followed: the APA Dictionary of Clinical Psychology (2013; 11,000 entries) and the APA Dictionary of Lifespan Developmental Psychology (2013; 8,000 entries). Staff's ongoing encounters with the material of the first edition in fashioning these derivatives resulted in many textual refinements, in many structural alterations (e.g., dropping entries, collapsing them, etc.), and, indeed, in the collection of both missing and entirely new vocabulary, all of which are now included in the second edition.

APA recently released one other specialty reference, the APA Dictionary of Statistics and Research Methods (2014, 4,100 entries). By some reckonings, this may have been the most important release between the two editions of the full dictionary: The statistics and methods dictionary did not simply derive from the first edition; under the editorship of Sheldon Zedeck and his editorial board, it more than doubled the number of entries of the original coverage of these two highly interrelated fields. A substantial number of these entries has been selected and adapted for the second edition as well.

Even while staff was busy with the preparation and release of these resources, APA Reference was engaged in organizing a series of editorial "rounds" to prepare for the release of this second edition of the full APA Dictionary of Psychology, of which there would be broadly three prior to the final production stages.

Round 1. Over 70 psychologists and allied health professionals were commissioned to review substantively about 18,000 (of the original 25,000) first-edition entries, organized into 45 core content areas. The superordinate areas of focus were, among others, clinical psychology, neuroscience and cognitive neuroscience, lifespan developmental psychology, and personality and social psychology. On the basis of these peer reviews, numerous entries were revised and updated, others now considered obsolete were removed, and roughly 2,000 altogether new entries were drafted. Two somewhat anomalous entry categories—biographical and institutional—were also reviewed in order to expand coverage and to update existing material. Indeed, the editorial staff undertook a significant expansion and novel treatment of biographies for the second edition: Now the entries on important figures in the history of psychology—and from areas with significant impact on the field—are much briefer and have been collected into a separate section following the lexical entries, a change of procedure and scope that allowed for a quadrupling of biographical coverage. In addition most of the biographical entries now carry cross-references to lexical entries in the preceding section.

Round 2. The 45 core entry subsets next passed through a second round of development, in which APA Reference staff and its consultant lexicographers refined the peer-reviewed existing and newly composed entries, with occasional further assistance from the original review panel. Reference staff additionally incorporated many minor corrections and substantive revisions collected by APA in the years since the release of the first edition.

During this round, staff also reviewed the remainder of the dictionary's original corpus of entries, about 7,000 in roughly 46 content areas, for (a) possible datedness; (b) typographical or grammatical errors; and (c) other concerns, such as lack of clarity or inconsistencies with related entries. Staff further decided that coverage in several areas would be cut back significantly. For instance, staff judi-
ciously pruned the first edition’s inclusion of the historical lexicon (e.g., that related to the field’s roots in philosophy and the discourse of logic). Not the least of our concerns was a desire to make space for new entries that had accumulated in the intervening years since the first edition.

**Round 3.** The interconnectedness and, indeed, interdependency of the entries in a specialty dictionary is something that is not typically visible to most users where an A-to-Z format is involved—nor does it need to be. Regular users perhaps only begin to perceive these ligaments when they take into account the extensive cross-referencing that underlies the dictionary and gives it its depth and broader utility. Thus, Round 3 centered on the effort to make sure that all the entries work together smoothly, a task that is more daunting than it may sound, especially when the clock is ticking down toward the production phase. An additional challenge was to reconcile the entries with those incorporated (about 2,000) from the more than doubled corpus in the new APA Dictionary of Statistics and Research Methods. In brief, it was essential not only to incorporate as much of the revised and added material as possible from this dictionary to the second edition, but also to adapt that material, as necessary, in the context of the greater number and diversity of entries in the full dictionary.

At the conclusion of this round, the content was returned to Market House Books for final editorial and lexicographical polishing and for the production phase.

**A Note Regarding Diagnostic Classification of Mental and Behavioral Disorders**

During the editorial review and production of the APA Dictionary of Psychology, Second Edition, a significant and long-developing shift occurred for U.S. psychology, with the move away from the use of the Diagnostic and Statistical Manual of Mental Disorders (DSM) to the mandated use of a diagnostic system based on the International Statistical Classification of Diseases and Related Health Problems (ICD) as the official diagnostic system in the United States. The ICD is the global standard in diagnostic classification for health reporting and clinical applications for mental disorders as well as for all other medical diagnoses. Many countries have used the ICD–10 (the edition released in 1992) since about 1995, but it was only adopted in the United States in 2015, the year of release for the APA Dictionary of Psychology, Second Edition. Preparation of the ICD–11, currently scheduled for release in 2017, is underway.

It may be seen, thus, that the timing for the release of the second edition of the dictionary proved to be problematic in relation to its editorial development. As a consequence, pertinent entries in this edition continue to refer to the two most recent editions of the Diagnostic and Statistical Manual of Mental Disorders, the DSM–IV–TR and the DSM–5. This is not entirely inappropriate or illogical, given the transitional stage in which most of American psychology finds itself, as clinicians and therapists gradually make the move to the use of the ICD. In the meantime, the American Psychological Association is publishing a number of books in both print and electronic form, training manuals, application software, and the like to educate its members about this significant transition, and, in years ahead, the APA Dictionary of Psychology will undoubtedly reflect this shift in clinical diagnosis in a revised edition.

**Acknowledgments**

First and foremost, I wish to thank the APA Reference staff, under the indefatigable and expert project direction of Marion Osmun, and the staff of Market House Books. From the latter, we sadly lost an important content editor with the passing of John Daintith, but we continued to benefit from the expertise of Jonathan Law and Elizabeth Martin in editorial and Amanda Garner-Hay and Anne Kerr in production. I would also like to single out APA Reference Manager Patricia Mathis, not only for her work in this edition but also for her editorial supervision of the statistics and research methods dictionary, which is so tidily reflected here. A complete list of all editorial participants can be found immediately hereafter. My sincere thanks go out to all of them.

It is challenging to get any edition of a dictionary to press. This is partly due to the challenge of loosening one’s grip of the editorial process to say: Now is the time to send this edition out into the world. That time has come, however, and the consolation rests in the hope that APA will continue to devote time and resources to keeping alive this attempt to capture the lexicon of psychology and make it accessible to professional and layperson alike in the form of new derivatives and, indeed, new editions.

Guide to the Dictionary

Headwords

All terms defined in the dictionary are described as headwords and are indicated in large boldface type:

aberrant response an abnormal or atypical behavior, commonly targeted during a behavioral intervention.

In this case, the headword is aberrant response.

Alphabetical Order

The arrangement of headwords is on a strict letter-by-letter basis rather than by word. For example, the following sequence of headwords is used:

game
game reasoning
gamete
gamete intrafallopian transfer
game theory

Note that the headword game theory does not directly follow game reasoning. In dictionaries, spaces, hyphens, or dashes between words are ignored in determining alphabetical order.

If two headwords differ only in whether the letters are upper- or lowercase, then the lowercase version comes first. For example, ecstasy (the emotional state) precedes Ecstasy (the drug).

In the majority of cases, numbers in headwords are ignored for the purposes of alphabetization. For example, 6-hydroxydopamine is alphabetized as if it were simply hydroxydopamine. The rare exceptions to this rule are terms in which the number is an essential element of the headword. For example, 80:20 rule follows eighth cranial nerve and 22q11.2 deletion syndrome follows twelve-step program.

In addition, in clusters of two or more headwords differing only by Arabic or Roman number, headword positioning necessarily follows numerical order within that cluster. Thus, Type I cell precedes Type II cell, Type III cell, and Type IV cell, but these numbers are otherwise ignored in the overall alphabetization of this cluster against adjacent terms: That is, the operative term cell means that this cluster alphabetically follows Type A personality and Type B personality.

Superscript and subscript numbers in headwords are also ignored for alphabetization purposes. Thus, for example, $H_1$ and $r^2$ are positioned at the beginning of H and R, respectively. However, headwords with super- or subscripted letters and words are positioned according to the usual letter-by-letter approach to alphabetization. Thus, for example, $S^0$ is positioned between sculpting and SD, and $r_{effect size}$ is positioned between referred sensation and reflectance.

Abbreviations and Variants

Common abbreviations of headwords, as well as alternative spellings and other variant forms, are given in parentheses immediately after the headword:

American Association of Clinical Psychologists (AACP) a professional organization founded in 1917.

dichelophagia (chilophagia) n. the repeated biting of one’s own lips.

However, when a term is more commonly known in the abbreviated form than in the full form, the entry is given at the abbreviation. A typical example is

DNA deoxyribonucleic acid: one of the two types of nucleic acid found in living organisms.

Parts of Speech

Part-of-speech labels are given for single words (but not for multiple-word headwords). The labels immediately follow the headword (and any variant) and are in italic type:

hue n. the subjective quality of color, which is determined primarily by wavelength and secondarily by amplitude.

In this example, the headword is a noun. The labels used in this dictionary are

adj. adjective
adv. adverb
n. noun
pl. n. plural noun
pron. pronoun
vb. verb

In addition, labels are used for

combining form
prefix
suffix

Irregular Forms

Irregular plurals of words are placed after the part-of-speech label in parentheses:

ampulla n. (pl. ampullae) any saclike enlargement of a duct or passageway.

cerebellum n. (pl. cerebella) a portion of the hindbrain dorsal to the rest of the brainstem, to which it is connected by the cerebellar peduncles.

A small number of noun headwords are most commonly
Guide to the Dictionary

used in their plural form, in which case the singular inflection is given:

**data** pl. n. (sing. datum) observations or measurements, usually quantified and obtained in the course of research.

**labia** pl. n. (sing. labium) four lip-shaped folds of tissue forming part of the female external genitalia (see VULVA).

Sense Numbers

Many entries have two or more distinct meanings (senses). These are indicated by boldface numbers. For example, the headword **reason** has five distinct senses:

**reason** 1. n. consecutive thought, as in deduction or induction. Although at one time reason was considered a mental faculty, this meaning is typically not intended in current usage. See DEDUCTIVE REASONING; INDUCTIVE REASONING. 2. n. in philosophy, the intellect (or NOUS) regarded as the source of true knowledge. See RATIONALISM. 3. n. soundness of mind. 4. n. a statement offered to justify an action or decision or to explain the occurrence of an event. 5. vb. see REASONING.

Cross-references

The dictionary contains a large number of cross-references, which are indicated in small capitals typeface. Cross-references can occur in normal running text:

**absent state** a vacant, dreamlike state of detachment that may occur in COMPLEX PARTIAL SEIZURES.

In this example, the cross-reference is to the entry on complex partial seizures.

Cross-references may also be introduced by “See,” “See also,” or “Compare”:

**saccade** n. a rapid eye movement that allows visual fixation to jump from one location to another in the visual field. Once initiated, a saccade cannot change course. See also MICROSCACADES. Compare SMOOTH-PURSUIT EYE MOVEMENT.

In this example, the cross-references are to the entries on microsaccades and smooth-pursuit eye movement.

Note that not all headwords in the book are cross-referenced when they are used in definitions. The intention is to direct the user of the dictionary to entries that will give additional information connected with the term of interest.

Some entries consist simply of a cross-reference. Entries for most abbreviations and for variants are treated in this way:

**AACP** abbreviation for AMERICAN ASSOCIATION OF CLINICAL PSYCHOLOGISTS.

**chilophagia** n. see CHILOPHAGIA.

Such cross-reference entries are also provided for terms treated as hidden entries or synonyms (see below).

Hidden Entries

Sometimes it is helpful to the user to define a term under the entry for a more general or a related term, rather than under its own headword. For example, the term **abductor** is treated as a hidden entry under the headword **abduction**:

**abduction** n. 1. movement of a limb away from the midline of the body. Any muscle that produces such movement is called an **abductor**. Compare ADDUCTION.

Note that the hidden entry is indicated in a sans serif semi-bold typeface.

Another example is the hidden entry for **expiration** at the headword **ablation**:

**ablation** n. the removal or destruction of part of a biological tissue or structure by a surgical procedure (e.g., mechanical or laser excision) or a toxic substance (e.g., chondroitinase), usually for treatment or to study its function. When the entire tissue or structure is excised, the process is called **expiration**. See also **BIOPSY**.

In such cases, there is a simple cross-reference from the headword for the hidden entry:

**expiration** n. see ABLATION.

Synonyms

Many of the terms defined in the dictionary have synonyms, which are displayed in boldface at the end of a given definition, preceded by “Also called.” If a headword has more than one synonym, these are presented in alphabetical order. Our general policy is to put definitions under the most commonly used names; alternative names are treated as cross-reference entries. Examples:

**acetone** n. a colorless volatile liquid with a sweet, fruity odor that forms in excessive amounts in the blood of people with diabetes or other metabolic disorders in which the body uses fat instead of glucose (sugar) for energy. Also called **dimethyl ketone**.

**dimethyl ketone** see ACETONE.

**diminished responsibility** a form of AFFIRMATIVE DEFENSE in which evidence of mental abnormality is presented to mitigate or reduce a defendant’s accountability for an act. It is distinct from an **INSANITY DEFENSE**, which takes an all-or-none perspective with regard to CRIMINAL RESPONSIBILITY. Also called **limited responsibility**. See also **PARTIAL INSANITY**.

**limited responsibility** see DIMINISHED RESPONSIBILITY.

Etymologies

Many entries provide information about the origin of the term defined. This information usually will take the form of brief biographical notes on figures who are identified in the headwords (eponymous entries) or who may have originated a term or significantly developed its meaning. In most cases, etymologies are presented in brackets at the end of a definition, following any synonyms and terminal
cross-references, but may alternatively be embedded within the definition. Some examples:

**Ajzen–Fishbein model** the original framework for what is now known as the **theory of reasoned action**. [Icek Ajzen (1942–) and Martin Fishbein (1936–2009), U.S. social psychologists]

**anorthoscopic perception** the holistically perceived form of an object revealed over time through a narrow slit aperture. It is distinct from ordinary object perception in that the perceived object arises from the temporal integration of visual information derived from the same retinotopic area (i.e., there is no spatially extended retinotopic image). Also called **slit viewing**. See **anorthoscope**. [first reported in 1862 by German astrophysicist Johann Karl Friedrich Zöllner (1834–1882)]

Note that figures who are identified in eponymous headwords are treated as hidden entries—that is, their surnames are printed in sans serif semibold type. Note also that some figures mentioned in etymologies are the subject of an entry themselves (in the dictionary’s biographical section), in which case their surnames are treated as cross-references and set in small capital letters. Example:

**animus** n. in **analytic psychology**, (a) an **archetype** that represents universal masculine characteristics or (b) the unconscious masculine component of the female psyche. Compare **anima**. [sense originated by Carl Jung]

In addition, some foreign-language terms have etymologies in the form of translations or explanations:

**ad hoc** for a particular purpose or in response to some particular event or occurrence. For example, an **ad hoc committee** is convened on a short-term basis to address a single problem, and an **ad hoc hypothesis** is an explanation of a particular phenomenon, rather than a general theory. [Latin, literally: “to this”]

**Derived Words**

Derived words are those that can be formed formulaically from headwords according to certain rules. When given, they are shown at the end of the entry in boldface type, preceded by an em dash and followed by a part-of-speech label:

**abiotrophy** n. loss of function or loss of resistance to a disease through degeneration or failure of body tissues, organs, or systems. Abiotrophy is used particularly to refer to premature degeneration caused by a genetic defect, as in Huntington’s disease. —**abiotrophic** adj.

**accessible** adj. 1. receptive or responsive to personal interaction and other external stimuli. . . . 4. in a tissue, reachable by means of standard surgical or diagnostic procedures. 5. in a **Markov chain**, describing a state *j* that there is a possibility of reaching from another state *i* in some number of steps. —**accessibility** n.

Here, **abiotrophic** is an adjective derived from the noun **abiotrophy**, and **accessibility** is a noun derived from the adjective **accessible**.
### Quick Guide to Format

| Headword | Microvillus n. (pl. microvilli) a slender, minute structure projecting from the surface of a cell. For example, in taste perception, a microvillus is the hairlike extension of each TASTE CELL that projects through the pore of a TASTE BUD to sample the environment. Although a microvillus accounts for only 3% of the surface area of a taste cell, it is studded with receptor proteins that recognize specific molecules and is the site of TASTE TRANSDUCTION. | Plural form |
| Part-of-speech label | Midbrain n. a relatively small region of the upper brainstem that connects the FOREBRAIN and HINDBRAIN. It contains the TECTUM (and associated inferior and superior COCCULI), TEGMENTUM, and SUBSTANIA NIGRA. Also called mesencephalon. |
| Alternative name | Middle-child syndrome a hypothetical condition purported to be shared by all middle-born children, based on the assumption that middle children in a family develop personality characteristics that are different from first-born and later born children. Current research indicates that a child’s birth order in a particular family may have small, subtle influences on personality and intelligence but not strong and consistent effects on psychological outcomes. See also birth order. |
| Abbreviation | Mild cognitive impairment [MCI] a decline in cognitive function that is small but detectable and that represents a transitional condition between the cognitive changes typically associated with normal aging and those changes that meet the criteria for dementia. |
| Sense number | Millenarianism n. [1] belief in the imminent end of human history, to be followed by a thousand-year period of peace and blessedness (often associated with the Second Coming of Christ). Such beliefs were current in the early Christian church and appeared sporadically, primarily from the 11th through the 17th centuries, in periods of political or intellectual crisis and among marginalized groups. Some groups proclaim similar beliefs but without the language and imagery of Christianity. [2] by extension, any belief that rapid and violent change can lead to a golden age of justice and peace. —Millenarian adj. |
| Derived word | Mimetic adj. relating to imitation, as in a young chimpanzee’s imitation of its parent’s actions or a parrot imitating the words of its owner. A mimetic response is a copying or imitative response. Mimetic can also refer to physical features, such as the pseudopenis of the female spotted hyena, which is an enlargement of the clitoris and vagina through which mating and birth are accomplished. —Mimesis n. |

---

**mimetic** adj. relating to imitation, as in a young chimpanzee’s imitation of its parent’s actions or a parrot imitating the words of its owner. A mimetic response is a copying or imitative response. Mimetic can also refer to physical features, such as the pseudopenis of the female spotted hyena, which is an enlargement of the clitoris and vagina through which mating and birth are accomplished. —mimesis n.
a- (an-) prefix not or without.

A1 abbreviation for primary AUDITORY CORTEX.

A2 abbreviation for secondary AUDITORY CORTEX.

AA 1. abbreviation for ACHIEVEMENT AGE. 2. abbreviation for ALCOHOLIC ANONYMOUS.

AAAP abbreviation for AMERICAN ASSOCIATION OF APPLIED PSYCHOLOGY.

AAAPP abbreviation for AMERICAN ASSOCIATION OF APPLIED AND PREVENTIVE PSYCHOLOGY.

AAAS abbreviation for AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

AAASP abbreviation for Association for the Advancement of Applied Sport Psychology. See ASSOCIATION FOR APPLIED SPORT PSYCHOLOGY.

AACP abbreviation for AMERICAN ASSOCIATION OF CLINICAL PSYCHOLOGISTS.

AACS abbreviation for AMERICAN ACADEMY OF CLINICAL SEXOLOGISTS, INC.

AAHPERD abbreviation for AMERICAN ALLIANCE FOR HEALTH, PHYSICAL EDUCATION, RECREATION AND DANCE.

AAI abbreviation for ADULT ATTACHMENT INTERVIEW.

AAIDD abbreviation for AMERICAN ASSOCIATION ON INTELLECTUAL AND DEVELOPMENTAL DISABILITIES.

A-alpha fiber see FIBER.

AAMI abbreviation for AGE-ASSOCIATED MEMORY IMPAIRMENT.

AAMR abbreviation for American Association of Mental Retardation. See AMERICAN ASSOCIATION ON INTELLECTUAL AND DEVELOPMENTAL DISABILITIES.

AAP abbreviation for ASSOCIATION FOR THE ADVANCEMENT OF PSYCHOLOGY.

AASECT abbreviation for AMERICAN ASSOCIATION OF SEXUALITY EDUCATORS, COUNSELORS AND THERAPISTS.

AASP abbreviation for ASSOCIATION FOR APPLIED SPORT PSYCHOLOGY.

AAVE abbreviation for African American Vernacular English. See BLACK ENGLISH.

ab- prefix away from or opposite to.

ABA abbreviation for APPLIED BEHAVIOR ANALYSIS.

A-B-A-C-A design a type of SINGLE-CASE DESIGN having five consecutive phases: a baseline condition in which no treatment is present (Phase A), a treatment condition in which a manipulation is introduced (Phase B), a return to the no-treatment condition (Phase A), a new treatment condition in which a different manipulation is introduced (Phase C), and a subsequent return to the no-treatment condition (Phase A). The A-B-A-C-A design helps to establish the effects on the DEPENDENT VARIABLE of alternating treatments by evaluating the relationship between the introduction and removal of one treatment and a subsequent introduction and removal of a second treatment.

A-B-A design a type of SINGLE-CASE DESIGN having three phases: a baseline condition in which no treatment is present (Phase A), a treatment condition in which a manipulation is introduced (Phase B), and a return to the no-treatment condition (Phase A). The design allows for evaluation of the introduction of the treatment by comparing the DEPENDENT VARIABLE between the first two phases (A-B sequence) as well as evaluation of the removal of the treatment by comparing the dependent variable between the last two phases (B-A sequence). This greatly reduces the possibility of a coincidental treatment effect, which may occur in the simpler A-B DESIGN.

abandonment n. desertion or substantial leave-taking by a parent or primary caregiver of his or her custodial and other responsibilities to a dependent. Dependents are usually children but may also be adult individuals who are ill. —abandon vb.

abandonment reaction a feeling of emotional deprivation, loss of support, and loneliness experienced by children who have been deserted or neglected by a parent or primary caregiver. Abandonment reaction is also experienced by adults who have lost a loved one on whom they have depended.

abasia n. severe impairment or complete loss of the ability to walk due to problems in motor coordination. —abasic adj.

abatement n. a reduction or lessening in the severity of pain or other symptoms of illness or disorder.

ABCDE technique an extension of ABC THEORY to include the procedure used in RATIONAL EMOTIVE BEHAVIOR THERAPY of disputing irrational beliefs to achieve several types of effects (e.g., self-enhancing beliefs, appropriate feelings, desirable behaviors). [devised by Albert ELLIS]

ABCL abbreviation for American Birth Control League. See PLANNED PARENTHOOD FEDERATION OF AMERICA.

ABC theory the conceptual framework underlying RATIONAL EMOTIVE BEHAVIOR THERAPY, which suggests that activating events (i.e., adversities) are mediated by irrational beliefs in determining inappropriate emotional and behavioral consequences. See also ABCDE TECHNIQUE. [devised by Albert ELLIS]

A-B design the simplest SINGLE-CASE DESIGN, comprising a pretreatment or baseline phase (Phase A) followed by a treatment phase (Phase B). Although it allows for evaluation of the treatment’s effect by comparing the dependent variable during the two phases, the design does not provide evidence of causality because it does not establish a repeated relationship between the introduction and removal of the treatment and a consequential change in the dependent variable (compare A-B-A DESIGN). See also PRETEST–POSTTEST DESIGN.

abdominal bloating see BLOATING.

abdominal migraine recurrent, severe episodes of ab-
A concept and his or her performance in that area or between an individual’s known aptitude for a subject area or

potential or probable performance on a task. It is assumed that test-takers possess some degree of underlying ability, and that for each individual at each ability level there is a specific item characteristic curve defining the probability of responding correctly.

**ability test** 1. a norm-referenced standardized test designed to measure competence or capacity to perform a physical or mental act. 2. a test measuring achievement.

**ability trait** a personality trait that involves an individual’s capacity to attain his or her goals. It is one of three classes of source traits in Cattell’s personality trait theory, the other two being dynamic traits and temperament traits.

**abiotic** adj. nonliving.

**abiotrophy** n. loss of function or loss of resistance to a disease through degeneration or failure of body tissues, organs, or systems. Abiotrophy is used particularly to refer to premature degeneration caused by a genetic defect, as in Huntington’s disease. —abiotrophic adj.

**ablation** n. the removal or destruction of part of a biological tissue or structure by a surgical procedure (e.g., mechanical or laser excision) or a toxic substance (e.g., chondroitinase), usually for treatment or to study its function. When the entire tissue or structure is excised, the process is called extirpation. See also biopsy.

**ableism** n. discrimination against individuals with disabilities or the tendency to be prejudiced against and to stereotype them negatively as, for example, less intelligent, nonproductive, or dependent on others. —ableist adj.

**ablation** n. 1. a largely obsolete therapeutic technique utilizing water to calm agitated patients, such as by wrapping them in wet towels or immersing them in water. It was abandoned with the advent of psychotropic drugs. 2. a symbolic cleansing of the body, or of possessions, with the intent of purification.

**ABMS** abbreviation for American Board of Medical Specialties.

**Abney’s effect** a perceptual phenomenon in which the addition of white light leads to a shift in the hue of a monochromatic color. [William Abney (1843–1920), British chemist and physicist]

**abnormal** adj. relating to any deviation from what is considered typical, usual, or healthy, particularly if the deviation is considered harmful or maladaptive. In statistics, for example, abnormal scores are those that are outside the usual or expected range. The term, however, is most often applied to behavior that differs from a culturally accepted norm, especially when indicative of a mental disorder. —abnormality n. —abnormally adv.

**abnormal behavior** behavior that is atypical or statistically uncommon within a particular culture or that is maladaptive or detrimental to an individual or to those around that individual. Such behavior is often regarded as evidence of a mental or emotional disturbance, rung-
ing from minor adjustment problems to severe mental disorder.

**abnormal fixation** in vision, the inability to focus on a given target of interest. Abnormal fixations may be the result of saccadic intrusions or oscillations (see SACCADIC) or NYSTAGMUS.

**abnormality** *n.* 1. the state or condition of being ABNORMAL. 2. a defect or malformation in structure or function.

**abnormal psychology** the branch of psychology devoted to the study, assessment, treatment, and prevention of maladaptive behavior. See also PSYCHOPATHOLOGY.

**aboiement** *n.* the involuntary, uncontrollable production of animalistic sounds. Aboiement (French, “barking”) is a symptom sometimes occurring in schizophrenia and Tourette’s disorder.

**abortifacient** *n.* any agent that induces abortion. Also called **abortient**.

**abortion** *n.* the expulsion from the uterus of an embryo or fetus before it is able to survive independently. An abortion may be either spontaneous, in which case it occurs naturally and is also called a **miscarriage**, or induced, in which case it is produced deliberately by artificial means such as drugs or surgery and done for therapeutic reasons or as an elective decision. The practice is controversial and may involve **abortion counseling**, the provision of guidance, advice, information, and support on issues concerning termination of pregnancy and the alternatives of adoption or raising the child.

**abortion laws** laws concerning the rights of women to obtain an abortion, which in the United States are provisioned through the 1973 U.S. Supreme Court decision in *Roe v. Wade*.

**abouilia** *n.* see **ABULIA**.

**above-average effect** the tendency of a person to hold overly favorable views of one’s own intellectual and social abilities relative to others. For example, students’ predictions of their own final exam score in a particular college class often are based on their highest score received to that point, but their predictions of someone else’s final exam score typically are based on that student’s mean score. The above-average effect appears to be common and consistent across a variety of judgment domains. Also called **better-than-average effect**. Compare **BELOW-AVERAGE EFFECT**.

**ABPI** abbreviation for AMERICAN BOARD OF PSYCHOLOGICAL HYPNOSIS.

**ABPP** abbreviation for AMERICAN BOARD OF PROFESSIONAL PSYCHOLOGY.

**ABR** abbreviation for auditory brainstem response. See **BRAINSTEM AUDITORY EVOKED RESPONSE**.

**abreaction** *n.* the therapeutic process of bringing forgotten or inhibited material (i.e., experiences, memories) from the unconscious into consciousness, with concurrent emotional release and discharge of tension and anxiety. See also **CATHARSIS**.

**abscess** *n.* a contained but often enlarging area of infection that includes pus and dead tissue. A brain abscess raises **INTRACRANIAL PRESSURE** and can cause substantial neurological deficits, such as poor coordination, decreased sensation, confusion, and other altered mental states.

**abscissa** *n.* the horizontal coordinate in a graph or data plot; that is, the *x*-axis. See also **ORDINATE**.

**absence** *n.* a brief **LOSS OF CONSCIOUSNESS** or period of mental inattentiveness, particularly when associated with a seizure (see **ABSENCE SEIZURE**), with no memory for the event afterward.

**absence culture** an informal organizational **NORM** that leads employees and managers to believe that they are entitled to take more days off work than the number allowed. In some organizations, for example, employees may have come to regard sick leave as a benefit to be claimed rather than a provision to be utilized only when strictly necessary.

**absence seizure** a type of **GENERALIZED SEIZURE**, formerly called petit mal seizure, in which the individual abruptly ceases activity and cannot afterward remember the event. The absences usually last from 5 to 15 seconds, during which the individual is unresponsive and motionless, staring blankly. Seizures of this type typically begin between ages 4 and 12 and rarely persist into adulthood.

**absence without leave** (AWOL) unauthorized or unreported absence, which may be grounds for disciplinary action.

**absenteeism** *n.* unjustified absence from work or school, especially when regular or persistent. Although absenteeism has been linked to job satisfaction, other factors, such as **ORGANIZATIONAL CULTURE** and the **ABSENCE CULTURE** in particular, may be more relevant.

**absent grief** a form of **COMPLICATED GRIEF** in which a person shows no, or only a few, signs of distress about the death of a loved one. This pattern of grief is thought to be an impaired response resulting from denial or avoidance of the emotional realities of the loss.

**absent-mindedness** *n.* a state of apparent inattention marked by a tendency to be preoccupied with one’s own thoughts and not with external conditions. See also **MIND WANDERING**.

**absent state** a vacant, dreamlike state of detachment that may occur in **COMPLEX PARTIAL SEIZURES**.

**absolute** *adj.* 1. not limited or subject to restriction, as in **ABSOLUTE POWER**. 2. not conditional on or relative to anything else, as in **ABSOLUTISM**. See also **CULTURAL UNIVERSALISM**. 3. denoting an ultimate limit, as in ** ABSOLUTE ZERO**. —**absolutist** *adj.*

**absolute difference** the distance between two numeric values, disregarding whether this is positive or negative. The absolute difference thus provides no information about relative magnitude. For example, the absolute difference between 11 and 20 is 9, as is the absolute difference between 13 and 4.

**absolute error** the degree to which an observation is inaccurate without specification of whether it errs by being too high or too low. Absolute error is computed as the average **ABSOLUTE DIFFERENCE** between the intended or expected value and the actual value. See also **CONSTANT ERROR**; **RANDOM ERROR**.

**absolute idealism** the philosophical position that both mental and material reality are manifestations of a universal and absolute mind or spirit. See **IDEOLOGISM**; **IDEALISTIC
**absolute impression** a psychophysical judgment based on implied or vague standards, such as *It was a bright day.*

**absolute judgment** a psychophysical judgment in which a single stimulus is placed in a particular category (e.g., *bright, loud*), as opposed to one in which several stimuli are compared to one another or to a given standard (e.g., *brighter, louder*). Compare COMPARATIVE JUDGMENT.

**absolute-judgment method** see METHOD OF ABSOLUTE JUDGMENT.

**absolute limen** see ABSOLUTE THRESHOLD.

**absolute measurement** a measurement made directly and independently of comparison with other measurements. An absolute measurement of an individual’s height, for instance, would yield a single definitive value that need not be assessed relative to another person to be meaningful. Compare RELATIVE MEASUREMENT.

**absolute pitch** the ability to identify the pitch of a sound accurately without the use of a reference pitch. Also called perfect pitch. Compare RELATIVE PITCH.

**absolute reality** in philosophy, the totality of what really exists, regarded as a unity transcending the world of phenomena experienced and interpreted by humans. The concept of an absolute reality is mainly of significance in the idealist tradition deriving from the work of Immanuel Kant. See NOUMENON; TRANSCENDENTALISM.

**absolute refractory period** see REFRACTORY PERIOD.

**absolute scotoma** see SCOTOMA.

**absolute threshold** the minimum amount of stimulation required to trigger a reaction or produce a sensation. Absolute threshold is measured across several trials. It is the lowest or weakest level of stimulation (e.g., the slightest most indistinct sound) that can be detected on 50% of trials. Although the name suggests a fixed level at which stimuli effectively elicit sensations, the absolute threshold fluctuates according to alterations in receptors and environmental conditions. Also called absolute limen; detection threshold; sensation threshold.

**absolute value** a number considered without regard to its algebraic sign (i.e., whether it is positive or negative). For example, assume that for each person in a weight management program there was a number indicating the difference between the current week’s weight and the weight on the previous week. This could reveal a negative number (e.g., —1) if the person lost one pound; conversely, it could be a positive value (e.g., +1) if the person gained one pound more than last week. If the absolute value of the weight difference was taken, it would simply reveal a difference of 1 pound, without any indication of whether it was plus or minus. Also called modulus.

**absolutism** n. the philosophical position that there are absolute ethical, aesthetic, or epistemological values. Phenomena are believed to have a fixed reality; thus, what is regarded as true in one circumstance will be regarded as true in all others as well. For example, a particular action will always be deemed immoral regardless of its outcome or any other individual or subjective consideration. Such a position involves a rejection (in whole or in part) of relativism.

**absorption** n. 1. an extreme involvement or preoccupa-

tion with one object, idea, or pursuit, with inattention to other aspects of the environment. Compare SUSTAINED ATTENTION. See also TELEGHEN ABSORPTION SCALE. 2. the uptake of fluid and dissolved substances into a cell across the plasma membrane. For example, an administered drug moves through various biological membranes from its site of administration to its target organ. Absorption into the target organ is dependent on a number of factors, including the method of ADMINISTRATION (e.g., oral, intravenous); the properties of the drug (e.g., molecular size, ability to cross lipid membranes); the amount of drug administered; and the characteristics or state of the individual (e.g., body mass, sex, age, presence of disease, presence of other drugs). 3. in physics, the conversion of energy from one form to another on entering a medium.

**absorption curve** a graph that plots the number of photons of light of different wavelengths absorbed by a photopigment.

**abstinence** n. the act of refraining from the use of something, particularly alcohol or drugs, or from participation in sexual or other activity. In most instances, abstinence from drugs or alcohol is the primary goal of substance abuse treatment. See also RELAPSE; SUBSTANCE WITHDRAWAL. —abstinent adj.

**abstinence delirium** a form of DELIRIUM that may result from rapid withdrawal from alcohol or drugs of abuse. See ALCOHOL WITHDRAWAL DELIRIUM; DELIRIUM TREMENS.

**abstinence rule** see RULE OF ABSTINENCE.

**abstinence syndrome** an older term for the characteristic set of physiological and behavioral events that may accompany rapid withdrawal from dependence-inducing substances.

**abstract ability** see ABSTRACT INTELLIGENCE.

**abstract attitude** a COGNITIVE STYLE that involves the ability to grasp essentials and common properties, to keep different aspects of a situation in mind and shift from one to another, to predict and plan ahead, and to think symbolically and draw conclusions. These capacities are often impaired in people with certain neurological or psychological disorders. Also called CATEGORICAL ATTITUDE. Compare CONCRETE ATTITUDE. See also ABSTRACT THINKING. [defined by Kurt GOLDBERG]

**abstract conceptualization** the process of forming abstract concepts, which may be general and apply to numerous particular instances (e.g., *dog, fish*) or wholly intangible and have no specific material referent (e.g., *liberty, youth*). See ABSTRACTION; CONCEPTUALIZATION.

**abstract idea** an idea or concept that has no specific material referent, such as *justice*, or one that applies to a great many particular instances, having a meaning apart from any particular, such as *dog*. See also UNIVERSALS.

**abstract intelligence** the intellectual ability to think in terms of abstract concepts. Also called abstract ability. See ABSTRACT THINKING. Compare CONCRETE INTELLIGENCE.

**abstraction** n. 1. the formation of general ideas or concepts by extracting similarities from particular instances. The precise cognitive processes by which this occurs remain a subject of investigation. 2. such a concept, especially a wholly intangible one, such as *goodness* or *truth*. 3. in conditioning, DISCRIMINATION based on a single property of multicomponent stimuli. —abstact vb.

**abstraction experiment** a study that investigates par-
participants' ability to induce the general properties of a category or concept from specific instances that are presented to them as examples or nonexamples. See also CONCEPT- DISCOVERY TASK; CONCEPT-FORMATION TEST.

abstract learning acquiring knowledge of general or intangible material, such as the meanings of concepts and propositions and the logical and systematic relations between them.

abstract representation in cognitive theory, a mental representation of an stimulus in an abstract or essential form that is not tied to any one of its variable surface forms. For example, the letter A can be thought about at an abstract level with no reference to specific surface forms, such as a, A, or a. Compare CONCRETE PICTURE.

abstract thinking thinking characterized by the use of general ideas or concepts. Compare CONCRETE THINKING. See also ABSTRACT ATTITUDE; CATEGORICAL THOUGHT.

abstract-versus-representational dimension the degree to which a work of art is nonrepresentational versus representational of reality. Representational art is characterized by a great amount of detail, whereas abstract art is highly selective in the inclusion of detail. See also REALISM FACTOR.

abstract word in linguistics, a word denoting a concept or idea not readily perceptible to the senses, such as curiosity or metaphor. Compare CONCRETE WORD.

absurdist test a type of test in which participants identify incongruities in a picture, story, or other written material. Absurdity tasks are intended to assess reasoning abilities and may be incorporated into intelligence tests and neuropsychological evaluations.

abulia (aboulia) n. extreme loss of initiative and willpower, resulting in an inability to make decisions or initiate voluntary actions. —abulaic adj.

abuse 1. n. interactions in which one person behaves in a cruel, violent, demeaning, or invasive manner toward another person or an animal. The term most commonly implies physical mistreatment but also encompasses sexual and psychological (emotional) mistreatment. 2. vb. to subject a person or animal to such treatment. 3. n. see SUBSTANCE ABUSE. 4. n. colloquially, the misuse of a substance to the extent that it causes the individual difficulty, whether or not it meets a formal diagnosis of substance abuse. —abuser n.

abuse excuse experience of prior abuse (e.g., physical, mental, or sexual) used as a defense for a person's violent acts.

abuse potential the relative likelihood that a particular psychoactive substance will reinforce drug-taking behavior to the point of abuse. Factors that determine abuse potential include subjective experience with a given substance, route of drug administration (e.g., intravenous, inhalation, oral), and the onset speed, duration, and nature of the drug effect. Substances with a high abuse potential include intravenous heroin, crack cocaine, morphine, and smoked opium. Substances with a low abuse potential include the hallucinogens and antipsychotic medications. Also called abuse liability.

abusive punishment use of excessive physical force to discipline a child that results in bodily injury, including noticeable marks, bruises, cuts, or welts; such punishment includes beating, burning, or tying up a child. Compare CORPORAL PUNISHMENT.

ABX paradigm a psychophysical procedure in which a pair of auditory stimuli (A and B) are presented, followed by another stimulus (X). In one version of the task, participants are asked to judge whether X is identical to A or B; in another version, they have to judge whether X was included in the A–B pair.

ACA abbreviation for AMERICAN COUNSELING ASSOCIATION.

academic adj. relating to formal learning with conventional or theoretical study at a school or other educational institution.

academic achievement 1. any identifiable success in the areas of scholarship or disciplined study. 2. in educational psychology, a level of proficiency in scholastic work in general or in a specific skill, such as arithmetic or reading. Evidence of future academic achievement is usually based on the results of standardized ability tests and assessment of performance by a teacher or other supervisor.

academic aptitude competence or capacity to perform a scholastic mental act, such as the ability to learn quickly in areas of scholarship or disciplined study. Academic aptitude may be either innate or acquired by education and practice. See also APTITUDE.

academic failure any marked insufficiency or inadequacy in the area of scholarship or study, for example, when a learner does not achieve an expected competence. Contributing factors may include home environment and family, peers, economic context, learning environment and attributes of instruction, and individual characteristics.

academic freedom within an institution of learning, the liberty of a teacher to educate, of a student to study, and of both to express opinions, particularly regarding controversial topics (e.g., morals, religion, politics), without interference from or punishment by government, school officials, teachers, or community groups.

academic intelligence the intellectual skills that, according to some theories, are particularly important to success in school environments (e.g., analysis, evaluation, judgment, recognition). See also ANALYTICAL INTELLIGENCE. [originally described in 1974 by Ulric NEISSER]

academic intelligence task a task that requires the use of academic skills and knowledge, such as one that involves solving arithmetic problems or verbal analogies. Compare PRACTICAL INTELLIGENCE TASK.

academic intervention the active involvement of school officials and teachers in developing and implementing an effective plan for the prevention or remediation of inappropriate and disruptive student behavior or for assisting students with academic difficulties. Successful programs of intervention are most often individualized, child focused, and minimally restrictive. Academic intervention is the antithesis of reactive strategies, such as loss of privileges and time out.

academic overachievement 1. academic performance that exceeds the expected level for a particular individual, or the usual predicted attainment level, especially as indicated by norm-referenced and standardized intelligence or aptitude tests. 2. the act of driving oneself relentlessly in attempting to reach a difficult scholastic goal.

academic problem a learning problem in a schoolchild who does not acquire the necessary grade-level knowledge
academic self-concept

or cannot successfully pursue the expected grade-level tasks and scholarly goals. It cannot be attributed to any underlying neurological, psychological, or other disorder and thus is distinct from a LEARNING DISABILITY.

academic self-concept an individual’s evaluation of his or her success in academic or educational studies. The two aspects of this evaluation are (a) a general academic self-concept in which students assess their overall learning skills and performance; and (b) a specific academic self-concept of their prowess in such specific subjects as mathematics, social science, or language studies. A major consideration for any individual is whether a positive self-concept is an aid to academic achievement. Another consideration is whether academic achievement, in itself, enhances a positive self-concept.

academic underachievement 1. performance below a particular person’s predicted capacity, especially as indicated by norm-referenced and standardized intelligence or aptitude tests. 2. lack of drive in pursuit of scholastic goals. Causative factors can include unstimulating curriculum and instruction, negative attitudes of parents or teachers, changes in the student, and individual choices that militate against learning.

Academy for Eating Disorders (AED) a global professional organization for eating disorders research, education, treatment, and prevention. It advocates for patients with eating disorders and the professionals who treat them, hosts an annual International Conference on Eating Disorders, and publishes the International Journal of Eating Disorders eight times a year. Intended for a wide membership of health care specialists, coverage includes epidemiology, psychobiology, sociology, and therapy of anorexia, bulimia, and other conditions involving atypical body weight regulation. The academy also has published the Annual Review of Eating Disorders Part 1 (2007) and Part 2 (2008), two clinically oriented books synthesizing the literature of the field, and has authored numerous position papers and media advisories. Founded in 1993, the AED is headquartered in Deerfield, Illinois.

Academy of Certified Social Workers (ACSW) a professional organization founded in 1960 by the NATIONAL ASSOCIATION OF SOCIAL WORKERS to provide certification of competence for social workers for independent, self-regulated practice and to ensure high standards of practice.

acalculia n. loss of the ability to perform simple arithmetic operations that result from brain injury or disease, usually to the PARIETAL LOBE. It is an acquired condition, whereas DYSCALCULIA is developmental.

acamprosate n. an analog of the inhibitory neurotransmitter GAMMA-AMINOBUTYRIC ACID (GABA) used in the management of alcohol dependence. Although exact mechanisms of action are unclear, acamprosate may act by directly binding to the GABA receptor complex (see GABA, RECEPTOR; GABAERGIC RECEPTORS); it may also act by inhibiting the actions of the excitatory amino acid GLUTAMATE, for example by inhibiting NMDA RECEPTORS. When administered in combination with behavioral treatments, it has some efficacy in reducing alcohol intake or increasing alcohol-free periods in people recovering from alcohol dependence. U.S. trade name: Campral.

acarophobia n. a former name for DELUSIONAL PARASITOSIS. Its use was discontinued upon recognition that the condition does not involve a persistent and irrational fear of being infested by parasites (a phobia) but rather a firmly held belief of having been infested (a delusion). —acrophobic adj.

acatamathesia (akatamathesia) n. loss of the ability to comprehend sensory stimuli in general or speech in particular.

acataphasia (akataphasia) n. the use of inappropriate or grammatically incorrect words and expressions. It is a speech disturbance frequently found in individuals with schizophrenia or aphasia. See also GRAMMATISM.

acathisia n. see AKATHISIA.

ACC abbreviation for ANTERIOR CINGULATE CORTEX.

accelerated longitudinal design see COHORT-SEQUENTIAL DESIGN.

acceleration n. 1. an increase in speed of movement or rate of change. Compare DECELERATION. 2. in mathematics and statistics, the rate of change in the SLOPE of a function or the rate of change in one variable as a function of an increase in a second variable.

acceleration-deceleration injury a form of HEAD INJURY caused by the head suddenly being placed into motion or abruptly stopped, as, for example, when the individual is in a car accident. The sudden motion or stop causes diffuse stretching of white matter tracts in addition to bleeding and other neurological effects (e.g., biochemical cascades that eventually lead to axonal injury). The injury may have a variety of consequences, including personality change, attention problems, memory disorders, and EXECUTIVE DYSFUNCTION.

acceleration effects physiological, biochemical, or psychological changes in the body resulting from acceleration imposing g-forces greater than 1. Examples include displacement of body fluids, changes in pupil size, changes in or disturbances of heart rhythm, increases in blood pressure, deficiency of oxygen in the blood (see HYPOXEMIA), disorientation and confusion, amnesia, GRAVOY, BLACKOUT, and GRAVITY-INDUCED LOSS OF CONSCIOUSNESS.

acceleration forces forces exerted on an object by the rate of change of its velocity. In psychology, the focus is on the range of forces sustained by the human body when it is in a moving vehicle, such as an automobile or aircraft, and the resultant physical, physiological, and psychological consequences. See ACCELERATION EFFECTS.

accent n. 1. in linguistics, phonetic features of an individual’s speech that are associated with geographical region or social class. The standard version of a language (see STANDARD LANGUAGE) is usually considered by native speakers to be unaccented. Compare DIALECT. 2. a STRESS placed on a syllable of a word, orthographically marked in some languages.

accentuation theory the proposition that classification of items produces encoding biases, that is, that individuals tend to exaggerate (accentuate) the similarities among items placed in the same category and the differences among items placed in different categories. This accentuation effect is an important component of SOCIAL IDENTITY THEORY. [proposed in 1959 by Polish-born British social psychologist Henri Tajfel (1919–1982)]

acceptance n. 1. a favorable attitude toward an idea, situation, person, or group. In the context of psychotherapy and counseling, it is the receptive, nonjudgmental attitude
of therapists or counselors, which conveys an implicit respect and regard for their clients as individuals. 2. willing acknowledgment of validity or correctness. In the context of recovery from substance abuse and other addictions, it is essential for a person to accept that he or she has a problem before any interventions can be effective.

**acceptance and commitment therapy (ACT)** a form of COGNITIVE BEHAVIOR THERAPY based on the premise that ineffective verbal strategies to control one’s thoughts and feelings actually lead to problem behaviors. It helps clients to abandon these restrictive strategies and instead experience and accept their difficult thoughts (conceived as just words put together in a certain way) and feelings as a necessary part of a worthy life. Clients then clarify their personal values and life goals, learn to make life-enhancing behavioral changes accordingly, and develop new and more flexible ways of thinking about and responding to challenges. ACT (pronounced act, not A-C-T) has been applied to a wide variety of problems, including depression, anxiety, stress, and substance abuse. It is based on the RELATIONAL FRAME THEORY of U.S. psychologist Steven C. Hayes (1948— ), proposing, among other concepts, that VERBAL BEHAVIOR is a contextually situated, learned ability to relate events arbitrarily; seen within ACT’s framework, verbal behavior, once developed, can create relational rules so extensive that they restrict behavioral repertoires and thereby promote negative psychological outcomes for the individual.

**acceptance region** the range of values for a test statistic that leads to acceptance of the NULL HYPOTHESIS, such that the ALTERNATIVE HYPOTHESIS is rejected as a valid explanation for observed data. Compare CRITICAL REGION.

**acceptance sampling** a process in which a random sample is chosen from a larger group of items and used to make a decision about the quality of the items in that group. It is often used in commerce to test the quality of merchandise in a batch: A random sample from the batch is inspected and the results used to determine whether the batch as a whole meets desired standards or whether it fails to meet standards and should be rejected as defective. Also called **lot acceptance sampling**.

**acceptance stage** the last of the five STAGES OF GRIEF described by Elisabeth Kübler-Ross. It is characterized by some degree of emotional detachment, objectivity, or resignation on the part of oneself or an important other to the reality of impending or actual death, other great loss, or trauma.

**acceptor** n. see **ALLOCATOR**.

**access** vb. to retrieve or recall a memory.

**accessibility** n. see **ACCESSIBLE; AVAILABILITY**.

**accessible** adj. 1. receptive or responsive to personal interaction and other external stimuli. A client in psychotherapy, for example, is thought to be accessible if he or she responds to the therapist in a way that facilitates the development of rapport and, ultimately, fosters the examination of cognitive, emotional, and behavioral issues. 2. retrievable through memory or other cognitive processes, as in ATTITUDE ACCESSIBILITY for example. 3. of a building or other site and its facilities and fixtures: easy to approach, enter, or use, particularly by people with disabilities. 4. in a tissue, reachable by means of standard surgical or diagnostic procedures. 5. in a MARKOV CHAIN, describing a state j that there is a possibility of reaching from another state i in some number of steps. —**accessibility** n.

**accessory** 1. adj. ANCILLARY, supplemental, or contributory. 2. n. a thing or person that is supplementary or subordinate.

**accessory nerve** the 11th CRANIAL NERVE, sometimes so named because one of its functions is that of serving as an accessory to the 10th cranial nerve (the VAGUS NERVE). It innervates the sternomastoid and trapezius muscles in the neck.

**accessory structure** in biology, a structure that assists or can take over the function of another (the primary) structure.

**accessory symptoms** see **SECONDARY SYMPTOMS**.

**accident** n. an unexpected or unintended event, especially one resulting in human injury or death, system damage, or system loss. —**accidental** adj.

**accidental chaining** learning by REINFORCEMENT, a sequence of two or more actions that includes an act unnecessary to obtain reinforcement (see also CHAINING). This occurs as a result of accidental temporal conjunction between the unnecessary act and a stimulus circumstance that precedes a reinforced response.

**accidental group** any self-organizing group that comes into existence gradually as individuals find themselves repeatedly interacting with the same subset of individuals. Commuters who ride the same daily trains to and from work are an example. Such a group will not normally have the defined goals, procedures, and structures of a FORMAL GROUP.

**accidental hypothermia** see **HYPOTHERMIA**.

**accidental property** a characteristic of an idea or entity that is not essential to its nature or existence. For example, being musical is an accidental property of human beings, whereas being mortal is an ESSENTIAL PROPERTY.

**accidental reinforcement** the accidental occurrence of a REINFORCER after an act, which may inadvertently strengthen the likelihood of occurrence of that act. Superstitious behavior is often a result of accidental reinforcement. For example, a golfer might lean as a putt nears the hole. Such leaning has been followed in the past by the ball going in the hole (the reinforcer), so even though leaning has no causal effect on whether the ball goes in, the accidental contingent relationship between leaning and the ball being holed leads to reinforcement of leaning. Also called adventitious reinforcement.

**accidental sampling** see **CONVENIENCE SAMPLING**.

**accident analysis** a systematic process undertaken to determine the causes of an accident, with the goal of reducing the likelihood that such an accident will occur again. The most frequently used accident analysis methods include FAILURE MODES AND EFFECTS ANALYSIS and FAULT TREE ANALYSIS.

**accident behavior** behavior that could result in injury to the individual or other people or in physical damage to equipment or the environment. Such behavior may arise from personal factors, such as inattention or risk taking, but may also reflect situational factors, such as long work hours or poorly designed work systems. See ACCIDENT PREVENTION.

**accident-path model** a model used in accident analysis to illustrate the antecedents and causes of an accident using a chronological or otherwise ordered pattern. The
goal is to determine the types and extent of interventions necessary to prevent accidents.

**accident prevention** the use of scientifically tested methods to reduce the number and severity of accidents. These include the systematic study of accidents and the circumstances in which they occur (see ACCIDENT ANALYSIS); the identification and control of workplace hazards (see JOB-SAFETY ANALYSIS); the evaluation and redesign of systems and processes (see SAFETY ENGINEERING); and the use of training programs, instruction, and other forms of safety education.

**accident proneness** a chronic susceptibility to accidents. This concept has been heavily debated since its introduction around 1920, and many question the existence of a fixed accident-prone personality. However, several individual variables and sociological and situational factors have been identified as important predictors of accident involvement, including aggressiveness, impulsiveness, thrill and adventure seeking, workload and cognitive demand, and stress.

**accident reduction** see ACCIDENT PREVENTION.

**acclimatization** n. adjustment or adaptation to new circumstances or environmental conditions, particularly the physiological changes that improve an individual’s ability to tolerate environmental alterations. Also called acclimation. —acclimatize vb.

**accommodation** n. 1. adjustment or modification. For example, regarding individuals with disabilities, it refers to reasonable accommodations made to meet their needs. In the context of bargaining and interpersonal negotiations, it refers to modification of the various parties’ demands or actions in order to achieve agreement or a mutually beneficial outcome. 2. the process by which the focus of the eye is changed to allow near or distant objects to form sharp images on the retina. Accommodation is achieved mainly by contraction or relaxation of the CILIAR MUSCLES, which exert tension on the ZONULES attached to the lens, but also involves adjustments in the CONVERGENCE of the eyes and the size of the pupils. 3. see PIAGETIAN THEORY. —accommodate vb.

**accommodation time** the time it takes for the eyes to focus on a visual stimulus following its presentation.

**accommodative coping** a stress-management strategy in which a person adjusts his or her preferences and orientations to suit given situational forces and constraints. Involving a devaluation of, or disengagement from, blocked goals and a lowering of personal performance standards and aspirations, accommodative coping thus represents a neutralization rather than an active solution of a particular problem. Accommodative processes generally appear following repeated unsuccessful attempts to change the situation through ASSIMILATIVE COPING. Additionally, accommodative processes are thought to be more prominent in later life, when individuals tend to experience an increasingly unfavorable balance of developmental gains and losses. [identified in 1990 by Jochen Brandstädter and Gerolf Renner, German psychologists]

**accommodative insufficiency** a reduction in the efficiency of the eye’s ability to change focus for objects at different distances (visual ACCOMMODATION), as evidenced primarily by blurring of near vision. It is usually caused by either dysfunction of the eye’s CILIARY MUSCLES or by midbrain injury.

**accommodative spasm** failure of the eye muscles involved in ACCOMMODATION to relax after focusing on near objects, resulting in transient myopia. Affecting one or both eyes, it is usually caused by an injury to the parasympathetic nervous system and can occur after head injury. The primary symptom is visual blurring at all distances, in many cases occurring over a period of months or even years.

**accomplishment quotient** see ACHIEVEMENT QUOTIENT.

**accountability** n. 1. the extent to which an individual is answerable to another (e.g., a supervisor, official review body, a group of peers) for his or her behavior, decisions, or judgments. In groups, accountability is influenced by anonymity and the extent to which the contributions of each member of the group are clearly identifiable. 2. in health care, the responsibility of individual providers, clinics, or hospitals to document their efforts, their resource utilization, and the outcome of their services and to report this information to insurance companies or state or federal agencies. —accountable adj.

**accreditation** n. the formal process in which an agency or organization evaluates and approves an institution or program of study as meeting predetermined standards. Accreditation applies to institutions as CERTIFICATION applies to individuals. —accredited adj.

**accrual** n. 1. a form of learning resulting from the cumulative effect of repeated associations and reinforcements. 2. the accumulation of objects or material in the environment, which may indicate the degree of individual responsibility of people who use a particular area. Littering is an example of accrual. Compare DESTRUCTION.

**acculturation** n. the processes by which groups or individuals adjust the social and cultural values, ideas, beliefs, and behavioral patterns of their culture of origin to those of a different culture. Psychological ACCULTURATION is an individual’s attitudinal and behavioral adjustment to another culture, which typically varies with regard to degree and type. Compare DECLASSIFICATION; ENCULTURATION. —accul- turate vb.

**acculturation strategies** in CROSS-CULTURAL PSYCHOLOGY, a framework proposing four ways in which members of a nondominant group (e.g., immigrants, racial or ethnic minorities) may experience ACCULTURATION and manage their contact with and participation in the culture of a larger, dominant group. The assimilation strategy is one in which individuals do not wish to maintain their original cultural identity and prefer instead to seek daily interaction with the dominant group. By contrast, the separation strategy is one in which individuals hold onto their original culture and avoid interaction with the dominant group. A third strategy is integration, in which individuals maintain their original culture while still seeking to participate as an integral part of the larger social network. The fourth strategy, marginalization, describes an unwillingness or inability of individuals to identify with and participate in either their culture of origin or that of the dominant group. These strategies are partly determined by the extent to which the dominant group does or does not force a nondominant group to adapt to its cultural mandates or constraints (e.g., through DISCRIMINATION). [proposed by Canadian psychologist John W. Berry (1939– )]

**accumbens** n. see NUCLEUS ACCUMBENS.

**accumulated advantage** see MATTHEW EFFECT.
accuracy n. 1. lack of error or bias in a measure; the more accurate the measure, the closer the measurement is to the true score for an individual. 2. a measure of performance on a task, usually defined as the proportion of correct responses. 3. more generally, exactness or freedom from error. See also precision. —accurate adj.

accuracy motive see self-assessment motive.

accuracy standards criteria used to assess the scientific value of the information and conclusions presented in an evaluation report. Such standards include ensuring the completeness of data collection and the reliability and validity of procedures and measures, conducting appropriate qualitative and quantitative analyses, and impartially reporting results to arrive at justified conclusions. See also feasibility standards; propriety standards; utility standards.

accusative n. in linguistics, the case of a noun, pronoun, or noun phrase that forms the direct object of a clause or sentence. In English, unlike more inflected languages, only certain personal and possessive pronouns change their form when they appear in accusative position (so that English speakers say, for example, She hit me and not She hit I). Also called objective. Compare dative; genitive; nominative.

Accutane n. a trade name for isotretinoin.

acenesesthesia n. 1. loss of the sensation of physical existence. 2. a lack of awareness of one’s own body. See de-personalization.

ACEP abbreviation for American Coaching Effectiveness Program. See American sport education program.

acetaldehyde n. a toxic and volatile initial product of alcohol (ethanol) metabolism that is thought to be responsible for the alcohol flush reaction and certain other physical sequelae of alcohol consumption, including unpleasant effects such as nausea, vomiting, and headache. Acetaldehyde is produced when alcohol is broken down by the enzyme alcohol dehydrogenase. It is then broken down by another liver enzyme (acetaldehyde dehydrogenase) into acetate and, ultimately, into carbon dioxide and water. Acetone is also a major component of tobacco smoke. It may influence the development, progression, and persistence of alcohol consumption, including un-

achieved status social standing and prestige acquired by means of one’s personal accomplishments.

achievement n. 1. the attainment of some goal, or the goal attained. See also need for achievement. 2. acquired knowledge (especially in a particular subject), proficiency, or skill. The term is most often used in this sense to mean academic achievement.

achievement age (AA) the achievement rating of an individual as measured in terms of the norm or standard for a particular chronological age.

achievement battery any group of achievement tests designed to provide an index of a person’s knowledge or specific physical or mental skills across a range of related topics.

achievement ethic a personal or cultural standard that requires a high level of accomplishment in both work and leisure activities. See also work ethic.

achievement goal theory a conceptualization of motivation that identifies two types of achievement goals, task-oriented (see task orientation) and ego-oriented (see ego orientation), and that relates these to differences in individuals’ perceived ability for the task and their achievement behavior. This theory emerged from the work of educational psychologists and subsequently was modified for use in sport psychology as well.

achievement level 1. the degree of proficiency attained in academic work in general or in a specific scholastic skill,
achievement measures

such as arithmetic. 2. an evaluation of individual or group performance on a task or activity (e.g., a chess match or athletic event), particularly following training.

**achievement measures** tasks, instruments, or systems designed to demonstrate a student’s level of proficiency and to ascertain the value, strength, or quality of performance by comparison with a peer standard.

**achievement motivation** 1. the desire to perform well and be successful. In this sense, the term often is used synonymously with need for achievement. 2. the desire to overcome obstacles and master difficult challenges. High scorers in achievement motivation are likely to set higher standards and work with greater perseverance than equally gifted low scorers. David McCLELLAND found a significant relationship between high achievement motivation and early independence in childhood; in addition, there is a positive correlation between high achievement motivation and actual achievement in later life. [first described by Henry Alexander MURRAY]

**achievement-oriented leadership** in the path–goal theory of leadership, a style in which the leader encourages excellent performance and continuous improvement by showing a high degree of confidence in followers and setting challenging goals.

**achievement potential** 1. the capacity of a person to develop certain skills or traits in order to attain a certain goal. 2. academic skills or abilities that may develop over time through education and practice.

**achievement quotient** (AQ) a measure obtained by dividing an individual’s results on an achievement test (i.e., the actual performance) by the results expected based on the person’s capacity (i.e., the potential performance, as assessed by an intelligence test). The achievement quotient formerly was called the accomplishment quotient.

**achievement test** any norm-referenced standardized test intended to measure an individual’s current level of skill or knowledge in a given subject. Often the distinction is made that achievement tests emphasize ability acquired through formal learning or training, whereas aptitude tests (usually in the form of intelligence tests) emphasize innate potential.

**achiever** n. a person who is able to accomplish some action or desired result.

**achieving stage** see Schaie’s stages of cognitive development.

**achiria** n. see ACHEIRIA.

**achondroplasia** n. a form of autosomal dominant dwarfism in which the bones derived from cartilage develop at a slower rate than the bones derived from connective tissue. This results in an enlarged cranial vault and abnormally high forehead. Motor development of infants with this disorder may be slow, but in most cases intelligence is normal. Also called achondroplastic dwarfism. —achondroplastic adj.

**ACHR** abbreviation for ACETYLCHOLINE RECEPTOR.

**achromatic adj.** 1. without hue and saturation. Thus, an achromatic color is black, white, or a shade of gray. 2. able to refract light without splitting it into its constituent wavelengths. The term generally refers to lenses that do not distort the color of objects viewed through them. Compare CHROMATIC.

**achromatic–chromatic scale** a scale of color values ranging through the CHROMATIC spectrum of hues and including the ACHROMATIC shades of black through gray to white.

**achromatic interval** in vision, the interval of light intensity between the amount required for detection of a monochromatic stimulus and the amount required to perceive the color of the stimulus.

**achromatism** n. color blindness marked by the inability to perceive any color whatsoever: Everything is seen in different shades of gray. It is a congenital condition stemming from a lack of RETINAL CONES. When acquired as a result of brain injury, it is called cerebral achromatopsia: the typical site of injury is the ventromedial occipital cortex of the brain (see V4). Also called achromatopsia. See also Dichromatism; Monochromatism; Trichromatism.

**acid** 1. adj. denoting one of the four primary odor qualities in the crocker–hENDERSON odor system. 2. n. a common colloquial term for LSD. See also Hallucinogen.

**acid flashback** a common colloquial term for the experience reported by some users of LSD in which part of the experience recurs later when the individual has not been using the drug.

**acidosis** n. an abnormally high level of acidity (hydrogen ion concentration) in the blood and tissues, which upsets the body’s acid–base balance. The condition has numerous causes and symptoms vary with each, potentially including such neurological abnormalities as confusion, fatigue or lethargy, and irritability. Rapid breathing is often seen as well. Compare ALKALOsis. —acidotic adj.

**acid trip** see TRIP.

**acmesthesia** n. a form of paresthesia in which a cutaneous stimulus normally sensed as pain is perceived instead as sharp touch or pressure.

**ACOa** abbreviation for ANTERIOR COMMUNICATING ARTERY.

**ACOA** abbreviation for ADULT CHILDREN OF ALCOHOLICS.

**ACOMA** abbreviation for ANTERIOR COMMUNICATING ARTERY.

**aconuresis** n. involuntary passage of urine. It is a rare synonym of enuresis.

**acoria (akoria)** n. a form of Polyphagia marked by an excessive appetite and a loss of the sensation of satiety. See also bulimia nervosa.

**Acosta’s syndrome** see ALTITUDE SICKNESS. [José de Acosta (1539–1600), Spanish geographer]

**acoustic** adj. associated with sound. The word is usually used to modify technical terms (e.g., acoustic wave, acoustic impedance, ACOUSTIC REFLEX). Acoustical is used as a modifier in all other contexts (e.g., acoustical engineer).

**Acoustical Society of America (ASA)** the major professional organization concerned with acoustics in the United States. The society consists of many technical areas, including psychological and physiological acoustics, speech communication, and musical acoustics. The ASA is part of the American Institute of Physics and publishes the Journal of the Acoustical Society of America (JASA).

**acoustic cue** in phonology, one of the physical properties of a speech sound (e.g., wave frequency, voice-onset time, intensity) that mark its identity.
acoustic encoding see VISUAL ENCODING.

acoustic environments the acoustic or sound-propagating qualities of a physical environment. In addition to sound intensity (i.e., loudness), an important feature of acoustic environments is reverberation time: the time taken for a sound to decay 60 dB. Perception of sound inside differs from that outside because of reverberation.

acoustic filter a component of some versions of the WORKING MEMORY model that allows only speechlike stimuli to access the model’s phonological store.

acoustic-mnestic aphasia a form of APHASIA resulting from lesions in the left TEMPORAL LOBE. It is marked by difficulty in remembering verbal material, particularly in recalling word lists and reproducing long sentences. Also called acoustic–amnestic aphasia.

acoustic nerve see AUDITORY NERVE.

acoustic neuroma a benign tumor arising from the AUDITORY NERVE, between the cochlea and the brainstem. Common symptoms include tinnitus, unilateral hearing loss, and vertigo.

acoustic phonetics the branch of PHONETICS that studies the physical properties of human speech sounds and the physiological means by which they are perceived. Compare ARTICULATORY PHONETICS.

acoustic pressure see SOUND PRESSURE.

acoustic reflex contraction of the middle ear muscles (the TENSOR TYPANI and STAPIDUS MUSCLE) elicited by intense sounds. This reflex restricts movement of the ossicles, thus reducing the sound energy transmitted to the inner ear and partially protecting it from damage.

acoustic resonance a frequency-dependent change in the response of an acoustic system. The response of a system is a maximum at its resonance frequency.

acoustics n. the science of sound: a branch of physics concerned with the study of sound, including its physical properties, production, transmission, and reception. See also BIOACOUSTICS; PSYCHOACOUSTICS.

acoustics as emotions acoustic patterns that are specific to particular emotions and therefore enable recognition of emotion in speech. These acoustic properties are measured by FORMANT analysis, spectral analysis, intonation scoring, and inverse filtering of the speech signal to arrive at an estimate of the glottal waveform.

acoustic spectrum see SOUND SPECTRUM.

acoustic store 1. a component of short-term memory that retains auditory information based on how items sound. Forgetting occurs when words or letters in acoustic store sound alike. Compare ARTICULATORY STORE. 2. see PHONOLOGICAL LOOP.

acoustic trauma physical injury to the inner ear resulting from exposure to intense noise, such as explosions, or continuous prolonged loud music or machinery noise. It is a common cause of SENSONEURAL DEAFNESS.

ACPT abbreviation for AUDITORY CONTINUOUS PERFORMANCE TEST.

acquaintance rape see DATE RAPE.

acquiescence n. agreement or acceptance, typically without protest or argument. —acquiesce vb. —acquiescent adj.

acquisitiveness n. the tendency or desire to acquire
acquisitive stage see SCHAIE’S STAGES OF COGNITIVE DEVELOPMENT.

acquisitive stage see SCHIAH’S STAGES OF COGNITIVE DEVELOPMENT.

across combining form 1. the extremities (e.g., ACRONEUGALLY). 2. height (e.g., ACROPHOBIA).

acroanesthesia n. an absence of sensitivity in one or more extremities.

acrocentric chromosome a chromosome in which the centromere is near one end, making one arm of the replicating chromosome shorter than the other. An acrocentric chromosome may be much smaller than others and may occur as additional genetic material in such disorders as CAT’S-EYE SYNDROME.

acrocephalopolysyndactyly n. see Carpenter’s Syndrome.

acrocephalosyndactyly n. any of several related inherited disorders (all dominant traits) that cause abnormalities of the skull, face, hands, and feet. APERT SYNDROME, Apert-Crouzon syndrome, and PFEIFFER’S SYNDROME (acrocephalosyndactyly Types I, II, and V) are due to different mutations in the FGF2 gene (encoding fibroblast growth factor receptor) on chromosome 10. CHOTZEN’S SYNDROME (Type III) is due to a mutation in the TWIST gene on chromosome 7 (locus 7p21.3–21.2), which affects the expression of FGF2.

acrocephaly n. see OXYCEPHALY.

acrocrines n. excessive motion or movement. Also called acrocinesis: acrokinesis.

acrodystosis n. see PERIPHERAL DYSTOSTOSIS WITH NASAL HYPOPLASIA.

acroesthesia n. an increased sensitivity to stimuli applied to the extremities.

acromegaly n. an abnormal enlargement of the bones in the hands, feet, face, and skull due to excessive secretion of growth hormone by the pituitary gland during adulthood.—acromegalic adj.

acromicria n. a type of underdevelopment marked by abnormally small fingers, toes, or facial features.

acroparesthesia n. a feeling of numbness, tingling, or other abnormal sensation in one or more extremities. Kinds of acroparesthesia include Nothnagel’s acroparesthesia, which is accompanied by circulatory disorders, and Schultze’s acroparesthesia, marked by peripheral-nerve irritability but without circulatory abnormalities.

acrophobia n. an excessive, irrational fear of heights, resulting in the avoidance of elevations or marked distress when unable to avoid high places.—acrophobic adj.

acrotomophilia n. a PARAPHILIA in which a person is sexually aroused by people whose body parts, typically arms or legs, have been amputated or by amputation sites in the body. Also called acrotophilia. Compare APOTEMNOPHILIA.

ACSI abbreviation for ATHLETIC COPING SKILLS INVENTORY.

ACSM abbreviation for AMERICAN COLLEGE OF SPORTS MEDICINE.

ACSW abbreviation for ACADEMY OF CERTIFIED SOCIAL WORKERS.

act n. a complex behavior, as distinct from a simple movement.

ACT 1. abbreviation for ACCEPTANCE AND COMMITMENT THERAPY. 2. abbreviation for ATROPINE-COMA THERAPY. 3. abbreviation for ATTENTION-CONTROL TRAINING. 4. abbreviation for AUDITORY CONSONANT TRIGRAM.

ACT® acronym (pronounced act-star) for adaptive control of thought theory, in revised form. ACT® is a theory of the mental representation of knowledge and of skilled behaviors that implement knowledge. [formulated by U.S. cognitive psychologist John R. Anderson (1947– )]

ACT Assessment American College Testing Assessment: a set of four multiple-choice academic college tests (English, mathematics, reading, science) administered nationally five times yearly; an optional, supplemental essay writing test may also be given. The assessment consists of 215 total questions intended to evaluate the participant’s overall academic achievement and mastery of the basic skills required for satisfactory performance in college, rather than the person’s aptitude or intelligence. The ACT Assessment is one of four major components of the American College Testing Program (ACTP), a system for gathering data about students and providing it to designated educational institutions.

ACTII abbreviation for adrenocorticotropic hormone. See CORTICOTROPIN.

ACTII-releasing factor see CORTICOTROPIN-RELEASING FACTOR.

acquisitive stage 

act n. see MUSCLE FIBER.

acting in in psychoanalysis, a form of RESISTANCE occurring within the therapy hour, in which the patient defends against repressed wishes, memories, or both by using actions (e.g., getting up and walking about) to impede the flow of FREE ASSOCIATION.

acting out 1. the behavioral expression of emotions that serves to relieve tension associated with these emotions or to communicate them in a disguised, or indirect, way to others. Such behaviors may include arguing, fighting, stealing, threatening, or throwing tantrums. 2. in psychoanalytic theory, reenactment of past events as an expression of unconscious emotional conflicts, feelings, or desires—often sexual or aggressive—with no conscious awareness of the origin or meaning of these behaviors.

action n. 1. a self-initiated sequence of movements, usually with respect to some goal. It may consist of an integrated set of component behaviors as opposed to a single response. 2. the occurrence or performance of a process or function (e.g., the action of an enzyme). 3. the state or process of being active.

actional verb in linguistics, a verb that denotes physical action, usually performed by an AGENT and resulting in an effect on a PATIENT, such as kick or kiss. A nonactional verb is one that denotes an occurrence, experience, state, or condition, such as be, have, see, think, or explain. Some psychologists believe that the distinction between actional and nonactional verbs is significant in explaining patterns of early language development. See also CAUSATIVE VERB.

action at a distance the interaction of bodies that are not in physical contact and have no intervening mechanical medium, as by a field of force, such as gravitation. See FIELD THEORY.

action-based model a version of COGNITIVE DISSO-
NANCE THEORY postulating that the existence of inconsistency, even in the absence of aversive consequences, is sufficient to produce cognitive dissonance. It further postulates that inconsistency is unpleasant because it is adaptive to have clear action tendencies (i.e., approach vs. avoidance tendencies) toward objects in the environment. See also NEW-LOOK THEORY: SELF-CONSISTENCY PERSPECTIVE. SELF-STANDARDS MODEL.[proposed by U.S. psychologist Eddie Harmon-Jones]

action disorganization syndrome (ADS) a cognitive deficit resulting from damage to the FRONTAL LOBES of the brain and causing individuals to make errors on multisteped but familiar or routine tasks. Types of errors include omissions or additions of steps, disordered sequencing of steps, and object substitutions or misuse.

action group a TASK-ORIENTED GROUP whose purpose is to achieve a modification of the environment. For example, a residential care facility may convene an action group to implement changes to its practices that help improve mealtime nutrition for residents.

action identification the way in which specific behaviors, ranging from low-level muscle movements to high-level, abstract goal pursuits, are construed. For example, the behavior of pressing a key on a keyboard could be construed as I am pressing a key, I am typing, or I am writing a novel.[introduced in 1985 by Robin R. Vallacher, U.S. psychologist, and Daniel M. Wegner (1948—). Canadian-born U.S. psychologist]

action orientation a style of responding to dilemmas or conflicts that is characterized by swift, decisive action to achieve mental and behavioral change. Action orientation has been suggested as a key moderator of COGNITIVE CONTROL under demanding conditions, such that action-oriented individuals are better able to exert control under high demands than are individuals with a STATE ORIENTATION.

action-oriented therapy any therapy that emphasizes doing and taking action rather than verbal communication or discussion.

action painting a form of painting, often used in ART THERAPY, in which individuals spontaneously create unplanned abstract works using unconventional techniques, such as splashing, dribbling, trickling, or slapping the paint more or less randomly onto the canvas. When used therapeutically, these productions are reviewed and incorporated into treatment. Also called tachisme.

action pattern a predictable behavioral sequence that is elicited by certain requisite stimuli. For example, during the mating season, a male fish aggressively defends its territory against other males. See also FIXED ACTION PATTERN.

action potential (AP) the change in electric potential that propagates along the axon of a neuron during the transmission of a nerve impulse or the contraction of a muscle. It is marked by a rapid, transient DEPOLARIZATION of the cell’s plasma membrane, from a RESTING POTENTIAL of about –70 mV (inside negative) to about +30 mV (inside positive), and back again, after a slight HYPERPOLARIZATION, to the resting potential. Each action potential takes just a few milliseconds. Also called spike potential.

action readiness a state of preparedness for action that is elicited as part of an emotional response and associated with such physiological indicators as changes in heart rate, respiratory rate, and muscle tension. The term is often used synonymously with ACTION TENDENCY but also refers to a general readiness for action that does not involve an urge to carry out a specific behavior.

action research 1. as originally defined in the mid-1940s by Kurt Lewin, research developed and carried out to address a social issue or problem, results of which are used to improve the situation. Exploring the most effective way to respond to prejudiced comments is an example of action research, as is investigating interventions to reduce the incidence and consequences of domestic violence. 2. more generally, any research directed toward a practical goal, usually an improvement in a particular process or system. In ORGANIZATIONAL DEVELOPMENT, for example, action research involves not only systematically collecting data about an organization but also providing feedback to the organization, taking actions to improve the organization based on the feedback, and then evaluating the results of these actions.

action slip any error that involves some kind of cognitive lapse and results in an unintended action, as in putting one’s spectacles in the refrigerator. Action slips are commonly identified as mistakes due to ABSENT-MINDEDNESS.

action-specific energy in classical ETHOLOGY, a hypothetical supply of motivational energy within an organism that is associated with specific unlearned behavioral responses known as FIXED ACTION PATTERNS. Each response has its own energy supply, which builds up until the organism encounters the appropriate stimulus (see releaser) that triggers the response and thus depletes the energy supply. After the response and in the absence of the releaser, the action-specific energy begins to build up again.[proposed by Konrad Lorenz]

action stream see DORSAL STREAM.

action teaching the use of classroom activities, fieldwork, Internet-based demonstrations, and other assignments to construct engaging learning environments that integrate coursework with societal issues. Similar to ACTION RESEARCH but in an educational context, action teaching turns textbook lessons into interactive experiences in which students learn not only topical information but also ways to address important social problems. Examples of this teaching method include an exercise in which students from an introductory psychology class learn about persuasion by using different strategies to solicit donations from community residents for a particular charitable organization or cause, and an exercise in which students from a research methods class learn about experimental design by creating and conducting their own study on the reasons many commuters do not take public transportation to work.[coined in 2000 by U.S. social psychologist Scott L. Dials (1959—)]

action tendency an urge to carry out certain expressive or instrumental behaviors that is linked to a specific emotion. For example, the action tendency of fear involves an urge to escape, and that of anger involves an urge to attack. Some theorists argue that the action tendency of an emotional reaction should be regarded as its essential defining characteristic. Compare ACTION READINESS.

action theory all those theories, collectively, that explain behavior in terms of goal-directed human beings acting intentionally with reference to the environment and present situation. Action theory was known originally as WIL Psychology, founded in Germany by Wilhelm Wundt,
action tremor
trembling of a body part that arises when the individual is engaged in directed voluntary activity and that increases as the movement progresses. Action tremors are classified into the following subtypes: Postural tremor occurs when the person maintains a position against gravity, such as holding the arms outstretched; kinetic tremor appears during movement of a body part, such as moving the wrists up and down; intention tremor is the trembling of a body part that arises near the conclusion of a directed, voluntary movement, such as touching a finger to one’s nose; task-specific tremor appears during the performance of highly skilled, goal-oriented tasks such as handwriting; and isometric tremor occurs during a voluntary muscle contraction that is not accompanied by any other movement. Compare RESTING TREMOR.

Action unit the simplest facial movement used as a code in the FACIAL ACTION CODING SYSTEM. Action units are the visible signs of the operation of single facial muscles.

Actiq n. a trade name for FENTANYL.

Activating event in RATIONAL EMOTIVE BEHAVIOR THERAPY, an event—current, past, or anticipated—that triggers irrational beliefs and disruptive emotions.

Activation n. 1. in many theories of memory, an attribute of the representational units (such as NODES or LOGOGENS) that varies from weaker to stronger, with more strongly activated representations competing to control processing. 2. the process of alerting an organ or body system for action, particularly arousal of one organ or system by another. An example is the pituitary gland’s release of hormones that activate the ovaries and testes for puberty. —activate vb. —activation adj.

Activational effect a transient hormonal effect that typically causes a short-term change in behavior or physiological activity in adult animals. For example, increased testosterone in male songbirds in spring leads to increased aggression in territory defense and increased courtship behavior. Compare ORGANIZATIONAL EFFECT.

Activation–arousal theory see ACTIVATION THEORY OF EMOTION.

Activation–elaboration a dual-process theory of memory holding that concepts stored in memory vary in their levels both of ACTIVATION and ELABORATION.

Activation hypothesis 1. the idea that numerical weightings assigned to the links or nodes of cognitive network models can represent their degree of activity or processing. Consciousness is sometimes attributed to above-threshold numbers in such models. 2. the hypothesis that high metabolic activity reflects activation of brain areas subserving mental tasks.

Activation pattern in electroencephalography, the suppression of ALPHA WAVES and a shift to low-voltage, rapid activity when the person undergoing the procedure opens his or her eyes to view an object or display. The alpha desynchronization may be localized or general, as measured in various cerebral areas, and transient or sustained.

Activation–synthesis hypothesis a hypothesis that explains dreams as a product of cortical interpretation of random neural activity rising from the brainstem (specifically thepons). It has been superseded by the AIM MODEL.

See PGO SPIKES. [originated by U.S. psychiatrists J. Allan Hobson (1933— ) and Robert W. McCarley (1937— )]

Activation theory of emotion the theory that emotion is measurable as change in the individual’s level of neural excitation of the RETICULAR FORMATION and associated degree of cortical and thalamic alertness, as revealed via electroencephalography. It is a refinement of an earlier activation-arousal theory equating emotion to change in the difficult-to-measure level of an individual’s energy expenditure. Also called arousal theory.

Active adj. 1. currently performing some action, either continuously or intermittently. 2. exerting an effect or influence on a process or thing. 3. in grammar, denoting the ACTIVE VOICE of a verb. 4. vigorous, lively, or energetic.

Active analytic psychotherapy the therapeutic approach of Viennese psychoanalyst Wilhelm Stekel (1868–1940) in which the analyst takes a much more active role than prescribed in CLASSICAL PSYCHOANALYSIS and gives more attention to intrapsychic conflicts in the patient’s current life than to exploring early childhood experiences. The therapist intervenes in the process of free association to discuss important issues, confronts the patient’s resistances directly, offers advice and exhortation, and helps the patient interpret his or her dreams intuitively in the light of current attitudes and problems. Through these methods, and by avoiding many of the Freudian steps such as ANALYSIS OF TRANSFERENCE, Stekel sought to shorten the therapeutic process considerably. Also called active analysis.

Active attention see SECONDARY ATTENTION.

Active avoidance a type of OPERANT CONDITIONING in which an explicit act prevents or postpones the delivery of an AVERSIVE STIMULUS, as when pressing a lever blocks the delivery of an electric shock. That is, avoidance is achieved by an overt action. Compare PASSIVE AVOIDANCE.

Active concretization in schizophrenia, the process of transforming abstract concepts into concrete representations or forms. For example, an individual with paranoid schizophrenia who experiences feelings that the whole world is hostile may later become convinced that the neighbors are trying to harm him or her. If this individual should then begin to have specific perceptual experiences that support this conviction, such as auditory hallucinations of threatening remarks made by the neighbors, PERCEPTUALIZATION of the concept has occurred; this is the most advanced level of active concretization. [defined by Italian-born U.S. psychiatrist Silvano Arieti (1914–1982)]

Active control trial a two-group experimental design in which one group receives the treatment under study and the second group receives a comparable standard treatment. Although efficacy generally is best evaluated by comparing a treatment to a PLACEBO, active control trials are used in situations when withholding treatment from individuals by assigning them to a placebo group is not ethical. Compare PLACEBO CONTROLLED TRIAL.

Active coping a stress-management strategy in which a person directly works to control a stressor through appropriately targeted behavior, embracing responsibility for resolving the situation using one’s available internal resources. This type of COPING STRATEGY may take various forms, such as changing established habits. Active coping generally is considered adaptive, having been associated with fewer mood disturbances, enhanced self-efficacy, and other favorable consequences. It is similar to the ear-
activity cage
activity cycle

freely while their behavior is observed, recorded, or measured.

activity cycle any regularly recurring sequence of events characterized by fluctuating levels of activity. Unlike activity rhythms, activity cycles may be learned and thus are not always associated with biological rhythms.

activity deprivation lack of opportunity to engage in physical activity due to restrictive circumstances, for example, confinement in a small area, which may result in distress and physical discomfort. See also activity drive.

activity drive an organism’s hypothetical innate desire or urge to be physically active, often expressed as a need to move about, even in the absence of any apparent stimuli motivating movement, such that activity deprivation may cause distress.

activity group therapy one of two main types of group therapy defined by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981), the other being analytic group psychotherapy. Designed for children 6 to 12 years old, activity group therapy emphasizes participation in games, crafts, and other age-appropriate activities. Its deliberate lack of restraint and absence of interpretation are intended to provide a permissive, non-threatening atmosphere that encourages children to express their feelings, the effect of which is believed to be fundamental change in personality structure. Slavson introduced activity group therapy in 1934 as a response to the distinct needs of individuals in this age group, which he saw as resulting from their weak ego organization, the basic narcissistic quality of their libido, and the surface nature of their unconscious.

activity-interview group psychotherapy a form of analytic group psychotherapy for children 6 to 12 years old who, because of excessively high levels of fear, anxiety, and guilt, do not benefit from the activity group therapy originally developed for this age group. It uses group discussions, work activities, recreational activities, and other verbal and nonverbal techniques to stimulate the expression and exploration of daydreams, fantasies, and other experiences. During the process, the therapist asks questions that encourage the children to understand the underlying meanings of their behavior, attitudes, and feelings and that thus address sources of intrapsychic conflicts. The therapist may also offer explanations and interpretations if appropriate. [introduced in 1943 by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981)]

activity log a diary kept by a researcher or research participant of activities in various settings. An activity log may include information about the location of the participant by time period (e.g., at home, at work, traveling) and whether the time is spent alone or with family, friends, or work associates. An activity log as a method of obtaining a record of events generally is superior to interviews based on a participant’s memory.

activity-passivity in psychoanalytic theory, polarities characterizing instinctual aims (see aim of the instinct). Sigmund Freud asserted that instincts are always active but that their aims can be either active (e.g., sadism, voyeurism) or passive (e.g., exhibitionism, masochism). The concept now plays a role in many trait theories of personality.

activity record the written or recorded data detailing a student’s extracurricular involvement in school activities, clubs, or special projects.

activity rhythm the pattern of individual behavior over the course of a day, month, or year that exhibits a clear cycle of activity more or less in synchrony with temporal cues. For example, rats are generally active for approximately 12 hours a day, during the hours of darkness. See biological rhythm.

activity system see behavior system.

activity theory 1. a school of thought, developed primarily by Soviet psychologists, that focuses on activity in general—rather than the distinct concepts of behavior or mental states—as the primary unit of analysis. In this context, an activity is a nonadditive unit that orients an organism in the world; it is essentially a system comprising an operation (a routine behavior requiring little thought, e.g., typing) that serves to accomplish an action (a behavior that involves planning, e.g., creating a bibliography) in the minimum meaningful context that provides understanding of the function of the individual in interacting with the environment (e.g., preparing a paper for a university course as part of a network of students). The theory emphasizes a hierarchical structure of activity, object-orientedness, internalization and externalization, mediation (by tools, language, and other cultural artifacts or instruments), and continuous development. Also called activity psychology.

2. a theory proposing that old age is a lively, creative experience characterized by maintaining existing social roles, activities, and relationships or replacing any lost ones with new ones. Compare continuity theory; disengagement theory.

activity therapy any type of therapy based on one or more of various activities, such as arts and crafts, exercise, music, and drama. See creative arts therapy.

activity wheel a revolving drum that turns by the weight of an animal running inside. The activity wheel records the number of revolutions and is often used for research purposes. Also called running wheel.

actomyosin n. see muscle fiber.

actor–observer effect in attribution theory, the tendency for individuals acting in a situation to attribute the causes of their behavior to external or situational factors, such as social pressure, but for observers to attribute the same behavior to internal or dispositional factors, such as personality. See fundamental attribution error. See also dispositional attribution; situational attribution. [introduced in 1971 by U.S. psychologists Edward E. Jones (1926–1991) and Richard E. Nisbett (1941–)]

ACTP abbreviation for American College Testing Program. See act assessment.

act psychology a philosophical and psychological approach based on the proposition that the act and content of psychological processes are separate functions; for example, the act of seeing color leads to a perception of the visual content, or image. Historically, proponents of act psychology held that acts (mental representation and transformation, judgment, emotion) rather than contents, are the proper subject of psychology, in contrast to Wilhelm Wundt’s emphasis on introspection and conscious contents. Compare content psychology. See also intentionality.

actual adj. in philosophy, existing as a real and present fact. The actual is often contrasted with the merely appar-
ent. Something may appear to the senses to be real but may not actually exist. In the intellectual tradition founded by Aristotle, the actual is contrasted to the potential, which is the capacity to change: An entity is actual when form and substance come together to produce it as an end. See also INTELECHY.

actualization n. the process of mobilizing one’s potenti-

potential alities and realizing them in concrete form. According to Carl Rogers, all humans have an innate actualizing ten-

actu-alization to grow and realize the self fully. See also SELF-ACTU-

alization. — actualize vi.

actual neurosis in the classical psychoanalytic theory of Sigmund Freud, a neurosis that stems from current sexual frustrations (e.g., coitus interruptus, otherwise incomplete sexual experience, forced abstinence), as contrasted with one that stems from past experiences or psychological conflicts. The term, originally applied primarily to anxiety neurosis and neurasthenia, has more recently been used to describe a preexisting psychological (i.e., actual neurotic) structure that makes some victims of trauma vulnerable to developing POSTTRAUMATIC STRESS DISORDER.

actual self in various psychodynamic writings, the real self or true self as it exists at a particular point in time, as opposed to an idealized, grandiose, or otherwise distorted self. The term is also used by client-centered therapists to describe the self untainted by societal constraints and parental expectations.

actuarial adj. statistical: based on quantified experience and data. In medicine, the use of data about prior instances to estimate the likelihood or risk of a particular outcome is sometimes cited as an alternative to clinical di-

actuarial risk assessment a statistically calculated prediction of the likelihood that an individual will pose a threat to others or engage in a certain behavior (e.g., violence) within a given period. Unlike in a CLINICAL RISK ASSESSMENT, someone conducting an actuarial risk assessment relies on data from specific, measurable variables (e.g., age, gender, prior criminal activity) that have been validated as predictors and uses mathematical analyses and formulas to calculate the probability of DANGEROUSNESS or violent behavior.

actus reus the illegal act (Latin, “guilty act”) that, combined with a criminal intent in committing it (see MENS REA), constitutes a crime.

acuity n. sharpness of perception. Whereas VISUAL ACUITY is sharpness of vision and AUDITORY ACUITY sharpness of hearing, SENSORY ACUITY is the precision with which any sensory stimulation is perceived.

acuity grating a stimulus used to measure an individu-

al’s sharpness of visual perception. It consists of alternating black and white lines spaced closely together; the point at which the participant perceives the lines to be homoge-

neous gives an indication of VISUAL ACUITY. When the con-

trast of the lines is varied, the acuity grating can be used to test CONTRAST SENSITIVITY.

acusalia n. nonsensical speech associated with lack of comprehension of written or spoken language, as occurs in WERNICKE’S APHASIA.

acupressure n. a form of COMPLEMENTARY AND ALTERNATIVE MEDICINE in which pressure is applied with the fingers or thumbs to specific points on the body to relieve pain, treat symptoms of disease, or improve overall health.

acupuncture n. a form of COMPLEMENTARY AND ALTERNATIVE MEDICINE in which fine needles are inserted into the body at specific points to relieve pain, induce anesthesia (ACUPUNCTURE ANESTHESIA), or treat disease. It is based on the concept in traditional Chinese medicine that “meridians,” or pathways, conduct a life-force energy known as Chi between places on the skin and the body’s organ sys-

achtus reus tems. Western scientists are unable to explain specifically how acupuncture produces its effects but theorize that the needling sites may be related to trigger points in the GATE-CONTROL THEORY of pain or may stimulate the release of ENDOGENOUS OPIOIDS. The technique is highly popular in many Western societies and has been deemed appropriate by the World Health Organization for use in treating more than 40 medical conditions. Compare ACUPRESSURE. —acupuncturist n.

acupuncture anesthesia the loss of sensation, often of pain, that results from the insertion of ACUPUNCTURE needles into the body at specific points. The technique may be used alone or in combination with other pain-manage-

ment techniques during surgery.

-acusia (-acusis; -cusis) suffix (e.g., PARACUSIA).

acute adj. 1. denoting conditions or symptoms of sudden onset, short duration, and often great intensity. Compare CHRONIC. 2. sharp, keen, or very sensitive (e.g., acute hearing).

acute alcoholic myopathy a condition of severe pain, tenderness, and swelling of the muscles, accompanied by cramps and muscular weakness, that develops after a period of heavy drinking. The effects may be general or fo-

fused in one body area. In some cases, muscle fibers may undergo necrosis (death of constituent cells). Recovery may require several weeks to several months.

acute alcoholism the complex of usually short-term symptoms associated with severe alcohol intoxication. Symptoms may include impaired motor control, incoordi-

nating, respiratory depression, stupor, vomiting, dehydra-

tion, and headache.

acute anxiety a sudden feeling of dread and apprehen-

sion accompanied by somatic symptoms of tension, usually precipitated by a threatening situation, such as an exam-

ination or court hearing. The feeling typically subsides as soon as the situation is over.

acute brain disorder any pattern of symptoms result-

ing from temporary, reversible impairment of brain func-

tioning.

acute cerebellar ataxia a disorder that occurs sud-

nally, most often in children, following a viral infection. It is characterized by slurred speech: muscular incoordina-

tion (ATAXIA); rapid, involuntary eye movements (NYSTAG-

MUS); and intention tremor (see ACTION TREMOR). Also called acute cerebral tremor.

acute cerebrovascular accident the onset of symp-

toms of stroke. See CEREBROVASCULAR ACCIDENT.

acute confusional state severe confusion that can in-

clude symptoms of agitation, memory disturbance, disori-

entation, and delirium. It often occurs as a result of severe mental or physical illness.

acute delirium a sudden but brief disturbance in con-

sciousness resulting from metabolic disturbance (e.g., high
acute delusional psychosis

fever) or toxic agents (e.g., excessive amounts of alcohol). It is marked by illusions, hallucinations, delusions, excitement, restlessness, and incoherence.

**acute delusional psychosis** a diagnostic entity specific to French psychiatry, in which it is known as **bouffée délirante** (French, “delirious outburst”), involving the sudden onset of schizophrenic symptoms in response to a stressful life event. It is temporary (lasting no longer than 3 months), has no strong evidence of a genetic link, and has a favorable prognosis: spontaneous resolution of symptoms is not uncommon. Acute delusional psychosis is essentially equivalent to **BRIEF PSYCHOTIC DISORDER**.

**acute depression** 1. a sudden onset of depression. 2. a severe episode of depression, characterized by many more symptoms than are necessary to meet the criteria for a **MAJOR DEPRESSIVE EPISODE**.

**acute dystonia** a sudden loss of normal muscle tone. See **DYSTONIA**.

**acute mania** the manic phase of bipolar I disorder (see **BIPOLAR DISORDER**), characterized by an extremely unstable euphoric or irritable mood with hyperactivity, excessively rapid thought and speech, uninhibited and reckless behavior, grandiosity, and disturbances in emotional responsiveness.

**acute mountain sickness** an illness that can affect mountain climbers, hikers, or skiers who have ascended too rapidly above 2,400 m (8,000 ft), especially when coming from sea level. Caused by the effects of reduced atmospheric pressure and oxygen pressure at high altitudes, it affects the nervous system, lungs, muscles, and heart. The faster the ascent and the higher the altitude, the greater is the degree of illness. In two out of every 10,000 cases, swelling occurs around the brain, causing confusion and leading to coma (high-altitude cerebral edema). See also **ALTIITUDE SICKNESS**.

**acute onset** a sudden, rapid, or unanticipated development of a disease or its symptoms.

**acute otitis media** see **OTITIS MEDIA**.

**acute preparation** the process by which a research animal undergoes an experimental procedure, often surgical in nature, and is then studied for a relatively short period (typically under anesthetic before being euthanized). Compare **CHRONIC PREPARATION**.

**acute psychotic episode** an appearance of florid (blatant) psychotic symptoms, such as hallucinations, delusions, and disorganized speech, that is of sudden onset and usually short duration.

**acute schizophrenic episode** an appearance of florid (blatant) schizophrenic symptoms, such as disordered thinking and disturbances in emotional responsiveness and behavior, that is of sudden onset.

**acute stress disorder (ASD)** a disabling psychological condition that can occur immediately after exposure to a traumatic stressor. Symptoms such as intrusive thoughts, hyperarousal, and avoidance of situations that recall the traumatic event are the same as those of **POSTTRAUMATIC STRESS DISORDER** but do not last longer than 4 weeks. This disorder may also include elements of dissociation, such as **DEPERSONALIZATION** and **DEREALIZATION**.

**acute stress response** see **HYPERAROUSAL**.

**acute tolerance** a type of TOLERANCE (physical dependence) that develops rapidly, sometimes in response to a single small dose of a particular drug. See also **TACHYPHYLANAXIS**.

**ada** prefix 1. to or toward. 2. near or adjacent to.

**ADA** abbreviation for **AMERICANS WITH DISABILITIES ACT**.

**Adam** n. slang for **MDMA**, a hallucinogen.

**ADAMHA** abbreviation for **ALCOHOL, DRUG ABUSE AND MENTAL HEALTH ADMINISTRATION**.

**Adapin** n. a trade name for **DEXEPIN**.

**adaptability** n. 1. the capacity to make appropriate responses to changed or changing situations. 2. the ability to modify or adjust one’s behavior in meeting different circumstances or different people. —adaptable adj.

**adaptation** n. 1. adjustment of a sense organ to the intensity or quality of stimulation, resulting in a temporary change in sensory or perceptual experience, as in **VISUAL ADAPTATION** when the pupil of the eye adjusts to dim or bright light. 2. reduced responsiveness in a sensory receptor or sensory system caused by prolonged or repeated stimulation. The adaptation may be specific, for example, to the orientation of a particular stimulus. Also called **sensory adaptation**. 3. modification to suit different or changing circumstances. In this sense, the term often refers to behavior that enables an individual to adjust to the environment effectively and function optimally in various domains, such as coping with daily stressors. It is also applied more widely, for example, in ergonomics, to denote a system that alters information presentation, interface design, or output according to the capabilities or characteristics of the user, system, or environmental state. Compare **MALADAPTATION**. 4. adjustments to the demands, restrictions, and mores of society, including the ability to live and work harmoniously with others and to engage in satisfying social interactions and relationships. Also called **social adaptation**. 5. the modification of an organism in structure or function that increases its ability to reproduce successfully and its offspring’s ability to survive and reproduce successfully. 6. in **PIAGETIAN THEORY**, the process of adjusting one’s cognitive structures to meet environmental demands, which involves the complementary processes of assimilation and accommodation. —adapt vb. —adaptational adj. —adaptive adj.

**adaptation level** (AL) the theoretical baseline or zero point, which forms a standard against which new stimuli are evaluated. For example, a person who first lifts a 40 lb weight would then likely judge a 20 lb weight as light, whereas if that person first lifted a 4 lb weight he or she would then likely judge the 20 lb weight as heavy. Although it originated in studies of sensory perception, **adaptation-level theory** has since been applied in other fields, such as aesthetics and attitude change. [originated by Harry HElSON]

**adaptation period** a period of time during which a research participant becomes accustomed to the materials, instruments, or equipment to be used in a study or reaches a certain performance level. Adaptation periods help reduce the influence of situational novelty on a participant’s behavior.

**adaptation stage** see **GENERAL ADAPTATION SYNDROME**.

**adaptation time** the period of time from the start of a stimulus until the sense organ stimulated has adapted completely and no longer responds.

**adapted child** one of the child ego states in **TRANSAC-**
adaptive act the process whereby an organism learns to make the appropriate responses that are needed for an adjustment to the environment. For example, a caged pigeon learns to peck on a lighted key in order to receive food.

adaptive behavior 1. the level of everyday performance of tasks that is required for a person to fulfill typical roles in society including maintaining independence and meeting cultural expectations regarding personal and social responsibility. Specific categories in which adaptive behavior is usually assessed include self-help, mobility, health care, communication, domestic skills, consumer skills, community use, practical academic skills, and vocational skills. Limitations in adaptive behavior are one of the criteria for diagnosis or classification of intellectual disability and for determining legal competence. 2. any behavior that enables an individual to adjust to the environment appropriately and effectively. It is often discussed in the context of evolution. See also ADJUSTMENT PROCESS.

adaptive behavior scale 1. any standardized assessment protocol with established psychometric properties used to document and quantify everyday performance of skills necessary for personal independence and social responsibility, consistent with cultural expectations (see ADAPTIVE BEHAVIOR). An example is the VINELAND ADAPTIVE BEHAVIOR SCALES. 2. any protocol assessing behavioral and social performance that is based on developmental norms, with domains structured in developmental sequence or degree of ascending task complexity or difficulty.

3. a component of the Bayley Scales of Infant and Toddler Development.

adaptive control of thought theory see ACT*.

adaptive hypothesis the view that the function of the primary autonomous ego is to cope with an “average expectable environment” through perception, memory, affect, regulation, and motility. This is the view taken by Austrian-born U.S. psychoanalyst Heinz Hartmann (1894–1970) in his version of ego psychology.

adaptive intelligence the ability to apply knowledge to novel situations, such as solving problems and conversing with others, demonstrating an effective ability to interact with, and learn from, the environment.

adaptive nonresponding theory a theory that sleep evolved as a means of creating species-specific daily periods of inactivity concurrent with periods of greatest threat from predators.

adaptive production system a production system able to change or adjust the rules in production memory as a result of interacting with an environment. Both SOAR and CLASSIFIER SYSTEMS fall into this category.

adaptive sampling a method of sampling data in which information from past outcomes is used to reduce the chances of collecting future data that correspond to poor outcomes. A group of individuals randomly chosen from the population of interest is evaluated, and the information gathered is used to concentrate additional selection efforts where they are most likely to be successful. For example, if a researcher is interested in studying a certain nonhuman animal of a particular age, he or she could first assess a subset of animals from a given geographical area and then target further sampling efforts in the specific portions of that area shown to possess the most individuals meeting the criteria.

adaptive skills abilities that enable one to meet new challenges, such as the ability to adjust to a new environment and to learn new things. Adaptive skills also involve self-management, such as the ability to control one’s impulses.

adaptive strategy choice model (ASCM) a theoretical model that postulates the existence of multiple strategies of problem solving within a child’s cognitive repertoire and describes how use of these strategies changes over time. According to this model, strategies compete with one another for use: With time and experience, more efficient strategies are used more frequently, whereas less efficient strategies are used less frequently but never totally disappear. This contrasts with stage theory of strategy development, which postulates that more efficient strategies replace less efficient ones. Also called strategy choice model. [proposed by U.S. developmental psychologist Robert S. Siegler (1949– ) and Christopher Shipley]

adaptive system in ergonomics, a system with the capability to alter information presentation, interface design, or output according to the capabilities or characteristics of the user, system, or environmental state.

adaptive task allocation in ergonomics, a design that supports allocation of tasks to the human operator or the machine according to the state of the system, the state of the operator (e.g., if fatigued), or other operational rules. Adaptive task allocation maintains a flexible function allocation policy.

adaptive testing a testing technique designed to adjust to the response characteristics of individual examinees by presenting items of varying difficulty based on the examinee’s responses to previous items. The process continues until a stable estimate of the ability level of the examinee can be determined. See also ITEM RESPONSE THEORY.

adapimeter n. an instrument used to measure the time taken to adapt to a given amount of light, used in the diagnosis of night blindness and other visual disorders.

ADC abbreviation for AIDS DEMENTIA COMPLEX.

ADD abbreviation for attention-deficit disorder. See ATTENTION-DEFICIT/HYPERACTIVITY DISORDER.

Adderall n. a trade name for DEXTROAMPHETAMINE in combination with AMPHETAMINE.

addict n. a person who has developed a SUBSTANCE DEPENDENCE or addiction. The term is also used colloquially to refer to a person with a compulsive behavior such as persistent gambling.

addicted athlete 1. an individual, especially a professional athlete, who is addicted to a substance for purposes of PERFORMANCE ENHANCEMENT in sport. 2. an individual habitually involved in an athletic activity who will experience withdrawal symptoms if deprived of participating in the activity. See also COMPULSIVE EXERCISER.

addiction n. a state of psychological or physical dependence (or both) on the use of alcohol or other drugs. The term is often used as an equivalent term for SUBSTANCE DEPENDENCE and sometimes applied to behavioral disorders, such as sexual, Internet, and gambling addictions. A chemical substance with significant potential for producing dependence is called an ADDICTIVE DRUG. —addictive adj.
additive behavior actions, often obsessive and destructive, that are related to one’s abuse of or dependence on a substance and that dominate one’s life. Addictive behaviors may include drug-seeking behavior, risk taking, and breaking laws in the course of sustaining one’s drug habit.

additive drug any psychoactive substance that has a high likelihood of producing substance dependence. Such substances include alcohol, amphetamines and amphetamine-like CNS stimulants, caffeine, cocaine and crack, hallucinogens, inhalants, nicotine, opioids, PCP (phenicyclidine) and phencyclidine-like substances, and CNS depressants.

additive personality a hypothetical personality pattern thought to increase the likelihood that a person will become dependent on one or more substances. Research has not supported the existence of such a personality but has identified traits associated with substance abuse, such as impulsivity, behavioral undercontrol, and characteristics associated with neurobehavioral disinhibition.

Addison’s disease see Adrenocortical Insufficiency.

addition rule a maxim of probability theory stating that the likelihood of observing a set of distinct events is equal to the sum of the probabilities of observing the individual events. Also called addition law or rule. Compare multiplication rule.

addition test a task requiring the solution of arithmetic addition problems. Early tests of intelligence, such as those of Louis L. Thurstone, sometimes included such tasks, but with the advent of modern computational devices, such as calculators and computers, the tasks have become less relevant.

additive adj. characterized or produced by addition. For example, a function is said to be additive when the quantities defining it may be summed to obtain a meaningful result. Compare nonadditive.

additive bilingualism the sociolinguistic situation in which a second language is adopted by a speech community without threatening the status of the first language. For example, most English-speaking Canadians learn French in order to gain access to prestigious jobs that require bilingualism but continue to use English as their main language. This contrasts with subtractive bilingualism, in which the second language comes to replace the functions of the first language. The bilingualism of many immigrant communities is considered subtractive, resulting in language shift within one or two generations.

additive color mixture the process and effect of combining colored lights, as manifested in new, composite colors; for example, in stage lighting, red and green spotlight lights are blended to form yellow. The color in television is another example of additive color mixture.

additive effect the joint effect of two or more independent variables on a dependent variable where this is equal to the sum of their individual effects: The value of either independent variable is unconditional upon the value of the other and there is no interaction effect.

additive-factors method a procedure for analyzing reaction-time data to determine whether two variables affect the same or different processing stages. If two variables influence different stages, their effects should be additive. If two variables influence the same stage, their effects should be interactive.

additive gene a gene in which there are neither dominant nor recessive alleles, although gradations may exist between extremes. The resulting phenotype does not follow a pattern of mendelian inheritance but instead is determined by the combined effect of the alleles. Additive genes are responsible for such traits as height and skin color and are also believed to be the genetic component of some pathologies such as autism, Alzheimer’s disease, and diabetes.

additive model a description of the relationship between a response variable and a set of predictor variables in which the effect of each predictor is assumed to be the same across all levels of the other predictors in the model. Thus, the combined effect of all predictors is determined by summing their individual effects.

additive scale a scale with all points distributed equally so that a meaningful result can be obtained by addition (e.g., a metric ruler).

additive task a task or project that a group can complete by aggregating individual members’ efforts or contributions. An example is a five-person team pulling together on a rope. Groups usually outperform individuals on such tasks, but overall group productivity rarely reaches its maximum potential owing to social loafing. Compare compensatory task; conjunctive task; disjunctive task.

adduction n. 1. movement of a limb toward the midline of the body. Any muscle that produces such movement is called an adductor. Compare abduction. 2. in conditioning, the production of new behavior by combining the discriminative stimuli of separate discriminated operants; adduct vb.

ADE abbreviation for adverse drug event. See adverse drug reaction.

ADEA abbreviation for Age Discrimination in Employment Act.

A-delta fiber see A fiber.

adendritic adj. describing neurons that lack dendrites.

adenine (symbol: A) n. a purine compound present in the nucleotides of living organisms. It is one of the four bases in DNA and RNA that constitute the genetic code, the others being cytosine, guanine, and thymine or uracil.

adeno- (aden-) combining form gland or glandular.

adenohypophysis n. see anterior pituitary; pituitary gland.

adenoma n. a benign (noncancerous) tumor derived from epithelium that has glandular properties. The most common adenoma in the central nervous system is in the pituitary gland (pituitary adenoma). —adenomatous adj.

adenosine n. a compound in living cells consisting of an adenine molecule and a ribose sugar molecule. Adenosine functions as a neuromodulator: By binding to special adenosine receptors, it influences the release of several neurotransmitters in the central nervous system. Combined with three phosphate units, adenosine becomes ATP (adenosine triphosphate), which functions as an energy source in metabolic activities.

adenosine 3’5’-monophosphate see cyclic AMP.

adenosine triphosphate see ATP.
**adjunctive therapy**

**adenylate cyclase** an enzyme that catalyzes the conversion of ATP to cyclic AMP, which functions as a second messenger in signaling pathways within cells. Also called adenyl cyclase.

**adequate sample** a sample that sufficiently represents the larger population from which it was drawn in terms of size, being large enough to provide satisfactory precision by minimizing the possibility of chance affecting the data obtained.

**adequate stimulus** the type of stimulus for which a given sensory organ is particularly adapted. Thus, the adequate stimulus for the eye is photic (light) energy. Although mechanical pressure on the eye or an electrical shock can stimulate the retina and produce sensations of light, these are not adequate stimuli for the eye.

ADH abbreviation for antidiuretic hormone. See vaso-pressin.

ADHD abbreviation for attention-deficit/hyperactivity disorder.

**adherence** n. the ability of an individual to conform to a treatment regimen, especially one involving drug treatment, as outlined by a health care provider. External factors that affect adherence may include appropriate education regarding a drug and its use, the individual’s ability to pay for or otherwise obtain the treatment recommended, and familial or cultural value systems influencing the acceptability of the treatment to the individual. Internal factors include the individual’s belief in the potency of the treatment, the presence or absence of unpleasant side effects, and the individual’s capability to understand or conform to instructions given by the health care provider. Also called compliance. See also nonadherence.

**adhesive otitis media** see otitis media.

**ad hoc** for a particular purpose or in response to some particular event or occurrence. For example, an ad hoc committee is convened on a short-term basis to address a single problem, and an ad hoc hypothesis is an explanation of a particular phenomenon, rather than a general theory. [Latin, literally: “to this”]

**ad hoc category** a category formed to meet a special criterion or demand, usually in the moment that it is needed. For example, one might form the category things I would take from my house if it were on fire. Compare basic-level category.

**adience** n. a response or behavior that results in movement toward a stimulus, either by physical approach or by an action that increases contact with the stimulus. Compare abience. —adient adj.

**adinazolam** n. a benzodiazepine of the triazolobenzodiazepine class with antidepressant as well as anxiolytic properties. It currently is not available in the United States. Italian trade name: Deracyn.

Adipex n. a trade name for phentermine.

adipo- (adip-) combining form fat or fatty.

adipocyte n. a cell that forms adipose tissue and is specialized for the synthesis and storage of triglycerides (triaclyglycerols), the form in which most fat is stored in the body. Adipocytes also contain enzymes that can mobilize the stored fat as fatty acids and glycerol (see fat metabolism). Also called fat cell.

**adipose tissue** connective tissue consisting largely of fat cells (see adipocyte), which is found beneath the skin and around major organs. It provides protection and insulation and functions as an energy reserve. See also brown fat; fat metabolism.

**adipsia** n. an absence of thirst, manifest as a lack of drinking. Adipsia is associated with lesions of the thirst center in the anterior hypothalamus but may also be caused by head injury, stroke, or other conditions. Compare polydipsia.

**adj** abbreviation for adjusting schedule of reinforcement.

**adjective checklist** 1. a self-inventory, used in personality assessment, consisting of a list of adjectives (e.g., intelligent, lazy, productive) that the respondent checks off as descriptive of or applicable to himself or herself. 2. in consumer psychology, a list of adjectives used, for example, in the assessment of a product image and in advertising research.

**adj R** symbol for adjusted R².

**adjudication** n. 1. any formal decision of a court. 2. the act or process of settling a matter by judicial proceedings or, in cases involving insurance claims, by insurance examiners or specialized software. —adjudicate vb.

**adjudicative competence** an umbrella term that encompasses all forms of meaningful participation in proceedings of the criminal justice system, including competency to stand trial, competency to plead guilty, and competency to waive Miranda rights.

**adjunct** n. 1. a drug that is used concurrently with another drug in treating a condition in order to provide additional therapeutic effects. It may have a mechanism of action that differs from that of the main drug used in treatment. 2. more generally, a supplementary or nonessential part of something. —adjunctive adj.

**adjective behavior** relatively unvaried behavior that occurs following, but is otherwise unrelated to, regular delivery of a reinforcer in operant or instrumental conditioning. It differs from simple respondent behavior in that the likelihood of its occurrence is influenced by the time between stimulus presentations. An example is schedule-induced polydipsia, in which excessive drinking of water occurs when small portions of food are delivered intermittently. Compare terminal behavior.

**adjunctive therapist** 1. in psychotherapy, a provider of any secondary adjunctive therapy. 2. in health care, a member of a multidisciplinary treatment team whose functions are ancillary to the main therapeutic program. Such therapists provide direct clinical services to patients in such areas as improvement of daily living skills, behavior management, coordination of educational activities, and management of leisure time.

**adjunctive therapy** one or more secondary interventions used concurrently with a primary intervention to enhance treatment effectiveness. For example, medication may be used concurrently with cognitive behavior therapy, with the latter as the primary form of intervention; group therapy may be used secondarily to individual psychodynamic psychotherapy, with each intervention bringing its own characteristic perspectives and methods to bear on the client’s mental awareness and healing. Adjunctive therapy is typically conducted by a different practitioner than is the primary intervention, which distinguishes it from combination therapy. The term is some-
adjusted effect

times used synonymously with ADJUVANT THERAPY. See also COLLABORATIVE CARE.

adjusted effect the effect of a predictor or INDEPENDENT VARIABLE on a response or DEPENDENT VARIABLE after the influence of one or more other predictors has been removed. For example, a researcher might find that education level predicts income via the MEDIATOR of residential area; an adjusted effect would be one without the influence of the mediator included.

adjusted R the correlation between scores on a response or DEPENDENT VARIABLE and the values predicted by a set of INDEPENDENT VARIABLES, after accounting for the number of predictors and the number of observations involved in the calculation. See also MULTIPLE CORRELATION COEFFICIENT.

adjusted $R^2$ (symbol: adj $R^2$; $R^2_{adj}$) the square of the correlation between scores on a response or DEPENDENT VARIABLE and the values predicted by a set of INDEPENDENT VARIABLES after accounting for the number of predictors and the number of observations involved in the calculation. It gives the proportion of the variance in a response that is accounted for by its relationship with the predictors and yields a better estimate of the population variance than the ADJUSTED $R$ upon which it is based. Also called shrunked $R^2$. See also COEFFICIENT OF MULTIPLE DETERMINATION.

adjusting schedule of reinforcement (ADJ) in conditioning, any arrangement in which the requirements for reinforcement are varied continuously based on some characteristic of the organism’s performance.

adjustive behavior any response of an organism that effectively incorporates environmental or situational demands.

adjustment n. 1. a change in attitude, behavior, or both by an individual on the basis of some recognized need or desire to change, particularly to account for the current environment or changing, atypical, or unexpected conditions. It may be assessed via a type of survey called an adjustment inventory, which compares a person’s emotional and social adjustment with a representative sample of other individuals. A well-adjusted person is one who satisfies needs in a healthy, beneficial manner and demonstrates appropriate social and psychological responses to situations and demands. 2. modification to match a standard. See METHOD OF ADJUSTMENT. —adjust vb.

adjustment disorder in DSM–IV–TR, impairment in social or occupational functioning and unexpected severe emotional or behavioral symptoms occurring within 3 months after an individual experiences a specific identifiable stressful event, such as a divorce, business crisis, or family discord. The event does not meet the traumatic stressor criteria of experiencing or witnessing actual or threatened death or serious injury or a threat to the physical integrity of oneself or others, which can lead to ACUTE STRESS DISORDER or POSTTRAUMATIC STRESS DISORDER. Symptoms may include anxiety, depression, and conduct disturbances and tend to remit following elimination of the stressor or acquisition of new coping skills. In chronic adjustment disorder, the symptoms last more than 6 months due to either the persistence or the severity of the stressor. DSM–5 retains the same symptom criteria for adjustment disorder but reconceputalizes it as a heterogeneous array of stress-response syndromes that occur after exposure to a distressing traumatic or nontraumatic event, rather than as a residual category for distress that does not meet criteria for a more discrete disorder (as in DSM–IV–TR).

adjustment inventory see ADJUSTMENT.

adjustment method see METHOD OF ADJUSTMENT.

adjustment process any means through which human beings modify attitudes and behaviors in response to environmental demands. Such attempts to maintain a balance between needs and the circumstances that influence the satisfaction of those needs are influenced by numerous factors that vary widely across situations and individuals and are the subject of much research.

adjustment reaction a temporary, maladaptive psychological response to a stressful situation. See ADJUSTMENT DISORDER.

adjutant therapy therapy that is provided after the initial (primary) form of treatment and that is intended to enhance effectiveness or to increase the chances of a cure. Adjutant therapy typically refers to medical treatment, particularly any drug therapy used in support of nondrug interventions. For example, in the treatment of cancer, chemotherapy and radiation are often used as adjuvant therapies after the primary intervention of surgery. The term is sometimes used in psychotherapy as a synonym for the preferred ADJUNCTIVE THERAPY.

Adlerian psychology see INDIVIDUAL PSYCHOLOGY.

Adlerian therapy a brief psychoeducational treatment based on the INDIVIDUAL PSYCHOLOGY of Alfred Adler; the therapy aims to decrease an individual's symptoms and improve his or her functioning by emphasizing the individual's strivings for success, connectedness with others, and contributions to society as hallmarks of mental health. It is used both in clinical settings with individuals, couples, families, and groups and in educational settings.

ad lib 1. in nonhuman animal experiments, denoting or relating to a schedule of unlimited access to food, water, or both. The body weight achieved by animals under such conditions is called the free-feeding weight. 2. more generally, without restriction. [from Latin ad libitum, “as desired”]

ad litem for the purpose of the suit (in a court of law). See GUARDIAN AD LITEM. [Latin, literally: “for the lawsuit”]

ADLs abbreviation for ACTIVITIES OF DAILY LIVING.

administration n. 1. the application of a drug or other agent in the diagnosis or treatment of a disorder. This may be accomplished enterally (via the digestive tract, as with oral administration) or parenterally (via all other means, including subcutaneous, intramuscular, and intravenous injection; rectal and vaginal suppositories; inhalation; and absorption through skin or mucous membranes). 2. the giving of a test for the purpose of obtaining information.

administrative controls in SAFETY ENGINEERING, managerial interventions—such as training, rotating work schedules to reduce exposure (e.g., to hazardous chemicals), and implementing CLEARANCE REQUIREMENTS—that can help to maintain a safe environment in the workplace. Administrative controls, supplemented by the use of PERSONAL PROTECTIVE EQUIPMENT, are considered the second resort after ENGINEERING CONTROLS. See also HAZARD-CONTROL PROTOCOL.

admission n. 1. the act of registering an individual for treatment or observation in a health care facility. See FIRST
adolescent

adolescence n. the period of human development that starts with puberty (10–12 years of age) and ends with physiological maturity (approximately 19 years of age), although the exact age span varies across individuals. During this period, major changes occur at varying rates in physical characteristics, sexual characteristics, and sexual interest, resulting in significant effects on body image, self-concept, and self-esteem. Major cognitive and social developments take place as well: Most young people acquire enhanced abilities to think abstractly, evaluate reality hypothetically, reconsider prior experiences from altered points of view, assess data from multiple dimensions, reflect inwardly, create complex models of understanding, and project complicated future scenarios. Adolescents also increase their peer focus and involvement in peer-related activities, place greater emphasis on social acceptance, and seek more independence and autonomy from parents. —adolescent adj., n.

adolescent egocentrism the feeling of personal uniqueness often experienced in adolescence; that is, the conviction that one is special and is or should be the constant focus of others’ attention. See also imaginary audience. [described by U.S. developmental psychologist David Elkind (1931– )]

adolescent growth spurt see pubescent growth spurt.

adolescent gynecomastia enlargement of the breasts in adolescent males, typically resulting from hormonal (estrogen–androgen) imbalances during puberty, in which case it is usually minor and transient. It may also occur as a side effect of medication or street drug use or in association with various conditions, such as klinefelter’s syndrome. See Gynecomastia.

adolescent pregnancy pregnancy that occurs during the period of adolescence. Adolescent pregnancy is a controversial social issue, particularly when it occurs during the early and middle years of adolescence, when teenagers are typically not emotionally or financially prepared to raise children. A number of possible causes contribute to variations in teenage pregnancy rates, including social and cultural customs, family background and education, and economic and social conditions. Also called teenage (or teen) pregnancy.

adolescent psychology the branch of psychology that describes and studies adolescents, their development, and their behavior.

adolescent psychotherapy psychotherapy for adolescents who are experiencing social, emotional, or behavioral problems.

adolescent rebellion the rejection by adolescents of family values and family control over their behavior, reflecting their desire for increased independence.

adolescent sex changes the physical and physiological changes that start at puberty. They include accelerated development of sex organs, the appearance of secondary sex characteristics, and the first occurrence of seminal ejaculation in boys and menstruation in girls.

adopter categories categories into which consumers who buy a new product or service can be grouped on the basis of how soon they adopt the innovation after it first appears on the market. The five main categories are innovators (see consumer innovator), early adopters, early majority, late majority, and laggards. Analysis of adopter categories is important in determining the likely success of a new product or service and in devising the most effective strategies for marketing it.

adoption n. the legal process by which an infant or child is permanently placed with a family other than his or her birth family. An adoption may be private, in which a birth parent voluntarily plans for the placement of the child with adoptive parents through intermediaries, or public, in which a child removed from his or her birth parent(s) because of neglect or abuse is placed with adoptive parents through public child welfare agencies. Adoptions may also be closed, allowing no contact between the birth and adoptive parents, or open, permitting varying degrees of pre- and postplacement contact and making possible a relationship between all three parties.

adoption study a research design that investigates the relationships among genetic and environmental factors in the development of personality, behavior, or disorder by comparing the similarities of biological parent–child pairs with those of adoptive parent–child pairs.

adoptive parent the adult who legally adopts a child and raises him or her. Compare birth parent.

ADR abbreviation for adverse drug reaction.

adren- combining form see adreno-.

adrenal cortical hyperfunction the excessive production of one or more of the hormones of the adrenal cortex. The manifestations vary with the hormone but potentially include (among others) virilism, hypertension, sudden weight gain, torso obesity, and low blood levels of potassium. Causes may include a tumor or congenital adrenal hyperplasia, a disorder marked by increased adrenal production of cortisol precursors and androgens.

adrenalectomy n. surgical removal of one or both of the adrenal glands.

adrenal gland an endocrine gland adjacent to the kidney. Its outer layer, the adrenal cortex, secretes such hormones as androgens, glucocorticoids, and mineralocorticoids. Its inner core, the adrenal medulla, secretes the hormones epinephrine and norepinephrine, both of which are catecholamines and also serve as neurotransmitters. Also called suprarenal gland.

adrenal hyperplasia see congenital adrenal hyperplasia.

adrenaline n. see epinephrine.

adrenal virilism see virilism.

adrenarche n. the stage of prepubertal development marked by the start of androgen secretion by the adrenal cortex, normally occurring between 6 and 8 years of age.
Premature adrenarche, characterized by pubertal levels of adrenal androgens, is manifested by the early appearance of pubic hair. It may be associated with psychological disturbances. By parent report on the DIAGNOSTIC INTERVIEW SCHEDULE for Children, 44% of the children with premature adrenarche met the diagnostic criteria for psychological disorders, primarily anxiety disorders. The condition is also associated with self-reported depression and parent-reported behavior problems, as well as low scores on various intelligence tests.

adrenergic adj. responding to, releasing, or otherwise involving EPINEPHRINE (adrenaline). For example, an adrenergic neuron is one that employs epinephrine as a neurotransmitter. The term often is used more broadly to include NOREPINEPHRINE as well.

adrenergic blocking agent any pharmacological substance that either partially or completely inhibits the binding of the neurotransmitters norepinephrine or epinephrine to ADRENERGIC RECEPTORS and thus blocks or disrupts the action of these neurotransmitters. Such blocking agents are classed according to whether they inhibit binding to alpha- or beta-adrenergic receptors. They include alpha blockers (also called alpha-adrenoreceptor blocking agents), used primarily to widen blood vessels in the treatment of hypertension, and beta blockers (also called beta-adrenoreceptor blocking agents), used to treat hypertension as well but by reducing the rate and force of heart contractions, arrhythmia, tremor, and anxiety-related symptoms. Also called adrenoceptor blocking agent: adrenoreceptor blocking agent.

adrenergic drug see SYMPATHOMIMETIC DRUG.

adrenergic reaction the response of organs innervated by the SYMPATHETIC NERVOUS SYSTEM to stimulation by the adrenergic hormones norepinephrine or epinephrine. Adrenergic reactions include increased heart rate, constriction of blood vessels, and dilation of the pupils.

adrenergic receptor a molecule in a cell membrane that specifically binds and responds to norepinephrine and, to a lesser extent, epinephrine, which act as neurotransmitters in the sympathetic nervous system. There are two types: ALPHA-ADRENERGIC RECEPTORS (or alpha receptors) and BETA-ADRENERGIC RECEPTORS (or beta receptors). Also called adrenoceptor: adrenoreceptor.

adrenergic system the part of the AUTONOMIC NERVOUS SYSTEM, including receptor sites, that is influenced by ADRENALINE neurotransmitters and drugs. The nerves included in the adrenergic system vary somewhat with species but generally include all postganglionic sympathetic fibers. Compare CHOLINERGIC SYSTEM.

adreno- (adren-) combining form the adrenal glands.

adrenoceptor n. see ADRENERGIC RECEPTOR.

adrenocorticotrophic hormone (ACTH) see CORTICOTROPIN.

adrenogenital syndrome see CONGENITAL ADRENAL HYPERPLASIA.

adrenoleukodystrophy n. a genetic disease characterized by destruction of the MYELIN SHEATH surrounding the neurons of the brain (i.e., demyelination) and progressive dysfunction of the adrenal gland. Nerve function becomes erratic, resulting in a variety of physiological and behavioral symptoms involving changes in body tone, motor movements, gait, speech, ability to eat, vision, hearing, memory, attention, and cognitive processes. There are several types of adrenoleukodystrophy, of which the childhood X-chromosome-linked form is the most common and severe.

adrenoreceptor n. see ADRENERGIC RECEPTOR.

Alcoholics Anonymous (AA) an international self-help group for adults who were raised in a family environment where alcoholism or other family dysfunctions were present. See also SELF-HELP GROUP.

adult day care a group program for the nonresidential care and supervision of adults with functional impairments, designed to meet their health, social, and functional needs in a setting other than their homes. See DAY CARE CENTER.

adult development biological, psychological, and sociocultural developmental processes that begin in late adolescence and continue through old age.
adult education formal schooling, often offered at night, that is specifically appropriate for adults who wish either to improve their work or career performance or to learn about a particular subject area of interest. See also CONTINUING EDUCATION.

adultery n. a voluntary sexual relationship between a married person and an individual who is not his or her spouse. In most Western countries, this is grounds for divorce; in some other cultures, adulterers may face severe social sanctions or legal penalties, including death. See also INFIDELITY. —adulterer n. —adulterous adj.

adult foster care the provision of community-based living arrangements to adults who require supervision, personal care, or other services in daily living on a 24-hour basis. Host families open their own homes to, and act as caregivers for, such adults who are unable safely to live independently, which is what distinguishes adult foster homes from other RESIDENTIAL CARE facilities.

adult home an ASSISTED-LIVING residence that provides shared rooms, common meals, personal care services, activities, and protective oversight to adults who are unable to live independently. Intensive medical or nursing services are generally not available.

adulthood n. the period of human development in which full physical growth and maturity have been achieved and certain biological, cognitive, social, personal, and other changes associated with the aging process occur. Beginning after adolescence, adulthood is sometimes divided into young adulthood (roughly 20 to 35 years of age); middle adulthood (about 36 to 64 years); and later adulthood (age 65 and beyond). The last is sometimes subdivided into young-old (65 to 74), old-old (75 to 84), and oldest old (85 and beyond). The oldest old group is the fastest growing segment of the population in many developed countries. See also EMERGING ADULTHOOD.

adultomorphism n. 1. the attribution of adult traits or motives to children. Compare PEDOMORPHISM. 2. more specifically, the tendency to reconstruct developmental phases by extrapolating from adult psychopathology. —adultomorphic adj.

adult-onset diabetes see DIABETES MELLITUS.

adult progeria see AGING DISORDER.

adult sensorineural lesion see SENSORINEURAL LESION.

adult stem cell see STEM CELL.

advance directive a legal mechanism for individuals to specify their wishes and instructions about prospective health care in the event they later become unable to make such decisions. This can be achieved by means of a durable power of attorney, a legal document designating a health care proxy to make health care decisions on another person’s behalf. Other advance directives include a living will, a legal document clarifying a person’s wishes regarding future medical or, increasingly, mental health treatment; and a do not resuscitate (DNR) order stating that cardiopulmonary resuscitation (CPR) is not to be performed if the patient’s heart or breathing stops. Federal law requires hospitals, nursing homes, and other institutions that receive Medicare or Medicaid funds to provide all patients upon admission with written information regarding advance directives. See also INFORMED CONSENT.

advanced organizers verbal or written information presented to students before a lecture or other teaching session to enhance their attentiveness and information acquisition in the subsequent lecture. The purposes are (a) to promote an initial understanding of the content, (b) to familiarize students with the way in which information is to be presented, and (c) to identify the purposes for learning the subsequent material. Schematic representations, templates, and prior knowledge information processing are ways of enhancing advanced organization.

advanced placement examinations (AP) ACHIEVEMENT TESTS that (a) give high school students an opportunity to gain admission to college with advanced standing in one or more subjects (the College Entrance Examination Board Advanced Placement Program) or (b) evaluate college-level education acquired through independent study and other nontraditional procedures (see COLLEGE LEVEL EXAMINATION PROGRAM).

advantage by illness see SECONDARY GAIN.

advantage law see LAW OF ADVANTAGE.

adventitious adj. appearing or occurring unexpectedly or in an unusual place; accidental. The term is often used specifically to describe a condition or disorder that has occurred as a result of injury or illness following a period of normal function. Compare CONGENTITAL.

adventitious deafness a loss of hearing that results from injury or illness following a period of normal hearing ability. Compare CONGENTITAL DEAFNESS.

adventitious reinforcement see ACCIDENTAL REINFORCEMENT.

adventitious visual impairment partial or total visual impairment that results from injury or illness following a period of normal visual ability: Onset of the impairment can produce severe grief, mourning reactions, and dependency. As a consequence, any residual visual capacity may not be used effectively, exacerbating psychological and social-adjustment problems. Also called acquired visual impairment. Compare CONGENTITAL VISUAL IMPAIRMENT.

adventure-recreation model a model for those who seek risk in outdoor recreational activities. It establishes the relationship among level of engagement, type and level of risk, social orientation, locus of decision making, frequency of participation, and preferred environment. Also called risk-recreation model.

adversarial system the type of legal system, as in the United States, in which a dispute between opposing parties is heard before an independent TRIER OF FACT (i.e., a judge or jury). In many European countries, but not the United Kingdom, an inquisitorial system is used, in which the judge leads the investigation by interrogating the parties.

adverse drug reaction (ADR) any unintended, harmful, and potentially fatal response to a drug. Reactions may be genetically determined (as in the case of HYPERSENSITIVITY), in which case they are highly individual and can be difficult to predict, or they may arise through interactions with other prescribed or nonprescribed drugs or with dietary items (as in the case of MONOAMINE OXIDASE INHIBITORS). This term sometimes is used synonymously with SIDE EFFECT, but an adverse drug reaction more properly denotes an unexpected negative occurrence, whereas side effects may be positive or negative and are usually anticipated. Also called adverse drug event (ADE); adverse event: adverse reaction.
adverse event 1. in health care, an injury or harmful effect resulting from medical intervention or research. 2. in pharmacology, see ADVERSE DRUG REACTION.

adverse impact the deleterious effect that certain hiring procedures or selection criteria may have on the employment chances of those in a PROTECTED CLASS. For example, testing for competence in written English might have an adverse impact on recent immigrants; such testing should therefore be avoided unless this skill is a BONA FIDE OCCUPATIONAL QUALIFICATION. Also called disparate impact. See also GRIFFS V. DUKE POWER CO.; UNIFORM GUIDELINES FOR EMPLOYEE SELECTION PROCEDURES.

adverse witness an individual who reveals bias against the party that called him or her to give evidence in a court of law. An adverse witness may be a HOSTILE WITNESS; the two terms often are used interchangeably.

advertisement n. 1. a public announcement appearing in print, broadcast, or electronic media that is designed to bring individuals' attention to a particular item or service in order to encourage the purchase, consumption, or increased use of that item or service. See also ADVERTISING PSYCHOLOGY; ADVERTISING RESEARCH. 2. in animal behavior, a signal or display that emphasizes or calls attention to the organism producing it. For example, a male bird defending a territory might use advertisement in the form of bright coloration and conspicuous song both to attract mates and to deter competing males. Compare CAMOUFLAGE.

advertising psychology the study of the psychological impact that advertisements in various media have on prospective buyers and of the factors contributing to their effectiveness, including different presentation techniques and physical and technological characteristics.

advertising research the study of (a) the selection of effective advertising APPEALS for specific products or brands; (b) the creation of PRODUCT IMAGES, including trade names and package designs; and (c) the development of methods of measuring the effectiveness of advertising campaigns in different media. Advertising research is also used in generic advertising, that is, in the advertising of an industry or product category, such as cigars or coffee, rather than of specific brands.

advertising response modeling (ARM) statistical techniques used to assess the ability of advertising messages to reach and influence target audiences. In combination with sales data, these techniques determine optimal levels of advertising.

advice giving a COUNSELING technique in which the therapist advises the client on alternatives or options for consideration.

advocacy n. speaking or acting on behalf of an individual or group to uphold their rights or explain their point of view. An individual engaged in advocacy is called an ADVOCATE, of which there are two general types: A CASE ADVOCATE represents a single individual, and a CLASS ADVOCATE represents a whole group. An example of a case advocate is a therapist who speaks for a client in court hearings or other situations involving decisions based on the client's mental health or related issues. An example of a class advocate is an individual in health care who represents consumers to protect their rights to effective treatment. See OMBUDSMAN.

AEA abbreviation for arachidonoylethanolamide. See ENDOGENOUS CANNABINOID.

AED abbreviation for ACADEMY FOR EATING DISORDERS.

AEP abbreviation for AVERAGE EVOKED POTENTIAL.

AEq abbreviation for AGE EQUIVALENT.

AERA abbreviation for AMERICAN EDUCATIONAL RESEARCH ASSOCIATION.

aerial perspective a monocular cue to DEPTH PERCEPTION consisting of the relative clarity of objects under varying atmospheric conditions. Nearer objects are usually clearer in detail, whereas more distant objects are less distinct and appear bluer.

aero- (aer-) combining form air or gas.

aerobic activity see ENDURANCE ACTIVITY.

aerobic exercise physical activity, typically prolonged and of moderate intensity (e.g., walking, jogging, cycling), that involves the use of oxygen in the muscles to provide the needed energy. Aerobic exercise strengthens the cardiovascular and respiratory systems and is associated with a variety of health benefits, including increased endurance, reduction of body fat, and decreased depression and anxiety. Compare ANAEROBIC EXERCISE.

aesthesiometer n. see ESTHESIOMETRY.

aesthesiometry n. see ESTHESIOMETRY.

aesthetic appreciation the extent to which a stimulus is enjoyed because of its beauty or some other factor associated with AESTHETIC PREFERENCE.

aesthetic emotion an emotion linked to the experience of natural beauty or art, including abstract visual displays, music, and dance.

aesthetic evolution the concept that the arts change in an orderly fashion over time because of intrinsic factors rather than as a response to extra-artistic forces. According to this conception, art has to be novel; this leads to systematic changes in content and styles.

aesthetic overshadowing the fact that a single prominent characteristic of a stimulus accounts almost entirely for preference for the stimulus generally, with other characteristics being largely ignored. For example, a person viewing a painting who finds the colors appealing will tend to disregard its size, complexity, and other aspects in determining his or her overall liking for the item.

aesthetic preference the extent to which a particular stimulus is preferred to others for reasons of beauty or taste. See also AROUSAL POTENTIAL.

aesthetics n. the philosophical study of beauty and art, concerned particularly with the articulation of taste and questions regarding the value of aesthetic experience and the making of aesthetic judgments. See also ENVIRONMENTAL AESTHETICS; PSYCHOLOGICAL AESTHETICS. —aesthetic adj.

aesthetic taste an individual's judgment of works of art as being more or less beautiful or otherwise pleasing.

aesthetic value the emotional or spiritual value attributed to a work of art or nature because of its beauty or other factors associated with AESTHETIC PREFERENCE.

affect n. any experience of feeling or emotion, ranging from suffering to elation, from the simplest to the most complex sensations of feeling, and from the most normal to the most pathological emotional reactions. Often described in terms of POSITIVE AFFECT or NEGATIVE AFFECT, both mood
and emotion are considered affective states. Along with cognition and conation, affect is one of the three traditionally identified components of the mind.

**affect-block** n. a condition marked by an inability to adequately express or experience emotions, especially strong ones, because of a dissociation of these emotions from ideas or thoughts. It is characteristically seen in individuals with schizophrenia or obsessive-compulsive disorder.

**affect display** n. a facial, vocal, or gestural behavior that serves as an indicator of affect. See emotional expression.

**affect intensity** the strength of experience of emotional states from very low to very high, irrespective of the nature (e.g., positive versus negative) of those states.

**affect inversion** see reversal of affect.

**affection** n. fondness, tenderness, and liking, especially when nonsexual. Feelings of emotional attachment between individuals, particularly human infants and caregivers, are called affectional bonds. They are particularly important to attachment theory, and their presence is evidenced by proximity-seeking behaviors and mutual distress if loss or involuntary separation occurs. —**affectionate** adj.

**affective** adj. demonstrating, capable of producing, or otherwise pertaining to emotion or feelings. —**activity** n.

**affective aggression** see aggression.

**affective ambivalence** see ambivalence.

**affective assessment** evaluation of an individual’s emotional state and degree of emotional intensity.

**affective-cognitive consistency** the degree to which the affective and cognitive aspects of an attitude are evaluatively consistent with one another. For example, if the affective basis is extremely negative and the cognitive basis is extremely positive, the overall attitude is extremely negative, affective–evaluative consistency is low. See also AFFECTIVE–COGNITIVE CONSISTENCY: COGNITIVE–EVALUATIVE CONSISTENCY.

**affective–cognitive structure** the combination of an emotional experience with a thought or image, such as the linking of the emotions of relief and fear reduction to the idea of a parent as a haven of safety.

**affective commitment** that element of an employee’s organizational commitment that can be attributed to a feeling of involvement with the organization and an identification with its goals and objectives. Compare continuance commitment.

**affective concordance** see concordance.

**affective development** see emotional development.

**affective discharge** the expression of strong emotions (e.g., sorrow or anger) by clients undergoing therapy in which the therapist uses techniques aimed at facilitating deeper exploration of past experiences. Affective discharge is believed to be a release of psychic energy. Also called cathartic discharge.

**affective discordance** see discordance.

**affective disorder** see mood disorder.

**affective domain** see bloom’s taxonomy.

**affective education** in bloom’s taxonomy of educational objectives, any program in which learning is focused on the relation between thoughts, feelings, and behavior. The goals of affective education are twofold: (a) to help children become familiar with a range of feelings (e.g., anger, fear, sadness, and excitement), differentiate among them, and understand the connections of these feelings to thoughts and behaviors; and thus (b) to encourage positive behavior change.

**affective engineering** see kansei engineering.

**affective equilibrium** the idea that a single affective judgment for a set of stimuli (e.g., pleasant or unpleasant) is formed around the median of the judgments made for individual stimuli in the set.

**affective–evaluative consistency** the degree to which the affective basis of an attitude (see basis of an attitude) and the overall attitude are evaluatively consistent with one another. For example, if the affective basis is extremely positive and the overall attitude is extremely negative, affective–evaluative consistency is low. See also AFFECTIVE–COGNITIVE CONSISTENCY: COGNITIVE–EVALUATIVE CONSISTENCY.

**affective forecasting** predicting one’s own future emotional states, especially in connection with some event or outcome that one faces. People often “forecast” more extreme and lasting emotional reactions to events than they actually experience.

**affective hallucination** a hallucination that occurs in the context of affective psychosis and has a manic or depressive content.

**affective interaction** 1. highly emotional interpersonal interactions, as may occur in individual or group therapy or in a family. 2. in robotics and computer design, the process of communicating emotional information to and from the user to improve the user experience.

**affective logic** the hypothesis that emotions have their own independent set of mental operations, distinct from those governing other forms of mental life. [proposed by Théodule Ribot]

**affectively based persuasion** an active attempt to change an attitude primarily by altering the emotions, feelings, or mood states associated with the attitude object. Also called emotionally based persuasion. See also BASIS OF AN ATTITUDE: FEAR APPEAL. Compare cognitively based persuasion.

**affective meaning** the attitude or emotion elicited by a stimulus, such as a musical piece, a drawing, or—especially—a word or phrase. The term is sometimes used interchangeably with connotative meaning (see denotative meaning).

**affective memory** see emotional memory.

**affective neuroscience** a discipline that addresses the brain mechanisms underlying emotions. In seeking to understand the particular roles of major subcortical and cortical structures in the elicitations, experience, and regulation of emotion, affective neuroscience provides an important framework for understanding the neural processes that underlie psychopathology, particularly the mood and substance-related disorders. Also called social affective neuroscience. [term coined by Estonian-born U.S. physiological psychologist Jaak Panksepp (1943—)]

**affective psychosis** a mood disorder accompanied by delusions or hallucinations (i.e., psychotic features). The mood disruption precedes the psychotic symptoms, and the
affective rigidity

psychotic symptoms only occur during a MAJOR DEPRESSIVE EPISODE or a MANIC EPISODE.

affective rigidity a condition in which emotions or feelings remain unchanged through varying situations in which such changes would normally occur. Affective rigidity is common in obsessive-compulsive disorder and schizophrenia.

affective theory a framework underlying certain approaches to psychotherapy that emphasizes the importance of feelings and emotions in therapeutic change.

affective tone the mood or feeling associated with a particular experience or stimulus. In psychotherapy, when a client fails to recognize his or her affective tone, the therapist may draw the client’s attention to it as a primary element of the therapeutic interaction. Also called feeling tone.

affective well-being see SUBJECTIVE WELL-BEING.

affectivity n. the degree of a person’s response or susceptibility to pleasure, pain, and other emotional stimuli. Evaluation of affectivity is an important component of a psychological examination; the therapist or clinician may look for evidence of such reactions as BLUNTED AFFECT, INAPPROPRIATE AFFECT, LOSS OF AFFECT, AMBIGUITY, DEREGULATION, elation, depression, or anxiety.

affect misattribution procedure (AMP) an IMPLICIT ATTITUDE MEASURE in which the target object to be evaluated is first presented and then is immediately followed by presentation of an ambiguous stimulus (e.g., a Chinese pictograph). The respondent is required to evaluate the ambiguous stimulus as pleasant or unpleasant. The procedure is based on the premise that affective responses to the initial target object will be misattributed to, and thus will influence evaluations of, the ambiguous stimulus, thereby providing insight into the evaluation of the target object. [developed by U.S. psychologist B. Keith Payne and his colleagues]

affect regulation the attempt to alter or control one’s mood or emotional state so as to maximize pleasant experiences and minimize unpleasant ones. Because people cannot usually change their emotions simply by deciding to feel differently, they use many indirect strategies for affect regulation. These include cognitive techniques such as REFRAMING and distraction, behavioral methods such as PROGRESSIVE RELAXATION and meditation, and unconscious processes such as DENIAL and DISSOCIATION.

affect scale any of several self-rated measures for quantifying the intensity of moods or emotional states. An example is the POSITIVE AND NEGATIVE AFFECT SCHEDULE.

affect theory the idea that feelings and emotions are the primary motives for human behavior, with people desiring to maximize their positive feelings and minimize their negative ones. Within the theory, affects are considered to be innate and universal responses that create consciousness and direct cognition. Eight primary affects are postulated: the positive ones of excitement and enjoyment; the negative ones of distress, fear, shame, disgust, and anger; and the relatively neutral one of interest. Despite their biological nature and triggering mechanisms, primary affects are subject to significant social modification and social causation. See also SCRIPT THEORY. [proposed in 1962 by Silvan S. Tomkins]

afferent adj. conducting or conveying from the periphery toward a central point. Compare EFFERENT.

afferent nerve fiber a nerve fiber, typically a sensory fiber, that conducts impulses toward the brain or spinal cord or from a lower to a higher center of the central nervous system. Compare EFFERENT NERVE FIBER.

afferent pathway a NEURAL PATHWAY that conducts impulses from a sense organ toward the brain or spinal cord or from one brain region to another. Compare EFFERENT PATHWAY.

afferent sensory neuron a neuron that conducts impulses from a sense organ to the brain or spinal cord.

affect stimulation stimulation of a sensory system, leading to conduction of neural impulses to the brain or spinal cord.

affiliation n. a social relationship in which a person joins or seeks out one or more other individuals, usually on the basis of liking or a personal attachment rather than perceived material benefits. Some propose that the seeking of cooperative, friendly association with others who resemble or like one or whom one likes is a fundamental human desire, referring to it variously as the affiliation motivation, affiliative drive, affiliative need, or NEED FOR AFFILIATION. See also BELONGING, —affiliative adj.

affinity n. 1. an inherent attraction to or liking for a particular person, place, or thing, often based on some commonality. See ELECTIVE AFFINITY. 2. relationship by marriage or adoption rather than blood. Compare CONSANGUINITY. 3. in pharmacology, see BINDING AFFINITY.

affirmative n. in linguistics, the form of a sentence used to make a positive assertion about something rather than a NEGATIVE statement or a question (see INTERROGATIVE).

affirmative action a policy designed to promote equal educational or employment opportunities by requiring active recruitment or promotion of people from minority groups or another PROTECTED CLASS. The policy is controversial in some of its aspects and has been subject to legal challenges, particularly on the grounds that it constitutes REVERSE DISCRIMINATION.

affirmative defense a defense in which the defendant admits committing the act with which he or she is charged but provides evidence that undermines the prosecution’s or plaintiff’s claim of criminal intent (see MENS REA). The IN-SANITY DEFENSE, DIMINISHED RESPONSIBILITY, contributory negligence (the defendant’s claim that the plaintiff acted carelessly or with disregard and was partially at fault), and self-defense are examples of affirmative defenses.

affirmative postmodernism a perspective in POSTMODERNISM holding that social, cultural, and political progress is possible within a postmodern framework of assumptions. It is associated most closely with French philosopher Jean-François Lyotard (1924–1998). Compare SKEPTICAL POSTMODERNISM.

affirmative therapy a socioculturally informed intervention that empowers clients and their communities, particularly in situations in which ethnic, gender, or sexual orientation diversity has been resisted or in which normal conditions (e.g., gay identity) have been pathologized. Emphasizing self- and cultural awareness, this therapy may be practiced as a distinct intervention or within the context of other psychotherapies.

affixation n. the linguistic process in which affixes (PREFIXES, SUFFIXES, and INFIXES) are added to words to create inflected or derived forms (e.g., un-glue, walk-ing, material-
age crisis

affordance n. 1. in the theory of ecological perception, any property of the physical environment that offers or allows an organism the opportunity for a particular physical action. An example is the location of the handle on a refrigerator. When the handle is on the left-hand side, it affords a left-hand reach-and-grasp movement. 2. the ease with which the action possibilities of an item or system can be discerned, as in “this remote control has bad affordance.”

affricate n. a speech sound consisting of a plosive (e.g., [t]) followed immediately by a fricative (e.g., [sh]), such as the [ch] sound in chair.

A fiber a myelinated nerve fiber (axon) of the somatosensory system. A fibers are subdivided by diameter, ranging from largest to smallest: A-alpha fibers are 13 to 20 μm in diameter and transmit information from proprioceptors of skeletal muscles. A-beta fibers are 6 to 12 μm and transmit information from mechanoreceptors of the skin, and A-delta fibers are 1 to 5 μm and transmit temperature and sharp pain information. See also B FIBER; C FIBER.

AFMET acronym for Air Force Medical Evaluation Test, the former name for the BIOGRAPHICAL EVALUATION AND SCREENING OF TROOPS program.

AFP abbreviation for ALPHA-FETOPROTEIN.

AFQT abbreviation for ARMED FORCES QUALIFICATION TEST.

AFR abbreviation for ALCOHOL FLUSH REACTION.

African American a citizen or resident of the United States whose ancestry, at least in part, can be traced to sub-Saharan Africa. Many are descendants of slaves from West Africa, but immigrants from other parts of Africa, the Caribbean, and South America also identify as part of this group, currently the largest racial minority in the United States.

African American Vernacular English (AAVE) see BLACK ENGLISH.

African trypanosomiasis see SLEEPING SICKNESS.

afterbirth n. the third and final stage of birth, involving expulsion of the placenta and other membranes from the uterus. See also DELIVERY; LABOR.

aftercare n. 1. a program of outpatient treatment and support services provided for individuals discharged from an institution, such as a hospital or mental health facility, to help maintain improvement, prevent relapse, and aid adjustment of the individual to the community. Aftercare may also refer to inpatient services provided for convalescent patients, such as those who are recovering from surgery. 2. a form of day care, as in programs designed to care for children after school. See CHILD CARE.

aftercurrent n. see AFTERPOTENTIAL.

afterdischarge n. continued production of nerve impulses after the stimulus that caused the activity has been removed.

aftereffect n. the altered perception of a sensory stimulus that results from prolonged exposure to another stimulus. Aftereffects are often visual and are usually the inverted form of the original stimulus. For example, viewing a pattern of lines tilted to the left will make a pattern of vertical lines appear to be tilted to the right (the TILT AFTEREFFECT). There are various other types of aftereffects, including the CONTINGENT AFTEREFFECT and the MOTION AFTEREFFECT.

afterimage n. the image that remains after a stimulus ends or is removed. A positive afterimage occurs rarely, lasts a few seconds, and is caused by a continuation of receptor and neural processes following cessation of the stimulus; it has approximately the color and brightness of the original stimulus. A negative afterimage is more common, is often more intense, and lasts longer. It is usually complementary to the original stimulus in color and brightness; for example, if the stimulus was bright yellow, the negative afterimage will be dark blue.

after-nystagmus n. the element of VESTIBULAR NYSTAGMUS that occurs after rotating the head, consisting of rapid, involuntary movement of the eyes in the direction opposite to that of the rotation.

afterplay n. affectionate and sensual activity (e.g., hugging, caressing, kissing) that continues after orgasm is achieved in sexual activity.

afterpotential n. the part of an ACTION POTENTIAL that remains after the electric potential has reached its peak, or spike. Also called aftercurrent. See also NEGATIVE AFTERPOTENTIAL; POSITIVE AFTERPOTENTIAL.

2-AG abbreviation for 2-arachidonoylglycerol. See ENDOGENOUS CANNABINOID.

agape n. a complex form of love involving feelings of tenderness, protectiveness, self-denial, and aesthetic preference for the features, gestures, speech, and other traits of a person. The term, which derives from a Greek word meaning “brotherly love,” is sometimes used to denote an unselfish love as taught by such religious figures as Jesus and the Buddha.

AGCT abbreviation for Army General Classification Test. See ARMY TESTS.

age 1. n. the amount of time that has passed since an organism’s birth; that is, an individual’s CHRONOLOGICAL AGE. Compare GESTATIONAL AGE. 2. n. a measure of physical or mental development (e.g., ANATOMICAL AGE, EDUCATIONAL AGE, or READING AGE). 3. n. a specific period of human life (as in middle age, old age). See DEVELOPMENTAL LEVELS. 4. vb. to grow older: See AGING; SECONDARY AGING.

age-associated memory impairment (AAMI) the minor memory deficits often associated with normal aging, for example, forgetting the name of a recently read book. These changes are not associated with dementias, such as Alzheimer’s disease, and affect the ability to acquire and recall new information rather than the recall of established memories (e.g., the name of one’s hometown). Also called benign senescence: benign senescent forgetfulness.

age calibration a process in which a test score is assigned a value so that the score may be interpreted relative to other test takers in the same age range.

age cohort see COHORT.

age crisis a theoretical, qualitative change in personality associated with inner conflicts occurring at a particular stage of life. Empirical research has failed to find indications of such radical changes in personality associated with a particular stage of life. See also MIDLIFE CRISIS.
age dedifferentiation hypothesis

age dedifferentiation hypothesis see DIFFERENTIATION–DEDIFFERENTIATION HYPOTHESIS.

age differentiation hypothesis see DIFFERENTIATION–DEDIFFERENTIATION HYPOTHESIS.

age discrimination differential treatment of individuals on the basis of chronological age. In the United States, federal legislation has been enacted making age discrimination illegal in various contexts. An example is the AGE DISCRIMINATION IN EMPLOYMENT ACT. See AGEMISM.

Age Discrimination in Employment Act (ADEA) a U.S. federal law, enacted in 1967, that prohibits employment practices that discriminate against those aged 40 or older, unless the employer can demonstrate that youth is a BONA FIDE OCCUPATIONAL QUALIFICATION for the job in question. See also FUNCTIONAL AGE.

age effect 1. in research, any outcome associated with being a certain age. Such effects may be difficult to separate from COHORT EFFECTS and PERIOD EFFECTS. 2. in the psychology of groups, any of various cognitive and interpersonal consequences that result when group members respond to others on the basis of their age. See also AGEMISM.

age equivalent (AEq) a measure of development or performance expressed in terms of the average chronological age at which the observed score is obtained. For example, assume a student obtains a score of 95 on a particular test, a value typical of the average performance of students in the eighth grade. Thus, the age equivalent of 95 is 13, the age of most eighth graders. Also called age-equivalent score; test age.

age-equivalent scale a system for expressing test scores in terms of the chronological ages at which the scores are typically obtained.

age-grade scaling a method of standardizing a test by establishing norms based on a sample of children who are of the typical chronological age for their grade in school.

ageism n. the tendency to prejudiced against older adults, to negatively stereotype them (e.g., as unhealthy, helpless, or incompetent), and to discriminate against them, especially in employment and health care. —ageist adj. [coined in 1969 by U.S. gerontologist and psychiatrist Robert N. Butler (1927–2010)]

agency n. the state of being active, usually in the service of a goal, or of having the power and capability to produce an effect or exert influence.

agency shop an arrangement between a labor union and an employer in which employees who are not union members pay a representational fee (usually equal to the dues paid by members) as a condition of employment. See also CLOSED SHOP; OPEN SHOP; UNION SHOP.

agency theory a theory that describes economic and organizational activity in terms of a series of agreements between principals, who require goods or services, and agents, who supply these goods or services. Central to this theory is the rational economic assumption that both agents and principals will attempt to maximize their respective UTILITIES. An agency problem may arise when the interests of principals (e.g., shareholders in a company) and agents (e.g., managers) are not congruent, or when principals have insufficient information about the activities of agents. Agency theory suggests ways in which these problems can be reduced, notably by redesigning contracts or compensation schemes so that agents have an incentive to act in the best interests of principals (e.g., by some form of GAINSHARING) and by improving monitoring procedures.

agenesis n. the failure of a body part to develop fully or to develop at all. An example is corpus callosum agenesis, in which the nerve tract joining the two cerebral hemispheres (see CORPUS CALLOSUM) fails to develop. —agenetic adj.

agenitalism n. 1. congenital absence of sex organs. 2. a condition caused by the lack of secretion of sex hormones.

age norm the standard score or range of scores that represent the average achievement level of people of a particular chronological age.

agent n. 1. a person or entity that acts or has the capacity to act, particularly on behalf of another or of a group. For example, an agent may be a therapist who helps a client gain self-understanding or an individual who initiates a social interaction. 2. a means by which something is done or caused. For example, an infectious agent is a bacterium or other microorganism that causes a particular disease. 3. in linguistics, the entity that performs the main action in a clause or sentence. It is prototypically an ANIMATE NOUN and usually, but not always, the grammatical SUBJECT of the clause. The agent is an important category in CASE GRAMMAR. Compare EXPERIENCER; INSTRUMENTAL; PATIENT.

agentive adj.

agentive orientation an emphasis on achieving, doing, succeeding, and making one’s own mark in the world, which may be expressed through such traits as COMPETITIVENESS and SELF-FOCUS.

agentic state a psychological condition that occurs when individuals, as subordinates to a higher authority in an organized status hierarchy, feel compelled to obey the orders issued by that authority. See BEHAVIORAL STUDY OF OBEDIENCE; Destructive obedience. [described by Stanley MILGRAM]

age of consent the age at which an individual is considered legally competent to consent to something, such as consensual sex, marriage, treatment, or participation in research. See also INFORMED CONSENT.

age of onset the chronological age at which symptoms of a disease or disorder first appear in an individual. One of the hallmarks of some genetic syndromes is that the age of onset is earlier in individuals with hereditary susceptibility than in other cases.

age ratio one indicator of the predictive power of an ATTITUDE TEST, obtained by dividing the student’s chronological age at one administration of a test by his or her age at a later administration of the same test.

age regression a hypnotic technique in which the therapist helps the client recall a crucial experience by inducing amnesia for the present, then suggesting that he or she return, year by year, to the earlier date when a particular experience took place. This technique is also used in foren-
sic contexts to help eyewitnesses and victims recall their experiences. The use of age regression in either context is controversial, given the potential for false memories and the debatable legitimacy of recovered memories.

agousia (agousia) n. loss or absence of the ability to taste. Causes may include a failure of taste receptors to form; a loss of taste receptors due to injury, disease, or advanced age; or damage to the sensory nerves that transport taste sensations to the central nervous system. —agousic adj.

agglutination n. in linguistics, the creation of a word from the combination of several morphemes that remain essentially unchanged in the process. For example, the word unbreakable is created by the agglutination of the morphemes un-, break, and -able. —agglutinate vb.

agglutinative language in linguistic typology, a language that expresses ideas in complex words formed by the agglutination of numerous distinct morphemes. Turkish is considered a typical agglutinative language. Compare fusional language; isolating language.

aggravated damages a sum of money a defendant is ordered to pay the plaintiff in a civil lawsuit to provide compensation for emotional harm. Aggravated damages are considered a type of compensatory damages and are awarded under circumstances in which the defendant’s actions were particularly malevolent and caused the plaintiff significant anguish, distress, embarrassment, grief, humiliation, or other pain and suffering.

aggravating factor a fact relating to a crime or to the defendant that makes the offense more serious or supports the argument for a harsher sentence. An example is the use of a deadly weapon in the commission of a crime. Also called aggravating circumstance. Compare mitigating factor.

aggregate data scores or observations that have been re-expressed by a summary statistic. Calculating the arithmetic average of a set of test scores obtained over time for each individual in a group and then using each person’s single average score as representative of his or her test performance would be an example of aggregating data.

aggregate idea an idea that is formed by recombination of the elements of a complex stimulus (such as the set of tones of a clanging noise) into a new compound stimulus (such as a musical chord). The new, aggregate idea can be characterized by its elements but is not itself contained in those elements. [defined by Wilhelm wundt]

aggregation n. 1. a collection of organisms in one location with no obvious social structure or social organization, possessing only a minimum of shared purpose or interdependence. Examples include people in a shopping mall, commuters on a subway platform, or a group of butterflies around a puddle of water. Compare group. 2. in statistics, a process of combining and summarizing a set of scores or observations that have been factorized into a smaller set of scores that capture an aspect of the original set. Compare disaggregation. —aggregate vb. —aggregative adj.

aggregation problems the difficulty of separating individual effects from situational effects when established groups or institutions are used as the unit of analysis in an evaluation. For example, investigators are likely to attribute characteristics of the institution to the individual.

aggression n. behavior aimed at harming others physically or psychologically. It can be distinguished from anger in that anger is oriented at overcoming the target but not necessarily through harm or destruction. When such behavior is purposely performed with the primary goal of intentional injury or destruction, it is termed hostile aggression. Other types of aggression are less deliberately damaging and may be instrumentally motivated (proactive) or affectively motivated (reactive). Instrumental aggression involves an action carried out principally to achieve another goal, such as acquiring a desired resource. Affective aggression involves an emotional response that tends to be targeted toward the perceived source of the distress but may be displaced onto other people or objects if the disturbing agent cannot be attacked (see displaced aggression). In the classical psychoanalytic theory of Sigmund Freud, the aggressive impulse is innate and derived from the death instinct, but many non-Freudian psychoanalysts and most nonpsychoanalytically oriented psychologists view it as socially learned or as a reaction to frustration (see frustration-aggression hypothesis). See also pathological aggression.

Aggression among nonhuman animals also exists, involving direct physical attack by one on another or the threat of such attack. Over the years, different researchers have identified different types of animal aggression based on such considerations as the members involved (e.g., intraspecific or interspecific), the apparent intent (e.g., offensive or defensive), or the stimuli eliciting them. One of the most influential classification schemes has been that proposed in 1968 by U.S. physiological psychologist Kenneth Evan Moyer (1919–2006). It describes predatory aggression to obtain food and the converse antipredatory aggression, territorial aggression to repel intruders from an area, intermale aggression against a competitor, fear-induced aggression, irritable aggression in response to pain or deprivation of an item required for survival, sexual aggression to secure mates, maternal aggression to protect young offspring, and instrumental aggression. See also dominance aggression. —aggressive adj.

aggression–frustration hypothesis see frustration-aggression hypothesis.

aggressive character a personality characterized by a hostile or competitive attitude to others and the pursuit of power, prestige, and material possessions. Karen D. Horney defined the development of such a character as one of three basic neurotic trends used as a defense against basic anxiety. Compare compliant character; detached character.

aggressive cue a signal or stimulus in a person’s environment that is interpreted as aggressive or that is typically associated with aggression.

aggressive instinct in psychoanalytic theory, a derivative of the death instinct that directs destructive impulses away from the self and toward the outside world.

aggressive mimicry the presence in a predatory species of physical or behavioral traits (or both) that closely resemble those of a nonpredatory species, with the result that potential prey more readily approach the predator. For example, the females of a species of firefly can imitate the sexual flash patterns of a different species, luring males of that species close enough to be eaten.

aggressiveness n. a tendency toward social dominance, threatening behavior, and hostility. It may occur sporadically or be a characteristic trait of an individual. —aggressive adj.
aggressive-rejected child

aggressive-rejected child in sociometric measures of peer acceptance, a child who is prone to hostile and antagonistic behavior toward, and is actively disliked by, his or her peers. Such children show more conduct-disorder psychopathology and delinquency later in adolescence. Compare WITHDRAWN-REJECTED CHILD. See also SOCIOMETRIC STATUS.

aging n. the biological and psychological changes associated with chronological age. A distinction is often made between changes that are due to normal biological processes (see PRIMARY AGING) and changes that are caused by age-related pathologies (see SECONDARY AGING).

aging disorder any disruption of the gradual structural and immune changes that occur with the passage of time, resulting in premature aging and increased probability of early death. An example is progeria (or Hutchinson-Gilford progeria syndrome), a very rare inherited disorder in which children age extremely rapidly and typically die of a heart attack or stroke between the ages of 10 and 15 years. Another example is adult progeria (or Werner syndrome), with an onset occurring before the age of 30 and an average life expectancy of 20 years from diagnosis; patients typically die of atherosclerosis or some form of cancer.

aging in place the ability of older individuals to live safely, independently, and comfortably in their own homes as they age and as their health-related and other needs change. Factors that influence whether an older individual can successfully age in place—that is, without need for long-term institutionalized care—include environmental characteristics of the “place” itself (e.g., home, neighborhood, community), such as its physical suitability, safety, and access to appropriate support services if needed, and personal characteristics or circumstances that support an individual’s independence, such as economic stability, positive relationships with family and friends, a sense of self-efficacy, and ability to manage ACTIVITIES OF DAILY LIVING.

agitated depression a MAJOR DEPRESSIVE EPISODE in which psychomotor agitation (excessive but purposeless activity), restlessness, and irritability predominate.

agitation n. a state of increased but typically purposeless and repetitious activity, as in PSYCHOMOTOR AGITATION.

agitographia n. very rapid writing with nonconscious omissions and distortions of letters, words, or parts of words.

agitophasia n. very rapid and cluttered speech in which sounds, words, or parts of words are omitted or distorted. Also called agitotalia.

aglossia n. congenital absence of the tongue. A condition that is rare in isolation but is often accompanied by other systemic abnormalities, such as cleft palate, malformed limbs, and missing fingers and toes. Hypoglossia refers to a short, incompletely developed tongue. Both aglossia and hypoglossia result in difficulty or inability to achieve articulation.

agnosia n. loss or impairment of the ability to recognize or appreciate the nature of sensory stimuli due to brain damage or disorder. Recognition impairment is profound and specific to a particular sensory modality. AUDITORY AGNOSIA, TACTILE AGNOSIA, and VISUAL AGNOSIA are the most common types, and each has a variety of subtypes.

agnosic alexia see ALEXIA.

agnosticism n. a skeptical position holding that the truth or falsity of certain metaphysical ideas or propositions cannot be known. The word is most often used in regard to theological doctrines, especially to belief in the existence of God. [coined in 1869 by British biologist Thomas Henry Huxley (1825–1895)] —agnostic adj., n.

agnus castus an herbal preparation derived from the flowers of the chasteberry tree and approved in Germany for use in the management of symptoms associated with the late luteal phase of the menstrual cycle (see PREMENSTRUAL DYSPHORIC DISORDER) and in the alleviation of menstrual cycle abnormalities or irregularities. Although its active components and mechanism of action are unknown, agnus castus has been shown to possess significant estrogenic activity and is thought to act upon the pituitary gland. Agnus castus may also possess dopaminergic activity, and thus its concurrent use with either DOPAMINE-RECEPTOR AGONISTS or DOPAMINE-RECEPTOR ANTAGONISTS is not recommended, given the potential interactions that may occur. Side effects of agnus castus use are rare but may include rashes and itching, nausea and vomiting, dizziness, headache, drowsiness, and confusion. Also called VITEX AGNUS CASTUS.

agonadal adj. denoting or resulting from absence of the primary sex organs (gonads, i.e., testes or ovaries).

agonist n. 1. a drug or other chemical agent that binds to a particular receptor and produces a physiological effect, typically one similar to that of the body’s own neurotransmitter at that receptor. There are PARTIAL AGONISTS, which stimulate the receptor only somewhat to produce the same physiological effect as the natural neurotransmitter but to a lesser degree, and INVERSE AGONISTS, which act at the receptor to produce a physiological effect opposite to that produced by another agonist at that same receptor. 2. a contracting muscle whose action generates force in the intended direction. Compare ANTAGONIST. —agonism n. —agonistic adj.

agonist-antagonist a substance that simultaneously binds to multiple receptors, mimicking the action of the body’s natural neurotransmitter at one type of receptor and inhibiting that action at another. Different type of receptor.

agonistic behavior competitive interactions involving components of both fear and aggression. In dominance or territorial encounters, behavioral interactions typically involve fluctuations in fearful and aggressive behavior within both parties, so that neither can be said to be purely aggressive or fearful.

agoraphobia n. an excessive, irrational fear of being in open or unfamiliar places, resulting in the avoidance of public situations from which escape may be difficult, such as standing in line or being in a crowd. In DSM–IV–TR, agoraphobia may accompany PANIC DISORDER (panic disorder with agoraphobia), in which an individual experiences unexpected panic attacks, or it may occur in the absence of panic disorder (agoraphobia without history of panic disorder), when an individual fears paniclike symptoms or limited symptom attacks but has not experienced full-blown panic attacks. In DSM–5, panic disorder and agoraphobia are treated as separate entities with separate criteria; their combined presence is considered two diagnoses. See also ANXIETY DISORDER. —agoraphobic adj.

agrammatic comprehension an inability to understand the meaning of sentences, even though the individual word items are understood correctly. This inability is
most often apparent where sentences depart from standard word order (in English, subject–active verb–object) or are syntactically complex. The impairment is associated with CONDUCTION APHASIA and agrammatism.

**agrammatism** n. a manifestation of APHASIA characterized by loss or impairment of the ability to use speech that conforms to grammatical rules, such as those governing word order. Also called **agrammatic aphasia: dysgrammatism. —agrammatic adj.**

**agranular cortex** the portion of the cerebral cortex that lacks GRANULE CELLS. It is found in layers I, III, and V of the cortex (see CORTICAL LAYERS) and refers particularly to the primary motor cortex (Brodmann’s area 4), in which layer V (the major projection area) is very thick. Compare GRANULAR CORTEX.

**agranulocytosis** n. a decline in the number of certain white blood cells (neutrophils), typically as a result of an immune reaction to a drug or other chemical or the toxic effect of this substance on the bone marrow, causing production of white blood cells to fall. Agranulocytosis is diagnosed when the neutrophil count is below 200/mm³ or when the total white-blood-cell count is below 500/mm³. The condition results in suppression of the immune response, rendering individuals vulnerable to opportunistic infections. Psychotropic drugs, such as clozapine and phenothiazine, can induce agranulocytosis.

**agraphia** n. loss or impairment of the ability to write as a result of neurological damage or disorder. The specific forms of writing difficulties vary considerably but may include problems with spelling irregular or ambiguous words, writing numbers or particular letters, or performing the motor movements needed for handwriting. Agraphia generally is seen in APHASIA, although there is considerable variability of writing ability within a given aphasia type. Also called **dysgraphia. —agraphic adj.**

**agreeableness** n. the tendency to act in a cooperative, unselfish manner, construed as one end of a dimension of individual differences (agreeableness vs. disagreeableness) in the BIG FIVE PERSONALITY MODEL. It is also a dimension in the FIVE-FACTOR PERSONALITY MODEL. —agreeable adj.

**agreement** n. in linguistics, the correct relation between the different grammatical elements of a sentence, so that, for example, the number of the verb corresponds to that of its subject, and the number and gender of a pronoun correspond to those of its noun.

**agreement coefficient** see COEFFICIENT OF AGREEMENT.

**agryria** n. see AGESIA.

**agyrria** n. see LISNESSCEPHALY.

**AIDS** acquired immune deficiency syndrome: a clinical condition in which the immune system is so severely damaged from infection with human immunodeficiency virus (see HIV) as to allow serious opportunistic infections and diseases.

**AIDS counseling** guidance, advice, and information provided to individuals on issues related to HIV infection and AIDS. Such counseling typically covers ways to avoid exposure to HIV infection, provision of HIV antibody testing, and the importance of adhering to medication, as well as dealing with the myriad psychological and social issues associated with AIDS, including stigma and the anxiety over having a life-threatening illness. Also called HIV/AIDS counseling.

**AIDS dementia complex (ADC)** neuropsychological dysfunction directly attributable to HIV infection, found most commonly in those who have developed AIDS. It is marked by impairment in four areas: (a) cognition (e.g., memory loss, inability to concentrate); (b) behavior (e.g., inability to perform normal activities of daily living); (c) motor coordination (e.g., unsteady gait, loss of balance, incontinence); and (d) mood (e.g., severe depression, psychosis). Brain scans of affected individuals reveal cortical atrophy. Also called HIV dementia.

**aim** n. 1. the symbolic or internal representation of a goal that may motivate and direct behavior toward achieving that goal: an intention or purpose. 2. a goal toward which an organism directs behavior, effort, or activity: an objective. 3. in psychoanalytic theory, see AIM OF THE INSTINCT; OBJECT OF INSTINCT.

**AIM** acronym for ACTIVE INTERMODAL MAPPING.

**aiming test** a test of VISUAL–MOTOR COORDINATION, pre-
cision, and speed. The participant either thrusts a stylus into a series of progressively smaller holes momentarily uncovered by a rotating shutter or places dots in small circles as rapidly as possible (see DOTTING TEST).

aim-inhibited adj. in psychoanalytic theory, describing a behavior—particularly an interpersonal behavior—in which the underlying drives are reflected from their original object and remain largely unconscious. According to the theory, aim inhibition characterizes those situations in which an INSTINCT fails to achieve direct satisfaction of its aim but obtains reduced gratification through activities or relationships similar to the original aim. Sigmund Freud used this idea to explain affectional relationships within families and platonic friendships as deriving from an aim-inhibited sexual instinct.

AIM model a model proposing that various states of consciousness may be defined and differentiated according to their position on three axes of brain activity: (a) Activation—how active is the brain when one is awake, in NREM SLEEP, or in REM SLEEP, as measured by electroencephalography?; (b) Input–output gating—how is information that is processed by the brain during each phase in the sleep-wake cycle generated, via external sensory input (as in external stimuli during waking) or internally (as in dreams)?; and (c) Modulation—which neurochemical modulatory system is predominant during each phase, the aminergic or the cholinergic? The model has been used to investigate ALTERED STATES OF CONSCIOUSNESS and various phenomena associated with dreaming (notably the LUCID DREAM); it has also been proposed more generally as an approach to the MIND–BODY PROBLEM. It was devised by U.S. psychiatrist J. Allan Hobson (1933– ) as an expansion of the earlier ACTIVATION–SYNTHESIS HYPOTHESIS that he developed with U.S. psychiatrist Robert W. McCarley (1937– ).

aim of the instinct in psychoanalytic theory, the activity through which an INSTINCT is gratified, resulting in the release of internal tension. For example, kissing may satisfy the oral instinct. Also called INSTINCTUAL AIM. See also REVERSAL OF AFFECT.

AIO abbreviation for activities, interests, opinions. See PSYCHOGRAPHICS.

air–bone gap the difference between the air-conduction and bone-conduction hearing levels at specific frequencies, which indicates the amount of conductive impairment in the ear tested.

air conduction the process of conducting sound waves through the ear canal to the eardrum, which vibrates in response to changes in adjacent air pressure.

air-conduction testing an audiological procedure that measures a person’s threshold for pure tones in each ear at individual frequencies.

Air Force Medical Evaluation Test (AFMET) the former name for the BIOGRAPHICAL EVALUATION AND SCREENING OF TROOPS program.

air-pollution adaptation habituation to local levels of air pollution through desensitization to their effects on health and aesthetic judgments. SIGNAL DETECTION THEORY suggests a shift in RESPONSE BIAS rather than in actual threshold effects.

air-pressure effects the adverse mental or physical effects of a significant variation in atmospheric pressure. The effects experienced at high pressures—for example, in diving more than 10 m (33 ft) beneath the surface of the sea—may include difficulty breathing, nitrogen poisoning marked by light-headedness and mental instability, and oxygen poisoning caused by breathing oxygen under extreme pressure. Exposure to low pressures, as in mountain climbing or air travel without oxygen or air-pressure modification, characteristically causes oxygen starvation, with impaired performance and eventual loss of consciousness and death. See also ACUTE MOUNTAIN STARVATION; ALTITUDE SICKNESS; DECOMPRESSION SICKNESS; GRAYOUT.

air sickness MOTION SICKNESS caused by air travel.

air traffic control personnel, equipment, and systems that support the safety and security of aircraft through information, communication, observation, and control of flight trajectories. See AVIATION PSYCHOLOGY.

AIS abbreviation for ANDROGEN-INSensitivity SYNDrome.

Ajzen–Fishbein model the original framework for what is now known as the THEORY OF REASONED ACTION. [Icek Ajzen (1942– ) and Martin Fishbein (1936–2009), U.S. social psychologists]

Akaike’s information criterion (AIC) a SUMMARY STATISTIC used in comparing the relative GOODNESS OF FIT of two or more models for a given set of data, while taking into account the number of parameters in each model. The model with the lowest AIC is considered the best among all models specified. [Hirotugu Akaike (1927–2009), Japanese statistician]

akatamathesia n. see ACATAMATHESIA.

akaphasia n. see ACAPHASIA.

akathisia (acathisia) n. extreme restlessness characterized by an inability to sit or stand still and by fidgety movements or jitteriness, as well as a subjective report of inner restlessness. It occurs as an EXTRAPYRAMIDAL SYMPTOM resulting from exposure to a neuroleptic (antipsychotic) medication or in response to SSRI antidepressant medications. Akathisia is also a feature of some neurological and general medical conditions (e.g., Parkinson’s disease and iron-deficiency anemia).

akinesia n. loss or reduction of voluntary movement. Also called akinesis. —akinetiC adj.

akinesia algera a condition in which severe pain is experienced with any body movement, a disorder often associated with psychogenic factors.

akinesia n. loss or impairment of the sense that provides information from muscles, tendons, and joints. Also called akinesia. —akinetic or akinesthetic adj.

akinetiC adj. characterized by loss of voluntary movement not due to paralysis. See AKINESIA.

akinetiC mutism an absence or gross reduction of voluntary movements and speech, although the individual does follow eye movements. The condition is associated with damage to the CINGULATE CORTEX and SUPPLEMENTary MOTOR AREA in the mesial part of the FRONTAL LOBES.

akinetiC seizure see ATONIC SEIZURE.

Akineton n. a trade name for biperiden.

akinetopsia n. inability to see objects in motion as a result of damage to the V5 area of visual cortex. Individuals with akinetopsia perceive moving stimuli as a series of stationary strobelike images and see visual trails behind mov-
alcoholic brain syndrome

resulting directly from alcohol use, including neglect of important personal, financial, social, occupational, or recreational activities; absenteeism from work or school; repeated encounters with the police; and the use of alcohol in situations in which drinking is hazardous (e.g., driving while intoxicated). In DSM–IV–TR, it is distinct from alcohol dependence in that the diagnosis does not require tolerance, withdrawal, or alcohol use-related compulsive behavior. In DSM–5, alcohol abuse and alcohol dependence have been subsumed into ALCOHOL USE DISORDER and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

alcohol-annestic disorder see ALCOHOL-INDUCED PERSISTING AMNestic DISORDER.

alcohol dependence in DSM–IV–TR, a pattern of repeated or compulsive use of alcohol despite significant behavioral, physiological, and psychosocial problems; it may also feature cravings, the development of tolerance, and characteristic withdrawal symptoms if use is suspended. The diagnosis is further differentiated from ALCOHOL ABUSE by the preoccupation with obtaining alcohol or recovering from its effects. Alcohol dependence is sometimes considered to be the equivalent of ALCOHOLISM. In DSM–5, it and alcohol abuse have been subsumed into ALCOHOL USE DISORDER and are no longer considered distinct diagnoses. See also SUBSTANCEDEPENDENCE.

alcohol derivative any drug that utilizes the sedative and hypnotic effects of alcohol for therapeutic purposes. In the 1890s, it was found that compounds derived from methyl alcohol had CNS DEPRESSANT effects. In the 1950s, a new generation of alcohol-based compounds with greater hypnotic activity was introduced. They included ETICHLOLVYNOL and ethinamate; the latter is a more potent sleep inducer than ethchlorvynol, but its abuse potential is similar to that of barbiturates. Due to their toxicity, alcohol derivatives are rarely used in modern clinical practice.

alcohol, Drug Abuse and Mental Health Administration (ADAMHA) an agency in the U.S. Department of Health and Human Services that was replaced in 1992 by the SUBSTANCE ABUSE AND MENTAL HEALTH SERVICES ADMINISTRATION (SAMHSA). In this reorganization, the three ADAMHA research institutes, the National Institute on Alcohol Abuse and Alcoholism (NIAAA), the National Institute on Drug Abuse (NIDA), and the National Institute of Mental Health (NIMH), were moved to the National Institutes of Health. The substance abuse and mental health services programs provided by ADAMHA remain the responsibility of SAMHSA.

alcohol flush reaction (AFR) reddening of the face, neck, or other parts of the body, sometimes accompanied by reduced blood pressure and increased heart rate, sweating, sleepiness, and nausea, following alcohol consumption. It is caused by the body's inability to metabolize alcohol efficiently due to a genetic variation of the ALDH2 gene, found in 40% to 50% of people of Asian descent. AFR is associated with an increased risk of cancer due to the carcinogenic properties of unmetabolized alcohol.

alcohol hallucinosis see ALCOHOLIC HALLUCINOSIS.

alcoholic n. a person who is dependent on alcohol, that is, who regularly drinks to the point of intoxication despite negative consequences. See also ALCOHOL DEPENDENCE.

alcoholic blackout see BLACKOUT.

alcoholic brain syndrome any of several syndromes resulting directly from alcohol use, including neglect of important personal, financial, social, occupational, or recreational activities; absenteeism from work or school; repeated encounters with the police; and the use of alcohol in situations in which drinking is hazardous (e.g., driving while intoxicated). In DSM–IV–TR, it is distinct from alcohol dependence in that the diagnosis does not require tolerance, withdrawal, or alcohol use-related compulsive behavior. In DSM–5, alcohol abuse and alcohol dependence have been subsumed into ALCOHOL USE DISORDER and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.
alcoholic cerebellar degeneration

associated with the acute or chronic effects of alcohol on brain function, including ALCOHOL INTOXICATION DELIRIUM, ALCOHOL WITHDRAWAL DELIRIUM, ALCOHOL-INDUCED PERSISTING DEMENTIA, ALCOHOL-INDUCED PERSISTING AMNESTIC DISORDER, and ALCOHOL-INDUCED PSYCHOTIC DISORDER.

alcoholic cerebellar degeneration degeneration of purkinje cells in the midline of the cerebellum caused by long-term alcohol abuse, commonly producing gait disturbances.

alcoholic dementia see ALCOHOL-INDUCED PERSISTING DEMENTIA.

alcoholic hallucinosis alcohol use–related hallucinations, often auditory, that the individual may not realize are hallucinations. The individual remains lucid but may feel persecuted and behave aggressively. Also called alcohol hallucinosis. See also ALCOHOL-INDUCED PSYCHOTIC DISORDER.

alcoholic Korsakoff's syndrome a form of KORSAKOFF'S SYNDROME caused by long-term alcohol abuse. See ALCOHOL-INDUCED PERSISTING AMNestic DISORDER.

alcoholic myopathy see ACUTE ALCOHOLIC MYOPATHY.

alcoholic neuropathy any of various neurological disturbances, including weakness and abnormal skin sensations, such as numbness, tingling, and burning, that are secondary to chronic heavy consumption of alcohol. Specific causative factors are not well understood but appear to include vitamin deficiencies and a directly toxic effect of alcohol on nerves.

Alcoholics Anonymous (AA) a worldwide voluntary organization of men and women who, through a TWELVE-STEP PROGRAM, seek to help each other stay sober and learn to live healthy, fulfilling lives. The only requirement for membership is a desire to stop drinking. Two critical components of the AA program are its focus on alcoholics helping alcoholics and its desire to put principles above personalities in conducting its business. Founded in the United States in 1935, AA is the oldest, largest, and best known self-help organization.

alcohol-induced persisting amnestic disorder a disturbance in memory caused by the persisting effects of alcohol. The ability to learn new information or to recall previously learned information is impaired severely enough to interfere markedly with social or occupational functioning and to represent a significant decline from a previous level of functioning. Formerly called alcohol-amnestic disorder. See also KORSAKOFF'S SYNDROME; WERNICKE-KORSAKOFF SYNDROME.

alcohol-induced persisting dementia a deterioration of mental function resulting from the persisting effects of alcohol abuse. It is characterized by multiple cognitive deficits, especially of memory, but also includes impairment of speech (see Aphasias), movement (see Aplasia), and sensory capabilities (see Agnosia), as well as executive dysfunction. Also called alcoholic dementia. See also SUBSTANCE-INDUCED PERSISTING DEMENTIA.

alcohol-induced psychotic disorder hallucinations or delusions due to the direct physiological effects of alcohol. See also ALCOHOLIC HALLUCINOSIS; SUBSTANCE-INDUCED PSYCHOTIC DISORDER.

alcohol intoxication in DSM–IV–TR and DSM–5, a reversible condition that develops soon after the ingestion of alcohol. It comprises behavioral or psychological changes, such as inappropriate or aggressive behavior, impaired judgment, or impaired social functioning; and physiological changes, such as slurred speech, unsteady gait, and disruption of attention or memory. The effects typically become more marked with increased alcohol intake. Severe intoxication levels can result in respiratory depression and death. See also SUBSTANCE INTOXICATION.

alcohol intoxication delirium in DSM–IV–TR and DSM–5, a reversible syndrome that develops over a short period (usually hours to days) following heavy alcohol consumption. Disturbance of consciousness (e.g., reduced ability to focus, sustain, or shift attention) is accompanied by changes in cognition (e.g., memory deficit, disorientation, or language disturbance) in excess of those usually associated with ALCOHOL INTOXICATION. See also SUBSTANCE INTOXICATION DELIRIUM.

alcoholism n. a syndrome of compulsive and dependent alcohol use. The term may be used synonymously with ALCOHOL DEPENDENCE or refer to persistent heavy alcohol use without a formal diagnosis.

alcohol myopia alcohol-induced impairment of perception and cognition, specifically, a narrowed focus on immediately salient events, desires, or behaviors to the exclusion of less immediate ones. This can lead, for example, to aggressive behavior if an intoxicated individual focuses on (and overinterprets) an immediate threat rather than considering the potential negative ramifications of responding to that threat. [identified by U.S. psychologists Claude M. Steele (1946– ) and Robert A. Josephs (1961– ]

alcohol rehabilitation interventions designed to enable the alcohol-dependent person either to achieve and maintain abstinence, which is the generally accepted goal of treatment for alcohol dependence, or to reach and maintain a stable pattern of nonproblem drinking, which is a controversial, less common goal of treatment. Also called alcoholism treatment; alcohol rehab.

alcohol use disorder a catchall diagnosis encompassing varying degrees of excessive use of alcohol. In DSM–5, the term specifically encompasses both abuse of and dependence on alcohol, thus superseding the DSM–IV–TR’s distinct diagnoses of ALCOHOL ABUSE and ALCOHOL DEPENDENCE. The disorder is characterized by such symptoms as alcohol craving, recurrent use of alcohol that interferes with the fulfillment of one’s daily responsibilities, alcohol-seeking behavior, inability to control one’s drinking, drinking despite potential hazards (e.g., drinking while driving), the need for increased amounts of alcohol to achieve its effects (tolerance), and withdrawal symptoms when one stops or reduces alcohol intake (e.g., hand tremors, nausea, agitation, hallucinations). The disorder is distinguished as mild, moderate, or severe depending on the number of these symptoms that an individual may have: Mild cases present with two to three symptoms; moderate cases four to five symptoms; and severe cases six or more symptoms.

alcohol withdrawal in DSM–IV–TR and DSM–5, a group of physical symptoms that arise after cessation of repeated and prolonged heavy alcohol consumption. Withdrawal symptoms include autonomic hyperactivity (sweating, pounding heart, dry mouth, etc.), hand tremor, insomnia, nausea or vomiting, psychomotor agitation, anxiety, and in some cases hallucinations or illusions, seizures, and delirium tremens. See also HANGOVER.

alcohol withdrawal delirium in DSM–IV–TR and DSM–5, a reversible syndrome that develops over a short
period of time (usually hours to days) following cessation of prolonged, heavy alcohol consumption. The features are disturbed consciousness (e.g., reduced ability to focus, sustain, or shift attention) and changes in cognition (e.g., memory deficit, disorientation, language disturbance) in excess of those usually associated with ALCOHOL WITHDRAWAL. See also DELIRIUM TREMENS.

**aldolase** (ALS) *n.* an enzyme found in muscle tissue, where it serves to split a complex sugar molecule. Excessive levels of aldolase in the blood may be an early indication of abnormal muscle function and a clue in the diagnosis of MUSCULAR DYSTROPHY.

**Aldomet** *n.* a trade name for METHYLDOPA.

**aldosterone** *n.* the principle MINERALOCORTICOID hormone secreted by the adrenal cortex, the outer layer of the ADRENAL GLAND. It helps to regulate mineral and water metabolism by promoting potassium excretion and sodium retention in the kidneys. Excess secretion of aldosterone results in a pathological condition called ALDOSTERONISM (or HYPERALDOSTERONISM), marked by headaches, muscle weakness, fatigue, hypertension, and numbness. Primary aldosteronism is caused by abnormal functioning of the adrenal cortex itself and is called Conn's syndrome, whereas secondary aldosteronism is the result of a liver, heart, or kidney disease affecting the adrenal glands.

**alert inactivity** an INFANT STATE OF AROUSAL marked by facial relaxation, calm and even breathing, open, luminous eyes, and considerable visual exploration.

**alerting device** an ASSISTIVE TECHNOLOGY device that alerts individuals with hearing loss to the occurrence of an event that is typically signaled by auditory means, such as the ringing of a doorbell, the buzzing of an alarm clock, or the beeping of a smoke or fire alarm. It might employ a flashing light, vibrations, or other nonauditory stimuli.

**alerting mechanisms** systems within the central nervous system that trigger a response or direct the attention of higher brain centers to possible threats. Most important is the arousal mechanism of the RETICULAR FORMATION in the brainstem.

**alertness** *n.* the state of being awake, aware, attentive, and prepared to act or react. Neurologically, alertness corresponds with high-frequency, low-amplitude brain waves resulting from stimulation of the RETICULAR FORMATION. See also AROUSAL. —alert adj.

**alexia** *n.* loss or impairment of the ability to comprehend written or printed words as a result of lesions, stroke, or other forms of neurological damage or disorder. It is generally seen in APHASIA but may occur in isolation, in which case it is called pure alexia (or alexia without agraphia) and characterized by reading impairment with preserved language production and auditory comprehension. Individuals with pure alexia can also write but are frequently unable to read what they have written (hence it is also called word blindness). See also DYSLEXIA.

**alexia with agraphia** a form of acquired DYSLEXIA in which both reading and writing ability are impaired. Often problems producing or comprehending speech are also present. The condition is traditionally associated with lesions of the ANGULAR GYRUS but is now known to involve other regions of the brain as well.

**alexithymia** *n.* an inability to express, describe, or distinguish among one’s emotions. It may occur in a variety of disorders, especially psychosomatic and some substance use disorders, or following repeated exposure to a traumatic stressor. It also may be a disorder in its own right. See also NORMATIVE MALE ALEXITHYMIA.

**Alfenta** *n.* a trade name for alfentanil. See FENTANYL.

**alfentanil** *n.* see FENTANYL.

**algebraic summation** SUMMATION that takes into account the signs of the terms. Thus, when both EXCITATORY POSTSYNAPTIC POTENTIALS and INHIBITORY POSTSYNAPTIC POTENTIALS are induced in a neuron, an ACTION POTENTIAL is evoked only if the excitatory potentials exceed the inhibitory potentials by at least a threshold amount.

**algedonic** adj. relating to pain associated with pleasure, or the pleasantness–unpleasantness dimension of experience. Algedonics is the study of the mixture of pleasure and pain.

**algedonic aesthetics** the concept that pleasure arises when sensory organs are in a hypernormal state of readiness to respond, and displeasure arises when they are in a hyponormal state of readiness. [formulated in the late 19th century by U.S. philosopher Henry R. Marshall (1852–1927)]

**algiesia** *n.* the ability to experience the sensation of pain. Compare ANALGESIA. —algic adj.

**algiesimeter** *n.* an instrument used to measure the sensitivity of an individual to pain. It contains a calibrated needle that is pressed against a body surface in order to determine the person's pain threshold. Also called algometer: algometer.

**algia** suffix pain or a painful condition (e.g., NEURALGIA).

**algo-** *combining form* pain.

**algolagnia** *n.* a sexual disorder in which sexual excitement is achieved by passively experiencing or actively inflicting pain. See SEXUAL MASOCHISM: SEXUAL SADISM.

**algometer** *n.* see ALGIESIMETER.

**algophilia** *n.* liking for the experience or infliction of pain. See also ALGOLAGNIA: MASOCHISM: SADISM.

**algoscopy** *n.* physical pain recognized by the patient as being of mental rather than physical origin, which sometimes accompanies mental difficulties and illness (e.g., anxiety, depression, schizophrenia). See also PSYCHALGIA; PSYCHIC PAIN.

**algorithm** *n.* a well-defined procedure or set of rules that is used to solve a problem or accomplish a task or that is used for conducting a series of computations. An example is trying all the possible combinations in sequence in order to open a combination lock. Algorithms, which may be represented visually as flow charts, are essential to computer programming and information processing. The word is derived from the name of the 9th-century Arab mathematician al-Khwārizmī. Compare HEURISTIC. See also BRITISH MUSEUM ALGORITHM; BRUTE FORCE; EXHAUSTIVE SEARCH. —algorithmic adj.

**alien abduction** a claim by individuals that they have been kidnapped by extraterrestrial beings. Although this phenomenon is commonly associated with delusional thinking, posttraumatic stress disorder, and acute stress reactions, many of these individuals have no other clear symptoms of mental disorder. There is no conclusive scientific evidence to support the validity of their claims. Also called EXTRATERRESTRIAL KIDNAPPING.
alienation n. 1. estrangement from others, resulting in the absence of close or friendly relationships with people in one's social group (e.g., family, workplace, community). 2. a deep-seated sense of dissatisfaction with one's personal existence and a lack of trust in one's social or physical environment or in oneself. 3. estrangement from one's own customary or expected ways of functioning. 4. the experience of being separated from reality or isolated from one's thoughts, feelings, or physical being, as in DERIALIZATION and DEPERSONALIZATION. —alienated adj.

alienation coefficient see COEFFICIENT OF ALIENATION.

alien hand syndrome a phenomenon in which an individual perceives his or her hand to be acting under its own control or to be "foreign." It is a specific kind of alien limb syndrome.

alien limb syndrome a neurological disorder characterized by unintended hand, arm, or leg movements, often accompanied by a feeling that one has no control over the limb. The individual may not even recognize the limb as his or her own. The syndrome may be associated with lesions to the SUPPLEMENTARY MOTOR AREA or the motor regions of the CORPUS CALLOSUM.

ALLI Guidelines abbreviation for American Law Institute Guidelines. See AMERICAN LAW INSTITUTE MODEL PENAL CODE INSANITY TEST.

alkalosis n. an abnormally high level of alkalinity (bicarbonate ion concentration) in the blood and tissues, which upsets the body's acid–base balance. The condition is often marked by slow, shallow breathing. It has a variety of causes and additional symptoms vary with each, potentially including neurological abnormalities such as muscle twitching, confusion, tremors or spasms, and numbness. Compare ACIDOSIS. —alkalotic adj.

allo- (all-) combining form difference or otherness.

allochthonous adj. stemming from sources or forces external to a particular system: not indigenous or innate. Compare AUTOCHTHONOUS.

allochthonism n. the extension of erotic feelings toward another male. See also THERAPEUTIC ALLIANCE.

allochthonous adj. stemming from sources or forces external to a particular system: not indigenous or innate. Compare AUTOCHTHONOUS.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.

allochthony n. a disturbance of sensation in which a person experiences pain or touch sensations on the opposite side of the body from the point actually stimulated. It is considered a DISCHERIA. It is also often used synonymously with ALLESTHESIA.
and the derivation of sexual satisfaction from others, as opposed to AUTOEROTICISM. Also called alloeroticism. —alloerotic adj.

 alloesthesia n. see ALLESTHESIA.

 allogrooming n. behavior that involves two or more nonhuman animals picking through each other’s fur, hair, or feathers. Often thought to have a solely hygienic function (i.e., the removal of dirt and parasites), allogrooming has been shown to have positive social effects as well, through production of endogenous opioids in recipients. It is thus a mechanism that reinforces social relationships.

 allomone n. a chemical signal that is released outside the body by members of one species and affects the behavior of members of another species. Compare PHEROMONE.

 allomorph n. in linguistics, any of several different speech sounds or written forms that are used to represent the same MORPHME. For example, the [s] sound at the end of cats and the [z] sound at the end of dogs represent the same noun-plural morpheme and are therefore allomorphs. Similarly, in writing, the -t at the end of burnt and the -ed at the end of turned are allomorphs representing the same past-tense morpheme. —allomorphic adj.

 allografting n. the provision by a female of nourishment for offspring that are not her own. Although seen in rodents, ungulates, primates, and other mammalian species, allonursing remains poorly understood in light of the fact that lactation imposes substantial physiological costs on mothers and thus seemingly should not be directed toward foreign offspring. The various explanations offered for this behavior include the parenting hypothesis, stating that the individual is practicing to improve her survival skills; the reciprocity hypothesis, stating that the individual helps one who has helped her by sharing responsibility for nourishment; the misdirected parental care hypothesis, stating that the individual is unaware the offspring is not her own; the milk evacuation hypothesis, stating that the individual nourishes others to get rid of surplus milk not consumed by her own offspring; and the kin selection hypothesis, stating that the individual obtains greater inclusive fitness by nourishing offspring to whom she is indirectly related. Additionally, allogrooming may have social benefits similar to those of ALLOGROOMING. Also called communal nursing; nonoffspring nursing.

 allonursing n. care of infants by individuals who are not their parents. It is seen especially among cooperative-breeding species where alloparents (also known as helpers or helpers at the nest) may provide essential services for offspring survival.

 allopathy n. a system of medicine in which a disease or disorder is treated with agents that produce effects different from or incompatible with those caused by the disease or disorder. Allopathy is often equated with conventional or pharmacological medical practice. Compare HOMEPATHY. —allopathic adj.

 allopatic adj. see SYMPATRIC.

 allophasis n. disorganized, incoherent speech.

 allophone n. in linguistics, any of several slightly different speech sounds that are regarded as contextual variants of the same PHONEME. For example, in English the aspirated [p] sound at the beginning of paid and the unaspirated [p] sound in spade have no contrastive function in the phonological system of the language and are therefore regarded as allophones of the same phoneme. /p/. —allophonic adj.

 alloplasty n. 1. a process of adaptive response that aims to alter the environment, as opposed to altering the self. Also called alloplastic adaptation. 2. surgical repair of diseased or damaged tissue through implantation using synthetic or organic material from outside the patient’s body. Compare AUTOPLASTY. —alloplastic adj.

 allopregnenolone n. a naturally occurring steroid that modulates GABA, RECEPTOR activity in a manner similar to that of benzodiazepine anxiolytics.

 allopsychic delusion a delusion about others or the world outside of the self. Compare AUTOPSICHE DELUSION.

 all-or-none law the principle that the amplitude of the action potential in a neuron is independent of the magnitude of the stimulus. Thus, all stimuli above the neuron’s threshold trigger action potentials of identical magnitude (although they may vary in frequency); stimuli below this threshold may produce local graded potentials but no propagated impulses. Also called all-or-none principle.

 all-or-none learning the theory that, in any given learning trial, learning occurs either completely and fully or not at all. This contrasts with a hypothesis of trial-by-trial incremental learning.

 allostasis n. stability through change. Allostasis refers particularly to the idea that parameters of most physiological regulatory systems change to accommodate environmental demands. Although allostatic processes are critical for adaptive functioning, chronic or repeated activation of physiological systems in response to life’s challenges is hypothesized to exact a toll on such systems.

 allosteric modulation the binding of a substance (called an allosteric modulator) to a certain site on a receptor in a way that alters the conformation of other sites on the receptor, thereby increasing or decreasing the affinity of the receptor for other molecules. Allosteric modulation has been recognized as an alternative pharmacological approach to gain selectivity in drug action.

 allotriophagy n. a desire to eat inappropriate foods or nonnutritive substances. Also called allotriophobia. See also PICA.

 all-payer system a health care system in which prices for health care services and payment methods are the same regardless of who is paying (e.g., the patient or an insurance company). Also called multipayer system.

 Allport's personality trait theory the theory that an individual's personality traits or personal dispositions are key to understanding the uniqueness and consistency of his or her behavior. Traits are regarded as dynamic forces that interact with each other and the environment to determine the characteristic actions or reactions that define the self (see PROPRIUM). See also COMMON TRAIT. [Gordon W. Allport]

 Allport–Vernon–Lindzey Study of Values (SOV) a two-part personality test designed to show the relative importance of six basic values in the participant’s life: theoretical, economic, aesthetic, social, political, and religious. The categories are based on Spranger’s Typology and presented in the form of 45 items to which participants respond. Part one consists of 30 statements, each describing a situation with two alternative choices; participants must choose which option they prefer and indicate the strength
all-possible-subsets regression

of that preference by distributing three points between the two alternatives. Part two consists of 15 questions, each with four alternative answers; participants must rank the answers in order of preference. The SOV was originally published in 1931 as the Allport–Vernon Study of Values but in 1951 was revised and renamed. A third edition was published in 1960 and a fourth in 2003, the latter developed by U.S. vocational psychologist Richard E. Kopelman (1941– ) and colleagues. Also called Study of Values. [Gordon W. Allport; Philip E. Vernon (1905–1987), British psychologist; Gardner Lindzey]

all-possible-subsets regression a method for predicting an outcome variable based on a series of equations formed by all possible subsets of predictors from a finite pool of predictors. The “best” subset is identified using criteria established by the researcher, such as the value of pool of predictors. Typically, blocked alpha waves are replaced by faster, low-amplitude, irregular waveforms on the EEG, a phenomenon called desynchronization.

alpha coefficient see Cronbach’s alpha.

alpha error see type I error.

alpha examination see army tests.

alpha female see alpha male.

alpha-fetoprotein (α-fetoprotein: AFP) n. a protein found in the blood plasma of fetuses and produced by some tumors in adult humans. In human fetuses, unusually high or low levels of this protein suggest fetal abnormality, as analyzed through a prenatal alpha-fetoprotein test of blood samples drawn from pregnant women. In adult humans, measurement of alpha-fetoprotein is used to diagnose liver cancer. In rodents, alpha-fetoprotein binds estrogens and prevents them from entering the brain, thus influencing sexual differentiation.

alpha level see significance level.

alpha male the top-ranked or dominant male within a group, with primary access to resources, including food and mates. In many species, the alpha male prevents other males from mating or from mating during the peak time of female fertility. There are alpha females as well, with primary access to resources within their social groups; in some species, they inhibit reproduction among other males.

alpha-mannosidosis n. a rare and progressive autosomal recessive, lysosomal storage disease involving deficient activity of an enzyme, alpha-D-mannosidase, needed to metabolize the sugar mannose. Mutations in the MAN2B1 gene cause the disease. Affected individuals have slow motor development; intellectual disability; skeletal abnormalities; and anomalous facial features (e.g., large head, low hairline, flattened bridge of the nose, protruding jaw, large tongue). Early-onset alpha-mannosidosis, the most severe form, can affect the fetus but most often begins in early infancy. It is typically fatal during childhood. Onset of the disorder later in childhood or early adolescence is associated with milder symptoms that progress more slowly and with an increased lifespan into middle age.

alpha-melanocortin stimulating hormone (α-MSH; alpha-MSH) a form of melanocyte-stimulating hormone that binds the melanocortin-4 receptor and is involved in diverse functions, such as regulation of feeding and sexual function.

alpha-methylparatyrosine (AMPT) a drug that inhibits the synthesis, from the amino acid tyrosine, of the catecholamine neurotransmitters dopamine, norepinephrine, and epinephrine. It is sometimes used to treat catecholamine-secreting tumors of the adrenal gland (e.g., phaeochromocytoma). Alpha-methyltyrosine has a similar action.

alpha motor neuron see motor neuron.

alpha movement a form of apparent movement in which an object appears to expand or contract when in...
increasingly larger or smaller versions of it are presented in rapid succession. Also called alpha motion.

**alpha-MSH** (ɑ-MSH) **abbreviation** for ALPHA-MELANOCYTE STIMULATING HORMONE.

**alpha neurofeedback** see ALPHA-WAVE TRAINING.

**alpha receptor** see ALPHA-ADRENERGIC RECEPTOR.

**5 alpha-reductase** an enzyme that catalyzes the conversion of the steroid hormone testosterone to dihydrotestosterone in males and females. It is necessary for the process of sexual differentiation and the masculinization of external genitalia in male fetuses.

**alpha rhythm** see ALPHA-WAVE.

**alpha state** a state of relaxed wakefulness associated with increased production of ALPHA WAVES in some individuals. It is claimed that alpha states may be induced by ALPHA-WAVE TRAINING, meditation, yoga, hypnotic suggestion, Iow experiences, and other calmy focused activities.

**Alpha test** see ARMY TESTS.

**alpha wave** in scalp electroencephalography, a type of low-amplitude BRAIN WAVE (frequency 8–12 Hz) that typically occurs when the eyes are closed or unfocused and no deliberate mental tasks are taking place; it is associated with a wakeful but relaxed state. There is some evidence that the occurrence of alpha waves can be increased, through meditation techniques or ALPHA-WAVE TRAINING for example. Also called alpha rhythm; Berger rhythm.

**alpha-wave training** a type of NEUROFEEDBACK training that aims to teach individuals how to achieve a state of peaceful wakefulness and relaxation by increasing alpha-band activity (ALPHA WAVES). The technique usually involves alpha neurofeedback (formerly called alpha biofeedback), the process of providing a feedback stimulus (typically an auditory tone) when alpha waves appear over the occipital cortex on a scalp electroencephalogram. The efficacy of such training is disputed. See also ALPHA STATE.

**Alport syndrome** a familial condition characterized by hematuria (bloody urine), nephropathy (disease of the kidney), and deafness. Hematuria may first appear in infancy, whereas deafness is likely to develop around puberty. The condition also may be accompanied by cataracts and intellectual disability. It is caused by mutation of the genes COL4A3, COL4A4, COL4A5, or COL4A6, which specify chains of basement membrane (Type IV) collagen. [described in 1927 by Arthur Cecil Alport (1879–1959), British physician]

**alprazolam** n. a BENZODIAZEPINE used for the treatment of generalized anxiety disorder and panic disorder. It is rapidly absorbed and has a relatively brief duration of action. Common side effects include drowsiness, light-headedness, headache, and confusion. U.S. trade name: Xanax.

**ALS** 1. abbreviation for ALDOLASE. 2. abbreviation for AMYOTROPHIC LATERAL SCLEROSIS.

**als ob** as if (German). The phrase is associated with the thought of German philosopher Hans Vaihinger (1852–1933), who proposed that certain “fictions,” such as free will, immortality, and objective morality, should be supported and lived as if (als ob) they were true, because there is biological advantage in doing so. Vaihinger’s work influenced that of Alfred ADLER.

**Alström–Hallgren syndrome** a familial disorder that is characterized by obesity, deafness, visual disorders, and diabetes and occasionally associated with mental disorders. [Carl-Henry Alström (1907–1993), Swedish physician; Bertil Hallgren, 20th-century Swedish geneticist]

**ALT** abbreviation for ALTERNATIVE SCHEME OF REINFORCEMENT.

**alteration hypothesis** a theoretical explanation of the MISTORTION EFFECT stating that misleading information introduced after a witnessed event replaces, transforms, or impairs the original memory of the event, leading to erroneous reporting of that event. Also called substitution hypothesis. Compare COEXISTENCE HYPOTHESIS.

**altercasting** n. in ROLE THEORY, the process of imposing identities and social roles on others (“alters”), usually by treating them in ways that are consistent with the imposed identity or role. —altercast vb.

**altered state of consciousness (ASC)** a state of psychological functioning that is significantly different from that experienced in ordinary states of CONSCIOUSNESS. Reports of the experience of ASCs are highly subjective, but the phenomenon is susceptible to some degree of empirical study. It tends to be characterized by altered levels of self-awareness, affect, reality testing, orientation to time and place, wakefulness, responsiveness to external stimuli, or memorability, or by a sense of ecstasy, boundlessness, or unity with the universe. ASCs may result from changes in neurobiological functioning due to oxygen depletion or psychoactive drug use; from hypnosis, meditation, and sensory deprivation; or from mystical or religious experience. Although classical psychoanalysis has tended to regard ASCs as symptoms of regressive states, other schools of thought, such as Jungian, humanistic, and TRANSPERSONAL PSYCHOLOGY, regard them as higher states of consciousness and, often, as indicative of a more profound level of personal and spiritual evolution.

**alter ego** 1. a second identity or aspect of a person that exists metaphorically as his or her substitute or representative, with different characteristics. For example, an avator is a digital alter ego that provides a virtual representation of a computer or Internet user in games, online discussion boards, or alternate online universes. 2. an intimate, supportive friend with whom an individual can share all types of problems and experiences, as if he or she were another self. 3. in psychodrama, a group member, other than the protagonist, who assumes the role of a significant figure in the PROTAGONIST’S life (see AUXILIARY EGO) but who also speaks as part of the protagonist in order to give voice to and portray actions felt but not expressed by the protagonist.

**alter-ego transference** see TWINSHIP TRANSFERENCE.

**alternate binaural loudness-balance test** a test for abnormal sensitivity to loud sounds (see RECRUITMENT). The individual hears two tones of the same frequency played alternately into the two ears, but the intensity of the sound at one ear is set to begin at a level 20 dB higher than the other. The intensity of the sound increases in the defective ear until it is perceived to match the sound level in the normal ear.

**alternate form** a set of test items that are developed to be similar to another set of test items, so that the two sets represent different versions of the same test. In order to demonstrate that one test is an alternate form of the other, a researcher usually must show that there is matching content (each test has the same number of each kind of item) and that FACTOR LOADINGS and MEASUREMENT ERRORS
are approximately the same across the two versions. Alternate forms of a test can be used to measure its reliability (see ALTERNATE-FORMS RELIABILITY). Also called comparable form: equivalent form: parallel form.

**ALTERNATE-FORMS RELIABILITY** a measure of the consistency and freedom from error of a test, as indicated by a CORRELATION COEFFICIENT obtained from responses to two or more ALTERNATE FORMS of the test. Also called comparable-forms reliability: equivalent-forms reliability: parallel-forms reliability.

**ALTERNATE-USES TEST** a test of DIVERGENT THINKING that requires the participant to cite as many uses as possible for a specified object other than its common use. For example, a newspaper could be used for starting a fire or packing objects in a box.

**ALTERNATING PERSONALITY** a personality with components that appear alternately. See DISOCIATIVE IDENTITY DISORDER.

**ALTERNATING PERSPECTIVE** the abrupt transition from one perspective to another that occurs when an AMBIGUOUS FIGURE is viewed. Only one perspective can be perceived at a given time. See NECKER CUBE; REVERSIBLE FIGURE; RUBIN’S FIGURE.

**ALTERNATING TREATMENTS DESIGN** a type of study in which the experimental condition or treatment assigned to the participant changes from session to session or within sessions. For example, a researcher comparing two methods for eliminating the disruptive classroom behavior of a student might have the teacher use one method throughout the morning and the other method throughout the afternoon and then evaluate the student’s behavior with each technique.

**ALTERNATION LEARNING** 1. A task in which an individual must learn to alternate responses, never making the same response twice in a row. 2. Alternation of reward and no-reward for a single response. In this case, responding is faster for a reward than it is when no reward is available.

**ALTERNATION METHOD** a technique used in studies of thinking, language, and problem solving, in which the participant is required to follow an increasingly complex sequence of activities in order to reach a goal or receive a reward. An example is RRR LLL, or triple alternation: turn-taking right three times, then left three times.

**ALTERNATIVE BEHAVIOR COMPLETION** a technique in BEHAVIOR THERAPY for extinguishing unwanted habits by substituting an incompatible behavior for the undesired behavior (e.g., substituting nail care for nail biting). This technique can be practiced in vivo (see IN Vivo DESENSITIZATION) or imaginally in the therapy session or assigned as homework. It is often used as an alternative to mild AVERTION THERAPY. See also COMPETING RESPONSE TRAINING.

**ALTERNATIVE DISPUTE RESOLUTION** the resolving of disputes between parties using neutral third parties, who act as arbitrators or mediators, rather than by engaging in a lawsuit.

**ALTERNATIVE DISTRIBUTION** see SPLIT RECOVERY.

**ALTERNATIVE HYPOTHESIS (AH)** symbol: H₁, H₂) a statement that is contrasted with or contradicts the NULL HYPOTHESIS as an explanation for observed data. Generally, it is a scientific prediction of significant results in HYPOTHESIS TESTING; that is, an alternative hypothesis posits meaningful differences or relationships between the variables under investigation.

**ALTERNATIVE HYPOTHESIS DISTRIBUTION** a theoretical set of plausible values of a characteristic under certain assumptions that is compared to its corresponding NULL DISTRIBUTION in the process of conducting a POWER ANALYSIS.

**ALTERNATIVE MEDICINE** see COMPLEMENTARY AND ALTERNATIVE MEDICINE.

**ALTERNATIVE PSYCHOLOGY** any approach to understanding psychological issues that ignores or rejects accepted academic, scientific, or mainstream views. These approaches may involve unorthodox metaphysical assumptions and focus on spiritualistic and mystical influences. Emphasis may be on aspects of human thought, feeling, and actions that are ignored by mainstream psychology.

**ALTERNATIVE PSYCHOTHERAPY** any treatment approach not considered to be within the mainstream of psychotherapy. For example, the use of PSYCHEDELIC THERAPY in the 1950s and 1960s was considered alternative. PRIMAL THERAPY and RICHTHIAN ANALYSIS are also considered alternative approaches by most therapists.

**ALTERNATIVE SCHEDULE OF REINFORCEMENT (ALT)** in conditioning, a rule that provides for reinforcement of a response according to either a FIXED-RATIO SCHEDULE or a FIXED-INTERVAL SCHEDULE, whichever is satisfied first.

**ALTERNATIVE SCHOOL** any school in the traditional or conventional educational system that provides flexible and innovative teaching, curriculum, grading, or degree requirements.

**ALTERNATIVE SENTENCING** the imposition of sanctions other than traditional imprisonment on those convicted of crimes so as to reduce recidivism and help individuals become successful members of society. Examples include DIVERSION PROGRAMS, electronic monitoring, and community service. Also called COMMUNITY CORRECTION.

**ALTIMETRY** the measurement of altitude.

**ALTIMETER** a device for indicating altitude.

**ALTITUDE SICKNESS** illness resulting from the oxygen deficiency experienced at high altitudes (see HYPOXIA). Symptoms include nausea, breathlessness, nosebleed, and impaired mental processes. Also called ACOSTA’S SYNDROME; D’ACOSTA’S SYNDROME; HYPOBAROPATHY; MOUNTAIN-CLIMBER’S SYNDROME; MOUNTAIN SICKNESS. See also ACUTE MOUNTAIN SICKNESS.

**ALTITUDE TEST** a type of assessment or examination intended to calculate an individual’s ability in a particular area as indicated by the level of performance that the individual can attain.

**ALTICIAL adj.** describing animals, such as primates (including humans), that are not fully developed at birth and require considerable and sustained parental care beyond nursing or feeding in order to survive. Compare PREOCIAL.

**ALTRUIST** n. an apparently unselfish behavior that provides benefit to others at some cost to the individual. In humans, it covers a wide range of behaviors, including volunteerism and martyrdom, but the degree to which such behaviors are legitimately without egoistic motivation is subject to debate. In animal behavior, it is difficult to understand how altruism could evolve in a species since NATURAL SELECTION operates on individuals. However, organisms displaying altruism can benefit if they help their relatives (see Kin Selection) or if an altruistic act is subsequently reciprocated (RECIPROCAL ALTRUISTIC). —ALTRUISTIC adj. —ALTRUIST n.
alturist对自己和他人的要求 vs. 被动的、无目的的要求

altruistic aggression a form of aggression among nonhuman animals in which the aggressor defends not itself but other group or family members.

altruistic suicide one of four types of suicide proposed in 1897 by Émile DURKHEIM, involving the belief that killing oneself will serve a greater societal good by saving others from suffering or otherwise benefiting them. Examples include suicides required by social norms (e.g., the act of Sati in India) and those in which people give their lives to save their friends (e.g., covering an explosion to protect fellow soldiers in combat). Whereas Durkheim considered egoistic suicide a function of deficient integration into social groups, he viewed altruistic suicide as resulting from excessive social integration. Indeed, altruistic suicide is generally committed by members of highly integrated groups: Individuals experience such great loyalty or identification with the rules and values of the group as to view death as an obligation or honorable sacrifice. See also ANOMIC SUICIDE; FATALISTIC SUICIDE.

alveolar 1. adj. denoting a speech sound made with the tongue touching or near the upper ALVEOLAR RIDGE, for example, [d], [t], [n], or [s]. See also DENTAL; INTERDENTAL. 2. n. an alveolar speech sound.

alveolar ridge the bony ridge of either the upper or lower jawbones that contains the sockets of the teeth (i.e., the alveoli).

Alzheimer’s Association a nonprofit organization that provides information, SUPPORT GROUPS, and other assistance to individuals with Alzheimer’s disease and their caregivers and that promotes research in the field to enhance early detection, prevention, and treatment of the disease. Originally known as the Alzheimer’s Disease and Related Disorders Association upon its founding in 1980, the organization adopted its current name in 1988. It is headquartered in Chicago, Illinois, and has more than 75 local chapters nationwide.

Alzheimer’s disease a progressive neurodegenerative disease characterized by cortical atrophy, neuronal death, synapse loss, and accumulation of AMYLOID PLAQUES and NEUROFIBRILLARY TANGLES, causing DEMENTIA and a significant decline in functioning. Early features include deficits in memory (e.g., rapid forgetting of new information, impaired recall and recognition). ANOMIA, executive dysfunction, depressive symptoms, and subtle personality changes such as decreased energy, social withdrawal, indifference, and impulsivity. As the disease progresses, there is global deterioration of cognitive capacities with intellectual decline. Aphasias, agnosia, and apraxia as well as behavioral features, including apathy, emotional blunting, mood-dependent delusions, decreased sleep and appetite, and increased motor activity (e.g., restlessness, wandering). Major risk factors for Alzheimer’s disease include advanced age (it typically occurs after age 70), a family history of the disease, and genetic factors, particularly the presence of the ApoE4 allele (see APOLIPOPROTEIN E) on chromosome 19. In a small minority (<10%) of cases, referred to as having early-onset Alzheimer’s disease, a diagnosis is made between the ages of 30 and 65 and is usually attributed to genetic causes. [first described in 1907 by Alois Alzheimer (1864–1915), German neurologist]

amacrine cell any of a diverse class of neurons in the retina that connect RETINAL BIPOLAR CELLS and RETINAL GANGLION CELLS, and other amacrine cells. Amacrine cells contribute to the CENTER–SURROUND ANTAGONISM of retinal ganglion cell receptive fields. However, they have no axons and do not contribute directly to the output of the retina.

amae n. an indigenous Japanese concept that describes a behavioral pattern roughly translated as indulgent dependency in which people ask others to perform actions for them that they could actually perform for themselves. Typically found in mother–child relationships, amae is distinguished from true dependency by the inappropriateness of the requests and their presumed acceptance. [first described by Japanese psychologist Takeo Doi (1920–2009)]

Amalric’s syndrome see DIALLINAS–AMALRIC SYNDROME. [French ophthalmologist Pierre Amalric (1923–1999)]

amantadine n. an antiviral drug that is also used to treat Parkinson’s disease and to ameliorate drug-induced EXTRAPYRAMIDAL SYMPTOMS. U.S. trade name: Symmetrel.

amaurosis n. partial or complete loss of sight without evidence of organic abnormality of the affected eye or eyes. The cause is often damage to the optic nerve or the brain. The condition may be hereditary, as in LEIBER’S DISEASE; transient (see AMAUROSIS FUGAX); part of a syndrome, such as TAY–SACHS DISEASE; or the result of complete destruction of the STRIATE CORTEX (cortical amaurosis). See also FUNCTIONAL BLINDNESS.

amaurosis fugax recurrent episodes of visual loss, which can be caused by, among other things, glaucoma, intoxication, optic neuritis, migraine, or retinal vascular disease. The visual loss is painless and usually lasts 2 to 3 minutes; recovery of vision is more gradual, marked by gray, blurred, or hazy vision. Also called transient monocular blindness.

amnestic syndrome see amnesia.

amnesia n. a condition characterized by an inability to form or retain new memories. Amnesia can be caused by a variety of factors, including brain injury, mental illness, aging, or drug use. It can also be a symptom of other medical conditions, such as Alzheimer’s disease.

ambient awareness 1. awareness of unattended aspects of visual and auditory scenes. A unique stimulus element is processed at some level even when attention is engaged elsewhere. Compare SITUATION AWARENESS; VIGILANCE. 2. an ongoing awareness of the activities of others (e.g., friends, families, colleagues) that is sustained by constant interaction with them through social networking media such as Facebook and Twitter and other information technologies.

ambient conditions the physical variables in a particular environment (e.g., temperature, humidity, air quality, noise level, and intensity of light) that, when taken as a whole, create an atmosphere that may evoke a distinct feeling or mood. Ambient conditions can be distinguished from specific elements of the environment.

ambient optic array the visual information contained in the reflected light that surrounds a viewer at any point in time. James J. Gibson proposed that the visual system evolved within this ambient optic array, enabling visual perception of the external environment to emerge directly and without need for mental representations of the environment. Also called optic array. See also ECOLOGICAL PERCEPTION.
**ambiguity** n. 1. the property of a behavior, behavior pattern, or situation that might be interpreted in more than one way. 2. in linguistics, the property of a word, phrase, or sentence that has more than one possible meaning. Ambiguity in a phrase or sentence may be lexical, as in *The students are revolting, or structural, as in black cats and dogs; often there is a combination of both factors.* In *psycholinguistics,* the main area of interest has been the process used to interpret sentences whose *surface structure* could reflect two quite different *deep structures,* as in the instruction *Before opening tin, stand in boiling water for 10 minutes.* In psychoanalytic theory, ambiguous words or phrases are usually interpreted as a reflection of the speaker’s conflicted hidden feelings or unconscious wishes about the subject. See also *homonym; polysemy; pun.* —*ambiguous* adj.

**ambiguity scale** any questionnaire used in evaluating tolerance or intolerance for vagueness, ambiguity, and indefiniteness.

**ambiguity tolerance** the degree to which one is able to accept, and to function without distress or disorientation in, situations having conflicting or multiple interpretations or outcomes.

**ambiguous figure** a visual stimulus that can be interpreted in more than one way, such as an *embedded figure* or a *reversible figure.* A well-known example is the young girl–old woman image, in which the black-and-white drawing sometimes appears to be of a young girl and sometimes of an old lady. This phenomenon is not restricted to the visual: An *ambiguous stimulus* is one of any sensory modality that can have multiple interpretations.

**ambiguous genitalia** sex organs that are not fully differentiated between male and female, as in girls born with a clitoris that could be mistaken for a penis. See also *hermaproditism.*

**ambisexual** adj. 1. denoting individuals or characteristics that manifest no sex or gender dominance. Compare *asexual.* 2. an older term for *bisexual* (see *bisexuality*), now rarely used. —*ambisexual* n.

**ambitendency** n. 1. the tendency to act in opposite ways, based on conflicting behavioral motivations. 2. a pattern of incomplete motor responses in anticipation of a voluntary action. It occurs in catatonic states as a type of *psychomotor retardation* in which the individual appears motormically stuck and exhibits hesitant, indecisive motions in the absence of voluntary movement. 3. in Jungian psychology, the psychic ambivalence that is caused by the existence of opposing tendencies.

**ambivalence** n. 1. the simultaneous existence of contradictory feelings and attitudes, such as pleasantness and unpleasantness or friendliness and hostility, toward the same person, object, event, or situation. Eugen Bleuler, who first defined *ambivalence* in a psychological sense and referred to it as *affective ambivalence,* regarded extreme ambivalence, such as an individual expressing great love for his or her mother while also asking how to kill her, as a major symptom of schizophrenia. 2. uncertainty or indecisiveness about a course of action. —*ambivalent* adj.

**ambivalence of an attitude** the extent to which the evaluative responses associated with an attitude are inconsistent with one another. If the responses are uniformly positive or uniformly negative, ambivalence is low. If both positive and negative responses are associated with the attitude, ambivalence is high. See also *affective–cognitive consistency; affective–evaluative consistency; cognitive–evaluative consistency; cross-dimension attitude consistency; within-dimension attitude consistency.*

**ambivalent attachment** 1. in the *strange situation,* a form of *insecure attachment* in which infants show a combination of positive and negative responses toward a parent. After separation, for example, infants may simultaneously seek and resist close contact with the returning parent. Also called *resistant attachment.* 2. an adult inter-personal style characterized by worry that a partner will break off a relationship or by hesitancy in forming deeply committed relationships despite a desire to do so. Also called *anxious–ambivalent attachment style.*

**ambivalent sexism** a type of *sexism* that is characterized by the coexistence of negative and positive attitudes toward one of the two sexes. For example, such attitudes toward women might involve fear and hostility on the one hand and an exaggerated chivalry and protectiveness on the other. [initially described in 1996 by U.S. social psychologists Peter Glick and Susan T. Fiske (1952–)]]

**ambiversion** n. the tendency to display characteristics of introversion and extraversion in approximately equal degrees. Such a person would be referred to as an *ambivert.*

**ambly-** combining form deficient or impaired.

**amblyacousia** n. dullness or loss of hearing.

**amblyopia** n. poor vision caused by abnormal visual experience in early life and not any physical defect of the eye. Common predisposing conditions include misalignment of the eyes (strabismus) and differing refractive powers of the eyes (anisometropia). Also called (colloquially) *lazy eye.* —*amblyopic* adj.

**amblyoscope** n. an instrument used to determine the angle of deviation of the eyes (the degree of strabismus), as well as the extent to which the eyes can be used together even though one or both are deviated. Also called *orthoscope.*

**ambrosiac** adj. in the *zwaaardemaker smell system,* denoting an odor quality that is smelled in musk and sandalwood. Also called *ambrosial.*

**ambulation** n. the act of walking from place to place. Ambulation training is often necessary in the rehabilitation of individuals who have had a spinal injury, stroke, or other trauma affecting the neuromuscular system and in the physical therapy of individuals with certain genetic or congenital disorders.

**ambulatory care** medical or psychological services provided to individuals on an outpatient, nonemergency basis. Such services may include observation, diagnosis, treatment (referred to as *ambulatory treatment*), and rehabilitation and are often provided at such places as a doctor’s office, health center, or hospital outpatient department.

**ambulatory schizophrenia** a condition in which a person who was previously hospitalized with extreme symptoms and then diagnosed as having schizophrenia no longer requires hospitalization but nonetheless behaves eccentrically and cannot function in a manner consistent with social expectations.

**ambulatory services** mental health, counseling, or medical services provided on an outpatient basis, that is, without the recipient of those services needing to be in or
American Counseling Association

remain in a hospital, clinic, or other health care facility. See also WALK-IN CLINIC.

ambulatory treatment see AMBULATORY CARE.

amelioration n. a change for the better in a condition, especially one involving a disease or disorder. \(\text{ameliorative} \ adj.\ n.

amenity move a type of residence change, often occurring around the time of retirement, that is made to improve the quality of one’s life.

amenorrhea n. the absence of menstruation. When menstruation fails to begin after puberty, the condition is called primary amenorrhea. If menstrual periods stop, in the absence of pregnancy or menopause, the condition is known as secondary amenorrhea. Changes in physical or mental health can be a causal factor.

American Academy of Clinical Sexologists, Inc. (AACS) a private, independent graduate school that offers a doctoral degree in clinical sexology and that is designed for licensed mental health professionals who wish to practice sex therapy independently or in addition to their clinical specialty.

American Alliance for Health, Physical Education, Recreation and Dance (AAHPERD) the largest professional organization in the United States to support research in and assist professionals involved with physical education, leisure, fitness, dance, health promotion, and health education.

American Anorexia/Bulimia Association see NATIONAL EATING DISORDERS ASSOCIATION.

American Association for the Advancement of Science (AAAS) a professional organization, founded in 1848 to represent all scientific disciplines, whose mission is to "advance science, engineering, and innovation throughout the world for the benefit of all people." AAAS promotes education in, public understanding of, and responsible conduct and use of science and technology. The world’s largest general scientific society, it publishes the journal Science.

American Association of Applied and Preventive Psychology (AAAPP) a professional organization whose purpose is to promote the interests of clinical and preventive psychology. It encourages a research orientation toward clinical and preventive work, emphasizing the consumer and public interest above guild or personal interests. Its main publication is the journal Applied and Preventive Psychology: Current Scientific Perspectives.

American Association of Applied Psychology (AAAP) a professional organization founded in 1937 by a group of consulting, clinical, educational, and industrial psychologists who broke from the AMERICAN PSYCHOLOGICAL ASSOCIATION in order to represent the applied interests of U.S. psychologists more effectively. Their main publication was the Journal of Consulting Psychology. In 1944, the group rejoined the American Psychological Association.

American Association of Clinical Psychologists (AACP) a professional organization founded in 1917 when clinical psychologists broke from the AMERICAN PSYCHOLOGICAL ASSOCIATION in order to promote training and certification standards for the practice of clinical psychology. The AACP returned to the American Psychological Association in 1919 as its first special-interest group, the Section of Clinical Psychology.

American Association of Mental Retardation (AAMR) the former name for the AMERICAN ASSOCIATION ON INTELLECTUAL AND DEVELOPMENTAL DISABILITIES.

American Association of Sexuality Educators, Counselors and Therapists (AASECT) a nonprofit, interdisciplinary, professional accrediting organization founded in 1967 whose mission is to provide professional education and certification of sexuality educators, counselors, and therapists and to promote understanding of human sexuality and healthy sexual behavior.

American Association on Intellectual and Developmental Disabilities (AAIDD) a professional organization, founded in 1876, whose mission is to promote progressive policies, sound research, effective practices, and universal human rights for people with intellectual and developmental disabilities. The oldest and largest interdisciplinary organization in this field. It was formerly called the American Association of Mental Retardation (AAMR).

American Birth Control League (ABCL) the former name of the PLANNED PARENTHOOD FEDERATION OF AMERICA.

American College of Medical Specialties (ABMS) the umbrella organization for 24 approved medical specialty boards in the United States. Established in 1933, its mission is to maintain and improve the quality of medical care in the United States by assisting the member boards in their efforts to develop and utilize professional and educational standards for the evaluation and certification of physician specialists.

American Board of Professional Psychology (ABPP) the umbrella organization for 14 psychological specialty boards in the United States. Established in 1947, its purpose is to establish, implement, and maintain standards and set examinations for specialty areas in the practice of psychology. A specialty is defined as a focused area in which special competency has been acquired through an organized sequence of education, training, and practical experience.

American Board of Psychological Hypnosis (ABPH) a professional organization, recognized by the American Psychological Association (APA), that certifies psychologists in clinical and experimental hypnosis. Applicants must have a doctoral degree, membership or eligibility for membership in the APA, and a minimum of 5 years of acceptable experience with hypnosis, among other requirements. Individuals seeking the Diplomate in Clinical Hypnosis must also be licensed or certified and possess or be eligible for the American Board of Professional Psychology Diplomate in a clinical or counseling area.

American Coaching Effectiveness Program (ACEP) see AMERICAN SPORT EDUCATION PROGRAM.

American College of Sports Medicine (ACSM) a multidisciplinary, international organization of exercise physiologists, sport medicine physicians, athletic trainers, and health and fitness educators that strives to provide the most current information on health and fitness. The organization, whose membership comes from over 90 countries, provides certification in the areas of health and fitness.

American College Testing Program (ACTP) see ACT ASSESSMENT.

American Counseling Association (ACA) a professional and educational organization dedicated to promoting the development of the counseling profession. It is the
world’s largest association of professional counselors and has been instrumental in setting professional and ethical standards. Founded in 1952 as the American Personnel and Guidance Association (APGA), it changed its name to the American Association of Counseling and Development (AACD) in 1983 and adopted its present name in 1992.

American Educational Research Association (AERA) a professional organization founded in 1916 to improve the educational process by encouraging scholarly inquiry related to education and by promoting the dissemination and practical application of research results.

American Indian see NATIVE AMERICAN.

American Law Institute Model Penal Code insanity test a legal standard for establishing CRIMINAL RESPONSIBILITY, adopted in 1962, that combines elements of the M’NAGHTEN RULE and the IRRESISTIBLE IMPULSE RULE. Assuming in this standard, individuals are not responsible for criminal conduct if mental illness or defect rendered them either unable to understand the time that they were doing was against the law or unable to control their behavior enough to keep from breaking the law. Also called American Law Institute Guidelines (ALI Guidelines); Brawner decision; Brawner rule. See also INSANITY DEFENSE REFORM ACT.

American Manual Alphabet see FINGERSPELLING.

American optical H–R–R plates see HARDY–RAND–RITTLE R PSEUDOSCHROMATIC PLATES.

American Orthopsychiatric Association an interdisciplinary professional organization engaged in preventive, treatment, and advocacy approaches to mental health. The prefix ortho- (from the Greek orthos, "straight") emphasizes the need for preventive approaches. The American Journal of Orthopsychiatry is its major publication. [founded in 1924 by U.S. physician Karl Menninger (1893–1990)]

American Pain Society (APS) a multidisciplinary professional organization whose mission is to advance pain-related research, education, treatment, and professional practice. It was founded in 1977 as the U.S. chapter of the International Association for the Study of Pain (IASP).

American Parkinson Disease Association, Inc. (APDA) an organization that provides support groups, information, and referrals for individuals with Parkinson’s disease and their families.

American Philosophical Society (APS) the oldest scholarly organization in the United States, founded in 1743 under the impetus of Benjamin Franklin in Philadelphia, Pennsylvania, where it is still headquartered. Members are elected on the basis of extraordinary accomplishments in the sciences and humanities. Publications include the society’s Transactions, first published in 1771: Memoirs; Proceedings; and a Yearbook. The society supports excellence in scholarly research through special prizes and grants.

American Psychiatric Association (APA) a national medical and professional organization whose physician members specialize in the diagnosis, treatment, and prevention of mental disorders. It was founded in 1844 as the Association of Medical Superintendents of American Insane Institutions for the Insane and renamed the American Medical-Psychological Association in 1892. The current name was adopted in 1922. Its objectives include the improvement of care for people with mental illnesses, the promotion of research and professional education in psychiatry, and the dissemination of psychological knowledge through nationwide public information, education, and awareness programs and materials. Its extensive publications include the Diagnostic and Statistical Manual of Mental Disorders (see DSM–IV–TR; DSM–5).

American Psychoanalytic Association (APsaA) a professional organization for psychoanalysts that focuses on education, research, and membership development. Founded in 1911, it is the oldest national psychoanalytic organization, with 30 accredited training institutes and 39 affiliate psychoanalytic societies. It is the U.S. chapter of the International Psychoanalytic Association and is an affiliate of the American Association for the Advancement of Science. Its major publication is the Journal of the American Psychoanalytic Association.

American Psychological Association (APA) a scientific and professional organization founded in 1892 that represents psychology in the United States and is the largest association of psychologists worldwide. Its mission is to advance the creation, communication, and application of psychological knowledge to benefit society and improve people’s lives. Some of its specific goals are to encourage the development and application of psychology in the broadest manner; to promote research in psychology, the improvement of research methods and conditions, and the application of research findings; to improve the qualifications and usefulness of psychologists by establishing high standards of ethics, conduct, education, and achievement; and to increase and disseminate psychological knowledge through meetings and a wide variety of scholarly material available through print and electronic media. Its major avenues of communication include some 70 scholarly journals, the APA Publication Manual, some 50 to 60 books and videotapes per year, and 7 electronic databases.

American Psychological Association of Graduate Students (APAGS) the largest organized group of psychology graduate students worldwide, established in 1988 as a constituency group of the AMERICAN PSYCHOLOGICAL ASSOCIATION. It develops and disseminates information about relevant education and training issues and supports students through scholarships and awards, association advocacy work, and professional development opportunities.

American Psychological Foundation (APF) a nonprofit, philanthropic organization, founded in 1953, that provides financial support for innovative research, scholarships, and programs in psychology. APF focuses on helping talented graduate students and early career psychologists to launch their careers and on seeding the knowledge base to promote a better understanding of human behavior and to benefit human welfare.

American Psychological Society (APS) the former name for the ASSOCIATION FOR PSYCHOLOGICAL SCIENCE.

American Psychosomatic Society (APS) an interdisciplinary professional organization founded in 1942 whose mission is to promote a scientific understanding of the interrelationships among biological, psychological, social, and behavioral factors in human health and disease. Its main publication is Psychosomatic Medicine.

American Sign Language (ASL) see SIGN LANGUAGE.

American Society for Psychical Research (ASPR) a scholarly society devoted to the scientific investigation of
parapsychological and paranormal phenomena. Initially founded in 1885 by a group including William James, it became a branch of the British Society for Psychical Research before becoming independent once more in 1906. It publishes the Journal of the American Society for Psychical Research (established 1907).

American Sport Education Program (ASEP) a series of educational courses for parents, coaches, officials, and administrators of volunteer youth sport that has an athlete-centered philosophy. It was formerly known as the American Coaching Effectiveness Program (ACEP).

Americans With Disabilities Act (ADA) a U.S. federal law that prohibits hiring and other employment practices that discriminate on the basis of physical or mental impairments, unless it can be shown that these would prevent the individual from performing the essential or primary functions of the job. Impairments are defined as limitations that detract from one or more major life activities. The ADA also prohibits discrimination in other areas, such as access to programs, services, and activities provided by a public agency (e.g., health care, social services, courts, community meetings); access to public accommodations (e.g., restaurants, hotels, schools and colleges, recreational facilities); and access to telecommunications (e.g., telephone, computers). See also BONA FIDE OCCUPATIONAL QUALIFICATION.

Ameslan n. a contraction of American sign language.

Ames room an irregularly shaped but apparently rectangular room in which cues for DEPTH PERCEPTION are used experimentally to distort the viewer’s perception of the relative size of objects within the room. Also called AMES DISTORTED ROOM. [Adelbert Ames Jr. (1880–1955), U.S. psychologist, inventor, and artist]

Amethystic n. see anti-intoxicant.

Ametropia n. any refractive abnormality of the eye, including myopia (nearsightedness), hyperopia (farsightedness), and astigmatism. The inability of the eye to bend (refract) light into perfect focus on the retina reduces visual acuity and causes blurriness.

AMI abbreviation for anti-Müllerian hormone. See MÜLLERIAN-INHIBITING HORMONE.

Amitriptyline n. a TRICYCLIC ANTIDEPRESSANT introduced into clinical use in 1961; with imipramine, it was the first widely used antidepressant agent. Its tertiary amine structure makes it a more potent inhibitor of SEROTONIN and NORPINEPHRINE reuptake than secondary amines (thereby increasing the availability of serotonin for neurotransmission). It is actually more noradrenergic than serotonergic, and it also has significant antihistaminic, anticholinergic, and adrenoreceptor-blocking activity (producing adverse side effects). It is an effective antidepressant, but its side effects and toxicity in overdose have led to a decline in its use in favor of the SSRIs and other agents. Although still used as an antidepressant, amitriptyline is no longer considered first-line medication and is more likely to be employed in low doses for chronic pain management or the prevention of migraine. It is also sold in combination with a benzodiazepine ANXIOLYTIC (as Limbitrol in the United States) or an antipsychotic (as Etrafon or Triavil in the United States). U.S. trade name: Elavil.

Ammon’s horn see HIPPOCAMPUS.

Amnesia n. partial or complete loss of memory. Either SEROTONIN. See also AMINE HORMONE; AMINO ACID; BIOGENIC AMINE.

Amino acid any of a class of chemical compounds that contain a single AMINO ACID that has been modified into a hormone, such as MELATONIN or NORPINEPHRINE. Also called monoamine hormone.

Amino acid imbalance a bodily condition characterized by a deficiency of certain essential amino acids in relation to others. It may result from an INBORN ERROR OF METABOLISM, such as phenylketonuria or homocystinuria, or be precipitated by improper diet. An amino acid imbalance may affect metabolic, neurological, and developmental processes.

Aminoketone n. the chemical classification of the antidepressant agent BUPROPION, whose structure and mechanism of action differ from other marketed antidepressants. Although the specific method of action is unknown, it is presumed to involve NORADRENERGIC or DOPAMINERGIC mechanisms.

Aminopterin n. a drug similar to methotrexate that is used in the treatment of leukemia. During the 1950s and 1960s, it was also sometimes used in nonclinical settings to induce abortions. Surviving infants showed teratogenic effects (see TERATOGEN), such as HYDROCEPHALUS, craniosynostosis (premature skull ossification) with skull defects, and mild to moderate intellectual disability.

Aminotransferase n. any of a class of enzymes that catalyze the transfer of an amino group (–NH2) from a donor molecule to a recipient molecule. Two of the better known aminotransferases are ASPARTATE AMINOTRANSFERASE and alanine aminotransferase, which are normally found in the liver and heart, respectively, and are released into the bloodstream as a result of damage to those organs. Hence, they are used as indicators in liver and heart function tests.

Amnesia n. partial or complete loss of memory. Either SEROTONIN. See also AMINE HORMONE; AMINO ACID; BIOGENIC AMINE.

Amino acid any of a class of chemical compounds that contain a single AMINO ACID that has been modified into a hormone, such as MELATONIN or NORPINEPHRINE. Also called monoamine hormone.

Amino acid imbalance a bodily condition characterized by a deficiency of certain essential amino acids in relation to others. It may result from an INBORN ERROR OF METABOLISM, such as phenylketonuria or homocystinuria, or be precipitated by improper diet. An amino acid imbalance may affect metabolic, neurological, and developmental processes.

Aminoketone n. the chemical classification of the antidepressant agent BUPROPION, whose structure and mechanism of action differ from other marketed antidepressants. Although the specific method of action is unknown, it is presumed to involve NORADRENERGIC or DOPAMINERGIC mechanisms.

Aminopterin n. a drug similar to methotrexate that is used in the treatment of leukemia. During the 1950s and 1960s, it was also sometimes used in nonclinical settings to induce abortions. Surviving infants showed teratogenic effects (see TERATOGEN), such as HYDROCEPHALUS, craniosynostosis (premature skull ossification) with skull defects, and mild to moderate intellectual disability.

Aminotransferase n. any of a class of enzymes that catalyze the transfer of an amino group (–NH2) from a donor molecule to a recipient molecule. Two of the better known aminotransferases are ASPARTATE AMINOTRANSFERASE and alanine aminotransferase, which are normally found in the liver and heart, respectively, and are released into the bloodstream as a result of damage to those organs. Hence, they are used as indicators in liver and heart function tests.

Amitriptyline n. a TRICYCLIC ANTIDEPRESSANT introduced into clinical use in 1961; with imipramine, it was the first widely used antidepressant agent. Its tertiary amine structure makes it a more potent inhibitor of SEROTONIN and NORPINEPHRINE reuptake than secondary amines (thereby increasing the availability of serotonin for neurotransmission). It is actually more noradrenergic than serotonergic, and it also has significant antihistaminic, anticholinergic, and adrenoreceptor-blocking activity (producing adverse side effects). It is an effective antidepressant, but its side effects and toxicity in overdose have led to a decline in its use in favor of the SSRIs and other agents. Although still used as an antidepressant, amitriptyline is no longer considered first-line medication and is more likely to be employed in low doses for chronic pain management or the prevention of migraine. It is also sold in combination with a benzodiazepine ANXIOLYTIC (as Limbitrol in the United States) or an antipsychotic (as Etrafon or Triavil in the United States). U.S. trade name: Elavil.

Ammon’s horn see HIPPOCAMPUS.

Amnesia n. partial or complete loss of memory. Either
amnesic syndrome

A disturbance in memory marked by inability to learn new information (anterograde amnesia) or to recall previously learned information or past events is called retrograde amnesia. When severe enough to interfere markedly with social or occupational functioning or to represent a significant decline from a previous level of functioning, the memory loss is known as AMNESIC DISORDER. —amnesiac adj., n. —amnesic or amnestic adj.

amnesic aphasia see ANOMIC APHASIA.

amnestic apraxia an inability to remember and therefore carry out a command, although there is no loss of ability to perform the task. Also called amnesic apraxia.

amnestic disorder in DSM–IV–TR, a disturbance in memory marked by inability to learn new information (anterograde amnesia) or to recall previously learned information or past events (retrograde amnesia) that is severe enough to interfere markedly with social or occupational functioning or represents a significant decline from a previous level of functioning. A distinction is made between amnestic disorder due to a general medical condition, SUBSTANCE-INDUCED PERSISTING AMNESIC DISORDER, and amnestic disorder not otherwise specified. The first of these can be caused by a variety of conditions, such as head injury, ANOXIA, HERPES-SIMPLEX ENCEPHALITIS, and posterior cerebral artery stroke, resulting in lesions in specific brain regions, including the MEDIAL TEMPORAL Lobe and the DIENCEPHALON, and their connections with various cortical areas. It may be transient, lasting from several hours to no more than a month (see also TRANSIENT GLOBAL AMNESIA), or chronic (lasting more than 1 month). In DSM–5, amnestic disorder, along with DEMENTIA, has been subclassed into the category MAJOR NEUROCOGNITIVE DISORDER and is no longer considered a distinct entity. Formally called amnestic (or amnesic) syndrome.

amniocentesis n. a method of examining fetal chromosones for any abnormality or for determination of sex. A hollow needle is inserted through the mother’s abdominal wall into the uterus, enabling collection of amniotic fluid, which contains fetal cells. Compare CHORIONIC VILLUS SAMPLING; PERCUTANEOUS UMBILICAL CORD BLOOD SAMPLING.

amniotic sac the fluid-filled membrane that encases and protects the embryo of a bird, reptile, or mammal.

amobarbital n. an intermediate-acting, rapidly excreted BARBITURATE that was formerly used as a sedative and hypnotic. Like other barbiturates, its toxicity has led to its clinical eclipse by safer agents, such as the BZD (BENZODIAZEPINES). Amobarbital abuse can result in addiction, stupor, and death. It was occasionally used to conduct interviews (Amytal interviews) designed to elicit unconscious material from patients, as well as information that was consciously withheld. Such interviews were also used in attempting to distinguish between patients who were malingering and those who had a bona fide conversion disorder. Due to numerous legal and ethical issues surrounding amobarbital interviews, in addition to the medical risks associated with administration of barbiturates, such techniques are no longer acceptable in modern clinical practice. U.S. trade name: Amytal.

amok (amuck) n. a CULTURE-BOUND SYNDROME observed among males in Malaysia, the Philippines, and other parts of southeast Asia. The individual experiences a period of social withdrawal and apathy, before making a violent, unprovoked attack on nearby individuals. The aggressor eventually collapses from exhaustion and afterward has no memory of the event. Also called mata elap. See also MAL DE PILEA.

amorphangiosis (amorphangnosis) n. see TACTILE AGNOSIA.

amorphosynthesis n. a disturbance in the ability to synthesize multiple sensory inputs from a particular side of the body, with the right side most commonly affected. The condition is usually a sign of a lesion in the left parietal lobe of the brain.

amotivational syndrome a behavior pattern characterized by loss of drive and initiative. It is commonly seen in schizophrenia. The pattern is also believed to be associated with CANNABIS ABUSE, based on anecdotal observations of the lifestyles of chronic cannabis users in various cultures around the world. There is, however, little empirical support for this association. See ANHEDONIA.

amount of masking see AUDITORY MASKING.

amoxapine n. an antidepressant, one of the secondary amine TRICYCLIC ANTIDEPRESSANTS (TCAs), that inhibits the reuptake of norepinephrine and serotonin. It may also have ANTIPSYCHOTIC activity. Amoxapine may cause EXTRAPYRAMIDAL SYMPTOMS and TARDIVE DYSKINESIA but is less associated with anticholinergic side effects than are other TCAs. U.S. trade name: Asendin.

AMP abbreviation for AFFECT MISATTRIBUTION PROCEDURE.

AMPA abbreviation for alpha-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid: an agonist that binds to AMPA receptors.

AMPA receptor a type of GLUTAMATE RECEPTOR that binds AMPA as well as glutamate. AMPA receptors are coupled to LIGAND-GATED ION CHANNELS and are responsible for most of the activity at synapses where glutamate is the neurotransmitter. Compare NMDA RECEPTOR.

amphetamine n. a CNS STIMULANT, closely related in structure and activity to ephedrine (see Ephedra), that is the prototype of the group of drugs known as the AMPHETAMINES. Amphetamine is a chiral molecule, composed of two stereoisomers (mirror images): levamphetaamine and DEXTROAMPHETAMINE. Specific amphetamines may be racemic mixtures of both stereoisomers. U.S. trade name: Benzedrine.

amphetamine abuse in DSM–IV–TR, a pattern of use of amphetamines or amphetamine-like substances that is marked by recurrent significant adverse consequences related to the repeated ingestion of these substances. This diagnosis is preempted by the diagnosis of AMPHETAMINE DEPENDENCE. If the criteria for amphetamine abuse and amphetamine dependence are both met, only the latter diagnosis is given. In DSM–5, however, both have been combined into one category, STIMULANT USE DISORDER, and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

amphetamine dependence in DSM–IV–TR, repeated or continued use of an amphetamine or amphetamine-like substance despite significant substance-related behavioral, physiological, and psychosocial problems, with or without....
tollertance or characteristic symptoms if use is suspended (see AMPHETAMINE WITHDRAWAL). In DSM–5, amphetamine dependence has been combined with AMPHETAMINE ABUSE into a single disorder, and neither is considered a distinct diagnosis any longer (see STIMULANT USE DISORDER). See also SUBSTANCE DEPENDENCE.

amphetamine-induced psychotic disorder a condition marked by paranoid delusions due to the direct physiological effects of an amphetamine or amphetamine-like substance. The delusions can continue as long as the use of these substances continues and might persist for weeks or months after withdrawal from the substances has been completed. Also called amphetamine psychosis.

amphetamine intoxication a reversible syndrome caused by the recent ingestion of amphetamines or amphetamine-like substances. It is characterized by behavioral or psychological changes (e.g., aggressive behavior, impaired judgment, suspiciousness, paranoia), as well as one or more signs of physiological involvement (e.g., unsteady gait, impairment in attention or memory). The equivalent term in DSM–5 is stimulant intoxication. See also SUBSTANCE INTOXICATION.

amphetamine intoxication delirium in DSM–IV–TR and DSM–5, a reversible syndrome that develops over a short period of time (usually hours to days) following the heavy ingestion of amphetamines or amphetamine-like substances. The features include disturbed consciousness (e.g., reduced ability to focus, sustain, or shift attention) and changes in cognition (e.g., memory deficit, disorientation, or language disturbance) in excess of those usually associated with AMPHETAMINE INTOXICATION. See also SUBSTANCE INTOXICATION DELIRIUM.

amphetamines pl. n. a group of synthetic drugs (substituted PHENETHYLAMINES) that stimulate the RETICULAR FORMATION in the brain and cause a release of stored noradrenaline. The effect is a prolonged state of arousal and relief from feelings of fatigue (see CNS STIMULANT). Amphetamines were introduced in 1932 for a variety of clinical uses. During World War II, they were widely dispensed to combat soldiers to enable them to remain alert for periods of up to 60 hours. TOLERANCE develops progressively with continued use until the individual reaches a point of exhaustion and sleeps continuously for several days. AMPHETAMINE ABUSE can result in dependence and a well-defined state of psychosis (see AMPHETAMINE DEPENDENCE: AMPHETAMINE-INDUCED PSYCHOTIC DISORDER). Although widely used in the past for weight loss, relief of depression, and other indications, modern use of amphetamines is more circumscribed because of their adverse effects. They are now used mainly in short- and long-acting preparations to manage symptoms of attention deficit/hyperactivity disorder and to treat certain cases of severe depression or narcolepsy, and they still maintain a military use in the management of fatigue. Amphetamines include AMPHETAMINE itself (the prototype), DEXTROAMPHETAMINE, and METHAMPHETAMINE. Related drugs, with a similar mode of action but different molecular structure, include METHYLPHENIDATE. In addition, some forms and derivatives (including DOM, MDA, and MDMA) have been manufactured as recreational hallucinogenic drugs.

amphetamine withdrawal in DSM–IV–TR, a characteristic withdrawal syndrome that develops after cessation of (or reduction in) prolonged, heavy consumption of an amphetamine or amphetamine-like substance. The essential characteristic is depressed mood, sometimes severe, and there may also be fatigue, disturbed sleep, increased appetite, vivid and unpleasant dreams, or PSYCHOMOTOR RETARDATION or agitation, or all of these features. Marked withdrawal symptoms (see CRASH) often follow an episode of intense, high-dose use. The equivalent term in DSM–5 is stimulant withdrawal. See also SUBSTANCE WITHDRAWAL.

amplification effect see DILUTION EFFECT.

amplitude n. magnitude or extent (e.g., of a stimulus) or peak value (e.g., of a sinusoid wave).

amplitude distortion a hearing disorder in which loud sounds are distorted or misjudged.

amplitude modulation see MODULATION.

amplitude of light wave the maximum deviation of a wave of light from its median intensity. The greater the amplitude of a light wave, the brighter it appears.

amplitude spectrum see SOUND SPECTRUM.

AMP abbreviation for ALPHA-METHYLPARATYPHORINE.

ampulla n. (pl. ampullae) any saclike enlargement of a duct or passageway. Ampullae located at each end of the SEMICIRCULAR CANALS of the inner ear contain HAIR CELLS that help maintain balance.

amputation n. the surgical or traumatic removal of a limb or other appendage from the body. Surgical amputation generally is performed as a life-saving measure following an injury, to prevent the spread of a malignant tumor or gangrene, or to remove a body part that no longer has adequate blood circulation (e.g., as a result of diabetes or severe frostbite).

amputation fetish see ACROTOMOPHILIA.

amputee identity disorder see BODY INTEGRITY IDENTITY DISORDER.

Amsterdam criteria the classic criteria for identifying a family with hereditary nonpolyposis colorectal cancer (HNPCC), also known as Lynch syndrome. The criteria are characterized by a 3–2–1 paradigm: To meet the criteria of HNPCC, a family must have at least 3 patients with colon cancer, one of whom is a first-degree relative of the other, in at least 2 generations, with an age of onset before age 50 in at least 1 patient. See also MLH1; MSI2.

Amsterdam dwarf disease see CORNELIA DE LANGE SYNDROME.

amuck n. see AMOK.

amurakh n. a CULTURE-BOUND SYNDROME observed among Siberian women and characterized by compulsive mimicking of other people’s words or behaviors. See also LATAH.

amusia n. loss of musical ability, usually associated with lesions in one or both of the TEMPORAL LOBES. The inability to reproduce melodies is called motor (or expressive) amusia, and the inability to recognize and appreciate various characteristics of musical tunes and sequences is called sensory (or receptive) amusia. The latter is also considered a type of AUDITORY AGNOSIA.

amygdala n. an almond-shaped structure in the TEMPO-
Amygdaloid stimulation

RAL LORE that is a component of the LIMBIC SYSTEM and considered part of the BASAL GANGLIA. It comprises two main groups of nuclei—the CORTICOMEDIAL GROUP and the BASOLATERAL GROUP—and through widespread connections with other brain areas has numerous viscerosensory and autonomic functions as well as an important role in memory, emotion, perception of threat, and fear learning. Also called AMYGDALOID BODY; AMYGDALOID COMPLEX: AMYGDALOID NUCLEI. —amygdaloid adj.

Amygdaloid stimulation electrical activation of the amygdala, which induces changes in emotional, behavioral, and motivational responses.

Amyl nitrite an organic nitrite, administered by nasal inhalation, that dilates (widens) arteries by relaxing smooth muscles in arterial walls. The main effects are to dilate the coronary arteries supplying the heart and to reduce blood pressure. Amyl nitrite has been used therapeutically in the treatment of angina pectoris and as an antidote to cyanide poisoning. It is now best known as a recreational drug that is reputed to enhance orgasm and other aspects of the sexual experience; adverse effects can include anxiety, nausea, dizziness, faintness, and loss of blood pressure, and impaired oxygen-carrying capacity of the blood.

Amyloid n. a chemically diverse protein that accumulates abnormally between neural and other bodily cells, negatively affecting their functioning. There are various types, each associated with different pathological conditions. For example, Beta-amyloid has received considerable attention for its detrimental influence upon memory and cognition in Alzheimer's disease. —amyoidal adj.

Amyloidosis n. a disorder marked by the accumulation of amyloid in the tissues. The cause is believed to be an immune-deficiency disease. Amyloidosis is eventually destructive because it interferes with the normal function of tissues, forming tumors in the respiratory tract, liver, kidney, and other organs. Primary amyloidosis occurs in association with multiple myeloma or in the absence of other diseases, whereas secondary amyloidosis is associated with a chronic disease, such as tuberculosis.

Amyloid plaque a clump of Beta-amyloid protein surrounded by degenerated dendrites that is particularly associated with symptoms of Alzheimer's disease. Increased concentration of such plaques in the cerebral cortex of the brain is correlated with the severity of dementia. Also called neuritic plaque; senile plaque.

Amyloid precursor protein (APP) see Beta-amyloid.

Amyotrophic lateral sclerosis (ALS) a rapidly progressive adult-onset disease involving degeneration of both lower MOTOR NEURONS, responsible for muscle contraction, and upper motor neurons, responsible for MUSCLE SPINDLE sensitivity, and leading to death within 5 years of diagnosis. Symptoms include muscular atrophy and weakness, partial and complete paralysis, speech impairment, and difficulties swallowing or breathing. Amyotrophic lateral sclerosis is often used interchangeably with MOTOR NEURON DISEASE, especially in the United States. Also called Lou Gehrig's disease.

Amytal n. a trade name for AMORBIRITAL.

Amytal interview see AMORBIRITAL.

A- prefix see A-.

Ana- prefix 1. up (e.g., anabolism). 2. back (e.g., ANACLI¬SIS). 3. again (e.g., ANALOGY).

Anabolic-androgenic steroid any synthetic form of testosterone used both legally (to treat delayed puberty and loss of lean muscle mass) and illegally (as a PERFORMANCE ENHANCING DRUG). The misuse of anabolic-androgenic steroids is associated with mood swings, violence, paranoia, impaired judgment, liver damage, hypertension, acne, and changes in genitalia (e.g., testicular shrinkage). Also called anabolic steroid.

Anabolism n. see METABOLISM. —anabolic adj.

Anacis n. 1. an extreme dependence on another person for emotional or physical support or both, just as an infant is dependent on the parents for the satisfaction of his or her basic needs. See ANACIS OBJECT CHOICE. 2. In the classical psychoanalytic theory of Sigmund Freud, the attachment of the sex drive to the satisfaction of another instinct, such as hunger or defecation. —anacistic adj.

Anacistic depression depression involving interpersonal dependency. It is characterized by intense fears of abandonment and feelings of helplessness and weakness. See SOCIOTROPY. Compare INTROJECTIVE DEPRESSION.

Anacistic identification in the classical psychoanalytic theory of Sigmund Freud, the first phase of the IDENTIFICATION process, which is rooted in the child's initial dependence on the mother (as well as others) for basic biological and emotional needs. The child acquires the mother's characteristics in the service of becoming his or her own source of reinforcement and comfort. The child also incorporates the mother into his or her superego (see BIOIDAL). A weaker version of this is seen with other significant figures in the child's life (e.g., teachers). Compare DEPENDENT IDENTIFICATION.

Anacistic object choice in psychoanalytic theory, the selection of a mate or other LOVE OBJECT who will provide the same type of assistance, comfort, and support that the individual received from the parents during infancy and early childhood: A woman chooses a man resembling her father and a man chooses a woman like his mother. Sigmund Freud contrasted this with NARCISSISTIC OBJECT CHOICE, which involves selecting a mate who is similar to oneself. According to Freud, these are the only two possible types of object choice. Also called anacistic love. See also ANACIS.

Anacistic personality according to some psychoanalytic theories, a line of personality development that is focused on feelings of powerlessness and fear of abandonment with regard to interpersonal relationships and—if the personality fails to develop properly—may result in psychopathological dependency. Compare INTROJECTIVE PERSONALITY.

Anacusis (anakusis) n. total deafness. Also called ana¬cousia: anacusia.

Anaerobic exercise strength-based physical activity, such as weight training and sprinting, that occurs in short, intense bursts with limited oxygen intake. The anaerobic threshold is the point at which energy use by the body is so great as to require the muscles to begin producing energy in the absence of adequate oxygen. Compare AEROBIC EXER¬CISE.

Anaesthesia n. see ANESTHESIA.

Anafranil n. a trade name for CLOMIPRAMINE.

Anaglyph n. a single picture made from two copies of the same image that differ in color and are slightly displaced
from one another in the horizontal plane. When viewed through identically colored glasses, the image appears three dimensional as a result of STEREOPSIS.

**anaglyptoscope** n. a device that reverses the areas of light and shadow on an object, altering the perception of depth. Shadow is a powerful DEPTH CUR. Also called **anaphylroscope**. See DEPTH FROM SHADING.

**analogic interpretation** the interpretation of dreams and other unconscious material as expressions of ideals or spiritual forces, in contrast to the instinct-based interpretations of classical psychoanalysis. [introduced by Carl Jung and developed by Austrian psychoanalyst Herbert Silberer (1882–1925)]

**anagram** n. a word puzzle with scrambled letters. In studies of problem solving and IMPLICIT MEMORY, a common task involves asking participants to determine the word that corresponds to an anagram (e.g., *rhinoebop*-problem).

**an-aggressive personality** in the classical psychoanalytic theory of Sigmund Freud, a personality type characterized by obstinacy, obstructionism, defiance, and passive resistance. Such traits are held to stem from the ANAL STAGE, in which the child asserted himself or herself by withholding feces. Also called **an-aggressive character**. See also ANAL PERSONALITY; ANAL SADISM; ANAL-SADISTIC PHASE.

**anal character** see ANAL PERSONALITY.

**ana-leptic** n. any stimulant other than amphetamines that produces subjective effects similar to those caused by amphetamine use. These effects may include alertness, elevated mood, increased energy, decreased appetite, irritability, and insomnia. The group includes DIETHYLPROPION, METHYLPHENIDATE, and PEMOLINE. See also APPETITE SUPPRESSANT.

**anal erotism** in psychoanalytic theory, pleasurable sensations associated with expulsion, retention, or observation of the feces or through stimulation of the anus. These sensations first arise in the ANAL STAGE of psychosexual development, between the ages of 1 and 3. Also called **anal erotism**. See also ANAL PERSONALITY; COPROPHILIA.

**anal-expulsive phase** in the classical psychoanalytic theory of Sigmund Freud, a phase of the ANAL STAGE in which pleasure is obtained by expelling feces and the sadistic instinct is linked to destruction of the object. According to the theory, fixation at this phase results in an adult ANAL PERSONALITY. See also ANAL-SADISTIC PHASE. Compare ANAL-RETENTIVE PHASE.

**analgesia** n. absence of or reduction in the sensation of pain. Compare ALGOSIS. —an-gesic adj.

**an-gesic** n. a drug or other agent that alleviates pain. Analgesic drugs usually are classed as opioid (narcotic) or nonopioid (nonnarcotic), depending on their chemical composition and potential for physical dependence. OPIOID ANALGESICS are generally the most effective in relieving pain. The most widely used of the less potent nonopioid analgesics are the NSAIDS (nonsteroidal anti-inflammatory drugs)—most notably ASPIRIN and ACETAMINOPHEN.

**anal intercourse** a form of sexual activity in which pleasure is achieved through the insertion of the penis into the anus. Also called **coitus anais**: **coitus in ano**. See also SODOMY.

**anal masturbation** a form of anal eroticism in which sexual excitement is achieved through manual or mechanical self-stimulation of the anus.

**analog adj.** relating to the representation of information by means of a continuously varying physical quantity, such as voltage, rather than by means of discrete digits. Compare DIGITAL.

**analog computer** a computer that solves problems, usually mathematical, by using a physical analog of the mathematical relationships expressed in the computer’s program. These analogs of computational variables are usually an electrical voltage or the rotation of a shaft. See DIGITAL COMPUTER.

**analogical thinking** thinking characterized by extrapolations from the familiar to the unfamiliar, rather than by the use of formal logic or consecutive reasoning. It is particularly important in problem solving and learning, in which known similarities between aspects of certain entities are used to make assumptions about other aspects or entities. Also called **analogical reasoning**.

**analogies test** a test of the participant’s ability to comprehend the relationship between two items and then extend that relationship to a different situation: For example, paintbrush is to paint as pen is to____.

**analogue** n. 1. something that is like, or similar in some respect to, something else. 2. an organ of one species that has a similar function to an organ of another species, although they have different structures and PHYLOGENY. The wings of bats and ilies are examples. See ANALOGY.

**analog observation** a response recorded from a participant in an ANALOGUE STUDY designed to induce a particular behavior in a controlled environment, such as a laboratory or clinic. Compare NATURALISTIC OBSERVATION; SELF-MONITORING OBSERVATION.

**analog study** an EXPERIMENTAL DESIGN in which the procedures or participants used are similar but not identical to the situation of interest. For example, if researchers are interested in the effects of therapist gender on client perceptions of therapist trustworthiness, they may use undergraduate students who are not clients and provide simulated counseling dialogues that are typed and identified as offered by a male or female therapist. The results of such studies are assumed to offer a high degree of experimental control. Also called **analog model**.

**analogy** n. 1. a similarity between two entities in certain limited respects. In biology, it refers to similarity of function in structures with different evolutionary origins, such as wings in bats and butterflies. See also HOMOLOGY; HOMOLOGY. 2. a method of argument that relies on an inference which known similarities between aspects of certain entities justifies a probable assumption that they will be similar in other attributes (see FALSE ANALOGY). Analogy is often used in arguments about the existence of God and of other minds. 3. in linguistics, the process by which the regular patterns of INFECTION, word formation, and the like in a language are extended to novel or anomalous instances. This can be observed in historical language change as well as in LANGUAGE ACQUISITION. A notable form of analogy occurs when children regularize irregular grammatical forms, such as applying the -ed past-tense ending to irregular verbs, creating novel forms such as goed. —**analogueous** adj. —**analogical** adj.

**analogy of the cave** a metaphor used by Plato to illustrate his contention that humans are only dimly aware of
the true nature of things. Plato likened human life to the state of being imprisoned in a cave, with the world outside casting shadows on the cave walls: He contended that these shadows are all one actually experiences of the real world, which is timeless and ideal. See PLATONIC IDEALISM; THEORY OF FORMS. See also TRANSCENDENTALISM.

anal personality in classical psychoanalytic theory, a pattern of personality traits believed to stem from the ANAL STAGE of psychosexual development, when defecation is a primary source of pleasure. Special satisfaction from retention of the feces will result in an adult anal-retentive personality, marked by frugality, obstinacy, and orderliness, whereas fixation on expelling feces will produce an aggressive and disorderly anal-expulsive personality. Also called anal character. See also ANAL-AGgressive PERSONALITY; HOarding ORIENTATION.

anal phase see ANAL STAGE.

anal-retentive phase in the classical psychoanalytic theory of Sigmund freud, a phase of the ANAL STAGE in which pleasure is obtained by retaining feces, thereby defying the parent, and in which the sadistic instinct is linked to possession and control of the object. Fixation at this phase results in an adult anal personality. See also ANAL-SADISTIC PHASE; Compare ANAL-EXPulsive PHASE.

anal sadism in the classical psychoanalytic theory of Sigmund freud, the expression of aggressive impulses in the ANAL STAGE of psychosexual development, involving both the destruction of the object and its possession and control. It is manifested in the adult in the form of an anal-aggressive personality.

anal-sadistic phase in the classical psychoanalytic theory of Sigmund freud, a phase of the ANAL STAGE in which the child manifests aggressive and destructive tendencies. One expression of these tendencies is withholding the feces in defiance of parental urging. See ANAL-AGgressive PERSONALITY. See also ANAL-EXPulsive PHASE; ANAL-RETENTIVE PHASE.

anal stage in the classical psychoanalytic theory of Sigmund freud, the second stage of psychosexual development, typically occurring during the 2nd year of life, in which the child’s interest and sexual pleasure are focused on the expulsion and retention of feces and the sadistic instinct is linked to the desire to both possess and destroy the object. Fixation during this stage results in an anal personality. Also called anal phase. See also ANAL-EXPulsive PHASE; ANAL-RETENTIVE PHASE; ANAL-SADISTIC PHASE.

analysand n. in psychoanalysis, a patient who is undergoing analysis.

analysis n. 1. the division of any entity into its component parts, typically for the purpose of investigation or study. 2. see psychoanalysis. —analytic or analytical adj.

analysis by synthesis any theory of information processing stating that both bottom-up processes and top-down processes interact in the recognition and interpretation of sensory input. According to theories of this type, which are associated particularly with speech perception and language processing, the person initially assesses (analyzes) the physical attributes and constituent elements of a stimulus (data-driven processing) and then, guided by contextual information and knowledge acquired from previous experience or learning (conceptually driven processing), determines the significant information from this preliminary analysis of the stimulus and assembles (synthesizes) it into an internal representation or interpretation of what the stimulus might be. This internal representation is compared to the stimulus input: If the two match, then the stimulus is recognized; if not, alternative representations are assembled for comparison until a match is found. In other words, one analyzes the original stimulus input, hypothesizes what it is, determines what the input would be like if the hypothesis were correct, and then assesses whether the input is actually like that.

analysis of covariance (ANCOVA) an extension of the analysis of variance that adjusts for the influence of a COVARIATE in testing whether there is a significant difference between means of two or more groups on one or more independent variables. In other words, it is a statistical method of studying the responses of different groups to a dependent variable that adjusts for the influence of a variable that is not being investigated but nonetheless is related to the dependent variable and thus may influence the study results. For example, suppose a researcher analyzes whether there is a difference in learning among three types of instruction—in-class lecture, online lecture, and textbook only. He or she divides a random selection of adult students into three groups, implements the different instruction types, and administers the same test to all participants to determine how much they learned. If the researcher knows each participant’s educational background, he or she could use an analysis of covariance to adjust the treatment effect (test score) according to educational level, which would reduce the observed variation between the three groups caused by variation in education levels rather than by the instruction itself.

analysis of resistance a basic procedure in psychoanalysis in which the patient’s tendency to maintain the repression of unconscious impulses and experiences that interfere with free association is subjected to analytic scrutiny. The process of explaining resistances is believed to be a major contribution to insight and positive change.

analysis of transference in psychoanalysis, the interpretation of a patient’s early relationships and experiences as they are reflected and expressed in his or her present relationship to the analyst. Also called transference analysis. See TRANSFERENCE.

analysis of variance (ANOVA) a statistical method of studying the variation in responses of two or more groups on a dependent variable. ANOVAs test for significant differences among the mean response values of the groups and can be used to isolate both the joint interaction effects and the separate main effects of independent variables upon the dependent variable.

analysis unit see UNIT OF ANALYSIS.

analyst n. generally, one who practices psychoanalysis. This is usually a psychoanalyst in the tradition of Sigmund freud; however, the term is also applied to therapists adhering to the methods of various neodynamic theorists.

analytical intelligence in the triarchic theory of intelligence, the skills measured by conventional tests of intelligence, such as analysis, comparison, evaluation, critique, and judgment. Compare CREATIVE INTELLIGENCE; PRACTICAL INTELLIGENCE.

analytical psychotherapy a method of psychotherapy using psychoanalytic principles but with less depth of analysis, more active intervention on the part of the thera-
anaphylaxis
anaplastic astrocytoma

nary edema, heart arrhythmia, shock, loss of consciousness, and potential respiratory or cardiac arrest—may occur if untreated. —anaphylactic adj.

anaplastic astrocytoma see GLIOMA.

anarthria n. a MOTOR SPEECH DISORDER characterized by an inability to speak because of damage to or disruption of the central nervous system. Individuals with anarthria cannot control the LARYNX and other muscles involved in producing speech sounds; other language functions generally are unaffected. The condition is distinct from DYSARTHRIA, which is a difficulty in speaking coherently. —anarthric adj.

anastomosis n. (pl. anastomoses) 1. the surgical connection of two normally separate structures. 2. an alternate pathway formed by branching of a main circuit, as found in nerves, blood vessels, and lymphatic vessels. The brain is served by arterial anastomoses that help ensure a continuing blood flow in the event of one pathway being blocked by a blood clot or rupture of a blood vessel.

anatomical age a measure of the stage of physical development of an individual, based on the condition of certain skeletal features as compared with the normal state of the bones for a specified CHRONOLOGICAL AGE. Also called physical age. See also MENTAL AGE.

anatomically detailed doll a doll with anatomically correct genitalia that is used as an assessment tool in the diagnosis of sexual abuse in children. There are currently no uniform standards or normative data for conducting interviews with such dolls, and their clinical reliability with very young children is questionable. Also called anatomically correct doll.

ancestor worship a practice found in various cultures, especially in Asia and Africa, that involves the veneration of departed kin and the summoning of ancestral spirits through rituals and prayer.

ancestral trait an evolutionary trait that is homologous within groups of organisms (see HOMOLOGY) that are all descended from a common ancestor in which the trait first evolved. Because an ancestral trait may occur across many species—for example, opposable thumbs in marmosets, ring-tailed lemurs, and gorillas—it cannot be used to further elucidate their genetic relationships.

anchor n. a reference used when making a series of subjective judgments. For example, in an experiment in which participants gauge distances between objects, the experimenter introduces an anchor by informing the participants that the distance between two of the stimulus objects is a given value. That value then functions as a reference point for participants in their subsequent judgments. Similarly, the options listed for a multiple-choice test item provide an anchor for the test taker to use when answering.

anchoring bias the tendency, in forming perceptions or making quantitative judgments under conditions of uncertainty, to give excessive weight to the starting value (or anchor), based on the first received information or one's initial judgment, and not to modify this anchor sufficiently in light of later information. For example, estimates of the product of $9 \times 8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1$ tend to be higher than estimates of the product of $1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8 \times 9$. Also called anchoring-and-adjustment heuristic; anchoring effect. See also ATMOSPHERE EFFECT.

anchor test a set of test items used as a reference point in comparing ALTERNATE FORMS of a test. One alternate form is administered to one group of participants, another is administered to a different group, and the items comprising the anchor test are administered to both groups. Scores on each alternate form are then compared with scores on the anchor test.

ancillary adj. supporting or supplemental but not necessarily critical to some function or event.

ANCOVA acronym for ANALYSIS OF COVARIANCE.

Andersen's disease a familial disorder marked by cirrhosis of the liver with involvement of the heart, kidneys, muscles, and nervous system. The disease is due to a deficit of an enzyme needed to convert glucose carried from the digestive tract into glycogen for storage by the liver. [Dorothy Hansine Andersen (1901–1963), U.S. pediatrician]

Andersen's syndrome a disorder consisting of three pathological conditions: cystic fibrosis of the pancreas, cerebellar disease, and vitamin A deficiency. The syndrome may be marked by symptoms of depression, muscle wasting, and hypotonia (weak, floppy muscles). Children may have difficulty in walking or standing. Also called Andersen's triad. [Dorothy Hansine Andersen] Andrade's syndrome a form of AMYLOIDOSIS characterized by iliac paralysis, sensory disorders, impotence, and premature menopause. Also called Corino de Andrade's paramyloidosis; familial Portuguese polyneuropathic amyloidosis; Wohllivill–Corino Andrade syndrome. [Corino de Andrade, Portuguese physician; Joachim Friedrich Wohllivill (1881–1958), German physician]

andro- (andr-) combining form male.

androcentric adj. denoting a male perspective, sometimes one that marginalizes or excludes women and their experience. See also PHALLOCENTRIC. —androcentrism n.

androgen n. any of a class of steroid hormones that act as the principal male SEX HORMONES, the major one being TESTOSTERONE. Androgens are produced mainly by the testes and influence the development of masculine SEX CHARACTERISTICS. They are also secreted in small quantities by the cortex of the ADRENAL GLAND and can be produced synthetically. —androgenic adj.

androgen antagonist n. see ANTIANDROGEN.

androgen-insensitivity syndrome (AIS) an inherited X-linked (see SEX-LINKED) recessive condition affecting genital development and caused by varying degrees of insensitivity to ANDROGENS. There are three forms: complete AIS, in which the insensitivity is total, resulting in external genitalia that are female; partial AIS, in which some sensitivity to the hormones results in external genitalia that fall anywhere within the range of male to female; and mild AIS, in which the external sex characteristics are male but there may be some breast growth at puberty. In all three
forms, the internal organs are male (i.e., testes). Also called feminizing testes syndrome: male pseudohermaphroditism. See also INTERSEX; PSEUDOHERMAPHRODITISM.

androgenization n. the masculinizing effect of androgens, especially TESTOSTERONE, on body tissues and organs sensitive to them, as in the development of male sex characteristics.

androgyne n. 1. sexual attraction to both males and females. See BISEXUALITY. 2. sexual attraction to someone who is androgynous in appearance.

androgyne 1. a personality style in which an individual displays both stereotypical masculine and stereotypical feminine psychological characteristics (e.g., both assertiveness and sensitivity).

androginophilia n. 1. male sexual attraction to both males and females. See BISEXUALITY. 2. male sexual attraction to someone who is androgynous in appearance.

androgyne 2. a personality style in which an individual displays both stereotypical masculine and stereotypical feminine psychological characteristics (e.g., both assertiveness and sensitivity).

androgyne n. —androgyne adj.

android 1. adj. possessing human features. 2. n. an automaton resembling a human being. The term was popularized by science fiction writers in the mid- and late 20th century. Also called humanoid.

androopause n. see MALE CLIMACTERIC.

androstenedione n. a steroid hormone secreted by the adrenal cortex (the outer layer of the ADRENAIJ GLAND) and the gonads as a precursor of the male and female sex hormones, particularly testosterone and estrone.

androsterone n. a steroid hormone, secreted by the adrenal cortex and testis, with weak androgenic effects.

and rule see MULTIPLICATION RULE.

anecdotal method an investigational technique in which informal verbal reports of incidents casually observed are accepted as useful information. The anecdotal method is scientifically inadequate but can offer clues to areas of investigation that warrant more systematic, controlled research.

anecdotal record in education, a factual, written record containing spontaneous, succinct, cumulative descriptions of a student’s behavior. Such observations are usually considered significant because they highlight a given aspect of the student’s personality and may prove useful in future evaluations.

anechoic chamber an enclosure designed to eliminate sound reverberations and echoes. This enclosure is usually located within or combined with a SOUND-ATTENUATING CHAMBER.

Anectine n. a trade name for SUCINICYLCHOLINE.

anencephaly n. congenital absence of the cranial vault (the bones forming the rear of the skull), with cerebral hemispheres completely missing or reduced to small masses. Infants born with anencephaly are usually blind, deaf, unconscious, and unable to feel pain. Anencephaly is an example of a NEURAL TUBE defect. —anencephalic adj.

anergia n. 1. absence of energy. 2. a state of passivity. Also called ainy.

anesthesia (anaesthesia) n. the loss of sensitivity to stimuli, either in a particular area (local) or throughout the body and accompanied by loss of consciousness (general). It may be produced intentionally, for example, via the administration of drugs (called anesthetics) or the use of techniques such as ACUPUNCTURE or hypnotic suggestion, or it may occur spontaneously as a result of injury or disease. —anesthetic adj.

anethopath n. a person lacking ethical or moral inhibitions. See also ANTISOCIAL PERSONALITY DISORDER. —anethopathy n.

aneuploidy n. the condition in which a cell or organism has fewer or more than the normal number of chromosomes, for example (in humans), 45 or 49 instead of the normal 46. Aneuploidy is often associated with neurological or cognitive defects. See AUTOSOME. —aneuploid adj., n.

aneurysm (aneurism) n. an enlargement (swelling) at some point in an artery caused by the pressure of blood on weakened tissues, often at junctions where arteries split off from one another. Aneurysms can rupture (burst) or dissect (split) the artery wall, causing internal bleeding that is often fatal. They are a common cause of HEMORRHAGIC STROKE. —aneurysmal adj.

angakok n. an Inuit name for a SHAMAN or spiritual guide. The angakok is a central figure of Inuit spiritual life; present at major ceremonies, he foretells weather and the movement of game animals, cures illness, retrieves lost or stolen souls, and converses with other spiritual beings.

angel dust a street name for crystals of TCP (phencyclidine). The crystals are sometimes sprinkled onto oregano, parsley, or alfalfa and sold as marijuana.

Angelman syndrome a congenital disorder caused by a genetic abnormality on chromosome 15 and characterized by abnormalities or impairments in neurological, motor, and cognitive functioning, including severe learning disabilities, absence of speech, and a stiff, jerky gait and movement of game animals, cures illness, retrieves lost or stolen souls, and converses with other spiritual beings. The condition was formerly called happy-puppet syndrome. [Harry Angelman (1915–1996), British pediatrician]

anger n. an emotion characterized by tension and hostility arising from frustration, real or imagined injury by another, or perceived injustice. It can manifest itself in behaviors designed to remove the object of the anger (e.g., determined action) or behaviors designed merely to express the emotion (e.g., swearing). Anger is distinct from, but a significant activator of, AGGRESSION, which is behavior intended to harm someone or something. Despite their mutually influential relationship, anger is neither necessary nor sufficient for aggression to occur.

anger control therapy a treatment that makes use of therapist-guided progressive exposure to anger-provoking cues in conjunction with therapist modeling, client rehearsal, assertiveness training, and other forms of coping skills training. Practiced in both individual and group settings, the intervention is used with clients who have general difficulty with anger (e.g., intensity, frequency, or mode of expression) or with clients who have specific disorders.

anger management techniques used by individuals—sometimes in counseling or therapy—to control their inappropriate reactions to anger-provoking stimuli and to express their feelings of anger in appropriate ways that are respectful of others. Such techniques include using re-
laxation methods (breathing deeply, repeating a word or phrase, visualizing a relaxing experience) to reduce physiological responses to anger, replacing exaggerated or overly dramatic thoughts with more rational ones (see COGNITIVE RESTRUCTURING), communicating more calmly and thoughtfully about one’s anger, and removing oneself from situations or circumstances that provoke anger or avoiding them altogether.

anger stage the second of the five STAGES OF GRIEF described by Elisabeth Kübler-Ross. It is characterized by anger, resentment, or even rage at one’s own (or at an important other’s) impending or actual death, other great loss, or trauma.

angio- (angio-) combining form blood vessels or lymph vessels.

angioedema n. a disorder marked by recurrent episodes of noninflammatory swelling of certain body tissues, particularly the skin, mucous membranes, viscera, and central nervous system. The disorder may begin suddenly and last for hours or days, sometimes causing death. Attacks may be triggered by food or drug allergies, insect stings or bites, or viral infection, but in most cases the cause is never known. A hereditary form may be associated with emotional stress. Also called angioneurotic edema; Quincke’s disease; Quincke’s edema.

angiography n. the visualization of blood vessels by radiological techniques, used as an aid in diagnosing abnormalities or discovering blockages in areas of the circulatory system. For example, it can identify blood clots, tumors, aneurysms, and the degree of narrowing of the coronary arteries, which supply the heart. A dye opaque to X-rays is injected into a vessel and any disruption of blood flow is revealed as a contrasting pattern. When the imaging is of arteries, it is also called arteriography. The image produced is called an angiogram (or arteriogram). See also CEREBRAL ANGIOGRAPHY; DIGITAL SUBTRACTION ANGIOGRAPHY.

angioma n. a tumor of the vascular system: an abnormal mass of blood vessels or lymph vessels.

angioscotoma n. a tumor of the oral cavity: a growth of blood vessels or lymph vessels that forms in the mouth or tongue as a form of sexual activity.

animal 1. n. a living organism generally distinguished from plants by having motility and mechanisms for rapid response to outside events. 2. n. any such organism other than humans. 3. adj. beastlike, or characteristic of lower animals; lacking human faculties and sensitivities.

animal aggression see AGGRESSION.

animal-assisted therapy the therapeutic use of pets to enhance individuals’ physical, social, emotional, or cognitive functioning. Animal-assisted therapy may be used, for example, to help people receive and give affection, especially in developing communication and social skills. It may be most effective for people who have suffered losses or separation from loved ones. Also called pet-assisted therapy; pet therapy.

animal behavior the scientific study of the behavior of animals, typically nonhuman animals. It includes the fields of ETHOLOGY, COMPARATIVE PSYCHOLOGY, and BEHAVIORAL ECOLOGY. Areas of study include AGGRESSION, COURTSHIP, GROOMING, MATE SELECTION, PLAY, FORAGING, and PARENTAL BEHAVIOR, among others.

animal care and use the treatment of nonhuman animals used in research and experimentation. Various regulations, standards, and principles have been developed to protect the well-being of such animals and ensure that they are treated in a humane and ethical manner. In the United States, examples include the Animal Welfare Act, passed by the U.S. Congress in 1966 and subsequently amended several times, most recently in 2008; and the American Psychological Association’s “Guidelines for Ethical Conduct in the Care and Use of Nonhuman Animals in Research,” developed in 1968 by the Committee on Animal Research and Ethics (CARE) and revised in 2012. See INSTITUTIONAL ANIMAL CARE AND USE COMMITTEE.

animal cognition the processes that are believed to be used by nonhuman animals in solving environmental and social problems but that cannot be observed directly. They include problem-solving abilities that appear not to depend on rote memory or trial-and-error learning, suggesting that some animals may be able to reason about potential solutions and therefore to solve problems with apparent
animal communication the study of how nonhuman animals communicate with each other either to provide honest signals or to manage or manipulate the behavior of others. Assessment of individuals based on their behavior or signals may be a major function of animal communication.

animal cooperation behavior in which two or more nonhuman animals act together in a way that leads to mutual benefit. Examples include the cooperative nest building, food finding, and care of young in social insects, the mobbing behavior of some animals toward a predator, and the production of specific signals to indicate sources of food or shelter to others. It is not known whether cases of animal cooperation require that the animals understand the need to cooperate (see cooperation).

animal courtship see courtship.

animal defensive behavior behavior used by a nonhuman animal to avoid being harmed by another. This might involve defensive aggression against a potential predator or against a member of its own species, from its own group or an outside group, or animal escape behavior to avoid the source of harm. It might also involve strategies to become inconspicuous, through camouflage or inactivity, or highly conspicuous, as in the noise that a rattlesnake makes to indicate potential danger if provoked or attacked.

animal dominance the relationship between nonhuman animals that allows some individuals to have greater access to resources (e.g., food, shelter, mates) than others in the group. Dominance ranks are thought to be linear in some cases, with a clear ordering from most to least dominant (see pecking order), but may also be dependent (i.e., based on kin or age relationships) or governed by coalitions in which subordinate individuals acting together can outrank dominant ones. Although dominance is usually thought to be based on aggression, stable dominance relationships may be maintained through the use of animal vocalizations or visual communication, with minimal aggression.

animal emotionality emotional reactions in nonhuman animals, often measured by exploratory behavior in an open field or by physiological correlates, such as heart rate or defecation rate. Individuals showing less exploratory behavior or greater physiological arousal are said to exhibit higher emotional reactivity.

animal escape behavior the attempt of a nonhuman animal to escape an aversive stimulus, such as pain, a distasteful food, a predator, or an attacking or threatening member of the same species. This is one form of animal defensive behavior. See also escape behavior.

animal–human comparison the use of information about nonhuman animal behavior to make generalizations about human behavior. Studies of animals are often specifically designed to provide explicit models for some aspect of human behavior, but studies of the diversity of behavior across different animal species can also be used to understand the origins of certain types of human behavior and to suggest alternative solutions to human problems. See comparative psychology.

animal hypnosis a state of motor nonresponsiveness in nonhuman animals, produced by stroking, salient stimuli, or physical restraint. It is called “hypnosis” because of a claimed resemblance to human hypnosis and trance.

animal intelligence the various abilities of nonhuman animals to solve problems in their environment through mechanisms of learning and animal cognition. Psychologists formerly thought that animal intelligence was best measured relative to human skills, with a linear progression of intelligence from simple to complex organisms. Research has revealed, however, that intelligence can take many forms and is best understood in the context of the particular problems that each species faces. For example, swarm intelligence is the cumulative problem-solving ability of a group of animals of one species, such as an ant colony or a flock of birds. See also comparative cognition.

animal learning a field of psychology that studies the learning ability of nonhuman animals.

animal magnetism a hypothetical physical force that allegedly can have a curative effect when focused on ailing parts of the body, often through the use of a magnetized wand, magnetized rods, or a magnetized bath (see baquett). This method was proposed in 1779 and popularized by Franz Anton Mesmer, who claimed some treatment success with it. In the 1840s, James Braid investigated the curative effects of animal magnetism, concluding that it worked not through the application of magnets to ailing parts of the body but through the practitioner’s induction of a sleep-like state in patients and through the interplay of patient belief and healer suggestion to elicit a positive result. Braid revised the treatment under the term hypnosis (see hypnosis). Both hypnosis and its forerunner, animal magnetism, are also sometimes called mesmerism.

animal model an animal whose characteristics or conditions are similar to those of humans, thus making it suitable for studying human behavior, processes, disorders or diseases, and so forth.

animal open-field behavior the activity of an animal measured in the form of exploratory behavior, movement, and number of defecations when it is exposed to an enclosed but otherwise relatively unrestricted laboratory environment, such as the open-field chamber.

animal phobia a persistent and irrational fear of a particular type of animal, such as snakes, cats, dogs, insects, mice, birds, or spiders. The focus of fear is often anticipated harm or danger. The emotion of disgust may also play a role in the maintenance of certain animal phobias (e.g., insects, mice, spiders). Situations in which the feared animal may be encountered are often avoided or else endured with intense anxiety or distress. Animal phobias typically start in childhood. The DSM–IV–TR and DSM-5 designation is specific phobia, animal type.

animal psychology see comparative psychology.

animal rights the rights of nonhuman animals to be treated with respect and to be free from exploitation and abuse by humans. Proponents of animal rights believe that it is morally wrong to harm, kill, or exploit animals for any human uses, including any type of research, and many advocate that all sentient creatures are in some ways the moral equals of humans. Proponents of animal welfare, however, typically make a moral distinction between humans and nonhuman animals and believe that, whereas individuals have an obligation to treat animals humanely, certain research involving animals is medically and scientifically necessary. See also animal care and use.
animal social behavior the aggregate of interactions between members of a nonhuman animal group or family, including aggression, animal communication, animal cooperation, courtship, animal dominance, play, and parental behavior. Social organization and social structure can be inferred from a detailed knowledge of animal social behavior.

animal spirits in the system of Galen, a vaguely defined force or substance that is pictured as flowing through hollow tubes from the brain to all parts of the body; as such, it is a precursor of the modern concept of the nerve impulse. Like other aspects of Galen’s system, the concept of animal spirits remained current well into the 17th century. In the mechanistic physiology of René Descartes, for example, the animal spirits are retained to provide a link between body and mind. Descartes, however, anticipated the modern concept of the peripheral nervous system by maintaining that nerves conduct in either direction between the muscles and sense organs. Also called vital spirits. See also HYDRAULIC MODEL.

animal starch see GLYCOCEN.

animal vocalization any call or sound produced by a nonhuman animal that can be said to communicate, that is, that can provide information about internal state or likeliness of subsequent action or can be used to assess or manage the behavior of others. Vocalizations are typically produced through vibration of an organ, such as the larynx in some mammals, the two syrings in birds, or the blowholes in whales. Frequently sounds are amplified through special organs, such as throat sacs in amphibians. See also VOCAL COMMUNICATION.

animal welfare see ANIMAL RIGHTS.

animate noun a noun denoting a living entity capable of being the agent of an action; an inanimate noun is one denoting any other entity. The distinction affects the form of the noun in some languages and can be significant in CASE GRAMMAR.

animatism n. the belief that within all entities, living and nonliving, there exist supernatural forces or powers.

animism n. the belief that natural phenomena or inanimate objects are alive or possess lifelike characteristics, such as intentions, desires, and feelings. A well-known and often cited phenomenon in PRECAUSAL THINKING, animism was considered by Jean Piaget to be characteristic of the thought of children in the PREOPERATIONAL STAGE, later fading out and being replaced by the strong belief in the universal nature of physical causality. —animistic adj.

animus n. in ANALYTIC PSYCHOLOGY, (a) an archetypal state of being different, especially with respect to direction or orientation, lack of symmetry of form, or lack of uniformity of responses in different parts of something. Anisotropy in vision can refer to differences between the right and left eyes (e.g., ANISOMETROPIA). Also called anisotropia. Compare ISOTROPY. —anisotropic adj.

ankylo- (ankyl-) combining form bent or crooked.

ankyloglossia n. restricted movement of the tongue due to abnormal shortness of the lingual frenum. Normal speech production may be affected. Also called tongue tie.

ankylosis n. an immobility and consolidation of a joint, usually due to the destruction of membranes lining the joint or to a defect in bone structure. It may occur naturally, as in rheumatoid arthritis, or by surgical fusion (arthrodesis).

Anna O., the pseudonym of Austrian social worker and feminist Bertha Pappenheim (1859–1936), who was a patient of Josef Breuer, a colleague of Sigmund Freud. Breuer’s treatment of her hysteria was written up in an early case study that was an important precursor to psychoanalysis and to Freud’s concept of TRANSFERENCE. See also TALKING CURE.

annihilation n. complete destruction. In psychoanalytic theory, annihilation is destruction of the self. In OBJECT RELATIONS THEORY, fear of annihilation (annihilation anxiety) is viewed as the earliest form of anxiety. Melanie Klein attributed it to the experience of the DEATH INSTINCT. The British psychoanalyst Donald Winnicott (1896–1971) saw it as the anxiety that accompanies IMPINGEMENTS from the environment. —annihilate vb.

anniversary reaction a strong emotional response on the anniversary of a significant event. It most commonly involves depressive symptoms around the same time of the year that the death of a loved one, a severe disappointment, or other adverse event occurred.

annual cycle a pattern of behavior that recurs over the course of a year. Hibernating animals eat more food and gain weight in the months before winter, migratory animals experience periods of activity twice a year coincident with migration, and seasonally breeding animals undergo annual changes in reproductive physiology and related be-
behavior (such as territory defense and song). Some annual cycles occur even in the absence of external seasonal cues.

annulment n. 1. in psychoanalytic theory, a process in which disagreeable ideas or events are neutralized or made ineffective by converting them into daydreams and fantasies. Compare repression. 2. a formal pronunciation that a marriage or judicial proceeding is invalid.

annulospiral ending a type of nerve fiber ending in muscle spindles in which the nerve fiber is wrapped around the muscle fiber near the center of the spindle. Annulospiral endings show a maximal discharge early in the stretch of a muscle and then adapt to a lower discharge rate. Also called primary sensory ending. Compare flower-spray ending.

annunciator n. in ergonomics, an early-warning system that uses sensors to monitor specific system attributes and some form of alert to warn the operator when deviation from the normal limits occurs. Action can then be taken to return the system attribute to its normal state. Compare check reading. —annunciate vb.

anodal polarization a condition in which the flow of electrical current is toward the positive pole. In a typical nerve cell, the positive pole would be in extracellular fluid, and the current flow would be from the inside toward the outside of the cell membrane.

anodyne n. any agent or procedure that relieves pain, including analgesics (e.g., aspirin), anesthetics, or acupuncture.

anoeic adj. 1. not involving or subject to intellectual or cognitive processes. Emotions are sometimes considered anoeic. 2. describing a state of knowledge or memory in which there is no consciousness of knowing or remembering. Anoeic consciousness is a corresponding kind of “unknowing knowing” in which one is aware of external stimuli but not of interpreting them. [defined by Endel Tulving] 3. lacking the capacity for understanding or concentrated thought. This meaning, originally applied to intellectual disability, is no longer common. Compare autoeotic, noetic. —anoeisis n.

anogenital adj. relating to the anatomical region in which the anus and genitalia are located.

anomalies n. see ANOMALOUS TRICHROMATISM.

anomalous dichromatism partial color blindness in which only two colors (usually blue and yellow) can be seen. Also called anomalous dichromasy. See dichromatism.

anomalous experience any of a variety of experiences that appear to be inconsistent with the usually accepted explanations of reality. Examples include out-of-body experiences, mystical experiences, lucid dreaming, and synesthesia. See also altered state of consciousness.

anomalous stimulus a stimulus that is unexpected in relation to an organism’s recent experience, which gives rise to unique neural events different from those caused by expected stimuli.

anomalous trichromatism a form of color blindness or color weakness in which affected individuals have three types of retinal cone but one of these has a color sensitivity that is different from that of the corresponding normal cones. It is usually marked by a diminished capacity to respond to the red–green color system. The ability to distinguish these colors increases in proportion to their intensity; that is, less brilliant shades are less easily identified. Also called anomalopia: anomalous trichromasy.

anomaly n. 1. anything that is irregular or deviates from the norm, often referring to a congenital or developmental defect. 2. in the analysis of scientific revolutions by U.S. philosopher of science Thomas Kuhn (1922–1996), an empirical fact that should be but cannot be explained or predicted by a particular theoretical system. —anomalous adj.

anomia n. 1. loss or impairment of the ability to name objects. All individuals with aphasia exhibit anomia, and the extent of naming difficulty is a good general measure of aphasia severity. 2. an obsolete term for a defective moral sense. [defined by U.S. physician Benjamin Rush (1745–1813)] —anomic adj.

anomic aphasia one of eight classically identified types of aphasia, characterized by impairment in object naming (anomia) and word recognition in the absence of other significant language deficits. Conversational speech is fluent, with normal utterance length and grammatically well-formed sentences. Auditory comprehension is good for everyday conversation, but there may be some difficulty with complex syntax. Also called amnestic (or amnesic) aphasia; nominal aphasia.

anomic suicide one of four types of suicide proposed in 1897 by Émile Durkheim, involving the perception that one’s relationship to society has changed so radically that its values and norms are no longer personally relevant. Feeling bereft of the societal standards upon which he or she had relied, the individual becomes frustrated, disillusioned, and disappointed. Anomic suicides often are associated with periods of social revolution or other significant widespread change. See also altruistic suicide; egoistic suicide; fatalistic suicide.

anomie n. a sense of alienation and hopelessness in a society or group that is often a response to social upheaval. It also may be accompanied by changes in personal and social values. —anomic adj.

anonymity n. a principle of research ethics stating that the identity of a study participant should remain unknown. Relatedly, confidentiality applies to situations in which a participant’s identity is known but should not be disclosed by the researcher.

anopia (anopsia) n. blindness in one or both halves of the visual field as a result of a defect in the peripheral or central visual system. See hemianopia; quadrantanopia.

anorchism n. congenital absence of one or both testes. The etiology is unknown but genetic factors may be involved. Also called anorchia.

anorectant n. see appetite suppressant. Also called anorexiant.

anorexia n. absence or loss of appetite for food or, less commonly, for other desires (e.g., sex), especially when chronic. It may be primarily a psychological disorder, as in anorexia nervosa, or it may have physiological causes, such as hypopituitarism. —anorectic or anorexic adj., n.

anorexia nervosa an eating disorder, occurring most frequently in adolescent girls, that involves persistent refusal of food, excessive fear of weight gain, refusal to maintain minimally normal body weight, disturbed perception
anorgasms

of body image, and amenorrhea (absence of at least three menstrual periods).

anorgasmia n. the inability to achieve orgasm. See also FEMALE ORGASMIC DISORDER; MALE ORGASMIC DISORDER. —anorgasmic adj.

anorthopia n. asymmetrical or distorted vision, sometimes associated with STRABISMUS.

anoscope n. a device consisting of two disks, one in front of the other, that rotate in opposite directions. The front disk is opaque with four slits through which a highly distorted image on the back disk is viewed. Although the image on the rear disk is both rotating and distorted, it will appear normal and stationary when viewed through the front disk if both disks are rotated at the appropriate speed. [first constructed by Belgian physicist Joseph Antoine Ferdinand Plateau (1801–1883)]

anoscope perception the holistically perceived form of an object revealed over time through a narrow slit aperture. It is distinct from ordinary object perception in that the perceived object arises from the temporal integration of visual information derived from the same retinotopic area (i.e., there is no spatially extended retinotopic image). Also called slit viewing. See ANOPTOPIA [first reported in 1862 by German astrophysicist Johann Karl Friedrich Zöllner (1834–1882)]

anosmia n. absence or loss of the ability to smell, which may be general or limited to certain odors. General or total anosmia implies inability to smell all odorants on both sides of the nose, whereas partial anosmia implies an inability to smell certain odorants. —anosmic adj.

anosognosia (anosagnosia) n. a neurologically based failure to recognize the existence of a deficit or disorder, such as cognitive impairment, hearing loss, poor vision, or paralysis. ANTÓN’S SYNDROME is an example of anosognosia for blindness.

A-not-B task see OBJECT PERMANENCE.

ANOVA acronym for ANALYSIS OF VARIANCE.

anovulatory menstrual cycle a menstrual cycle that occurs without ovulation. It results from an imbalance between hormone production of the pituitary gland and the ovaries and is marked by irregular menstruation. An anovulatory menstrual cycle is most likely to be associated with menarche or menopause.

anoxemia n. the severe reduction or absence of oxygen in the arterial blood. This condition can result in loss of consciousness and brain damage. See also HYPOXEMIA. —anoxic adj.

anoxia n. a decrease in the level of oxygen in the body tissues, including the brain. Consequences depend on the severity of the anoxia and the specific areas of the brain that are affected but can include generalized cognitive deficits or more focal deficits in memory, perception, or executive function. Anoxia sometimes is used as a synonym of hypoxia. —anoxic adj.

ANP abbreviation for ACTIVE NOISE PROTECTION.

ANR abbreviation for ACTIVE NOISE REDUCTION.

ANS abbreviation for AUTONOMIC NERVOUS SYSTEM.

Anschauung n. intuition (German, in which it can also mean “view” or “perception”). In the thought of Immanuel Kant, Anschauung is that means of knowing in which knowledge is immediate and not based on concepts. According to Kant, one’s knowledge of sensible objects is of this kind.

ANT abbreviation for Attention Network Test.

ant- prefix see ANTE-; ANTI-.

Antabuse n. a trade name for DISULFIRAM.

antagonist n. 1. a drug or other chemical agent that inhibits the action of another substance. For example, an antagonist may combine with the substance to alter and thus inactivate it (chemical antagonism); an antagonist may reduce the effects of the substance by binding to the same receptor without stimulating it, which decreases the number of available receptors (pharmacological antagonism); or an antagonist may bind to a different receptor and produce a physiological effect opposite to that of the substance (physiological antagonism). 2. a contracting muscle whose action generates force opposing the intended direction of movement. This force may serve to slow the movement rapidly as it approaches the target or it may help to define the movement end point. Compare AGONIST. —antagonism n. —antagonistic adj.

antagonistic colors colors at opposite sides of the color circle, such as red and green or blue and yellow. Also called complementary colors.

antagonistic muscles pairs of muscles (or muscle groups) that oppose each other in function. For example, the biceps flexes the arm at the elbow, whereas the opposing triceps straightens the arm.

ante- (ante-) prefix before or in front of.

antecedent n. 1. an event or stimulus that precedes some other event or stimulus and often elicits, signals, or sets the occasion for a particular behavior or response. See also CONTINGENCY. 2. in linguistics, the noun or noun phrase to which a pronoun (especially a relative pronoun, such as who, that, or which) refers back. For example, in the train that I caught yesterday, the antecedent of that is train. See ANAPHORA. 3. see CONSEQUENT.

antecedent-focused emotion regulation in the PROCESS MODEL OF EMOTION REGULATION, a form of emotion regulation in which one faced with a potentially emotional situation attempts to reappraise it in a way that decreases its emotional relevance. For example, reappraising an upcoming task as a challenge rather than as a threat, or thinking of an upcoming medical procedure as beneficial rather than painful, can reduce one’s subjective emotional experience of the actual event. Thus, reappraisal as antecedent to the event can, if effective, preempt full-blown emotional responses to it. Compare RESPONSE-FOCUSED EMOTION REGULATION. [proposed in 1998 by U.S. clinical psychologist James J. Gross]

antecedent variable any variable that precedes a response variable. For example, in REGRESSION ANALYSIS it is the INDEPENDENT VARIABLE, and in PATH ANALYSIS it is the variable beginning a chain of causal links. Compare CONSEQUENT VARIABLE.

antergic adj. exerting force in opposition. For example, antergic pairs of muscles or muscle groups oppose each other in flexing or extending a joint. Compare SYNERGY.

anterior adj. in front of or toward the front. In reference to two-legged upright animals, this term is sometimes used interchangeably with VENTRAL to mean toward the front surface of the body. Compare POSTERIOR. —anteriorly adv.
anterior cerebral artery a branch of the internal carotid artery that forms part of the circle of willis. The anterior cerebral artery passes above the optic chiasm and extends forward into the longitudinal fissure, where it curves around the horn of the corpus callosum before arching back along the upper surface of the corpus callosum. It supplies blood to portions of the frontal lobe, which is involved in motor functions and higher level cognitive processes, and portions of the parietal lobe, which is involved in sensory functions. Specific structures served include the corpus callosum itself, the cingulate cortex, parts of the basal ganglia, and the septal area.

anterior choroidal artery a relatively narrow artery that is a posterior branch of the middle cerebral artery. It passes across the optic tract toward the temporal horn of the lateral ventricle and into the choroid plexus, hippocampus, thalamus, amygdala, and related deep structures.

anterior cingulate cortex (ACC) the front, more curved part of the cingulate cortex, a structure in the forebrain that forms a collar around the corpus callosum. It is divided into two distinct areas believed to have essential roles in numerous activities. The dorsal anterior cingulate cortex (dACC), often considered the “cognition” division, is implicated in a range of executive functions, such as attention allocation, error and novelty detection, working memory modulation, cognitive control, response conflict, and response selection. The ventral anterior cingulate cortex (vACC), often considered the “emotion” division, is thought to be involved in mediating pain, fear, aggression, anger, empathy, and sadness; in perceiving both physical and psychological pain; and in regulating autonomic functions (e.g., blood pressure, heart rate, respiration). Although the precise mechanisms by which these processes occur in the ACC remain unknown, researchers have theorized that a reciprocal relationship between the dACC and the vACC helps maintain a balance between cognitive and emotional processing so as to enable self-regulation. Additionally, ACC abnormalities may contribute to the etiology of various mental disorders, such as major depressive disorder, bipolar disorder, and attention-deficit/hyperactivity disorder. See also posterior cingulate cortex.

anterior commissure see commissure.

anterior communicating artery (ACoA; AComA) a short blood vessel that connects the left and right sides of the anterior cerebral artery. Part of the circle of willis, the anterior communicating artery passes in front of the optic chiasm and stretches across the beginning of the longitudinal fissure. Although its anatomy varies widely across individuals, the ACoA typically gives off two or three fine branches that supply oxygenated blood to the anterior commissure, caudate nucleus, cingulate cortex, corpus callosum, fornix, optic chiasm, septum pellucidum, and other structures within the basal forebrain and frontal lobes. The ACoA is one of the most common sites in the brain for the formation and subsequent rupture of aneurysms, the well-documented effects of which have been termed anterior communicating artery syndrome. These effects generally include problems with reasoning, abstraction, and other higher level cognitive processes (i.e., executive dysfunction), memory impairments, personality changes, and deficits in perceptual abilities and motor control.

anterior corticospinal tract see corticospinal tract.

anterior cranial fossa see fossa.

anterior horn 1. the frontmost division of each lateral ventricle in the brain. 2. see ventral horn.

anterior pituitary the anterior lobe of the pituitary gland. It manufactures and releases hormones such as prolactin, growth hormone, and trophic hormones. Also called adenohypophysis.

anterior–posterior axis a line or plane running from the front to the back of the body.

anterior–posterior development gradient the more rapid growth of the head region compared with posterior areas of the body during fetal development. In the early embryonic stages, the head and brain make up half of the body mass, and at birth, head size represents one quarter of the infant’s total height. See cephalocaudal.

anterior rhizotomy see rhizotomy.

anterior root see ventral root.

anterior spinothalamic tract see spinothalamic tract.

anterograde adj. moving or extending forward in time or in space.

anterograde amnesia see amnesia.

anterograde degeneration a pattern of neuron destruction following axonal injury that spreads forward along the axon, away from the nerve cell body. Also called Wallerian degeneration. Compare retrograde degeneration.

anterograde memory the ability to retain events, experiences, and other information following a particular point in time. When this ability is impaired (i.e., by injury or disease), it becomes very difficult or even impossible to recall what happened from that moment forward, a condition known as anterograde amnesia. For example, an individual with deficits of anterograde memory resulting from a stroke might not remember the name of a new person introduced to him or her but would remember the name of a close childhood friend. Compare retrograde memory.

anterograde transport see axonal transport.

anterolateral system a major somatosensory system consisting of the nerve fibers that originate mostly from dorsal horn cells and ascend in the white matter of the spinal cord, conveying information about pain, temperature, and touch to higher centers. It includes the spinothalamic tract, the spinoetocircular tract, traveling through the spinal cord to the reticular formation of the brainstem; and the spinomesencephalic tract, traveling through the spinal cord to the mesencephalon (midbrain).

anthropo- combining form human.

anthropocentrism n. the explicit or implicit assumption that human experience is the central reality and, by extension, the idea that all phenomena can be evaluated in the light of their relationship to humans. —anthropocentric adj.

anthropogenesis n. the scientific study of the origins and development of humans. Also called anthroplogy. —anthropogenetic or anthropogenetic adj.
anthropoid adj. resembling a human being. The term is usually applied to apes: specifically, gorillas, orangutans, chimpanzees, bonobos, and gibbons.

anthropological linguistics the branch of linguistics that draws connections between the characteristics of a particular language and the cultural practices, social structures, and worldview of the society in which it is spoken (see LINGUISTIC DETERMINISM; LINGUISTIC RELATIVITY). The field developed primarily from an interest in describing languages indigenous to North America, such as Navajo and Hopi.

anthropology n. the study of human beings. This typically involves the description and explanation of similarities and differences among human groups in their languages, aesthetic expressions, belief systems, and social structures over the range of human geography and chronology. Physical anthropology focuses on the origin, evolution, and environmental adaptation of human groups, whereas sociocultural anthropology is concerned with the development and functioning of customs, beliefs, and institutions. Outside of the United States, this latter subdivision is often called ETHNOLOGY. —anthropological adj. —anthropologist n.

anthropometry n. 1. the scientific study of how the size and proportions of the human body are affected by such variables as age, sex, and ethnicity. 2. the taking of measurements of the human body for purposes of comparison and study. —anthropometric adj. —anthropometrist n.

anthropomorphism n. 1. the attribution of human characteristics to nonhuman entities such as deities, spirits, animals, plants, or inanimate objects. It is a fundamental tendency of the human imagination as reflected in language, religion, and art. 2. in COMPARATIVE PSYCHOLOGY, the tendency to interpret the behavior and mental processes of nonhuman animals in terms of human abilities. A variation is ANTHROPONCENTRISM, which uses human experience as the standard by which the behavior or mental processes of nonhuman animals, for example, ANIMAL INTELLIGENCE, is evaluated. See also LLOYD MORGAN’S CANON. Compare ZOOPHORISM. —anthropomorphic adj.

anthroponomy n. the science of human development as it relates to the development of other organisms and to the environment. —anthroponomical adj.

anthroposcopy n. the practice of judging the body build of an individual by inspection, rather than by use of anthropometric techniques of body measurement. —anthroposcopic adj.

anti- (ant-) prefix 1. opposing or against (e.g., ANTICONFORMITY). 2. opposite to (e.g., ANTIMITROPIA). 3. counteracting or inhibiting (e.g., ANTIDEPRESSANT).

antiaging remedy any intervention that is hypothesized to slow down or reverse the effects of aging. Typically these interventions are pharmacological (e.g., antioxidants, vitamin C, growth hormones), but they also can be lifestyle changes (e.g., exercise).

antiandrogen n. a substance that reduces or blocks the physiological effects of androgens, the male sex hormones, on tissues normally responsive to these hormones. Examples include bicalutamide (U.S. trade name: Casodex), finasteride (U.S. trade name: Propecia; Proscar), flutamide (U.S. trade name: Eulexin), and nilutamide (U.S. trade name: Nilandron). They correct the effects of excessive levels of male sex hormones and may be used to control hair loss and prostate cancer in males and to reverse masculine traits (e.g., excessive facial hair) in females. More controversially, antiandrogens have been used in the treatment of repeat sex offenders (see CHEMICAL CASTRATION). Also called androgen antagonist.

antianxiety medication see ANXIOLYTIC.

antibiotic n. a drug used to destroy pathogenic or otherwise harmful microorganisms, especially bacteria. Antibiotics can be produced by or obtained from living cells (e.g., molds, yeasts, bacteria) or manufactured as synthetic chemicals with effects similar to natural antibiotics. Some work by interfering with bacterial reproduction, whereas others may disrupt the normal life functions of the pathogen. Antibiotics are ineffective against viruses. Overuse and inappropriate use of these agents are contributing to the development of bacterial resistance to many commonly used antibiotics.

antibody n. a modified protein molecule, produced by B LYMPHOCYTES, that interacts with an ANTIGEN and renders it harmless (see IMMUNE RESPONSE). Each type of antibody is designed to interact with a specific antigen and can be mass-produced by the body following exposure to an identical antigen. See ANTIGEN–ANTIBODY REACTION; IMMUNITY.

anticathexis n. in psychoanalytic theory, a process in which the ego withdraws psychic energy from certain unconscious wishes and ideas and uses it to strengthen other wishes and ideas capable of blocking the decathected material’s entrance into consciousness. The anticathedted material may be similar to the original or opposite but related to it: For example, philanthropy may neutralize an unconscious wish to hoard. Also called countercathexis. See also CATHEXIS. —anticathedected adj.

anticholinergic drug any pharmacological agent that blocks or otherwise interferes with the release of the neurotransmitter acetylcholine and thus disrupts the transmission of impulses along parasympathetic routes. Anticholinergic drugs act at acetylcholine receptors, with the majority of such drugs acting at MUSCARINIC RECEPTORS and known as antimuscarinic drugs; the others act at NICOTINIC RECEPTORS and are known as antinicotinic drugs. In large doses, anticholinergic drugs may also interfere with actions of histamine, serotonin, and norepinephrine. Natural anticholinergic drugs include ATROPINE and SCOPOLAMINE. A variety of synthetic anticholinergic drugs are used to treat neurological disorders, many as ANTI-PARKINSONIAN DRUGS. They include BENZTROPINE, BIPERIDEN, PROCYCLIDINE, and TRHYXYPHENIDYL, which are administered primarily to relieve the symptoms of muscular rigidity. Anticholinergic drugs are often used in combinations to control specific symptoms. TRICYCLIC ANTIDEPRESSANTS and some conventional ANTISPASTICS also have anticholinergic activity. Also called PARASYMPATHOLYTIC DRUG.

anticholinergic effects side effects that are characteristic of anticholinergic drugs and are also associated with other agents (e.g., TRICYCLIC ANTIDEPRESSANTS). MONOAmine OXIDASE INHIBITORS that exert antagonist effects at MUSCARINIC RECEPTORS. They include dry mouth, blurred vision, urinary hesitancy or retention, and constipation. Similar antagonistic effects may occur at NICOTINIC RECEPTORS as well. Depending on the specific receptors involved, some effects may also be called antimuscarinic effects or antinicotinic effects.

anticholinergic syndrome a disorder produced by
anticholinergic drugs and due to their antagonistic effects at acetylcholine receptors, marked by symptoms involving both the peripheral and central nervous systems. The former include dry mucous membranes, dry mouth, and flushed skin and face, whereas the latter include ataxia (unsteady gait), drowsiness, slurred speech, confusion and disorientation, hallucinations, and deficits of short-term memory. Tricyclic antidepressants, aliphatic phenothiazines, antiparkinsonian agents, and scopolamine are examples of drugs that can cause anticholinergic syndrome. This syndrome is often observed in patients receiving combinations of such drugs.

**anticholinesterase** n. see CHOLINESTERASE.

**anticipation** n. 1. looking forward to a future event or state, sometimes with an affective component (e.g., pleasure, anxiety). 2. the onset of a hereditary disease at earlier and earlier ages in successive generations.

**anticipation learning method** see SERIAL ANTICIPATION METHOD.

**anticipatory anxiety** worry or apprehension about an upcoming event or situation because of the possibility of a negative outcome, such as danger, misfortune, or adverse judgment by others. The worry or apprehension is often accompanied by somatic symptoms of tension. Anticipatory anxiety is a common feature of PANIC DISORDER, in which the concern is over the possibility of experiencing future panic attacks.

**anticipatory attitude change** an alteration in one’s attitude toward something that occurs when one is told to expect a persuasive message on the subject (the direction is unknown). When the topic of the anticipated message is very important, attitudes polarize in the direction of the initial attitude. When the topic is of little importance, attitudes become more moderate.

**anticipatory coping** a stress-management strategy in which one seeks to avoid or minimize problems associated with a critical event occurring in the near future that involves potential risk. Examples of such events include a scheduled public speech, a job interview, an exam, or a promotion. Anticipatory coping thus can be understood as the management of known risks, involving efforts to solve the actual problems (e.g., by increasing effort, by enlisting help, by investing other resources) or to feel good in spite of the risks (e.g., by redefining the situation as less threatening, by distraction, by gaining reassurance from others). It is assumed to increase with middle and old age and is one of four types of coping proposed by German psychologists Ralf Schwarzer (1943— ) and Nina Knoll, the others being PREVENTIVE COPING, PROACTIVE COPING, and REACTIVE COPING.

**anticipatory error** 1. the error of making a response before it should be made. 2. an error in which an item is recalled as having been earlier in a list than it actually was.

**anticipatory grief** sorrow and anxiety experienced by someone who expects a loved one to die within a short period. The period of anticipatory grief can be regarded as having both stressful and constructive possibilities: It might cushion the emotional impact when the death actually occurs, but it could have the unfortunate consequence of leading a person to withdraw from the relationship, treating the other person as though he or she were already dead. See also COMPLICATED GRIEF: TRAUMATIC GRIEF, [introduced as a concept in 1944 by U.S. psychiatrist Erich Lindemann (1900–1974)].

**anticipatory guidance** counseling and educational services provided to individuals or families before they reach a turning point or significant developmental change in their lives. Examples include parental guidance before a child enters school and counseling of employees soon to reach retirement age.

**anticipatory image** a mental image that allows one to envision transformations of that image, even if one has never experienced such transformations in the past. According to PIAGETIAN THEORY, anticipatory images are not produced until the CONCRETE OPERATIONAL STAGE. Compare REPRODUCTIVE IMAGE.

**anticipatory movement** a movement that is based on (a) expected changes in the environment (e.g., predictive smooth eye or hand movements to track a moving stimulus); (b) expected postural necessity (e.g., to maintain balance when shifting a limb); or (c) preparation for an upcoming action (e.g., prepositioning movements, such as lip rounding in speech).

**anticipatory nausea** nausea that occurs prior to chemotherapy (typically during the day before administration). Nausea and vomiting can also occur after an individual has received a few treatments, usually in response to triggers in the environment (e.g., odors and sights of the hospital room) that have been associated with the physical side effects of chemotherapy.

**anticipatory pleasure** enjoyment that is related to reward motivation and to activities targeting desired outcomes; that is, pleasure from knowing that one will soon be rewarded in goal-directed behavior. It contrasts with CONSUMMATORY PLEASURE, which results from the satisfaction of a desire.

**anticipatory regret** a sense of the potential negative consequences of a decision that influences the choice made. For example, an individual may decide not to make an investment because of the feelings associated with an imagined loss. See PROSPECT THEORY.

**anticipatory response** a response that occurs before the evoking stimulus is presented.

**anticipatory schema** in the PERCEPTUAL CYCLE HYPOTHESIS, a structured pattern of knowledge (a “preunderstanding”) that influences an organism’s expectations in a given situation, thus guiding the organism’s perception of that situation (i.e., by preparing it to receive certain kinds of information or to perceive particular aspects of the situation) and ultimately directing its exploration and action. For example, a student entering an unfamiliar classroom for the first time may invoke a general classroom schema, which likely contains information about the general characteristics of such a room (the presence of a floor, a ceiling, four walls, a blackboard, desks, etc.) and leads the person to expect to encounter these things within this novel classroom. Since the general classroom schema does not contain information suggesting the presence of, say, a washing machine, the student would not spend time looking for this unanticipated item. Anticipatory schemas are dynamic rather than static; although based on previous experience, they are continuously being revised as a result of new experiences. [defined in 1976 by Ulric NEISSER]

**anticonfirmationism** n. the position that it is not possible to confirm the truth of general propositions, including scientific hypotheses, either by accruing positive instances or by probability estimates. See FALSIFICATIONISM.
anticonformity

**anticonformity** n. a deliberate, self-conscious refusal to comply with accepted social standards, often accompanied by the expression of ideas, beliefs, or judgments that challenge those standards. Anticonformity is motivated by rebelliousness or obstinacy rather than the need to express oneself sincerely. Also called **counterconformity**. Compare **CONFORMITY**; **NONCONFORMITY**.

**anticonvulsant** n. any drug used to reduce the frequency or severity of epileptic seizures or to terminate a seizure already underway. Until the advent of the HYDANTOINS in the 1930s, anticonvulsants consisted mainly of BROMIDES and BARBITURATES; PHENOBARBITAL was first used in the treatment of epilepsy in 1912 and remained the mainstay of treatment until the introduction of the hydantoin PHENYTOIN. Drugs now used to treat partial or tonic–clonic seizures include phenytoin, CARBAMAZEPINE, VALPROIC ACID, phenobarbital, and newer anticonvulsants, such as LAMOTRIGINE, GABAPENTIN, tiagabine, TOPIRAMATE, vigabatrin, and zonisamide. Ethosuximide and other SUCCINIMIDES may be used in managing absence seizures. The BENZODIAZEPINES are also effective antiseizure medications. Also called **antiepileptic**.

**antidepressant** n. any drug administered in the treatment of depression. Most antidepressants work by increasing the availability of monoamine neurotransmitters such as norepinephrine, serotonin, or dopamine, although they do so by different routes. The MONOAmine OXIDase INHIBITORS (MAOIs) work by inhibiting monoamine oxidase, one of the principal enzymes that metabolize these neurotransmitters. Most of the other antidepressants, including the TRICYCLIC ANTIDEPRESSANTS (TCAs) and the selective serotonin reuptake inhibitors (see SSRIs), inhibit the reuptake of serotonin or norepinephrine (and to a much lesser degree dopamine) into the presynaptic neuron. Either process leaves more of the neurotransmitter free to bind with postsynaptic receptors, initiating a series of events in the postsynaptic neuron that is thought to produce the actual therapeutic effect. In 2007, a BOXED WARNING was added to the labeling of all antidepressants, stating that the risk of suicidal thinking and actual suicide increased in children, adolescents, and young adults taking antidepressants versus those taking placebo in short-term studies of MAJOR DEPRESSIVE DISORDER and that, since depression itself is associated with an increased suicide risk, all patients newly on antidepressant medications should be monitored appropriately.

**antidiuretic hormone (ADH)** see VASOPRESSIN.

**antidromic conduction** the conduction of a nerve impulse in a reversed direction (i.e., from axon to cell body), produced for experimental purposes. Also called **antidromic activation**: **antidromic phenomenon**.

**antiepileptic** n. see **ANTICONVULSANT**.

**antiestrogen** n. a substance that reduces or blocks the physiological effects of estrogens, the female sex hormones, on tissues normally responsive to these hormones. Examples include tamoxifen (U.S. trade name: Nolvadex), TOREMIFENE (U.S. trade name: Fareston), fulvestrant (U.S. trade name: Faslodex), and selective estrogen receptor modulators (SERMs), such as raloxifene (U.S. trade name: Evista), which have both inhibitory and facilitative effects upon different pathways mediated by estrogen receptors. Antiestrogens are used in the treatment or prevention of breast cancer and some estrogenically mediated effects of menopause, as well as in the treatment of some types of female infertility. Also called **estrogen antagonist**.

**antigen** n. any substance that is treated by the immune system as foreign and is therefore capable of inducing an IMMUNE RESPONSE, particularly the production of **ANTIBODIES** that render it harmless. The antigen may be a virus, a bacterium, a toxin (e.g., bee venom), or tissue (e.g., blood) of another individual with different genetic characteristics. —**antigenic adj**.

**antigen–antibody reaction** the binding of an ANTI- BODY to its particular ANTIGEN as part of the body’s natural defense against the introduction of a foreign substance. The bound antibody renders the foreign substance more susceptible to degradation by immune cells, for example, engulfment by phagocytic cells. Once the individual’s IMMUNE SYSTEM has developed antibodies to fight a certain type of antigen, the antibodies can be mobilized quickly to destroy any repeated invasion by the antigen; thus, the first antigen attack induces IMMUNITY to future attacks. See also **IMMUNE RESPONSE**.

**antignadal action** the blocking of gonadal function by an agent or process, such as a lesion in the pituitary gland or amygdala.

**antiharassment policies** policies and procedures adopted by an organization or institution to prevent and counter harassment due to gender, race, or sexual orientation. They typically include alerting people that antiharassment policies are in place, conducting awareness training designed to educate people about harassment, implementing disciplinary measures when necessary, and having formal grievance procedures.

**antihistamine** n. any drug or agent that inhibits the effects of HISTAMINE at central or peripheral histamine receptors, especially H1 receptors. They may have sedative effects and are a common component of over-the-counter sleeping aids. Some are used in the treatment of allergic reactions or motion sickness (see **DIPHENDYDRAMINE; DI-MENHYDRINATE**). The so-called **nonsedating antihistamines** have less ability to cross the BLOOD–BRAIN BARRIER and are used solely in the management of allergic responses. Also called **histamine antagonist**.

**anti-intoxicant** n. a theoretical drug that would have the effect of countering the intoxicating effects of alcohol. Also called amethystic.

**antilibrinal ego** in the OBJECT RELATIONS THEORY of British psychoanalyst W. Ronald D. Fairbairn (1889–1964), the portion of the EGO structure that is similar to Sigmund Freud’s SUPEREGO. The antilibidinal ego constitutes a nonpleasure-gratifying, self-deprecatory, or even hostile self-image; it is posited to develop out of the unitary ego present at birth when the infantile libidinal ego (similar to the ID) experiences deprivation at the hands of the parent and the infant suppresses his or her frustrated needs. Also called **internal saboteur**. See **FAIRBAIRNIAN THEORY**.

**Antilirium** n. a trade name for PHYSOSTIGMINE.

**antimanic drug** see MOOD STABILIZER.

**antimetabolite** n. a substance that has a molecular structure so similar to that of another substance required for a normal physiological function that it may be accepted as the required molecule, thereby disrupting a normal metabolic process. For example, the anticoagulantbishydroxycoumarin functions as an antimetabolite by interfering...
with vitamin K in producing the blood-clotting agent prothrombin.

**antimetropia** n. a condition in which one eye is myopic (nearsighted) and the other is hyperopic (farsighted).

**anti-Müllerian hormone** (AMH) see MÜLLERIAN-INHIBITING HORMONE.

**antimuscarinic drug** see ANTICHOLINERGIC DRUG.

**antinicotinic drug** see ANTICHOLINERGIC DRUG.

**antinociceptive adj.** describing or relating to any factor that increases tolerance for, or reduces sensitivity to, harmful stimuli, usually stimuli that cause pain. See also PAIN PERCEPTION.

**antinodal behavior** see NODAL BEHAVIOR.

**antinomy** n. 1. In common usage, a state of opposition or contradiction between two things. 2. In the thought of Immanuel Kant, a contradiction between two a PRIORI propositions in metaphysics, each of which can be supported by equally valid proofs. Kant cited a series of such antinomies as part of his argument against speculative metaphysics and in favor of his own position that the only world one can have knowledge of is the world of PHENOMENA.

**antioxidant** n. a substance, such as beta-carotene, lutein, lycopene, selenium, and vitamins A, C, and E, that may protect cells against the effects of FREE RADICALS by inhibiting or removing oxidation.

**antiparkinsonian drug** any pharmacological agent that reduces the severity of symptoms of Parkinson’s disease or drug-induced parkinsonism (common with the use of conventional ANTIPTSYCHOTICS), including tremors, movement and gait abnormalities, and muscle rigidity. Such agents include antihistamines (e.g., DIPHENYDRAMINE), anticholinergic drugs (e.g., BENZTOPINE, TRIHEXYPHENIDYL), Dopamine-Receptor AGONISTS, and specific enzyme inhibitors of CATECHOL-O-METHYLTRANSFERASE (COMT) and of MAO-B (see MONOAMINE OXIDASE).

**antipathy** n. strong aversion or deep-seated dislike. See also PREJUDICE. —antipathetic adj.

**antipredator behavior** all forms of action by an organism that function to avoid being captured, wounded, or killed by another organism, including ANTIPTSYCHOTIC AGGRESSION, DEFENSIVE BEHAVIOR, and MOBBING as well as VIGILANCE, IMMObILITY, THE CONFUSION EFFECT, the DELTION EFFECT, and flight or other evasive action. To respond adaptively to predation threats and increase their chances of survival, prey animals have to be able to recognize their potential predators. Even though a few studies have demonstrated innate predator recognition, the vast majority of animals have to rely on learning to acquire this information.

**antipredator defense** any means by which nonhuman animals avoid predation. It can take the form of CAMOUFLAGE, BATESIAN MIMICRY, MÜLLERIAN MIMICRY, WARNING COLORATION, or various forms of ANTIPTSYCHOTIC BEHAVIOR.

**antipredatory aggression** attack behavior directed toward a potential predator as a form of defense. See AGGRESSION: DEFENSIVE BEHAVIOR.

**antipsychiatry** n. an international movement that emerged in the 1960s under the leadership of British psychiatrist R. D. Laing (1927–1989). South African psychiatrist David Cooper (1931–1986), Italian psychiatrist Franco Basaglia (1924–1980), and U.S. psychiatrist Thomas S. Szasz (1920–2012). Antipsychiatrists contested the scientific and practical validity of psychiatry and radically opposed what they understood as a hospital-centered medical specialty legally empowered to treat and institutionalize individuals with mental disorders. Indeed, many antipsychiatrists argued against the very existence of mental disorders themselves, advancing the notion that they are not illnesses at all but rather alternative ways of behaving that alarm people. They viewed psychiatry as a form of social repression and a means to control deviance, and treatment as a disguised form of punishment. —antipsychiatrist n.

**antipsychotic** n. any pharmacological agent used to control the symptoms of schizophrenia and other disorders characterized by impaired reality testing, as evidenced by severely disorganized thought, speech, and behavior. Formerly called major tranquilizers and later neuroleptics, antipsychotics are commonly divided into two major classes: CONVENTIONAL or typical (first-generation) antipsychotics, which were developed in the 1950s and include the PHENOTHIAZINES and BUTYROPHENONES, and the newer atypical (novel or second-generation) antipsychotics, of which CLOzapine is the prototype, first marketed in the United States in 1990. The latter class has fewer adverse side effects than the former, particularly the neurologically based EXTRAPYRAMIDAL SYMPTOMS but also the less serious yet unpleasant autonomic effects, such as dry mouth and blurred vision. However, the newer drugs have been associated with some serious metabolic and other effects (e.g., hyperglycemia, agranulocytosis).

**antipyretic** n. a drug that helps control fever or other manifestations of hyperthermia (raised body temperature) by acting on the thermoregulatory center in the hypothalamus. Antipyretics may also help the body to dissipate heat faster by diluting peripheral arteries. Aspirin and other nonopiod analgesics function as antipyretics.

**Anti-Semitism Scale** (A-S Scale) a personality test that measures five aspects of anti-Semitism, including perceptions of Jews as personally offensive and socially threatening, hostile attitudes that suggest what should be done to Jews, and presumptions that Jews are too exclusive. See also F SCALE. [constructed in 1950 by German-born U.S. philosopher and social theorist Theodor Adorno (1903–1969), Polish-born U.S. psychologist Else Frenkel-Brunswik (1908–1958), and colleagues in their analysis of the AUTHORITARIAN PERSONALITY]

**antisocial adj.** denoting or exhibiting behavior that sharply deviates from social norms and also violates other people’s rights. Arson and vandalism are examples of antisocial behavior. Compare PROSOCIAL.

**antisocial aggression** any act of instrumental AGGRESSION that has socially destructive and undesirable consequences, such as rape or murder. Compare PROSOCIAL AGGRESSION.

**antisocial personality disorder** the presence of a chronic and pervasive disposition to disregard and violate the rights of others. Manifestations include repeated violations of the law, exploitation of others, deceitfulness, impulsivity, aggressiveness, reckless disregard for the safety of self and others, and irresponsibility, accompanied by lack of guilt, remorse, and empathy. The disorder has been known by various names, including dyssocial personality.
psychopathic personality, and sociopathic personality. It is among the most heavily researched of the personality disorders and the most difficult to treat. It is included in both DSM–IV–TR and DSM–5.

antispasmodic drug any pharmacological agent used in the management of spasms of smooth muscle. Such drugs are commonly used to treat gastrointestinal conditions such as IRRITABLE BOWEL SYNDROME.

antiterrorist activities security programs to detect and counter terrorist activities, including those involving potential chemical and biological attacks.

antithesis n. 1. a THESIS, idea, or proposition that is opposite to or contradicts another. 2. in philosophy, the second stage of a dialectical process based on proposition, contradiction, and the reconciliation of these (thesis, antithesis, and SYNTHESIS). The term is often associated with German philosopher Georg Wilhelm Friedrich Hegel (1770–1831) and his theory of the dialectical development of ideas, although it was not a term he used in his analysis. See also DIALECTICAL MATERIALISM. —antithetical adj.

antitussive n. a drug that suppresses coughing by affecting the cough-control center in the medulla oblongata of the brain. Among antitussives are the opioid codeine and dextromethorphan; from 1898 until 1924 when it became illegal, heroin was marketed as an antitussive. Also called cough suppressant.

antiviral drug any substance that interferes with the normal functioning of viruses. Antiviral drugs may act by blocking host-cell enzyme systems required for viral reproduction, by blocking signals carried in messenger RNA, or by uncoating the nucleic acid molecule of the virus. These drugs are difficult to manage in clinical practice because chemicals that block viral processes may also interfere with the patient’s normal cell functions. However, antivirals occasionally interact with substances in human tissues to yield unexpected benefits, as with AMANTADINE, which can be used as an antiparkinsonian agent.

antivitamin n. a substance that interferes with the functions of vitamins. Most antivitamins are chemicals that are similar in structure to the vitamins they render ineffective. They are used mainly in studies and tests of vitamin deficiencies.

Antoni’s syndrome a rare disorder marked by the lack of awareness of blindness. The person genuinely believes he or she can see despite clinical evidence of loss of vision, such as difficulties in getting around, handling objects, and so forth. The condition is a type of visual ANOSOGNOSIA resulting from injury to the occipital lobe of the brain. [first described in 1899 by Gabriel Anton (1858–1933), Austrian physician]

antonym n. a word that has the opposite meaning to another word in the same language. After, for example, is the antonym of before. Compare SYNONYM. —antonymous adj.

antonym test an examination in which the respondent is presented with a word and asked to supply a word with the opposite meaning to it (e.g., being given true and replying false). Also called opposites test.

anvil n. see OSSICLES.

anxiety n. an emotion characterized by apprehension and somatic symptoms of tension in which an individual anticipates impending danger, catastrophe, or misfortune. The body often mobilizes itself to meet the perceived threat: Muscles become tense, breathing is faster, and the heart beats more rapidly. Anxiety may be distinguished from FEAR both conceptually and physiologically, although the two terms are often used interchangeably. Anxiety is considered a future-oriented, long-acting response broadly focused on a diffuse threat, whereas fear is an appropriate, present-oriented, and short-lived response to a clearly identifiable and specific threat. —anxious adj.

anxiety attack see PANIC ATTACK.

anxiety discharge any anxiety-reducing action or repetitive activity (e.g., exercise, knitting, weeding a garden) associated with normal daily living, viewed as an alternative to suppression of anxiety.

anxiety disorder any of a group of disorders that have as their central organizing theme the emotional state of fear, worry, or excessive apprehension. This category includes, for example, PANIC DISORDER, various phobias (e.g., SPECIFIC PHOBIA, SOCIAL PHOBIA), and GENERALIZED ANXIETY DISORDER. Anxiety disorders have a chronic course, albeit waxing and waning in intensity, and are among the most common mental health problems in the United States. They may also occur as a result of the physiological effects of a medical condition, such as endocrine disorders (e.g., hyperthyroidism), respiratory disorders (e.g., chronic obstructive pulmonary disease), cardiovascular disorders (e.g., arrhythmia), metabolic disorders (e.g., vitamin B12 deficiency), and neurological disorders (e.g., Parkinson’s disease). OBSESSIVE-COMPULSIVE DISORDER and POSTTRAUMATIC STRESS DISORDER were traditionally considered anxiety disorders; however, they are increasingly considered, as in DSM–5, to be separate, if still related, entities.

anxiety fixation in psychoanalysis, the maintenance or continuation of an anxiety reaction from an earlier developmental stage into a later one.

anxiety hierarchy a series of graduated anxiety-arousing stimuli centering on a specific source of anxiety in a specific individual. It is used in the treatment of phobias by SYSTEMATIC DESENSITIZATION: Patients proceed along the hierarchy from the least threatening situation toward the most threatening situation.

anxiety hysteria in psychoanalysis, a neurosis in which the anxiety generated by unconscious sexual conflicts is expressed in phobic symptoms, such as an irrational fear of dirt or open spaces, and in physical disturbances that are conversion symptoms. The term is seldom used because it combines disorders that are now classified separately. See ANXIETY DISORDER; CONVERSION DISORDER. [defined by Sig-mund FREUD]

anxiety management cognitive-behavioral, behavioral, or other techniques that aid in the reduction of anxiety, such as BIOFEEDBACK training, RELAXATION TECHNIQUES, or medication.

anxiety neurosis in psychoanalysis, a disturbance in which the most prominent symptoms are persistent anxiety and feelings of impending disaster, accompanied by such symptoms as difficulty in making decisions, insomnia, loss of appetite, and heart palpitations. This term is now seldom used: The current classification of chronic anxiety of this nature is GENERALIZED ANXIETY DISORDER. Also called anxiety state. See also ANXIETY DISORDER.

anxiety object in psychoanalysis, an object upon which
anxiety originally caused by another source is displaced. For example, a nonhuman animal may be feared because it represents the father who caused the original anxiety. See LITTLE HANS.

**anxiety-performance relationship** see Arousal-performance relationship.

**anxiety reaction** an emotional response characterized by marked apprehension and accompanied by somatic symptoms of tension.

**anxiety-relief response** in BEHAVIOR THERAPY, the repetition of reassuring or tranquilizing words (e.g., _calm_) in anxiety-provoking situations.

**anxiety scale** any of numerous assessment instruments designed to measure the severity of anxiety symptoms. An important example is the TAYLOR MANIFEST ANXIETY SCALE. Such scales usually take the form of self-report tests but can also be based on clinician ratings or actual performance.

**anxiety sensitivity** fear of sensations associated with anxiety because of the belief that they will have harmful consequences. For example, an individual with high anxiety sensitivity is likely to regard feeling light-headed as a sign of impending illness or fainting, whereas an individual with low anxiety sensitivity would tend to regard this sensation as simply unpleasant. Research indicates that anxiety sensitivity is a traitlike risk factor that has been linked to the development of PANIC ATTACKS and PANIC DISORDER. [defined in 1985 by U.S. clinical psychologists Steven Reiss and Richard J. McNally]

**anxiety state** 1. see ANXIETY NEUROSIS. 2. formerly, a traumatic neurosis precipitated by a wartime experience in which the ego-ideals of war conflict with customary ideals. [defined by Sigmund Freud]

**anxiolytic** n. a drug used in the treatment of anxiety, mild behavioral agitation, and insomnia. Formerly called _minor tranquilizer_. anxiolytics can also be used as adjunctive agents in the treatment of depression, panic disorder, and several other disorders. The most widely used are the _BENZODIAZEPINES_. Other drugs, such as certain SSRIs, have also been shown to have anxiolytic effects. See also _AZAPIRONE_, _SEDATIVE_, _HYPNOTIC_, and _ANXIOLYTIC DRUG_.

**anxious-ambivalent attachment style** see AMBIVALENT ATTACHMENT.

**anxious-avoidant attachment** 1. in the STRANGE SITUATION, a form of INSECURE ATTACHMENT in which an infant explores only minimally and tends to avoid or be indifferent to the parent. 2. an adult interpersonal style characterized by discomfort in being with others and a tendency to avoid intimate relationships with them. Also called _avoidant attachment style_. it is sometimes identified as taking two forms: _DISMISSIVE ATTACHMENT_ and _FEARFUL ATTACHMENT_.

**anxious depression** a MAJOR DEPRESSIVE EPISODE accompanied by high levels of anxiety.

**anxious-resistant attachment** in the STRANGE SITUATION, a form of INSECURE ATTACHMENT in which an infant appears anxious in the parent’s presence, distressed in the parent’s absence, and angry upon the parent’s return, often resisting contact with him or her.

**aortic arch syndrome** a disorder caused by progressive obliteration of the main branches of the aortic arch because of arteriosclerosis, aneurysm, or a related problem. Usually only one or two of the branches are involved, affecting blood flow to a local area. If the carotid or vertebral arteries are involved, the brain will be affected. The patient may experience fainting spells, epilepsy-like seizures, temporary blindness, paralysis on one side of the body, aphasia, memory disturbances, or a combination of symptoms. A typical effect is the _carotid-sinus syndrome_, in which the patient faints after turning the head.

**aortic stenosis** see STENOSIS.

AP 1. abbreviation for ACTION POTENTIAL. 2. abbreviation for advanced placement. See ADVANCED PLACEMENT EXAMINATIONS.

**APA** 1. abbreviation for AMERICAN PSYCHIATRIC ASSOCIATION. 2. abbreviation for AMERICAN PSYCHOLOGICAL ASSOCIATION.

**APAGS** abbreviation for AMERICAN PSYCHOLOGICAL ASSOCIATION OF GRADUATE STUDENTS.

**APAP** n. see ACETAMINOPHEN.

**apareunia** n. the inability to perform sexual intercourse.

**apasia** n. fasting or abstinence from food.

**APA style** guidelines and standards for writing (e.g., grammar) and formatting (e.g., data display, headings) for students, instructors, researchers, and clinicians in the social and behavioral sciences, as collected in the PUBLICATION MANUAL OF THE AMERICAN PSYCHOLOGICAL ASSOCIATION.

**apathy** n. lack of motivation or goal-directed behavior and indifference to one’s surroundings. Apathy is commonly associated with severe depression or schizophrenia, but it also is a major behavioral symptom in Alzheimer’s disease, Parkinson’s disease, and other neurodegenerative disorders. —apathetic adj.

**apathy syndrome** 1. the lack of motivation and interest displayed by many patients with Alzheimer’s disease, Parkinson’s disease, stroke, and such mental disorders as schizophrenia and severe depression. 2. the pattern of emotional insulation (indiffERENCE, detachment) adopted by many prisoners-of-war and victims of catastrophes in an effort to maintain their stability.

**APDA** abbreviation for AMERICAN PARKINSON DISEASE ASSOCIATION, INC.

**aperiodic reinforcement schedule** a former name for VARIABLE-INTERVAL SCHEDULE.

**Apert syndrome** an inherited condition in which an abnormally shaped head due to premature closure of some of the cranial sutures (see CRANIOSYNDOSTOSIS SYNDROME) is accompanied by intellectual disability and syndactyly. The syndactyly usually involves both hands and feet and typically results in fusion of the skin and bones, marked by “mitten hands” and “sock feet.” Apert syndrome may be complicated by CROUZON SYNDROME (and called Apert–Crouzon syndrome), in which case fusion of the digits is partial. See also ACROCEPHALOSYNDACTLY. [Eugène Apert (1868–1940), French pediatrician]

**aperture, draw, syntax model** (ADS model) a cognitive model in which ATTENTION is seen as having three principal characteristics: (a) _aperture_—attention is understood as a pathway comprised of multiple subpathways that open up for the processing of information according to specific domains of activity; (b) _draw_—attention involves a mechanism by which relevant stimuli are actively drawn
into processing (as opposed to irrelevant information being filtered out); and (c) *syntax*—attention involves a system of rules by which cues are recognized and assimilated and responses are initiated. [proposed in 2010 by U.S. philosopher and cognitive scientist Brian Bruya (1966—)]

**APF** abbreviation for AMERICAN PSYCHOLOGICAL FOUNDATION.

**Apgar score** an evaluation of newborn infants on five factors: skin color, heart rate, respiratory effort, reflexes, and muscle tone. The evaluation is typically performed at 1 minute and again at 5 minutes after birth to assess the physical condition of the infant and to determine quickly if he or she needs immediate medical care. Each factor is scored 0, 1, or 2, with a maximum total of 10 points. A score below 3 indicates that the infant is in severe distress; a score of 4 to 7 indicates moderate distress; and a score of 7 to 10 indicates that the infant’s condition is normal. [developed in 1952 by Virginia Apgar (1909—1974), U.S. anesthesiologist]

**aphagia** n. inability to swallow or eat. —*aphagic* adj.

**aphakia** n. the absence of the lens from the eye, a condition that may be congenital or the result of disease, injury, or surgery. —*aphakic* adj.

**aphanisis** n. 1. an obsolete term defined by British psychoanalyst Ernest Jones (1879—1958) to indicate total extinction of sexual desire. 2. more broadly, a term defined by French psychoanalyst Jacques Lacan (1901—1981) to mean total extinction of self. [from Greek *aphanes*, “invisi-”]

**aphasia** n. an acquired language impairment that results from brain damage typically in the left hemisphere. Common causes of damage include stroke, brain tumors, and cortical degenerative disorders (e.g., Alzheimer’s disease). Traditionally, a distinction has been made between expressive and receptive forms of aphasia, whereby individuals with the former primarily have difficulty producing spoken and written language and those with the latter primarily have difficulty comprehending spoken and written language. A more contemporary distinction, however, is commonly made between *fluent aphasias*, characterized by plentiful oral output consisting of well-articulated, easily processed, rational, and harmonious (from Greek *aphaeresis*, “invisi-”)

**aphasia** n. an acquired language impairment that results from brain damage typically in the left hemisphere. Common causes of damage include stroke, brain tumors, and cortical degenerative disorders (e.g., Alzheimer’s disease). Traditionally, a distinction has been made between expressive and receptive forms of aphasia, whereby individuals with the former primarily have difficulty producing spoken and written language and those with the latter primarily have difficulty comprehending spoken and written language. A more contemporary distinction, however, is commonly made between *fluent aphasias*, characterized by plentiful oral output consisting of well-articulated, easily produced, but inappropriate or meaningless utterances of relatively normal length and prosody (rhythm and intonation), and *nonfluent aphasias*, characterized by sparse, effortful utterances of short phrase length and disrupted prosody. Fluent aphasias are associated with posterior lesions that spare cortical regions critical for motor control of speech, whereas nonfluent aphasias are associated with anterior lesions that compromise motor and premotor cortical regions involved in speech production. Numerous types of aphasia exist, with eight classically identified: *anomic aphasia*, *Broca’s aphasia*, *conduction aphasia*, *global aphasia*, *mixed transcortical aphasia*, *transcortical motor aphasia*, *transcortical sensory aphasia*, and *Wernicke’s aphasia*. Also (but much less preferably) called *dysphasia*. —*aphasic* adj.

**aphemia** n. as originally defined by Paul Broca, a motor aphasia with nonfluent speech but intact language functions, as evidenced by intact writing. It contrasts with Broca’s aphasia, in which writing is also disrupted.

**aphonia** n. loss of the voice resulting from disease of or damage to the larynx or vocal tract.

**aphrodisiac** n. any agent or substance that facilitates sexual desire. Perfumes, foods such as raw oysters, and various drugs, particularly alkaloids such as YOHIMBINE, are thought to be aphrodisiacs.

**apical dendrite** the dendrite that extends from a pyramidal cell to the outermost surface of the cerebral cortex. Compare *basal dendrite*.

**aplasia** n. the arrested development of a body tissue or organ.

**Aplysia** n. a genus of molluscs that have a very simple nervous system and are often used to study neurophysiology; especially the neurophysiology of learning and memory. [initially studied by Austrian-born U.S. neuroscientist Eric Kandel (1929—)]

**apnea (apnoea)** n. temporary suspension of respiration. If the *apneic period* is long, the heart may slow and electroencephalogram changes may occur. Apnea can occur during sleep (see *SLEEP APNEA*) and is also found in many disorders, such as epilepsy and concussion. —*apneic* adj.

**apo-** prefix away from.

**apodia** n. the condition of being born with only one foot or with no feet. See also *ACHIERIA*.

**ApOE** abbreviation for *APOLIPOPROTEIN E*.

**apoenzyme** n. the protein component of an ENZYME. It must combine with a second component, a COENZYME, to make the enzyme functional.

**apolipoprotein E** (**ApOE**) a protein that may help break down *BETA-AMYLloid*. Individuals carrying a particular form of the ApOE gene, the ApoE4 allele, are more likely to develop Alzheimer’s disease and other conditions that damage the nervous system.

**Apollonian** adj. describing a state of mind that is well ordered, rational, and harmonious (from *Apollo*, the god of prophecy, music, and healing in Greek mythology). This modern use of the term was originated by Friedrich Nietzsche, who drew a contrast between the Apollonian and the dionysian sides of human nature.

**apomorphine** n. a morphine derivative used as an expectorant and to induce vomiting. It is also used in the treatment of dyskinesias in Parkinson’s disease and of erectile dysfunction.

**apoplexy** n. 1. an obsolete term for a HEMORRHAGIC STROKE. 2. hemorrhage into an organ, as in a pituitary apoplexy. —*apoplectic* adj.

**apoptosis** n. see *PROGRAMMED CELL DEATH*. —*apoptotic* adj.

**aposematic coloration** see *WARNING COLORATION*.

**a posteriori** denoting conclusions derived from observations or other manifest occurrences: reasoning from facts. Compare *a PRIORI*. [Latin, “from the latter”]

**a posteriori comparison** see *POST HOC COMPARISON*.

**apostilb** (symbol: asb) n. a unit of LUMINANCE equal to the luminance of a uniform diffuser emitting $1/\pi$ cd/m$^2$.

**apotemnophilia** n. 1. a PARAPHILIA in which a person is sexually aroused at the idea of having a limb amputated. Compare *ACROMOPHILIA*. 2. see *BODY INTEGRITY IDENTITY DISORDER*.

**APP** abbreviation for amyloid precursor protein. See *BETA-AMYLOID*.
apparatus n. 1. any instrument or equipment used in an experiment or other research. 2. in biology, a group of structures that perform a particular function. It may be microscopic, as in the intracellular GOLGI APPARATUS, or macroscopic, as in the VESTIBULAR APPARATUS.

apparent adj. 1. seeming or illusory. 2. in physics, denoting an observed state that is not in accordance with actual physical conditions. For example, apparent motion is a perception of motion induced by the motion of the observer rather than that of the observed entity. 3. obvious or manifest.

apparent distance the perceived distance of an object from an observer. The visual angle subtended by the image of the object is a powerful but imperfect cue for the apparent distance of the object.

apparent magnitude the brightness of an object, which depends on its luminosity and its distance from the observer.

apparent movement an illusion of motion or change in size of a visual stimulus. Several types have been identified and labeled with Greek letters, among them the familiar beta movement, in which successive presentations of stationary stimuli across the visual field produce the perception of a single, smoothly moving stimulus, and gamma movement, the seeming expansion of an object when it is suddenly presented and contraction when withdrawn. Also called apparent motion.

apparent size the perceived size of a stimulus. This depends on many factors in addition to the size of the stimulus on the retina, most importantly the perceived distance from the observer to the object. See also size constancy, size cue.

apparition n. 1. a visual illusion that results from distortion of a perceived object. Often interpreted as threatening, apparitions may be associated with a neurological or toxic disorder, such as ALCOHOL-INDUCED PSYCHOTIC DISORDER. 2. the perceived manifestation of a ghost or spirit. See also materialization, phantasm. 3. the act of becoming visible.

appeal n. in advertising, any aspect of a product or service that is highlighted in an attempt to arouse a sympathetic response from consumers. Appeals may be based on psychological studies of consumer desires or needs and may be as obvious as a practical package design or as subtle as an implied suggestion that the product might enhance the purchaser’s sexual attractiveness. Advertising appeals also may be directed toward a specific type of consumer personality. For example, a product appeal for a “conservative family car” might be directed toward younger or older men and women with fewer family responsibilities. Also called product appeal. —appeal vb.

appearance and performance enhancing drug see PERFORMANCE ENHANCING DRUG.

appearance–reality distinction the knowledge that the appearance of an object does not necessarily correspond to its reality. For example, a sponge shaped like a rock may look like a rock but is really a sponge. Children younger than 3 may have difficulty making appearance–reality distinctions.

appeasement behavior actions by one nonhuman animal that reduce the likelihood of attack or threatening behavior from another. This may involve taking a submission posture, reducing apparent body size (e.g., by crouching), or using vocal signals typical of young animals.

Appelt–Gerken–Lenz syndrome see ROBERTS SYNDROME.

apparence n. 1. the mental process by which a perception or an idea is assimilated into an individual’s existing knowledge (APPARECtIVE MASS). See also TENDENTIOUS APPERENCE. 2. the act or process of becoming conscious of a perception, so that it is recognized and understood. In appercptive forms of VISUAL AGNOSIA, this ability is lost or impaired. —apperceive vb. —appercptive adj.

appercptive mass the previously acquired knowledge with which a new perception or idea must be assimilated if it is to be understood by the perceive. [defined by German philosopher Johann Friedrich Herbart (1776–1841)]

appercptive visual agnosia see VISUAL AGNOSIA.

appersonation n. a delusion in which the individual believes himself or herself to be another person and assumes the characteristics of that other person. Also called appersonification.

appesstat n. a hypothetical area in the brain believed to regulate appetite and food intake. Although parts of the hypothalamus (see LATERAL HYPOTHALAMUS; VENTROMEDIAL NUCLEUS) and brainstem (see SOLITARY NUCLEUS) have been shown definitively to be involved in appetite and food intake, the idea of a single appesstat is probably overly simplistic.

appetite n. any desire, but particularly one for food or one relating to the satisfaction of any physiological need. Appetite is influenced by learning and prior experience and thus can be highly flexible. See also APPETITIVE BEHAVIOR. —appetitive adj.

appetite suppressant any agent that reduces desire for food and thus controls body weight, including the amphetamines and other stimulants (e.g., phenetermine, diethylpropion), sibutramine, and serotonin agonists (fenfluramine, dexfenfluramine). Use of the latter compounds, particularly in combination with phenetermine (so-called phen-ten), resulted in heart-valve defects, and this combination was removed from the market. Although appetite suppressants may result in short-term weight loss, there is no evidence that they achieve long-term weight reduction unless used in conjunction with a behavioral management program. Also called anorectant, anorexiant.

appetitive behavior 1. an active searching process that precedes consummatory behavior (see CONSUMMATORY RESPONSE) and is indicative of desire. Influenced by learning and prior experience, it is highly flexible and—in mating behavior—helps to establish or maintain sexual interaction prior to copulation. 2. feeding activity, which is influenced in part by the central nervous system, including areas of the brainstem and nuclei of the hypothalamus in the brain. Lesions of the ventromedial nucleus may result in excessive eating, whereas lesions of nuclei in the lateral hypothalamus may cause deficient eating.

appetitive conditioning a type of CLASSICAL CONDITIONING in which the UNCONDITIONED STIMULUS is a positive reinforcer, such as food.

appetitive stimulus a positive reinforcer (see POSITIVE REINFORCEMENT) or an UNCONDITIONED STIMULUS that an organism will approach, the effectiveness of which can be
modified by deprivation. For example, hunger can increase the effectiveness of food as an appetitive stimulus.

**appetitive system** 
EXTRAVERSION as represented by an individual’s relative sensitivity to positive or rewarding (appetitive) cues and stimuli and his or her processes for approaching them. Compare AVERSIVE SYSTEM. See also BEHAVIORAL APPROACH SYSTEM. [proposed by British psychologist Jeffrey Alan Gray (1934–2004)]

**applied behavior analysis (ABA)** the extension of B. F. SKINNER’S behavioral principles (i.e., operant conditioning) to practical settings. Variations of applied behavior analysis may be used clinically (in the form of BEHAVIOR MODIFICATION or BEHAVIOR THERAPY) as treatment for abnormal or problematic behaviors.

**applied linguistics** the field in which linguistic theories and methods are put to practical use. Contexts in which this occurs include language teaching, the treatment of language disorders, and various aspects of ARTIFICIAL INTELLIGENCE.

**applied psychoanalysis** the application of psychoanalytic principles to the study of art, literature, religion, anthropology, biography, history, philology, and philosophy. Sigmund FREUD’s own interpretations of Leonardo da Vinci, Moses, and Hamlet, as well as his studies of folklore and mythology, are prime examples.

**applied psychology** the application of the theories, principles, and techniques of psychology to practical concerns, such as problems of living or coping, education, vocational guidance, industry, ergonomics, consumer affairs, advertising, political campaigns, and environmental issues. It may be contrasted with theoretical psychology or academic psychology, in which the emphasis is on understanding for its own sake rather than on the utility of the knowledge.

**applied psychophysiology** the use or study of the principles and techniques of PSYCHOPHYSIOLOGY to improve health, performance, or quality of life. See also CLINICAL PSYCHOPHYSIOLOGY.

**applied relaxation** a technique in which clients are taught, in a stepwise fashion, to relax more and more rapidly over a series of sessions in order to master panic, anxiety, phobias, pain, and other symptoms. The goal is for clients to be able to relax in 20 to 30 seconds in situations in which their symptoms typically occur. See also PROGRESSIVE RELAXATION.

**applied research** studies conducted to solve real-world problems, as opposed to studies that are carried out to develop a theory or to extend basic knowledge. Examples include ACTION RESEARCH and EVALUATION RESEARCH. Compare BASIC RESEARCH.

**applied science** the use of scientific principles and theories to serve a practical human purpose rather than to extend knowledge for its own sake. Compare BASIC SCIENCE.

**applied sport psychology** the use or study of the use of SPORT PSYCHOLOGY to enhance or make consistent the performance of athletes.

**applied statistics** the use of statistical methods and procedures to understand data in psychology, sociology, economics, and other disciplines. Compare THEORETICAL STATISTICS.

**applied tension** a technique in BEHAVIOR THERAPY that focuses on changing physiological responses (e.g., low blood pressure leading to fainting) by having the client practice muscle tensing and releasing during exposure to increasingly anxiety-evoking stimuli associated with a feared situation. The technique was developed and is still primarily used for blood, injury, and injection phobias.

**applied verbal behavior** see VERBAL BEHAVIOR THERAPY.

**apport n.** 1. In SPIRITUALISM, the manifestation, allegedly by supernatural means, of physical objects during a séance. Such objects are regarded as signs or gifts from the spirits. See also MATERIALIZATION. 2. An object produced in this way.

**appraisal n.** the cognitive evaluation of the nature and significance of a phenomenon or event. —appraise vb.

**appraisal dimension** any of the criteria that account for a person’s evaluation of an interaction with the environment and the generation of an appropriate emotional response. Examples of appraisal dimensions include the goal relevance of an event, its stimulus novelty, its judged pleasantness or unpleasantness, and a judgment of one’s COPING POTENTIAL in relation to this event. Different AP- PRIAL THEORIES emphasize different appraisal dimensions. See also STIMULUS EVALUATION CHECKS.

**appraisal motive** see SELF-ASSESSMENT MOTIVE.

**appraisal theory** a group of theories stating that people’s cognitive appraisals or evaluations of a situation determine the emotions they feel in response to the situation. See also COGNITIVE APPRAISAL THEORY.

**apprehension n.** 1. Uneasiness or dread about an upcoming event or the future generally. Also called APPREHENSIVENESS. 2. The act or capability of grasping something mentally. Compare COMPREHENSION. —apprehend vb. —apprehensible adj. —apprehensive adj.

**apprehension span** the number of items that an individual can report from a single brief exposure to an array of items. Typically the number reported is four or five. Also called span of apprehension. See also SCOPE OF ATTENTION.

**apprehension-span test** a test in which participants report some aspect of a briefly presented array of items (e.g., letters). The WHOLE REPORT task requires participants to report as many letters as they can. Recent studies have used a PARTIAL REPORT task, in which individuals must report the presence of a particular letter among a group of distractor letters in the briefly flashed display.

**apprenticeship n.** a means by which a novice gains practical experience in a trade or profession, often through a formal program of instruction and supervision from an experienced practitioner or a mentor. See also MENTORING.

**approach n.** 1. A move toward something (e.g., a stimulus, a goal). 2. A particular method or strategy used to achieve a goal or purpose, for example, a psychodynamic approach in therapeutic practice.

**approach–approach conflict** a situation involving a choice between two equally desirable but incompatible alternatives. Also called DOUBLE-APPROACH CONFLICT. See also APPROACH–VOIDANCE CONFLICT; VOIDANCE–VOIDANCE CONFLICT.

**approach–avoidance conflict** a situation involving a single goal or option that has both desirable and undesirable aspects or consequences. The closer an individual
comes to the goal, the greater the anxiety, but withdrawal from the goal then increases the desire. See also APPROACH—APPROACH CONFLICT; AVOIDANCE—AVOIDANCE CONFLICT; DOUBLE APPROACH—AVOIDANCE CONFLICT.

Approach Control Test a test for simulation and assessment of air traffic control for management of aircraft approaching airports. It assesses the influence of stress factors, such as time pressures.

approach coping any strategy for managing a stressful event or situation in which a person actively focuses on the problematic event or situation. Approach strategies may be cognitive in nature (e.g., trying to see the positive side of the situation, considering several alternatives for handling the situation) or behavioral (e.g., trying to find out more about the situation, seeking help from other people who have had similar experiences, praying for guidance, and bargaining or compromising to get something positive from the situation). Although generally seen as more adaptive than AVOIDANCE COPING, approach strategies do have certain potential costs as well: The orientation toward threatening material can lead to increased distress and, when there is no possibility for changing the situation or for assimilating emotionally to it, nonproductive worry.

approximation the process of obtaining a value that is at least close to the desired or actual value. For example, one might round a measurement to the nearest decimal place for ease of subsequent calculations. The degree of inaccuracy inherent to this process is known as approximation error.

approximation conditioning see SHAPING.

apprurtenance n. in GESTALT PSYCHOLOGY, interaction or mutual influence between parts of a perceptual field so that the parts appear to belong together. [defined in 1935 by Kurt Koffka]
for ASSOCIATION FOR PSYCHOLOGICAL SCIENCE, formerly called American Psychological Society.

APsaA abbreviation for AMERICAN PSYCHOANALYTIC ASSOCIATION.

aptitude n. the capacity to acquire competence or skill through training. Specific aptitude is potential in a particular area (e.g., artistic or mathematical aptitude); general aptitude is potential in several fields. Both are distinct from ABILITY, which is an existing competence.

aptitude measure a unit, instrument, or system for calculating one's capacity to acquire competence or skill through training, by comparison with a peer standard.

Aptitude Research Project tests see ARP TESTS.

aptitude test any assessment instrument designed to measure potential for acquiring knowledge or skill. Aptitude tests are thought of as providing a basis for making predictions for an individual's future success, particularly in educational or occupational situations. In contrast, ACHIEVEMENT TESTS are considered to reflect the amount of learning already obtained.

aptitude–treatment interaction (ATI) a phenomenon in which people with certain attributes (e.g., personality traits, cognitive styles) respond better to one type of intervention, whereas people with different attributes respond better to another. For example, people with high spatial aptitudes might learn better when material is presented to them visually with charts and diagrams, whereas people with high verbal aptitudes might learn better when the same material is presented in words. The influence of personal characteristics on treatment outcome is of particular interest in educational and psychotherapeutic contexts, given the goal of finding the optimal instructional method or intervention for different types of people. [Identified in 1977 by U.S. psychologists Lee J. CRONBACH and Richard Eric Snow (1936–1997)]

AQ abbreviation for ACHIEVEMENT QUOTIENT.

AQS abbreviation for ATTACHMENT Q-SET.

Aquachloral n. a trade name for CHLORAL HYDRATE.

aqueduct of Sylvius see CEREBRAL AQUEDUCT. [Franciscus Sylvius (1614–1672), Dutch anatomist]

aqueous humor the clear fluid that occupies the anterior and posterior chambers of the eye. It is produced by the epithelium of the CILIARY PROCESSES, which are part of the CILIARY BODY.

arachidonic acid a long-chain, polyunsaturated fatty acid that is a component of cell membranes. When liberated from the membrane by the enzyme phospholipase A2, it is transformed into a series of compounds known as eicosanoids, which serve as precursors for prostaglandins, thromboxanes, anandamide, and leukotrienes.

arachidonoylthanolamide (AEA) n. see ENDOGENOUS CANNABINOID.

2-arachidonoylglycerol (2-AG) n. see ENDOGENOUS CANNABINOID.

arachneophobia n. see SPIDER PHOBIA.

arachnoid n. see ARACHNOID MATER.

arachnoid granulations a series of extensions of the middle layer of the meninges (ARACHNOID MATER) through the outer layer (DURA MATER) that permits cerebrospinal fluid to drain into the bloodstream.

arachnoid mater the middle one of the three membranous layers (MENINGES) covering the surface of the brain and spinal cord, so called because its strands of tissue resemble spiders’ webs. Also called arachnoid: arachnoid membrane.

arachnophobia n. see SPIDER PHOBIA.

Arago phenomenon the impaired sensitivity to light that exists in the center of the visual field under poor light conditions. It is presumably caused by the absence of RETINAL RODS in the FOVEA CENTRALE. See SCOTOTIC VISION. [Dominique Arago (1786–1853), French physicist]

Aran–Duchenne disease see SPINAL MUSCULAR ATROPHY. [François Aran (1817–1861), French physician; Guillaume Duchenne (1806–1875), French neurologist]

ARAS abbreviation for ASCENDING RETICULAR ACTIVATING SYSTEM.

arbitrary inference a COGNITIVE DISTORTION in which a person draws a conclusion that is unrelated to or contradicted by the evidence.

arbitrary matching to sample a variation of MATCHING TO SAMPLE in which the correct alternative during the choice phase bears an arbitrary relationship to the stimulus presented as the sample. For example, after presentation of a blue stimulus as a sample, the correct choice may be to select a triangle. Also called symbolic matching to sample.

arbitrary symbol a linguistic sign (a written or spoken word) that bears no obvious resemblance to the thing or concept signified (see REFERENT). Because the vast majority of words in all languages are considered to fall into this category, arbitrariness is often cited as an important characteristic of human languages: this idea is of central significance in the structuralist approach to linguistics (see STRUCTURALISM). Compare ICONIC SYMBOL. See also PHONETIC SYMBOLISM.

arbitration n. a method of settling controversies in which the parties involved present their arguments and supporting information to an impartial agent, such as a judge or, in a labor dispute, an ARBITRATOR or ARBITRATION BOARD. By mutual agreement, the arbitrator’s decision is final. This process is distinguished from MEDIATION, in which the outside agent (the MEDIATOR or conciliator) seeks to help the parties reach a mutually acceptable agreement. —arbitrate vb.

arborization n. a branching, treelike structure, as of the DENDRITICs of a neuron. Arborization adds to the complexity of neurons and neuronal circuitry.

archaic inheritance presumed phylogenetic influences in the development of the individual’s mental processes, such as the RACIAL MEMORY and ARCHETYPES of Carl Jung’s ANALYTIC PSYCHOLOGY. See PHYLOGENY.

archetype n. 1. a prototypical example of something or the original model from which something is held to derive. See also PROTOTYPE. 2. in the ANALYTIC PSYCHOLOGY of Carl Jung, any one of a set of symbols representing aspects of the psyche that derive from the accumulated experience of humankind. These inherited symbols are held in the COLLECTIVE UNCONSCIOUS and serve as a frame of reference with which individuals view the world and as one of the foundations on which the structure of personality is built.
Examples are ANIMA, ANIMUS, PERSONA, SHADOW, supreme being, and hero. Also called archetypal image: primordial image. —archetypal adj.

archicerebellum n. the phylogenetically oldest part of the CEREBELLUM. Compare NEOCEREBELLUM; PALEOCEREBELLUM.

archicortex n. see ALLOCORTEX.

Archimedes spiral a simple spiral, formed by a curve whose tangent is maintained at a constant angle. A line drawing of an Archimedes spiral is often rotated to induce a MOTION AFTEREFFECT. [Archimedes of Syracuse (287–212 BCE), Greek philosopher and mathematician]

archipallium n. see ALLOCORTEX.

architectonic structure see CYTOARCHITECTURE.

architectural constraints the limitations imposed by the structure of the brain on the type of information that it can process and on the methods it uses for processing. See also CHRONOTOPIC CONSTRAINTS; REPRESENTATIONAL CONSTRAINTS.

architectural determinism the mistaken belief that the designed environment dictates behavior or directly causes certain behaviors to occur or not to occur. Design more typically facilitates or inhibits behavior, providing opportunities that influence the probability that certain behaviors will or will not occur. See also PERSON–ENVIRONMENT INTERACTION.

architectural programming determination of the performance requirements of buildings and other physical facilities prior to construction. Key considerations include the behavior expected to occur or not to occur in the space, user groups with special needs, and any trade-offs in the behavioral consequences of various design decisions. See also BEHAVIOR MAPPING; POSTOCCUPANCY EVALUATION.

architectural psychology the study of the role of the built environment in human behavior, a major subsite in ENVIRONMENTAL PSYCHOLOGY. Also called design and behavior.

archival research the use of books, journals, historical documents, and other existing records or data available in storage in scientific research. Archival research allows for unobtrusive observation of human activity in natural settings and permits the study of phenomena that otherwise cannot easily be investigated. A persistent drawback, however, is that causal inferences are always more tentative than those provided by laboratory experiments. Also called archival method.

arch of Corti see RODS OF COR TI.

arc sine transformation a means of changing proportional data to approximate a NORMAL DISTRIBUTION; Percentages that denote counts or frequencies are converted into a new set of scores whose distribution assumes a bell-shaped curve. The process minimizes variances across the different groups being compared and allows for the application of certain analytic techniques requiring that normality and other ASSUMPTIONS be met. Also called angular transformation; arcsine transformation.

arctic hysteria see PIBLOKTO.

carinate fasciculus a bundle of nerve fibers linking the parts of the brain involved in the interpretation and control of speech (WERNICKE’S AREA and BROCA’S AREA, respectively). See also CONDUCTION APHASIA.

arcuate nucleus 1. an arc-shaped collection of neurons in the hypothalamus that produce hormones. 2. any of various small groups of gray matter on the bulge of the medulla oblongata. They are extensions of neurons in the basal PONDS and project to the cerebellum.

arcuate zone of the brain the bow-shaped portion of the RETICULAR FORMATION that extends from the spinal cord to the pons and includes the internal and external arcuate fibers and ARCULATE NUCLEI. The arcuate fibers are concentrated in the OLIVARY NUCLEUS of the medulla oblongata.

areal linguistics the study of languages and dialects within a defined geographical area and with an emphasis on regional influences. This approach differs from both LINGUISTIC TYPOLOGY and GENETIC LINGUISTICS.

area postrema a highly vascularized region of the brain located in the basal wall of the lateral VENTRICLE. Brain capillaries in this area form a relatively permeable region of the BLOOD–BRAIN BARRIER, enabling the passage of toxic substances to the underlying CHEMORECEPTOR TRIGGER ZONE, which elicits a vomiting response.

area sampling a method of selecting individuals for research in which specific neighborhoods, streets, homes, or other geographic areas are designated in advance as the source of participants.

area under the curve (AUC) in a graphical display of a DISTRIBUTION, the region between the plotted function and the horizontal x-axis. It is used in such calculations as determining the probability of the occurrence of specific values of a RANDOM VARIABLE.

arecoline n. a drug, related to MUSCARINE, that stimulates smooth muscles and glands that respond to postganglionic cholinergic agents. It is used in veterinary medicine to eliminate internal parasites and was formerly used in the management of melancholia.

areflexia n. an absence of motor reflexes.

arginine vasopressin (AVP) see VASOPRESSIN.

argininosuccinic aciduria a disorder resulting from an inborn error of metabolism that is characterized by the presence of argininosuccinic acid in the urine, blood, and cerebrospinal fluid and that sometimes leads to epilepsy and intellectual disability. Treatment is based on control of protein intake to prevent hyperammonemia. The trait is transmitted by an autosomal recessive gene, ASL, on chromosome 7.

argot n. unconventional jargon words or phrases (French, “slang”), generally of a particular group.

argument n. 1. a sequence of propositions that provides logical reasons for accepting a CONCLUSION as valid or true. A single one of these statements is referred to as a PREMISE. Argumentation is the process of making an argument from premise to conclusion. 2. a parameter on which the value of a mathematical FUNCTION depends. 3. a disagreement involving varied, often opposite, positions. 4. in the ELABORATION–LIKELIHOOD MODEL, a variable that under conditions of high elaboration influences persuasion by providing information about the central merits of an ATTITUDE OBJECT.

argument framing the extent to which a persuasive message presents information in a manner that stresses the positive consequences of adopting the advocated position...
argument quality

versus the negative consequences of failing to adopt the advocated position.

argument quality the extent to which an argument elicits primarily positive evaluative responses toward the ATTITUDE OBJECT rather than primarily negative ones. The greater the number of positive responses relative to negative responses, the higher the quality of the argument.

argument quantity the number of arguments included in a persuasive message.

Argyll Robertson pupil a pupil that is nonresponsive to bright light (see PUPILLARY REFLEX) or reacts slowly to drugs that induce pupil constriction but constricts with changes in focus (see ACCOMMODATION). It is a sign of several diseases of the central nervous system, such as a brain tumor, multiple sclerosis, and neurosyphilis. [Douglas Argyll Robertson (1837–1909), British ophthalmologist]

arthrinencephaly n. see ARRhinencephALY.

ARI abbreviation for ARMY RESEARCH INSTITUTE.

Aricept n. a trade name for DONEPEZIL.

aripiprazole n. an ATYPICAL ANTIPSYCHOTIC agent that is thought to exert its effects by acting both as a partial agonist of the dopamine D2 receptor and the serotonin 5-HT, receptor and as an antagonist of the serotonin 5-HT, receptor. It is used in the treatment of schizophrenia, bipolar I disorder, and irritability associated with autism and as an adjunct to SSris and SNris in treatment-resistant depression. U.S. trade name: Abilify.

Aristotelian adj. 1. of or relating to the tradition of formal logic founded by ARISTOTLE and developed especially by the Scholastic philosophers of the Middle Ages (see SCHOLASTICISM). The term Aristotelian is often used to distinguish this tradition of logic from that of modern SYMBOLIC LOGIC. 2. of or relating to Aristotle, his works, or his thought. In this more general sense, an Aristotelian approach, which gives primacy to particulars over UNIVERSALS and grants a higher value to empirical knowledge, is often contrasted with the approach of PLATONIC IDEALISM or NEOPLATONISM. —Aristotelianism n.

Aristotle's illusion the tactile perception that a single object is two objects when felt with the crossed index and middle fingers. [ARISTOTLE]

arithmetic disability a disturbance in the ability to calculate that is associated with neurological impairment. See ACALCULIA.

arithmetic mean see MEAN.

Arizona v. Fulminante a case resulting in an influential 1991 U.S. Supreme Court ruling that admitting into evidence a CORRECTED CONFESSION can be considered a harmless error and does not violate DUE PROCESS rights if the remaining evidence is considered to be sufficient to convict the defendant.

ARM acronym for ADVERTISING RESPONSE MODELING.

armamentarium n. 1. the complete equipment of an institution, often a medical institution, necessary or sufficient for instruction, research, or practice. Such equipment includes books, supplies, and instruments. 2. the complete materials necessary to undertake any field of activity.

armchair psychology a form of psychological inquiry based on introspection and rational processes without recourse necessarily to empirical observation. It may be contrasted with EMPRICAL PSYCHOLOGY, in which the data come from laboratory procedures or controlled forms of observation and measurement. See RATIONAL PSYCHOLOGY; SPECULATIVE PSYCHOLOGY.

Armed Forces Qualification Test (AFQT) a screening test developed in 1950 by the Department of Defense to determine a person’s eligibility for acceptance into U.S. military service by assessing his or her mental ability qualification. Originally consisting of 100 multiple-choice items measuring vocabulary, arithmetic, spatial relations, and mechanical ability, the AFQT was used as a stand-alone test until 1976, when the ARMED SERVICES VOCATIONAL APITUDE BATTERY became the official screening instrument of all U.S. military branches.

Armed Services Vocational Aptitude Battery (ASVAB) a TEST BATTERY developed in 1966 by the Department of Defense for use by the U.S. military as a standardized instrument for personnel selection and classification (specific job assignment); in 1976, it became the official testing instrument of all U.S. military branches. It underwent a major revision in 2002 and currently consists of nine (or 10, if taken on the computer as opposed to the paper-and-pencil version) timed multiple-choice tests in the areas of word knowledge, paragraph comprehension, arithmetic reasoning, mathematics knowledge, general science, auto and shop information, mechanical comprehension, electronics information, and assembling objects. The first four tests are used to determine eligibility for service (see ARMED FORCES QUALIFICATION TEST); the remainder are used to determine interests and aptitudes. Although sometimes administered to high school students to assist in career planning, the ASVAB is a required part of the application process for all potential military recruits.

armodafinil n. see MODAFINIL.

AR model abbreviation for AUTOREGRESSIVE MODEL.

armoring n. a defense mechanism used to protect oneself by BLOCKING one’s experience and expression of life-affirming emotions (sadness, joy, anger, grief, and fear).

Army Alpha Test see ARMY TESTS.

Army Beta Test see ARMY TESTS.

Army General Classification Test (AGCT) see ARMY TESTS.

Army Research Institute (ARI) the U.S. Army Research Institute for the Behavioral and Social Sciences, which has its headquarters in Alexandria, Virginia, and opened in 1939. Its function is to maximize combat effectiveness by means of research in the acquisition, development, training, and utilization of soldiers in military forces. It conducts basic, exploratory, and advanced research and development.

Army tests group intelligence tests for military personnel, developed by Lewis M. TERMAN, Robert M. YERKES, and others and used by the U.S. Army beginning in World War I. The Army Alpha Test (Alpha test or examination) was a verbal test, measuring such skills as ability to follow directions. The Army Beta Test (Beta test or examination) presented nonverbal problems to illiterate subjects and recent immigrants who were not proficient in English. Both the Alpha and Beta tests were replaced at the outbreak of World War II by the 150-item Army General Classification Test (AGCT), designed to measure verbal comprehension, quantitative reasoning, and spatial perception and used to classify inductees according to their ability to learn mili-
tary duties. The AGCT was itself replaced in 1950 by the ARMED FORCES QUALIFICATION TEST.

Arnold–Chiari malformation a congenital deformity in which the MEDULLA OBLONGATA and CEREBELLUM protrude through the foramen magnum (see FORAMEN), so that the cerebellum overlaps the top of the spinal cord. HYDROCEPHALUS and MENINGOMYELOCLEFT are commonly associated with the different types of the deformity. [Julius Arnold (1835–1915), German pathologist; Hans Chiari (1851–1916), Austrian pathologist]

ARO abbreviation for ASSOCIATION FOR RESEARCH IN OTOLARYNGOLOGY.

aromachology n. the field of scientific study that attempts to specify the relationships between psychology and fragrance technology. The focus is on temporary effects of stimuli mediated by the olfactory pathways and moderated by cognition.

aromatase n. an enzyme that converts many male sex hormones (ANDROGENS) into female sex hormones (ESTROGENS). See also AROMATIZATION HYPOTHESIS.

aromatherapy n. a type of therapy purported to improve psychological and physical health through the use of selected essential oils extracted from seeds, herbs, flowers, fruits, and trees. The fragrances of these oils are inhaled or the oils themselves are applied topically, using compresses, baths, or massages, in an effort to induce relaxation, reduce stress and emotional distress, and enhance well-being. Evidence supporting the effectiveness of aromatherapy is largely inconclusive. See also COMPLEMENTARY AND ALTERNATIVE MEDICINE.

aromatic adj. in the ZWAARDEMAKER SMELL SYSTEM, denoting an odor quality smelled in spices and camphor.

aromatic L-amino acid decarboxylase see DOPA DECARBOXYLASE.

aromatization hypothesis the hypothesis that, in some rodents, testicular ANDROGENS enter the brain and are converted there into ESTROGENS by the action of the aromatase enzyme contained in neurons therein in order to masculinize the developing nervous system.

arousal n. 1. a state of physiological activation or cortical responsiveness, associated with sensory stimulation and activation of fibers from the RETICULAR ACTIVATING SYSTEM. 2. a state of excitement or energy expenditure linked to an emotion. Usually, arousal is closely related to a person's appraisal of the significance of an event or to the physical intensity of a stimulus. Arousal can either facilitate or debilitate performance. See also CATASTROPHE THEORY. —arouse vb.

arousal-boost mechanism any steadily increasing degree of general arousal associated with or produced by contact with a stimulus that gives rise to a measurable hedonic (pleasure) effect. For example, a person listening to a piece of music might find it pleasurable precisely for the heightened anticipation induced by its harmonic structure. Compare AROUSAL-REDUCTION MECHANISM. [proposed in 1967 by Daniel E. BERLYNE as part of his theory of positive hedonic value as a psychological effect of art]

arousal jag an increase of arousal followed by a more or less sudden decrease, often accompanied by laughter as a release of tension. The abrupt fall from elevated levels of arousal to a lower, more appropriate level is thought to produce a pleasurable response. Common experiences that can produce an arousal jag include a roller-coaster ride or watching a scary movie. [introduced in 1970 by Daniel E. BERLYNE]

arousal level the extent to which an organism is alert to stimuli.

arousal–performance relationship the pattern of association between cognitive or physiological arousal (or both) and achievement at physical or cognitive tasks. Also called anxiety-performance relationship. See CATASTROPHE THEORY; INVERTED-U HYPOTHESIS; REVERSAL THEORY.

arousal phase see SEXUAL-RESPONSE CYCLE.

arousal potential the capability of a stimulus to induce arousal. According to Daniel E. BERLYNE, preference for a work of art is due to the amount of general arousal it produces, which derives from its PSYCHOPHYSICAL PROPERTIES (e.g., intensity), COLLABORATIVE PROPERTIES (e.g., novelty), and ecological properties (meaningfulness, or signal value). See also ISOHEdonic TRAP.

arousal-reduction mechanism any stimulus or inhibitory reaction that decreases the degree of arousal of an individual after it has reached an uncomfortably high level. According to Daniel E. BERLYNE, a sharp increase in arousal can have unpleasant or aversive effects, but an arousal-reduction mechanism can produce positive hedonic value by lowering the arousal curve. The mechanism may have a natural inhibitory effect on central nervous system circuits, or it may result from a stimulus that conveys a sense of harmony or CONCINNITY. Compare AROUSAL-BOOST MECHANISM.

arousal regulation the controlling of cognitive and physiological activation using cognitive behavioral methods. See AUTOGENIC TRAINING; IMAGERY CUE; PROGRESSIVE RELAXATION.

arousal system a diffuse system of nerve cells that controls arousal by activating both the central nervous system and the autonomic nervous system. A principal component is the RETICULAR FORMATION.

arousal theory 1. the theory that the physical environment can affect arousal levels by stimulation and by stress created when psychological or physical needs are not met. Arousal increases when personal space is diminished (see CROWDING) or when people are subjected to noise, traffic congestion, or other adverse conditions. 2. see ACTIVATION THEORY OF EMOTION.

arousal training a technique in BEHAVIOR THERAPY that teaches clients to detect levels of physiological arousal and then to enhance or reduce these levels depending on therapeutic goals. This technique is often used in ANGER CONTROL THERAPY and BEHAVIORAL SEX THERAPY.

arousal transfer see EXCITATION-TRANSFER THEORY.

arpeggio paradox the apparent refutation of the stimulus–response view of behavior patterns that is provided by the speed at which accomplished pianists play arpeggios. Key strikes are too fast for nerve conduction to the brain to occur between them, so that one strike cannot serve as a stimulus for the next.

ARP tests Aptitude Research Project tests; tests of DIVERGENT THINKING produced by the Southern California Aptitude Research Project. Test items include writing a series of words containing a specified letter (word fluency), writing titles for short-story plots (ideational fluency, originality), writing words similar in meaning to a given word (associa-
arranged marriage

a marriage planned and contracted by the parents or other relatives of the partners or by significant figures (e.g., elders) in the partners’ culture or social group. In cultures in which arranged marriages are the norm and in contrast to the concept of the “love match,” marriage is typically seen as the union of two kinship groups and not merely of two individuals.

array n. any ordered arrangement of data, particularly a two-dimensional grouping of data into rows and columns. The following listing of students’ scores on a test is an example of a simple array:

<table>
<thead>
<tr>
<th>Student</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>55</td>
</tr>
<tr>
<td>B</td>
<td>76</td>
</tr>
<tr>
<td>C</td>
<td>81</td>
</tr>
<tr>
<td>D</td>
<td>82</td>
</tr>
<tr>
<td>E</td>
<td>89</td>
</tr>
<tr>
<td>F</td>
<td>90</td>
</tr>
<tr>
<td>G</td>
<td>90</td>
</tr>
<tr>
<td>H</td>
<td>90</td>
</tr>
<tr>
<td>I</td>
<td>94</td>
</tr>
<tr>
<td>J</td>
<td>98</td>
</tr>
</tbody>
</table>

The concept may be extended to more than two dimensions.

arrested testis see CRYPTORCHIDISM.

arrest reaction a behavioral response, usually studied in cats, characterized by sudden immobility, or “freezing.” The arrest reaction can be produced by electrically stimulating various areas of the brain. See also STARTLE RESPONSE.

arhinencephaly (arhinencephaly) n. a congenital absence of the RHINENCEPHALON, the part of the brain that includes the olfactory bulbs, tracts, and other structures associated with the sense of smell.

arhythmia n. any variation from the normal rhythm of the heartbeat. Kinds of arrhythmia include tachycardia, a rate above 100 beats per minute; bradycardia, a rate of less than 60 beats per minute; premature beats; atrial flutter, in which an upper chamber contracts up to 400 times per minute; and heart block, in which the heart fails to contract because of the interruption or delay of an electrical stimulus needed to trigger the contraction. —arhythmic adj.

arrowhead illusion see MÜLLER-LYER ILLUSION.

ART acronym for ASSISTED REPRODUCTIVE TECHNOLOGY.

Artane n. a trade name for TRIHEXYPHENIDYL.

arterial circle see CIRCLE OF WILLIS.

arterio- combining form arteries.

arteriography n. see ANGIOGRAPHY.

arteriole reaction a response controlled by the AUTONOMIC NERVOUS SYSTEM and marked by a change in the diameter of the arterioles, which control the flow of blood from the arteries to the capillaries. Smooth muscle in the walls of the arterioles is particularly sensitive to sympathetic nerve impulses and may react to anger, fear, or other emotions by producing dramatic changes of blood pressure.

arteriopathia hypertonica a form of arterial degeneration associated with hypertension. The muscle and elastic tissue of the walls of the arterial system increase and form layers that are eventually replaced by connective-tissue fibers. The condition can be both a cause and an effect of hypertension, leading to cerebrovascular accidents (i.e., strokes) if not controlled by medication.

arteriosclerosis n. a group of diseases characterized by hardening and loss of elasticity of the walls of the arteries. A common type is ATHEROSCLEROSIS. —arteriosclerotic adj.

arteriovenous malformation (AVM) an abnormal, congenital tangle of arteries and veins that are directly connected and lack intervening capillaries. When such malformations occur in the brain, they can cause mild to severe brain damage and result in a range of neurological symptoms.

arteritis n. inflammation of an artery or arteries. A common form is temporal (or giant cell) arteritis, a chronic disease, usually in older people, that largely involves the carotid arterial system, especially the arteries of the temple and scalp. It is marked by the appearance of giant, multinucleate cells and granulomas in the affected arteries. Symptoms include severe temporal-area headaches on both sides and visual disturbances, which may result in loss of sight in one eye. See also PANARTERITIS.

arthritis n. inflammation of a joint or joints, causing pain, swelling, and stiffness. A potentially severe and disabling form is rheumatoid arthritis, an autoimmune disorder (see AUTOIMMUNITY). Arthritis can be chronic, recurrent, and debilitating; psychosocial effects can include lifestyle changes, stress on personal relationships, and depression. —arthritic adj.

arthro- (arthr-) combining form joints.

arthrogryposis multiplex congenita a group of congenital nonprogressive conditions characterized by multiple joint contractures (stiff joints) and abnormal muscle development. Symptoms vary greatly in range and severity. In some cases, only a few joints may be affected and the range of motion may be nearly normal. In most cases, the hands, wrists, elbows, shoulders, hips, feet, and knees are affected. In the most severe cases, nearly every joint in the body may be involved, including those of the jaw and back. The joint contractures are often accompanied by muscle weakness, which may further limit movement. The disorder is thought to have a genetic cause in 30% of cases and is also associated with decreased movement in utero, connective tissue disorders, or maternal illness. Treatment focuses on the specific findings in each individual and may include physical therapy, removable splints, exercise, and surgery. Also called arthrogryposis: Guérin–Stern syndrome.

arthrometer n. see GONIOMETER.
arthropathy n. any inflammatory, neuropathic, or other disease involving a joint.

article n. in linguistics, a DETERMINER that limits a noun with respect to its definiteness and number (e.g., a, the in English) and with respect to its gender in many Romance languages (e.g., el, la in Spanish; le, la in French). See DEFINITE ARTICLE; INDEFINITE ARTICLE.

articulation n. 1. The shaping and production of the sounds required for intelligible speech. Articulation is a complex process that involves accuracy in the placement of the apparatus of the VOCAL TRACT, timing, direction of movements, force expended, speed of response, and neural integration of all actions. Compare MISARTICULATION. 2. a clearly articulated sound or utterance. 3. a joint between bones, which may be fixed or movable. 4. in Gestalt psychology, the level of complexity within a structure. —articulate vb.

articulation disorder any disorder of speech involving the substitution, omission, distortion, or addition of speech sounds (PHONEMES). See also DYSARTHRIA; PHONOLOGICAL DISORDER; SPEECH AND LANGUAGE DISORDER.

articulation index an index used to measure SPEECH INTELLIGIBILITY within an operational environment. It reflects the degree of separation between speech and background or other system noise.

articulation test 1. the phonetic analysis and recording of the speech of an individual with faulty sound production according to such criteria as developmental sequence, correct placement of the ARTICULATORS, and intelligibility. 2. in audition, a hearing test designed to measure the intelligibility of speech.

articulator n. any of the elements of the vocal tract (e.g., lips, tongue, soft palate) that are involved in articulation, that is, in the shaping and production of speech sounds. Some authorities include the cheeks, larynx, uvula, alveolar ridge, nose, and teeth as articulators.

articulatory apraxia see DEVELOPMENTAL APRAXIA OF SPEECH.

articulatory control process see PHONOLOGICAL LOOP.

articulatory loop see PHONOLOGICAL LOOP.

articulatory phonetics the branch of PHONETICS concerned with the relationship between the physiology of the articulatory mechanisms in human beings and the physical properties of human speech sounds. Compare ACOUSTIC PHONETICS.

articulatory rehearsal system see PHONOLOGICAL LOOP.

articulatory store 1. a component of short-term memory that retains auditory information based on the motor systems involved in pronouncing items, rather than on how they sound. Compare ACOUSTIC STORE. 2. see PHONOLOGICAL LOOP.

articulatory suppression a method used to inhibit subvocal rehearsal of items in a memory test or experiment by requiring the participant to perform a distracting verbal task, such as counting or naming, during the RETENTION period.

artifact n. 1. an experimental finding that is not a reflection of the true state of the phenomenon of interest but rather is the consequence of a flawed design or analytic error. For example, characteristics of the researcher (e.g., expectations, personality) or the participant (e.g., awareness of the researcher’s intent, concern over being evaluated) are common sources of artifacts. See also CONFOUND; DEMAND CHARACTERISTICS. 2. any manufactured object, particularly a product of historical significance.

artificial consciousness see MACHINE CONSCIOUSNESS.

artificial insemination (AI) the use of medical or surgical techniques to achieve conception by introducing sperm into the female reproductive system. In humans, this is done by introducing sperm collected from a woman’s partner or from an anonymous donor (hence called DONOR INSEMINATION) into the vagina or through the cervical opening directly into the uterus. As with intercourse, artificial insemination may need to be done more than once for pregnancy to occur. It is usually scheduled to coincide with the days of ovulation to maximize success.

artificial intelligence (AI) a subdiscipline of computer science that aims to produce programs that simulate human intelligence. AI researchers often develop very high-level computer languages for this purpose, such as LISP, PROLOG, and SMALLTALK. There are many branches of AI, including ROBOTICS, computer vision, machine learning, game playing, and EXPERT SYSTEMS. AI has also supported research in other related areas, including COGNITIVE SCIENCE and COMPUTATIONAL LINGUISTICS. See also MACHINE CONSCIOUSNESS; TURING TEST.

artificialism n. the assumption that anything that exists must have been made by a conscious entity, such as God or a human being, who is directly responsible for its qualities and movements. Jean Piaget, who introduced the term, drew a contrast between artificialism and ANIMISM, which assumes entities have an innate power or energy to direct their movements and determine their ultimate nature. Both assumptions are characteristic of children in the PREOPERATIONAL STAGE of development. —artificialist adj.

artificial language any language or languagelike system that is not a NATURAL LANGUAGE. The category includes invented languages, such as Esperanto, and the various languages used in computer programming; the formal languages of logic and mathematics are also sometimes included. In linguistics and psycholinguistics, artificial languages are sometimes invented to simulate or to violate certain aspects of natural-language rules.

artificial life a research area of ARTIFICIAL INTELLIGENCE in which computer-based systems exhibit behavioral characteristics of living systems. Often constructed using CELLULAR AUTOMATA, these systems fall into three categories depending on the approach: software (simulators), hardware (robotics), and wetware (synthetic DNA). This research area often attempts to simulate the effects of communication and other society-based skills on survival.

artificial pupil an artificial aperture that limits the amount of light entering the eye.

artificial selection human intervention in animal or plant reproduction to improve the value or utility of succeeding generations. Compare NATURAL SELECTION.

arts and crafts creative activities that involve skilled hand fabrication, such as painting, weaving, woodworking, or leatherworking. Arts and crafts are often used in re-
Art test

habilitation programs as directed by recreational or occupational therapists. See also Art therapy.

Art test a test designed to identify special abilities in the fine arts (e.g., painting, architecture), to assess creativity in the arts, or to evaluate art productions. A variety of techniques are utilized for these different purposes, which include comparing the individual’s judgment of pictures with that of experts, reproducing an object from memory, and identifying mechanical or judgment errors in a standard drawing.

Art therapy the use of artistic activities, such as painting and clay modeling, in psychotherapy and rehabilitation. The process of making art is seen as healing, an experience that provides the opportunity to express oneself imaginatively, authentically, and spontaneously; over time, this process can lead to personal fulfillment, emotional reparation, and transformation. The products made in art therapy are seen as a means of symbolic communication and a vehicle for developing new insights and understandings, resolving conflicts, solving problems, and formulating new perceptions to achieve positive changes, growth, and rehabilitation.

Arugamama n. see Morita therapy.

ASA 1. abbreviation for acetylsalicylic acid. See aspirin. 2. abbreviation for acoustical society of America.

ASA model abbreviation for attraction–selection–attrition model.

Asana n. a yoga posture or position. Each asana is said to have both physical and psychological effects that may be therapeutic or cathartic.

Aspholalia n. mumbled or indistinct speech.

Asb symbol for apostilb.

ASC abbreviation for altered state of consciousness.

Ascendance n. a personality trait involving a desire to be prominent in group situations, to assert oneself, and to acquire positions of authority over others. Traditional paper-and-pencil measures of ascendance can predict an individual’s emergence as the leader in small groups. Also called ascendency. See also dominance. —ascendant adj.

Ascendancy–submission see dominance–submission.

Ascending–descending series in psychophysics, the two sets of stimuli—one of increasing magnitude, one of decreasing magnitude—used in the method of limits. In the ascending series, the stimulus, initially below threshold, is increased incrementally until it exceeds threshold; in the descending series, the initial stimulus exceeds threshold and is decreased incrementally until it is below threshold. This procedure controls for habituation and perseveration errors.

Ascending pathway 1. a route formed by nerve fibers that carry nerve impulses toward the brain from lower levels of the nervous system. 2. see ascending tract.

Ascending reticular activating system (ARAS) the pathways that transmit nervous impulses from the reticular formation of the midbrain up through the thalamus to all parts of the cerebral cortex; the ARAS regulates sleep and sleep–wake cycles.

Ascending tract a bundle of nerve fibers that carries sensory inputs through the spinal cord toward the brain.

Also called ascending pathway. Compare descending tract.

Ascertainment bias error in selecting individuals or units for a sample, such that those units selected are not representative of the relevant population. For example, a medical researcher who studies a sample of patients that omits certain types of people who have the disorder of interest is likely to obtain results having an ascertainment bias. The term is often preferred over sampling bias in clinical contexts.

Ascesicism n. a character trait or lifestyle characterized by simplicity, renunciation of physical pleasures and worldly goods, social withdrawal, and extreme self-discipline. —ascetic adj.

Asch situation an experimental paradigm used to study conformity to group opinion. Participants make judgments as part of a group of confederates who make errors deliberately on certain trials. The extent to which participants publicly agree with the erroneous group judgment or resist the pressure to do so and remain independent provides a measure of conformity. [Solomon Asch]

ASCM abbreviation for adaptive strategy choice model.

Ascorbic acid the chemical name for vitamin C, a nutrient found in many fruits and vegetables, particularly citrus fruits (see vitamin). Unlike most mammals, primates cannot make ascorbic acid, so they must obtain it from foods. Ascorbic acid aids formation of connective tissue and prevents oxidation of cellular components. Deficiency can result in scurvy (marked by bleeding gums and delayed wound healing) and neurological disorders.

Ascriptive responsibility the judgment that an individual who has committed an illegal act can be ascribed criminal responsibility and should therefore be punished. Compare descriptive responsibility.

ASD 1. abbreviation for acute stress disorder. 2. abbreviation for autism spectrum disorder.

-ase suffix an enzyme (e.g., transferase).

A* search (pronounced “A star”) a type of best-first search in which “best” for any state is measured by the distance that state is from the start state plus the heuristic estimate of the quality of that state. The heuristic estimate must be less than or equal to the actual cost of going from that state to a goal state.

Asemia n. see asymbolia.

Asenapine n. an atypical antipsychotic agent of the dibenzo-oxepino pyrrrole class that is thought to exert its effects by acting as a dopamine D2 and serotonin 5-HT2A receptor antagonist. It is used in the treatment of schizophrenia and, alone or as adjunctive therapy, for acute treatment of manic or mixed episodes of bipolar I disorder. U.S. trade name: Saphris.

Asendin n. a trade name for amoxapine.

ASEP abbreviation for American sport education program.

Asep meningitis see meningitis.

Asexual adj. 1. lacking sexual characteristics or drive. 2. capable of reproduction without fertilization. Asexual reproduction occurs in many plants and in certain animal species, for example, by budding or by forming an entirely
new individual from each separate part after it spontaneously breaks up (fragmentation). —asexual adj.

Asian American a citizen or resident of the United States whose ancestry, at least in part, can be traced to the Far East, Southeast Asia, or the Indian subcontinent.

Asian influenza a type of influenza caused by the H2N2 strain of influenza virus, which first appeared in north China in 1957. The mortality rate was not high, but the infection was complicated by severe staphylococcal pneumonia in many cases. Some patients also developed postinfluenzal asthma with psychogenic factors.

as-if hypothesis an unproven hypothesis that is treated "as if" it were correct, usually because of its value as an explanatory model or its utility as a basis for experiment and research. Many of the hypothetical entities postulated by psychology and psychoanalysis are of this nature.

as-if personality a type of personality style in which the individual behaves as if well adjusted but, in fact, is doing only what is expected and is unable to behave in a genuine or spontaneous manner. This condition has reportedly been observed in individuals with schizophrenia before they exhibit psychotic symptoms, such as hallucinations or delusions. [first described in 1942 by U.S. psychologist Helene Deutsch (1884–1982)]
-asis suffix see -ASIS.

asitia n. repulsion at the thought or sight of food. See also ANOREXIA.

ASL abbreviation for American SIGN LANGUAGE.

asocial adj. 1. declining to engage, or incapable of engaging, in social interaction. 2. lacking sensitivity or regard for social values or norms. —asociality n.

asomatognosia n. lack of sensory awareness of one's body. Individuals with this disorder may be unable to recognize parts of their body as their own. Asomatognosia affecting one side of the body is known as hemiasomatognosia. See NEGLECT.

asonia n. see TONE DEAFNESS.

aspartate n. an amino acid neurotransmitter that is excitatory at many synapses.

aspartate aminotransferase an enzyme that may be involved in the cause of muscular dystrophy. Increased levels in the blood are a clinical sign of this disease and also of damage to the heart and liver, as in cases of jaundice or myocardial infarction. The former name of this enzyme was glutamic-oxaloacetic transaminase. Also called aspartate transaminase.

aspect n. see TENSE.

Asperger's disorder a disorder associated with varying degrees of deficits in social and conversational skills, difficulties with transitions from one task to another or with changes in situations or environments, and preference for sameness and predictability of events. Obsessive routines and preoccupation with particular subjects of interest may be present, as may difficulty reading body language and maintaining proper social distance. Some people with Asperger's disorder have reported oversensitivity to sounds, tastes, smells, and sights, but the nature of such sensitivities is not well researched. In contrast to AUTISM, language skills develop, and there is no clinically significant delay in cognitive or adaptive functioning other than in social interactions. By definition, people with Asperger's disorder have an IQ in the normal to superior range, and some may exhibit exceptional specific skills or talents. Classified as a Pervasively DEVELOPMENTAL DISORDER in DSM–IV–TR, Asperger's disorder has been subsumed into AUTISM SPECTRUM DISORDER in DSM–5 and is no longer considered a distinct diagnosis. Also called Asperger's syndrome. [described in 1944 by Hans Asperger (1906–1980), Austrian psychiatrist]

aspermia n. failure of the male reproductive organs to produce or emit semen. Also called aspermatism.

asphyxia n. a condition in which the level of oxygen in the blood falls below normal while the proportion of carbon dioxide increases. It may be associated with labored or difficult breathing and marked by signs of pallor or cyanosis. Causes include choking, drowning, electric shock, inhaled smoke or toxic fumes, or disease or injury involving the respiratory system.

asphyxophilia n. arousal and enjoyment obtained from being unable to breathe during sexual activity. As a PARAPHILIA, this may involve being choked or strangled by a partner. Compare AUTOEROtIC ASPHYXIA.

aspiration n. 1. an ambition, goal, or any kind of desired end that might be achieved through personal effort. 2. in phonetics, the articulation of a stop consonant with a sudden plosive burst of air. In English, the consonants p, t, and k are aspirated at the beginning of a syllable but not at the end or in combination with certain other consonants (see ALLOPHONE). The difference can be easily experienced by placing a finger close to one's mouth and saying pot (aspirated) and then top (unaspirated).

aspirational group a REFERENCE GROUP that an individual aspires to join. An aspirational group may be an actual group characterized by interaction and interpersonal structures (e.g., a professional association, a sports team) or an aggregation of individuals who are thought to possess one or more shared similarities (e.g., the rich, intellectuals). Compare MEMBERSHIP GROUP; DISSOCIATIVE GROUP.

aspirin n. acetylsalicylic acid: a commonly used nonopioid ANALGESIC, which also has ANTI PYRETIC and anti-inflammatory properties and the ability to prevent formation of blood clots. Aspirin alleviates pain mainly by peripheral mechanisms (see NSAID); in controlling fever, it acts on the body's thermoregulatory center in the hypothalamus. Adverse effects include gastric irritation or ulceration with bleeding and occasional allergic reactions. Overdosage affects the central nervous system and other body systems (see SALICYLISM).

aspirin combinations drug mixtures that include aspirin as one of the components, the others commonly being other analgesics (e.g., acetaminophen, codeine, propoxyphene), stimulants (usually caffeine), or both. Aspirin combinations may also include a barbiturate (e.g., butalbital), a skeletal muscle relaxant (e.g., carisoprodol, orphenadrine), or other drugs. Because many of these preparations can be obtained without a doctor's prescription, individuals with the habit of regular self-medication are at risk of developing gastrointestinal symptoms (e.g., peptic ulcer) and other toxic reactions (see SALICYLISM; CAFFEINE INTOXICATION).

aspirin poisoning see SALICYLISM.

ASPR abbreviation for AMERICAN SOCIETY FOR PSYCHOLOGICAL RESEARCH.

ASR abbreviation for AUTOMATED SPEECH RECOGNITION.
assault n. 1. a violent attack on an individual. 2. illegal conduct occurring when an individual either attempts to injure another person or threatens to do so and has the capacity to carry out the threat. —assaultive adj.

A-S Scale abbreviation for ANTI-SEMITISM SCALE.

assembly bonus effect in groups working on a decision-making or intellectual task, an outcome that is superior to what would be achieved by the most capable member or by any simple pooling of individual member efforts. See also GROUP SYNERGY. [first proposed in 1964 by U.S. social psychologists Barry E. Collins and Harold Guetzkow (1915–2008)]

assembly test a test requiring participants to put together elements, such as pieces of a puzzle or of an object.

assertion n. 1. the forceful statement of or insistence on one’s beliefs, claims, rights, or the like. 2. in sport, the use of force within the rules of the game to achieve a strategic advantage over an opponent. Also called proactive aggression.

assertive community treatment a service delivery system for individuals with severe mental illness that includes a range of treatment, rehabilitation, and support services provided by a mobile multidisciplinary team comprised of, for example, a psychologist, a psychiatrist, a social worker, a case manager, and a nurse. The team establishes a close, consistent relationship with each individual and delivers services and supports to him or her at home and work.

assertiveness n. an adaptive style of communication in which individuals express their feelings and needs directly while maintaining respect for others. A lack of assertiveness may contribute to depression and anxiety, whereas maladaptive approaches to assertiveness may manifest as aggression.

assertiveness training 1. a method of teaching individuals to change verbal and nonverbal signals and behavioral patterns and to enhance interpersonal communication generally through techniques designed to help them express emotions, opinions, and preferences—positive and negative—clearly, directly, and in an appropriate manner. ROLE PLAY or BEHAVIOR REHEARSAL is often used to prepare clients to be appropriately assertive in real-life situations. 2. in sport, the use of specific drills that have the purpose of increasing the physicality of play within the rules.

assessment n. 1. in general, a judgment of the quality, worth, importance, or value of something or someone. 2. in research, a systematic process of obtaining information from participants and using it to make inferences or judgments about them. In a clinical context, this process is known as a PSYCHOLOGICAL ASSESSMENT. 3. in animal behavior, an evaluation of an individual based on its behavior or communication signals. A potential rival might use the degree of vigor and complexity of a male’s song or the intensity of its plumage color to assess the probability of displacing that male. Similarly, a female might evaluate the relative quality of different potential mates in MATE SELECTION. Assessment may be a major function of animal communication.

assessment center an office or department in which participants are observed and evaluated with regard to their future growth and development within an organization. A variety of assessment procedures may be used, including IN-BASKET TESTS, ROLE PLAY, and individual or group exercises constructed to simulate important activities at the organizational level to which the participants aspire. The assessment center may be used for currently employed personnel, job applicants, or both.

assessment instrument any test, interview, questionnaire, or other tool for the evaluation of ability, achievement, interests, personality, psychopathology, or the like.

assessment of intelligence the administration of standardized tests to determine an individual’s ability to learn, reason, understand concepts, and acquire knowledge. See also MEASURES OF INTELLIGENCE.

assessment research the study of an organizational unit in order to understand its functioning and make recommendations for improvements or changes. See also EVALUATION RESEARCH.

assignment therapy a technique used in group therapy to enhance cohesiveness and communication among the participants so as to obtain maximum therapeutic benefit. A SOCIOMETRIC TEST is administered to determine the patterns of intermember relations within the group as a whole, and these patterns are then used to assign individuals to smaller, more focused groups. [articulated by Jacob L. Moreno]

assimilation n. 1. the process of absorbing, incorporating, or making similar. In making judgments, for example, it refers to finding similarities between the target being judged and features of the context in which it is judged. Thus, meeting a person at an enjoyable party could lead to a more positive evaluation of that person than would have been the case otherwise. The evaluation of the person has been assimilated toward the positive social context. Compare CONTRAST. 2. the process by which an immigrant to a new culture adopts the culture’s beliefs and practices. This is more properly called SOCIAL ASSIMILATION. See also ACCULTURATION STRATEGIES. 3. see PLAGETIAN THEORY. —assimilate vb.

assimilation effect in psychology experiments, an effect in which participants’ judgments shift toward an anchor after it is introduced. For example, judgments of relative distance or weight will usually be evenly distributed along a scale before the experimenter provides an anchor. If, once the anchor is introduced, judgments cluster around the anchor, an assimilation effect is said to have occurred. Compare CONTRAST EFFECT.

assimilative coping a stress-management strategy in which a person actively tries to transform a situation in such a way that it conforms to his or her goals and aspirations. Examples of assimilative coping include asking for another person’s help or acquiring a new problem-solving skill. Such attempts at modifying the environment are particularly evident during the initial stage of coping and are intended to avoid or diminish actual or anticipated losses. This type of COPING STRATEGY generally dominates as long as people feel actively able to change the situation or to enact efficient compensatory or self-regulatory interventions. In the event these efforts fail, an ACCOMMODATIVE COPING strategy may be adopted instead. [identified in 1990 by Jochen Brandtstädter and Gerolf Renner, German psychologists]

assisted death an action taken by one person to end the life of another, at the request of the latter. This action can take the form of either PASSIVE EUTHANASIA or ACTIVE EU- THANASIA. Assisted death differs from MERCY KILLING in
that it is generally performed by a physician and is not in response to an acute situation. It is sometimes called "physician-assisted suicide," which assumes a firm determination of the cause of death. See also "suicide in which the person ending his own life is provided the means to do so (e.g., a prescription) by another." See ASSISTED DEATH.

**assistive device** see ASSISTIVE TECHNOLOGY.

**assistive listening device** a device used by a person with hearing loss to emphasize a single specific sound. Unlike conventional hearing aids, which amplify all sounds in the environment, assistive listening devices focus on a single sound, such as the voice of a person with whom one is conversing in a noisy restaurant, and make it more prominent than the background noise. An assistive listening device typically consists of a transmitter and microphone that are placed near the source of the sound in which one is interested and a receiver and output device, such as headphones, that direct the sound to a particular individual.

**assistive software** computer programs designed to enable individuals with disabilities to use computer applications. For example, a SCREEN READER, a software program designed for users with visual impairment, can be used with a SPEECH SYNTHESIZER to convert information on a computer monitor into speech.

**assistive technology (AT)** 1. the field concerned with development and service provision of tools that improve the functioning of individuals with limitations or disabilities. See also "bioengineering, 2. any equipment or system designed to maintain or improve the functional capabilities of individuals with disabilities. **Assistive devices** or **assistive technology devices** range from simple low-technology items such as canes, walkers, and reaching to high-technology items such as voice-controlled computers and computerized speech-output devices. These devices are also occasionally referred to as "daily-living aids" or "independent-living aids.

**assistive technology service** any organization, business, facility, or supplier that directly assists individuals with disabilities in the choice, purchase, or leasing, or use of an ASSISTIVE TECHNOLOGY device, including customization, maintenance, and replacement.

**associate** 1. n. something that accompanies or is catego-

---

**Association for the Advancement of Psychology**

The Association for the Advancement of Psychology (AAP) was founded in 1988 to advance the needs and interests of scientific, applied, and academic psychologists as opposed to those engaged in clinical practice. Its mission is to promote, protect, and advance the interests of scientifically oriented psychology in research, application, and the improvement of human welfare. Originally called the American Psychological Association (APA), the organization changed to its present name in 2006. The APS publishes five journals: Psychological Science, Current Directions in Psychological Science, Psychological Science in the Public Interest, Perspectives on Psychological Science, and Clinical Psychological Science.

**Association for Research in Otolaryngology (ARO)** an association of scientists and physicians who are engaged in basic and clinical research on hearing, balance, speech, taste, and smell. The ARO publishes the Journal of the Association for Research in Otolaryngology (JARO).

**Association for the Advancement of Psychology (AAP)** an organization founded in 1974 to promote human welfare through the advancement of the profession.
and science of psychology. The AAP promotes the interests of psychologists through (a) representation before public and governmental bodies, (b) cooperation with other organizations and agencies in furtherance of the profession and science of psychology, and (c) the operation of a political committee known as Psychologists for Legislative Action Now (AAP/PLAN).

**associationism** n. the theory that complex mental processes, such as thinking, learning, and memory, can be wholly or mainly explained by the associative links formed between ideas (see ASSOCIATION OF IDEAS) according to specific laws. Although ARISTOTLE cited some of these laws (similarity, difference, contiguity in time or space, etc.), the theory was first stated systematically by Thomas HOBES, who held that all knowledge is compounded from relatively simple sense impressions. The laws and applications of association were later developed by John LOCKE and other members of the British empiricist school (see EMPIRICISM), notably George BERKELEY, David HUME, David HARTLEY, James MILL, and John Stuart MILL. Although the approach taken by such thinkers was relatively static and nonexperimental, there are echoes of associationism in much historical and contemporary psychology. Most importantly, associationism has been invoked to explain the pairing of stimuli and responses. As such, it is a fundamental assumption of modern LEARNING THEORY and all behaviorist approaches (see BEHAVIORISM). Also called **British associationism**.

**associationist** n. a theorist who believes that the process of learning can be best described as the acquisition, modification, or elaboration of associations. See ASSOCIATIONISM.

**associationistic learning theory** see ASSOCIATIVE LEARNING.

**association model** a method used to study the strength of relationship between a predictor variable and a response variable when values for the latter take the form of ORDINAL DATA. More specifically, it tests for STATISTICAL INDEPENDENCE between the variables.

**association nuclei** nuclei of the THALAMUS that do not receive direct input from ascending sensory systems. They connect widely with other thalamic nuclei and send axons to ASSOCIATION CORTEX.

**association of ideas** the process by which simple perceptions and ideas are combined into totalities of varying degrees of complexity and abstractness, as, for example, connecting the relatively simple ideas of four legs, furry coat, a certain shape and size, and so on, into the compound concept cat. The same process is held to explain one’s understanding of entirely ABSTRACT IDEAS, such as power or liberalism. The association of ideas was a key concept for the British empiricist school of philosophers (see EMPIRICISM) and remains fundamental in LEARNING THEORY and BEHAVIORISM. See also MENTAL CHEMISTRY; MENTAL MECHANICS.

**association psychology** a psychological approach based on the premise that learning and knowledge are derived from the formation of connections (associations) between ideas or representations of stimuli and responses. Association psychology developed from British empiricist and associationist philosophy (see ASSOCIATIONISM).

**association-reaction time** in a WORD-ASSOCIATION TEST, the elapsed time between stimulus and response.

**association study** research designed to identify possible genetic relationships among individuals who do or do not have a particular disease or disorder.

**association value** 1. the extent to which a stimulus is associated with other ideas, memories, or values. 2. the extent to which people are able to ascribe meaning to an apparently meaningless stimulus, for example, an arbitrary consonant-vowel-consonant trigram (e.g., KEX or DAG) presented during an association test.

**associative anamnesis** a psychiatric interview technique in which the patient gives an autobiographical account of his or her history and difficulties, while the therapist listens for key words and expressions that are then used to establish an **associative linkage** that will bring the patient closer to the unconscious roots of his or her disturbance. [developed by Austrian-born U.S. physician and psychoanalyst Felix Deutsch (1884–1964)]

**associative-chain theory** in LEARNING THEORY and behaviorist psychology (see BEHAVIORISM), a theory of how complex behaviors, including linguistic behaviors, are formed from combinations of simple stimulus–response associations.

**associative clustering** the tendency for items with preexisting associations to be recalled together.

**associative–dissociative strategy** a plan of shifting one’s ATTENTIONAL FOCUS between internal (associative) feedback (e.g., breathing rate, muscle soreness) and external (dissociative) stimuli (e.g., what others are doing, the scenery). Athletes in ENDURANCE ACTIVITIES use such strategies to check body functions at specific times and to pay attention to external stimuli at others.

**associative fluency** the ability to make a wide range of connections when presented with an object, event, word, or concept. High associative fluency has been identified as an aspect of creativity that in many individuals is not positively correlated with high intelligence. See also CREATIVE THINKING; DIVERGENT THINKING.

**associative illusion** a visual illusion produced by the interaction of parts of a design (e.g., the MÜLLER-LYER ILLUSION).

**associative law** any of the principles according to which associations are acquired and strengthened, originally derived from British empiricist philosophy (see ASSOCIATIONISM). These include the LAW OF CONTRAST, the LAW OF FREQUENCY, and the law of recency (see RECENCY EFFECT).

**associative learning** the process of acquiring new and enduring information via the formation of bonds or connections between elements. In different types of ASSOCIATIONIST LEARNING THEORIES, these associated elements may be stimulus and response, mental representations of events, or elements in neural networks. Historically, the associationistic theories of Clark L. HULL and Kenneth W. SPENCE are contrasted with the nonassociative and cognitive theory of Edward C. TOLMAN. Compare NONASSOCIATIVE LEARNING.

**associative linkage** see ASSOCIATIVE ANAMNESIS.

**associative memory** retrieval or activation of a memory (e.g., of a stimulus, behavior, place, or past event) that occurs upon recall or presentation of something associated with it.

**associative play** see SOCIAL PLAY.
associative strength  the strength of the connection (association) between two or more items (e.g., between stimulus and response or between items in memory), as measured by the capacity of the first item to elicit the second (forward associative strength) or the second item to elicit the first (backward associative strength).

associative thinking  a relatively uncontrolled cognitive activity in which the mind wanders without specific direction among elements, based on their connections (associations) with one another, as occurs during reverie, daydreaming, and free association.

associative visual agnosia  see visual agnosia.

assonance n.  a similarity in the vowel sounds of two or more words, for example, through and flute or same and stay.

assortative mating  mating behavior in which mates are chosen on the basis of a particular trait or group of traits (e.g., attractiveness, similarity of body size). Also called assortive mating. See also mate selection; random mating.

assumed role  a behavior pattern adopted by a person in the belief that such behavior is expected for a particular position or status; taking on a role is also a method for dealing with uncertainty about how to behave. An example of an assumed role is the sick role. Also called role enactment.

assumed similarity bias  the tendency for perceivers to assume that other people possess the same qualities and characteristics that they have. This bias is thought to inflate the accuracy that perceivers attribute to their judgments about others. [first proposed in 1955 by Lee J. Cronbach]

assumption n. 1. the premise or supposition that something is factual or true: that is, the act of taking something for granted. 2. one or more conditions that need to be met in order for a statistical procedure to be fully justified from a theoretical perspective. For example, the analysis of variance assumes homogeneity of variance and independence of observations, among other criteria. If the assumptions were to be violated to an extreme extent, the results would be invalid. See also robustness.

astasia n.  severe impairment or complete loss of the ability to stand due to problems in motor coordination. —astatic adj.

astasia-abasia  the ability to walk only with a wobbly, staggering gait, although control is normal while lying down. This is believed to be psychogenic in origin and may be manifested as a symptom of conversion disorder. Also called BLOCq’s disease.

astereognosis n.  inability to identify the form and nature of an object by touch. It is a form of tactile agnosia. Also called tactile amnesia.

asterixis n.  transient loss of a fixed position of the hands or arms followed by a jerking recovery movement, usually occurring in association with metabolic disorders. Also called flapping tremor.

asthenia n.  severe weakness or loss of strength, often associated with general fatigue or certain disorders. Asthenia formerly was thought to be a common symptom of a major depressive episode but is no longer defined as such. —asthenic adj.

asthenic type  a body type characterized by a frail, long-limbed, narrow-chested physique. According to Kretschmer typology, individuals so characterized tend to be shy, sensitive, and introversive in temperament (and in extreme cases schizophrenic). Also called leptosome type. See also constitutional type.

asthenopia n.  weakness or fatigue of the eyes, usually due to strain and tiring of the eye muscles. —asthenopic adj.

asthma n.  a chronic disorder in which intermittent inflammation and narrowing of the bronchial passages produces wheezing, gasping, coughing, and chest tightness. Though the precipitating cause is usually an allergen, such as dust or pollen, environmental irritants, respiratory infection, anxiety, stress, and other agents may produce or aggravate symptoms. —asthmatic adj.

astigmatism n.  a visual disorder in which the light rays of a visual stimulus do not all focus at a single point on the retina due to uneven curvature of the cornea or lens. As a result, light rays are refracted more in one meridian (that of the greatest curvature) than in the other at right angles to it (that of least curvature). The effect is an aberration or distortion of the visual image that makes it difficult to see fine detail. —astigmatic adj.

astigmatoScope n.  an instrument used to diagnose and measure astigmatism in the eye.

astral projection  the alleged ability to enter into a trancelike state in which one leaves the physical body and operates in the astral plane (i.e., a hypothesized level of existence accessible to the consciousness or spirit, which acts as a link between the physical and spirit or divine worlds). See out-of-body experience.

astroblastoma n.  see glioma.

astrocyte n.  a star-shaped nonneuronal central nervous system cell (GLIA) with numerous extensions that run in all directions. Astrocytes provide structural support for the brain, are responsible for many homeostatic controls, and may isolate receptive surfaces. Recent research suggests that they may play a role in potassium neurotransmission. Also called astroglia.

astrocytoma n.  see glioma.

astrocytosis n.  a pathological condition marked by a proliferation of astrocytes into tissues of the central nervous system in which neurons have died due to lack of oxygen or glucose, as during episodes of HYPoxia or HYPOGlyCEMIA. Also called astrogliosis.

astrology n.  a pseudoscience based on the belief that the movements and positions of the planets in relation to the constellations of the zodiac influence the lives of individuals and the course of events. The systematic study of astrology originated in ancient Babylon and spread to Greece, India, and the Islamic world. China also developed an astrological system that incorporated astronomy and philosophy. Despite the disapproval of the Church, astrology remained widely influential during the medieval and Renaissance periods in Europe. Even in the modern scientific world, many people believe that their horoscope determines their personal characteristics, tendencies to particular diseases, and liability to good or bad fortune. There is no evidence to support this belief, except perhaps as a self-fulfilling prophecy. Astrology is mainly of interest to psychology because it involved an early theory of personality types, relating the physical and psychological charac-
teristics of individuals to the supposed influence of the heavens. —astrologer n. —astrological adj.

ASVAB abbreviation for ARMED SERVICES VOCATIONAL AP-
TITUDE BATTERY.

asylla/bia n. a type of APRAXIA in which a person can rec-
ognize individual letters of the alphabet but is unable to form or comprehend syllables or words.

asylum n. 1. originally, a refuge for criminals (from Greek asylion, "sanctuary"). From the 19th century, the terms asylum or insane asylum were applied to MENTAL INSTITU-
TIONS. These names are now obsolete, discarded because of their emphasis on refuge rather than treatment. 2. the right to remain in a country, granted by the government of that country to individuals escaping oppression, war, or political unrest in their country of origin or allegiance.

asymbolia n. loss of the ability to understand or use sym-
bols of any kind, including words, gestures, signals, musical notes, chemical formulas, or signs. Also called asemia.

asymmetrical distribution any nonnormal distribu-
tion: a set of ordered scores in which the frequency of values is not equal above and below the center or midpoint of the set. If one divides the distribution at its MEAN, the ar-
rangement of scores differs across the two halves. See SKEWNESS. Compare SYMMETRICAL DISTRIBUTION.

asymmetry n. SKEWNESS: the condition in which the values of a data set are not arranged equally around a center point. Compare SYMMETRY. —asymmetrical adj.

asymptomatic adj. not showing any symptoms. For ex-
ample, hypertension is considered asymptomatic because usually it does not have any outright physical or behavioral symptoms and can be detected only by measuring the blood pressure.

asymptomatic neurosyphilis a form of NEUROSYPHI-
LIS in which laboratory findings show abnormalities in the cerebrospinal fluid but the patient does not show symp-
toms of the disease.

asymptote n. a straight line that defines the limit of a
curve, such that the curve continues to approach but never reaches the line. The concept of asymptote is often invoked in relation to the LEARNING CURVE. Participants in learning studies frequently show a steady improvement in perfor-
ma nce that then levels off as the curve approaches asymp-
tote; any further improvements will be minimal, regardless of further practice or training. —asymptotic adj.

asymptotic method any statistical procedure for esti-
mating a population quantity that becomes more accurate as the number of observations involved in the calculation increases. Asymptotic methods use assumptions—including EFFICIENCY, NORMALITY, and SYMMETRY—that generally are not absolutely true for finite samples but that become steadily more true as sample sizes increase. Also called large-sample method.

asymptotic normality a property of a distribution whereby that distribution increasingly resembles a bell-
sheaped curve as one or more of its characteristics become very large (i.e., it tends toward a NORMAL DISTRIBUTION as the sample size upon which it is based approaches infinity).

asynchronous brood offspring (usually birds) that hatch successively (rather than simultaneously, as in a syn-
chronous brood). In cattle egrets, for example, eggs hatch 1 or 2 days apart, giving a growth advantage to the first-
hatched chick. Often, older chicks will attack young sib-
lings to the point of killing them (see SIBILCIDE). However, in terms of parental efficiency in feeding chicks and mean chick survival, producing asynchronous broods is a better strategy than producing synchronous broods.

asynchrony n. lack of temporal correspondence in the occurrence of different events or processes, for example, the delay in time between a child’s language comprehen-
sion and language production.

asynergia n. faulty coordination of muscle groups in-
volved in the performance of complex motor movements, such as standing, walking, or kneeling. Also called asyn-
ergy. —asynergic adj.

asynergic speech see CEREBELLAR SPEECH.

AT abbreviation for ASSISTIVE TECHNOLOGY.

ataque de nervios a CULTURE-BOUND SYNDROME found among Latinos, characterized by shaking, uncontrol-
able shouting or crying, a sense of rising heat, loss of control, and verbal or physical aggression, followed by fainting or seizure-like episodes. Symptoms often occur following a stressful event related to the family, and most individuals quickly return to their previous level of functioning.

ataractic 1. adj. the adjectival form of ATARAXY. 2. n. an agent that has a calming or quieting effect, producing a state of ataraxy. The name was introduced as an alterna-
tive to TRANQUILIZER. Also called ataractic.

Atarax n. a trade name for HYDROXYZINE.

ataraxy n. a state of mind that is characterized by perfect peace or detached serenity without loss of mental abilities or clouding of consciousness. Also called ataraxia. —ata-
raxic or ataractic adj.

ataxism n. 1. the presence of a genetic trait inherited from a remote ancestor that did not appear in more recent ancestors, that is, a reversion to an earlier type. 2. more generally, the reappearance of or reversion to an earlier or more primitive characteristic or form (e.g., behavioral ata-

ism). See CRIMINAL ANTHROPOLOGY. —atavistic adj.

ataxia n. inability to perform coordinated voluntary movements. It may be seen as a symptom of various disorders, such as multiple sclerosis or cerebral palsy, or it can occur in isolation. It can be heritable, as in FRIEDREICH’S ATAXIA, or acquired from injury or infection affecting the nervous system. When due to damage to the CEREBELLUM, it is called CEREBELLAR ATAXIA, and when due to loss of sen-
ory feedback from the muscles and joints, it is called SEN-
SORY ATAXIA. —ataxic adj.

ataxiograph n. a device that measures ATAXIA by assess-
ing the amount a person’s body sways when he or she is standing upright with eyes closed. Also called ataxim-
eter.

ataxia telangiectasia an autosomal recessive genetic disor-
der characterized primarily by an inability to coordinate voluntary muscle movements and by the dilution of small blood vessels in the eyes and skin of the nose and ears. Initial symptoms include limb ataxia and truncal ataxia (swaying of the head and trunk while standing or sitting), which eventually become so severe that the individ-
ual must remain in a wheelchair. Other symptoms in-
clude increasingly slowed speech, the appearance of such movements as MYOClonus, and intention tremors (see AC-
tion tremor), and a proneness to infection, particularly respiratory infection. Also called Louis-Bar syndrome.
ataxic dysarthria a speech disorder characterized by slurring, poorly controlled volume, and sudden spastic irregularities of vocal cord function. Also called ataxic speech.

ataxic feeling a subjective feeling that the ability to coordinate muscular movement has been lost. The feeling may be psychogenic or caused by such psychotropic drugs as antipsychotics, benzodiazepines, and lithium.

ataxic gait a wide-based, staggering gait seen in individuals with cerebellar damage, disease, or degeneration.

ataxic speech see ATAXIC DYSARTHRIA.

ataxic writing uncoordinated or irregular writing caused by brain damage. See also AGRAPHIA.

ateliosis n. 1. incomplete development of the body or of any of its parts, as in infantilism or dwarfishness. 2. formerly, the persistence of infantile or childlike cognitive or emotional developmental stages. Also called atelia.

atherosclerosis n. a common form of arteriosclerosis resulting from accumulations of lipids such as cholesterol on the inner walls of arteries and their hardening into atherosclerotic (or atheromatous) plaques. —atherosclerotic adj.

athetosis n. slow, involuntary, writhing movements of the body, particularly the extremities such as the fingers and toes, caused by damage or degeneration of the basal ganglia. —athetoid adj. —athetotic adj.

athlete-based intervention 1. an intervention that develops an athlete’s perceptions, experiences, or both. 2. an intervention that is initiated and conducted by the athlete.

Athletic Coping Skills Inventory (ACSI) a self-report inventory used to assess an individual’s psychological skills in seven sports-specific areas: (a) coping with adversity, (b) peaking under pressure, (c) GOAL SETTING and mental preparation, (d) concentration, (e) freedom from worry, (f) confidence and ACHIEVEMENT MOTIVATION, and (g) coachability. The most recent version of the inventory is the ACSI–28, published in 1995. It consists of 28 statements (e.g., “I feel confident that I will play well”) to which participants respond using a 4-point Likert scale, ranging from almost never to almost always. [developed by U.S. psychologist Ronald E. Smith (1940– ), statistician Robert W. Schutz, U.S. psychologist Frank L. Smoll (1941– ), and U.S. psychologist John T. Pateck (1962– )]

Athletic Motivation Inventory (AMI) a self-report inventory used to assess 11 personality traits purportedly associated with successful athletic performance: aggressiveness, coachability, conscientiousness, determination, drive, emotional control, guilt proneness, leadership, mental toughness, self-confidence, and trust. Developed in the late 1960s, the AMI currently consists of 190 sports-specific statements (e.g., “I usually compete best without the advice of others”) or questions (e.g., “Which would you say is the most true of coaching?”) to which participants respond using a multiple-choice format. [developed by U.S. sport psychologists Thomas A. Tutko (1931– ), Leland P. Lyon, and Bruce C. Ogilvie (1920–2003)]

athletic triad the combination of AMENORRHEA, disordered eating, and osteoporosis observed in some female athletes, particularly those in subjectively evaluated sports (e.g., gymnastics, diving) or endurance sports (e.g., cross-country running).

athletic type a body type characterized by a muscular, well-proportioned, broad-shouldered physique. According to KRETSCHEMER TYPOLOGY, such individuals tend to be energetic and aggressive in temperament. See also CARUS TYPOLOGY: CONSTITUTIONAL TYPE.

athymia n. 1. absence of feeling or emotion. 2. congenital absence of the THYMUS.

athyreosis n. a form of HYPOTHYROIDISM found in newborns in whom the thyroid gland has failed to develop normally. Affected children either have no thyroid gland or a gland that is abnormally small and whose essential elements are replaced by fibrous tissue. Also called athyreotic cretinism. See also CRETINISM.

ATI abbreviation for APTITUDE–TREATMENT INTERACTION.

Ativan n. a trade name for LORAZEPAM.

atmosphere effect 1. the tendency for particular behaviors to be stimulated by a particular environment or situation, even when inappropriate, such as gesturing when using the telephone or applauding a poor speech. 2. the tendency for an individual’s thinking on a question to be affected illogically by an impression made by the terms in which the question is stated, as when positively worded premises in a syllogism increase the perceived validity of a false but positively worded conclusion. Also called framing effect. See also ANCHORING BIAS.

atmospheric conditions various aspects of the atmosphere (e.g., temperature, humidity, barometric pressure, composition, toxic conditions) as they affect the comfort and performance of people in their living or working environment.

atmospheric perspective a cue that aids the perception of depth and distance. Atmospheric perspective is the acquired ability to differentiate near and distant objects on the basis of their clear or indistinct appearance.

atomism n. 1. the view that psychological phenomena can best be understood by analyzing them into elementary units, such as sensations or conditioned responses, and by showing how these units combine to form thoughts, images, perceptions, and behavior. Also called atomicist psychology: molecularism. See also ELEMENTARISM: REDUCTIONISM. 2. in vision, the principle that visual perception of a complex stimulus results from an analysis of its elementary components. —atomicist adj.

atonia n. lack of normal muscle tone. See also DYSTONIA. —atomic adj.

atonic seizure a rare type of GENERALIZED SEIZURE in which there is a rapid loss of muscle tone and the individual suddenly falls. It was formerly called an akinetic seizure.

ATP adenosine triphosphate: a nucleotide in living cells that is the source of chemical energy for biological processes. A bond between two of its three component phosphate groups is easily split by a particular enzyme, ATPase (adenosine triphosphatase), yielding energy when a cell requires it.

atrial flutter see ARRHYTHMIA.

at risk vulnerable to a disorder or disease. Risk status for an individual is defined by genetic, physical, and behavioral factors or conditions. For example, children of people with schizophrenia may be considered at risk for schizophrenia,
and heavy cigarette smokers are at risk for emphysema and lung cancer.

**at-risk mental states** psychological symptoms or mental processes that render individuals vulnerable to mental illnesses or to adverse behaviors, such as violence.

**atrium** *n.* (pl. atria) a body cavity or chamber, such as either of the two upper chambers of the heart. —atrial adj.

**atrophy** *n.* a wasting away of the body or a body part, as from lack of nourishment, inactivity, degenerative disease, or normal aging. —atrophic adj.

**atropine** *n.* an anticholinergic drug derived from certain plants, particularly belladonna (see belladonna alkaloid), and also produced synthetically. Its effects include increases in heart rate and rate of breathing, relaxation of smooth muscles, and reduction of secretions (e.g., saliva). It may be used to treat organophosphate poisoning and bradycardia (slowing of the heart rate), or as an adjunct to anesthesia, but it is most commonly employed in eye examinations to dilate the pupil. Atropine is closely related, chemically and pharmacologically, to SCOPOLAMINE.

**atropine-coma therapy** (ACT) a now-abandoned method of treating tense, agitated, and anxious people with psychoses by administering atropine sulfate to induce coma.

**attachment** *n.* the emotional bond between a human infant or a young nonhuman animal and its parent figure or caregiver; it is developed as a step in establishing a feeling of security and demonstrated by calmness while in the parent’s or caregiver’s presence. Attachment also denotes the tendency to form such bonds with certain other individuals in infancy as well as the tendency in adulthood to seek emotionally supportive social relationships.

**attachment and biobehavioral catch-up intervention** an ATTACHMENT-BASED INTERVENTION designed to address the special needs of infants in FOSTER CARE by creating a predictable interpersonal environment that encourages and sustains their nurturance by their foster parents. By attending to the disrupted attachment needs of these infants, many of whom have been put in foster care because of previous maltreatment by their original caregivers, the intervention seeks to develop their regulatory capacity at both the physiological and behavioral level. Research suggests, for example, that the intervention is effective in helping to decrease levels of cortisol, a stress hormone, in these children. They are also reported to show less avoidance behavior and to seek their caregivers’ comfort when distressed. The intervention is proposed to be particularly effective when involving foster caregivers predisposed to value secure attachments; see AUTONOMOUS STATES OF MIND. [developed by U.S. psychologist Mary Doy- ier (1954–)]

**attachment-based intervention** any early intervention based on ATTACHMENT THEORY and focused on enhancing parents’ or caregivers’ ability to perceive their children’s attachment signals accurately and to respond to those signals in an adequate and prompt way. The goal is to foster secure attachment relationships and prevent less optimal or deviant developmental pathways in children.

**attachment behavior** 1. behavior associated with the formation of and investment in significant relationships; 2. infant behavior that results in the infant gaining proximity to or contact with his or her caregiver. Its manifestations include crying, smiling, calling, and clinging. See ATTACHMENT THEORY. [first described by John BOWLBY]

**attachment bond** the primary, enduring, special relationship that gradually develops between an infant and caregiver.

**attachment disorder** see REACTIVE ATTACHMENT DISORDER.

**Attachment Q-set** (AQS) a procedure utilizing the Q SORT technique to measure individual differences in the attachment behavior of infants and young children. Consisting of 90 items on which observers or parents rate a child’s behavior, the procedure was developed (a) to better understand a child’s tendency to use a parent or caregiver as a secure base; (b) to examine this secure base phenomenon in relation to the attachment classifications identified in the STRANGE SITUATION; and (c) to promote interest in normative secure base behavior and individual differences in attachment security beyond infancy. Q-sort ratings of behavior such as the AQS have been used by researchers to explore the origins and consequences of attachment security in home and day care settings. [devised in 1985 by U.S. psychologists Everett Waters (1951–) and Kathleen E. Deane]

**attachment style** the characteristic way people relate to others in the context of intimate relationships, which is heavily influenced by SELF-WORTH and interpersonal TRUST. Theoretically, the degree of attachment security in adults is related directly to how well they bonded to others as children. Four distinct categories of adult attachment style are typically identified: DISMISSIVE ATTACHMENT, FEARFUL ATTACHMENT, PREOCCUPIED ATTACHMENT, and SECURE ATTACHMENT. Attachment styles with respect to infant–mother relationships were first described by Mary D. Salter AINSWORTH and her colleagues, who identified two main styles: SECURE, ATTACHMENT and INSECURE ATTACHMENT; the latter characterized by various patterns (e.g., AMBIGUOUS ATTACHMENT; ANXIOUS–AVOIDANT ATTACHMENT). Different attachment styles in infancy are associated with different psychological outcomes in childhood and later life.

**attachment theory** a theory that (a) postulates an evolutionarily advantageous need, especially in primates, to form close emotional bonds with significant others; specifically, a need for the young to maintain close proximity to and form bonds with their caregivers; and (b) characterizes the different types of relationships between human infants and caregivers. These relationships have been shown to affect the individual’s later emotional development and emotional stability. See also INSECURE ATTACHMENT; SECURE ATTACHMENT; STRANGE SITUATION. [originally developed by John BOWLBY and later expanded by Mary D. Salter AINSWORTH]

**attack behavior** an aggressive use of force or violence against an adversary, usually with intent to harm. Attack behavior often occurs when signals of warning or threat have been ignored. Some humans and nonhuman animals may use attack as a form of DEFENSIVE BEHAVIOR.

**attempted suicide** a deliberate but unsuccessful attempt to take one’s own life. Research has suggested that older men who are of low socioeconomic status and who are single, divorced, or widowed have an especially high risk for suicide. Many studies have found an association between childhood physical or sexual abuse and a history of suicide attempts as well. Additional risk factors include hopelessness, heightened impulsivity, problem-solving defi-
cits, perfectionism, a family history of suicide, and certain mental disorders (i.e., depression, bipolar disorder, substance dependence disorders, psychotic disorders). Although protective factors are studied far less commonly, one of the most consistently identified is a supportive social network or family. Also called suicide attempt.

attend vb. to direct attention to a location, object, feature, or event, which is presumed to increase processing of the attended information and make it more prominent in conscious awareness.

attendance n. 1. the number of pupils present in a class, school, or educational function. 2. a record of how consistently a pupil has been present on the days that a class or school is in session.

attendant care 1. nonmedical, in-home assistance with dressing, feeding, and other activities of daily living provided to individuals with a physical or developmental disability who otherwise are able to live independently. 2. one-on-one direct supervision by a trained attendant of a juvenile who has been taken into custody in a nonsecure setting.

attending behavior any behavior engaged in by an individual while attentively listening to and observing a speaker, for example, exhibiting an open, interested posture and maintaining eye contact. Helpful attending behaviors, along with active listening, are considered cornerstones of a therapist’s or counselor's general ability.

attention n. a state in which cognitive resources are focused on certain aspects of the environment rather than on others and the central nervous system is in a state of readiness to respond to stimuli. Because it has been presumed that human beings do not have an infinite capacity to attend to everything—focusing on certain items at the expense of others—much of the research in this field has been devoted to discerning which factors influence attention and to understanding the neural mechanisms that are involved in the selective processing of information. For example, past experience affects perceptual experience (we notice things that have meaning for us), and some activities (e.g., reading) require conscious participation (i.e., voluntary attention). However, attention can also be captured (i.e., directed involuntarily) by qualities of stimuli in the environment, such as intensity, movement, repetition, contrast, and novelty. See also DIVIDED ATTENTION; EIGHTLESS ATTENTION; FOCAL ATTENTION; INVOLUNTARY ATTENTION; POSTVOLUNTARY ATTENTION; PRIMARY ATTENTION; SECONDARY ATTENTION; SELECTIVE ATTENTION; SPATIAL ATTENTION; VISUAL ATTENTION.

attentional blindness a general term for any failure to notice visual stimuli that can be attributed to attentional factors rather than perceptual impairment. See ATTENTIONAL NARROWING; CHANGE BLINDNESS; INATTENTIONAL BLINDNESS; PERCEPTUAL SET; REPEITION BLINDNESS.

attentional blink the inability to detect a second target presented within 500 ms of the first, where the two targets appear in a rapid sequential presentation of distractors and targets. It is attributed to attentional requirements for processing the target and not to perceptual impairment.

attentional capture the involuntary focusing of attention, for example by a change in a stimulus, which interrupts other processing.

attentional control of action model see CONTROL OF ACTION MODEL.

attentional dyslexia a type of VISUAL WORD-FORM DYSLEXIA in which a person is able to read words but has difficulty identifying their constituent letters. This is thought to be caused by a failure of the letter-to-word binding system, resulting in the “migration” of letters between words. People with attentional dyslexia are able to read letters significantly better when they are presented in isolation than when presented together with others as part of a text.

attentional focus the focus of an individual’s attention at a particular moment. This focus may be internal (i.e., attending to cognitive, emotional, or pain cues) or external (i.e., attending to environmental cues). See ASSOCIATIVE-DISSOCIATIVE STRATEGY; TEST OF ATTENTIONAL AND INTERPERSONAL STYLE.

attentional narrowing the restricting of attention in high-stress situations to a small set of information sources, with the potential omission of critical, task-relevant information. For example, when driving to the hospital for a medical emergency, the driver may focus attention only on the road ahead and not notice events at the side of the road, such as a pedestrian entering a crosswalk.

attentional strategy a pattern of ATTENTIONAL FOCUS for the purpose of efficient execution of a task. The pattern may be specifically learned or habitually developed. For example, a quarterback in football starts with a broad external focus (determining the opposition’s defense pattern) and moves to an internal focus (selecting the appropriate play), then back to a broad external focus after snap (determining pass patterns), and finally to a narrow external focus (selecting the receiver and executing the throw). See also ASSOCIATIVE-DISSOCIATIVE STRATEGY.

attention-control training (ACT) a program that assists an individual to be more effective at maintaining appropriate ATTENTIONAL FOCUS. It is achieved by assessment of the individual’s attentional strengths and weaknesses, the attentional demands of the environment in which the individual’s performance occurs, environmental and personal characteristics likely to induce stress and dictate behavior under pressure, and typical error patterns and situations in which they occur. This assessment leads to the planning of an intervention protocol, the purpose of which is to teach the individual to concentrate on all the task-relevant cues and ignore all the task-irrelevant cues in a given situation. Also called attention training.

attention decrement the tendency for people to pay less attention to stimuli coming later in a sequential occurrence or presentation and thus to remember them less well. For example, students studying a list of terms and their meanings will have more difficulty focusing on and committing to memory those at the end.

attention-deficit/hyperactivity disorder (ADHD) a behavioral syndrome characterized by the persistent presence of six or more symptoms involving (a) inattention (e.g., failure to complete tasks or listen carefully, difficulty in concentrating, distractibility) or (b) impulsivity or hyperactivity (e.g., blurting out answers; impatience; restlessness; fidgeting; difficulty in organizing work, taking turns, or staying seated; excessive talking; running about; climbing on things). The symptoms, which impair social, academic, or occupational functioning, start to appear before
attention disorder

the age of 7 and are observed in more than one setting. ADHD has been given a variety of names over the years, including the still commonly used attention-deficit disorder (ADD).

attention disorder a disturbance characterized by an inability to maintain focus on an activity or by difficulties in taking notice of, responding to, or being aware of the behavior, demands, or requests of other people. Previously, this term was frequently used interchangeably with MINIMAL BRAIN DYSFUNCTION, as impairments of attention are among the most common manifestations of brain damage. See also LEARNING DISABILITY.

attention fluctuation see FLUCTUATION OF ATTENTION.

attention-getting adj. describing a type of behavior, often inappropriate, that is used to gain attention. Childhood TANTRUMS are an example of such behavior.

attention load measure a method that uses competing cognitive tasks to assess the processing demands made by each task. The degradation in performance of one task is taken to be a measure of the attentional demands made by the other task. See DUAL-TASK COMPETITION.

Attention Network Test (ANT) a test that provides independent measures of efficiency for the three aspects of attention specified in the ATTENTION NETWORK THEORY: the alerting function, the orientating function, and the executive function. It takes the form of a simple computerized task in which participants are required to recognize and react to target stimuli under various cue conditions. The test has been widely used to investigate attentional disorders, notably ATTENTION-DEFICIT/HYPERACTIVITY DISORDER. [devised by U.S. psychologist Jin Fan and colleagues in 2002]

attention network theory a theory holding that attention is dependent on three separate but interacting neural networks: an alerting or vigilance network, an orientation and selection network, and an executive and conflict network. The theory has been investigated using neuromaging techniques and a range of experimental tests. See also ATTENTION NETWORK TEST. [proposed in 1990 by U.S. psychologists Michael I. Posner (1936–) and Steven E. Petersen]

attention overload a psychological condition that results from excessive demands on attention. The effect is temporary depletion of available attention and an inability to cope with tasks that demand attention. Attention overload can occur in work tasks, such as supervising activity of commercial aircraft in an airport control tower. In resource models of attention, such as the UNITARY-RESOURCE MODEL, overload refers specifically to situations in which the demand for attentional resources exceeds the supply. See also INFORMATION OVERLOAD.

attention shifting moving the focus of attention from one location to another. Shifts can be made intentionally or caused automatically by the abrupt onset of a stimulus. For intentional shifts, a spatial cue must be presented a few hundred milliseconds before the displayed information to allow attention to be shifted to the cued location.

attention span the length of time an individual can concentrate on one specific task or other item of interest. Compare APPREHENSION SPAN. See also SCOPE OF ATTENTION.

attention-span test any measure of an individual’s ability to focus on a task or of his or her susceptibility to distraction. A problem with all such tests is variance in scores attributable to other variables (e.g., hunger, fatigue, factors in the testing environment).

attention training see ATTENTION-CONTROL TRAINING.

attentiveness n. 1. the state of being alert and actively paying attention. 2. the quality of actively attending to the needs of others.

attenuated positive symptoms in schizophrenia, a reduction in hallucinations, delusions, bizarre behavior, or conceptual thought problems. See also POSITIVE SYMPTOM.

attenuated psychotic symptoms in schizophrenia and other PSYCHOTIC DISORDERS, an increase in reality-based perceptions and a reduction in symptoms, such as delusions, hallucinations, markedly incoherent speech, and disorientation.

attenuation n. 1. the lessening or weakening in the intensity, value, or quality of a stimulus. 2. an underestimation of the size of an effect or relationship due to poor measurement or RESTRICTION OF RANGE. See also CORRECTION FOR ATTENUATION.

attenuation theory a version of the FILTER THEORY of attention proposing that unattended messages are attenuated (i.e., processed weakly) but not entirely blocked from further processing. According to the theory, items in unattended channels of information have different thresholds of recognition depending on their significance to the individual. Thus, a significant word (e.g., the person’s name) would have a low threshold and, when mentioned, would be recognized even if that person’s attention is concentrated elsewhere (e.g., in conversation with someone else). See also COCKTAIL-PARTY EFFECT. [proposed in 1960 by British psychologist Anne Marie Treisman (1935–)]

attenuator n. a calibrated device that accurately controls the decrease in the intensity of tones or light on electronic instruments, such as AUDIOMETERS, stereophonic sound systems, or video equipment.

attitude n. a relatively enduring and general evaluation of an object, person, group, issue, or concept on a dimension ranging from negative to positive. Attitudes provide summary evaluations of target objects and are often assumed to be derived from specific beliefs, emotions, and past behaviors associated with those objects. —attitudinal adj.

attitude accessibility the likelihood that an attitude will be automatically activated from memory on encountering the ATTITUDE OBJECT. Accessibility is assumed to depend on the strength of the associative link in memory between the representation of the object and the evaluation of the object: The stronger the memory link between the object and its evaluation, the more quickly the attitude will come to mind. Attitudes that come quickly to mind are believed to be better guides to behavior. Accessibility is a determinant of ATTITUDE STRENGTH.

attitude–behavior consistency the extent to which behavior toward an ATTITUDE OBJECT is consistent with the attitude associated with that object. Positive attitudes are associated with approach behaviors; negative attitudes are associated with withdrawal behaviors.

attitude change any alteration in an attitude, which may result from active attempts by others to change the attitude or from processes initiated by the person holding the attitude.
attribute-congeniality effect the tendency to remember information that is evaluatively consistent with an attitude better than information that is evaluatively inconsistent with an attitude.

attitude measure a procedure in which individuals are assigned quantitative values that reflect systematic variation on some underlying attitude. Several broad categories have been developed, including direct attitude measures, indirect attitude measures, explicit attitude measures, and implicit attitude measures.

attitude object any target of judgment that has an attitude associated with it. Attitude objects may be people, social groups, policy positions, abstract concepts, or physical objects.

attitude-relevant knowledge information that is directly associated with an attitude object and is activated in memory when the object is encountered. Attitude-relevant knowledge is usually measured in terms of the amount of information associated with the object. Also called issue-relevant knowledge: working knowledge.

attitude scale a self-report measure used to assess an attitude. See Likert scale: semantic differential; Thurstone attitude scales.

attitude strength the extent to which an attitude persists over time, resists change, influences information processing, and guides behavior. Strong attitudes possess all four of these defining features, whereas weak attitudes lack them. A number of attitude properties have been shown to be predictors of an attitude's strength, including attitude accessibility, ambivalence of an attitude, and centrality of an attitude, among others.

attitude survey a set of attitude measures usually designed to assess attitudes toward more than one attitude object.

attitude system a set of two or more attitudes that are associated with one another in memory. Attitude systems can be characterized in terms of the number of attitudes in the system, the strength, number, and pattern of associations among the attitudes, and the evaluative consistency of the attitudes in the system. See also interattitudinal consistency.

attitudinal involvement see ego involvement.

attitudinal reflex a reflex that helps put an animal in a position or condition to make a complex response, as in preparing to attack an adversary.

attitudinal types in Carl Jung's analytic psychology, two personality types defined by habitual extraversion on the one hand and habitual introversion on the other. See introversion—extraversion. See also functional types.

attraction n. 1. the interest in and liking of one individual by another, or the mutual interest and liking between two or more individuals. Interpersonal attraction may be based on shared experiences or characteristics, physical appearance, internal motivation (e.g., for affiliation), or some combination of these. Also called interpersonal attraction. 2. in environmental psychology, a quality affecting proximity between individuals. For example, male–female and female–female pairs who enjoy each other's company position themselves closer to each other than do pairs who feel no personal liking or affection for each other. Environmental influences, such as noise, heat, and humidity, decrease attraction between pairs of individuals. See pronemics. —attractive adj.

attraction relations patterns of liking-disliking, acceptance-rejection, and inclusion-exclusion among members of a group. Such patterns are also called sociometric structures, particularly when assessed through the use of sociometry.

attraction—selection—attrition model (ASA model) a model proposing that (a) people are attracted to organizations that are congruent with their values, personalities, and needs; (b) the organization, in turn, employs people with attributes that fit the organizational culture; and (c) those employees who do not fit the organizational culture leave. Over time the characteristics of the people who constitute the organization become increasingly homogeneous as the result of this process. [proposed by U.S. organizational psychologist Benjamin Schneider (1938–) in 1987]

attractor dynamics an approach to analyzing and understanding the interactions of goals, feedback, and the environment in the evolution of a movement trajectory, especially for repetitive movements.

attributable risk in epidemiology, the incidence rate of a disease or disorder that can be considered to have been caused by exposure to a risk factor. A large portion of lung cancers can be attributed to tobacco use, constituting a substantial attributable risk for this disease.

attribute 1. n. a quality or property of a person, sensation, or object, for example, the tonal attribute of a note. 2. vb. to assign an effect to a particular causal factor or agent. See attribution theory.

attribute model of memory a model in which different brain regions process different dimensions or attributes of a learning or memory situation—space, time, sensory dimensions, response, and emotional aspects.

attribution n. 1. an inference regarding the cause of a person's behavior or an interpersonal event. Three dimensions are often used to evaluate people's attributional styles, or characteristic tendencies when inferring such causes: the internal–external dimension (whether they tend to attribute events to the self or to other factors), the stable–unstable dimension (whether they tend to attribute events to enduring or transient causes), and the global–specific dimension (whether they tend to attribute events to causes that affect many events or just a single event). 2. in the two-word stage of language development, a noun qualified by an attribute, for example, blue car.

attributitional analysis of persuasion an approach to understanding persuasion in terms of the reasons given by people for why communicators of persuasive messages adopt particular attitudes.

attribution error an error or bias in ascribing motives to behaviors or causes to outcomes. See fundamental attribution error: group attribution error; ultimate attribution error.

attraction of emotion see schachter–singer theory.

attraction theory a theoretical proposition about the processes by which people ascribe motives to their own and others' behavior, and particularly whether these motives are either internal and personal (a dispositional attribution) or external and circumstantial (a situa-
attributive theory of leadership

1. A model of LEADERSHIP EMERGENCE and evaluation that assumes that individuals make inferences about leadership ability by observing and interpreting certain environmental and behavioral cues. Like LEADER CATEGORIZATION THEORY, this theory assumes that followers respond more positively to a leader who displays the qualities and behaviors that match their IMPLICIT LEADERSHIP THEORIES. See also LEADER PROTOTYPE; LEADERSHIP THEORIES. [proposed in 1982 by U.S. industrial and organizational psychologists Robert G. Lord (1946— ), Roseanne J. Foti (1954— ), and James Steven Phillips].

2. A model that suggests leaders observe their followers’ behavior, make inferences about the causes of that behavior (i.e., whether it is the result of internal, personal factors or of external, circumstantial ones), and then respond on the basis of those inferences. For example, a manager who makes an internal attribution by concluding that an employee’s poor performance on a recent project was due to some characteristic of that person (e.g., lack of motivation) is likely to decide on a harsher disciplinary action than if he or she made an external attribution by concluding the poor performance was due to the situation (e.g., a rushed completion schedule), [proposed in 1979 by U.S. social psychologist Stephen G. Green (1945— ) and U.S. industrial and organizational psychologist Terence R. Mitchell (1942— )].

attribution therapy a form of therapy in which the therapist tries to change a client’s views concerning the causes of events and behavior.

attrition n. the loss of study participants over time. Attrition may occur for a variety of reasons (e.g., the nature of the data being collected, participant relocation, aversive or costly data collection procedures) and can threaten the EXTERNAL VALIDITY and INTERNAL VALIDITY of research. It also creates the potential for bias—individuals who drop out may have unique characteristics that are relevant to the phenomenon of interest such that the remaining sample is no longer representative of the population—and may reduce the POWER of statistical analyses.

attunement n. the matching of affect between infant and parent or caregiver to create emotional SYNCHRONY. The parent’s response can take the form of mirroring (e.g., returning an infant’s smile) or be cross-modal (e.g., a vocal response “uh oh” to the infant’s drooping cerebral on the floor). Attunement communicates to the infant that the parent can understand and share the infant’s feelings. Compare EMOTIONAL FAILURE; MISATTUNEMENT. [first described by U.S. psychiatrist and psychoanalyst Daniel Stern (1934–2012)]

atypical adj. differing from the norm in being unusual, unrepresentative, or uncharacteristic.

atypical antipsychotic a class of ANTIPSYCHOTIC drugs used in the treatment of schizophrenia, delusional disorders, and other disorders characterized by psychotic symptoms, including psychotic bipolar mania. Atypical antipsychotics are also used to treat aggression associated with autism and as adjunctive agents in the treatment of some nonpsychotic conditions, such as obsessive-compulsive disorder, explosive disorder, and severe depression. They are DOPAMINE-RECEPTOR ANTAGONISTS and also block the effects of serotonin at 5-HT_2A receptors. They have additional actions at other neurotransmitter receptors but are not identical in these additional actions. The prototype of the group is Clozapine; others in current clinical use include ARIPIPRAZOLE, ASEPAPINE, ILOPERIDONE, LURASIDONE, OLANZAPINE, QUETIAPINE, RISPERIDONE, and Ziprasidone. Compared with conventional (typical or first-generation) antipsychotics, atypical antipsychotics produce fewer EXTRAPYRAMIDAL SYMPTOMS, are less likely to alter serum levels of PROLACTIN, and appear to be less likely to cause TARDIVE DYSKINESIA, all of which are significant adverse effects of the conventional drugs. However, they have been associated with metabolic effects, such as obesity, diabetes, and high cholesterol. In addition, extreme hyperglycemia, sometimes associated with diabetic ketoacidosis or hyperosmolar coma or death, has been reported. Clozapine use is also associated with AGRANULOCYTOSIS; later atypical antipsychotics (e.g., olanzapine) do not have this side effect. Also called NOVEL ANTIPSYCHOTIC; SECOND-GENERATION ANTIPSYCHOTIC.

atypical depression a MAJOR DEPRESSIVE EPISODE or, less commonly, DYSTHYMIC DISORDER characterized by ATYPICAL FEATURES.

atypical features symptoms of a disorder other than the standard diagnostic criteria. For a MAJOR DEPRESSIVE EPISODE or DYSTHYMIC DISORDER, for example, they would include hypersomnia or improvement of mood in response to positive events.

atypical psychosis any of various conditions involving psychotic symptoms that do not meet the criteria for any specific disorder.

Aubert phenomenon the illusion that a vertical line tilts in the opposite direction from the direction the head is tilted when viewing it. Also called Aubert illusion. [Her mann Aubert (1826–1892), German physician]

AUC abbreviation for AREA UNDER THE CURVE.

audibility curve the relationship between the threshold of hearing for a PURE TONE, expressed in DECIBELS sound-pressure level (dB SPL), and the frequency of the tone. Compare AudioGRAM.

audibility range the sound frequencies that elicit the sensation of hearing. For humans with average hearing, the audible range is usually specified as 20 Hz to 20 kHz. However, humans are much less sensitive to frequencies at the extremes of this somewhat arbitrary range. The frequency range of speech is approximately 100 Hz to 4 kHz. In audiology, pure-tone thresholds are typically measured at frequencies from 250 Hz to 8 kHz. Also called audible range.

audible thought a type of hallucination in which one hears one’s own thoughts as if they were projected by an inner voice.
audience n. 1. a body of onlookers that observes some performance, event, or activity. Unlike street crowds or mobs, audiences are usually restrained and conventional in manner; individuals usually join them deliberately and withdraw when the observed performance or activity is completed. Audiences are, in some cases, widely scattered, as in the audience for a television broadcast. 2. the people reached by communication, particularly when selected as the target of a persuasive message. 

audience effect the influence on behavior of the presence of bystanders. In humans, performance is often improved when the action is simple and well learned (see social facilitation) but may be inhibited when it is complicated, novel, or difficult to perform or when the person believes the behavior might incur the audience's disapproval (see social inhibition). The audience effect has also been observed in fish, birds, nonhuman primates, and other animals. For example, studies of Siamese fighting fish (Betta splendens) have shown that the presence of a male audience can increase aggression during interactions. See also COACTION EFFECT; EVALUATION APPREHENSION.

audience task any performance, competition, work assignment, or goal-oriented activity that is executed in the presence of one or more individuals who watch the activity. See also SOCIAL FACILITATION. Compare COACTION TASK.

audio-combining form sound or hearing.

audiogenic seizure a seizure induced by loud noises. See REFLEX EPILEPSY.

audiogram n. a graph relating an individual's pure-tone thresholds at selected frequencies to those of people with normal hearing. The x-axis is the frequency of the tone; the y-axis is hearing level (HL), expressed in decibels (dB). For example, a person whose threshold is 30 dB above normal for a 4 kHz tone would have an audiogram that shows a point at 4 kHz and 30 dB HL. The audiogram is a basic clinical measurement for assessing and diagnosing hearing disorders. See AUDIOMETER; AUDIOMETRIC ZERO. Compare AUDIBILITY CURVE.

audiogravic illusion mislocalization of sounds that occurs when the body is tilted or the apparent direction of gravity is altered.

audiological illusory the apparent movement of a stationary source of sound when the listener is rotated.

audiology n. the study of hearing, with an emphasis on the evaluation and treatment of hearing disorders and the rehabilitation of individuals with hearing loss or related disorders (e.g., balance disorders). —audiological adj.; —audiologist n.

audiometer n. an electronic device used to measure auditory sensitivity, usually in clinical settings. Its primary use is to produce an AUDIOTRAG. —audiometric adj.

audiometric chamber see SOUND-ATTENUATING CHAMBER.

audiometric zero the level of a pure tone of a given frequency that is just detectable by a person with normal hearing. For example, the audiometric zero for a 1 kHz pure tone is 7.5 dB SPL (decibels sound-pressure level) for TDH49 headphones, according to U.S. standards (ANSI S3.6-1996 Specification for Audiometers). Audiometric zero is used to calibrate audiometers and, by definition, is 0 dB HL (hearing level). See AUDIOTRAG.

audiometry n. the measurement of an individual's hearing ability with electronic AUDIOMETERS to diagnose hearing loss and determine the nature and extent of such loss. Audiometry provides an assessment of the need for hearing aids, aural habilitation (training to help the individual make use of any residual hearing), and possible surgery. Also called diagnostic audiometry. See also ELECTROENCEPHALOGRAPHIC AUDIOMETRY; ELECTROPHYSIOLOGIC AUDIOMETRY; SCREENING AUDIOMETRY; SPEECH AUDIOMETRY. —audiometrician n.

audiotactile device an ASSISTIVE TECHNOLOGY device consisting of a touch-sensitive pad and a SPEECH SYNTHESIZER, which generates a voice output in response to input from the pad.

audiovisural instruction in academic education, technical training, and personnel training, the use of audio aids, visual aids, or both, such as films, slides, videotapes, audiotapes, television, and computers. Also called audiovisual training.

audit n. an evaluation of a service, intervention, or outcome. For example, in health administration it refers to an examination of the care proposed or rendered by a provider, whereas in research it refers to an examination of the soundness of a study’s findings. See MEDICAL AUDIT; TREATMENT AUDIT.

audition n. see HEARING.

auditory abilities abilities to encode and discriminate different sounds or tones, which, according to some theories of intelligence (such as the THREE-STRATUM MODEL OF INTELLIGENCE and the CATTELL–HORN THEORY OF INTELLIGENCE), are distinguished from visual abilities of the kind used in discriminating visual stimuli.

auditory acuity sharpness of hearing: the extent to which one is able to detect and discriminate between sounds that are very similar. For example, auditory frequency acuity is the ability to distinguish between sounds that differ in their frequency composition: A 1 kHz tone can be distinguished from a 1005 Hz tone (a 0.5% change), indicating a high degree of auditory frequency acuity.

auditory agnosia loss or impairment of the ability to recognize and understand the nature of verbal or nonverbal sounds. Subtypes are distinguished on the basis of the type of auditory stimulus the person has difficulty recognizing, for example, environmental sounds such as a dog barking or keys jingling (nonverbal auditory agnosia or environmental sounds agnosia), spoken words (PURE WORD DEAFNESS), or music (sensory AMUSIA).

auditory aphasia a form of APHASIA characterized by impairment in or loss of the ability to comprehend spoken language despite normal hearing. Also called word deafness.

auditory attributes perceptual qualities of sound, including LOUDNESS, PITCH, and TIMBRE.

auditory blending the ability to synthesize the individual sounds (PHONEMES) of a word so that the whole word can be recognized.

auditory brainstem response (ABR) see BRAINSTEM AUDITORY EVOKED RESPONSE.

auditory canal see EXTERNAL AUDITORY MEATUS.

auditory closure the ability to fill in parts of words that were omitted in auditory presentation. It is typically an au-
Auditory Consonant Trigram

A transient form of hearing loss due to short- or long-term exposure to loud noise.

Auditory feedback the sound of one’s own voice heard while one is speaking, which enables adjustments in intensity, pacing, or clarity of speech. In addition to naturally occurring feedback, there are several types of speaking control systems that provide auditory feedback in voice, speech, and language therapy, including REAL-TIME AMPLIFICATION, DELAYED AUDITORY FEEDBACK, and METRONOMIC PACING.

Auditory filter the process responsible for the FREQUENCY SELECTIVITY of the auditory system. The initial stages of auditory processing are often described as consisting of a bank of auditory filters with different center frequencies. The term is closely related to the concept of a CRITICAL BAND but with more emphasis on the “shape” or characteristics of the filter rather than simply its critical bandwidth. See TONOTOPIC ORGANIZATION; TUNING CURVE.

Auditory flicker sound presented as discrete units (with brief gaps) rather than as continuous. See also CRITICAL FLICKER FREQUENCY.

Auditory fusion the combining of separate acoustic items into a single perceptual image.

Auditory hallucination the perception of sound in the absence of an auditory stimulus. Hallucinations may, for example, be of accusatory or auditory voices or of strange noises and other nonverbal sounds. They occur frequently in schizophrenia and other psychotic disorders but may be associated with other conditions as well (e.g., delirium, dementia).

Auditory induction perceptual restoration of a brief (up to 300 ms) sound segment that is masked or replaced by a louder sound having an appropriate spectral composition.

Auditory labyrinth see LABYRINTH.

Auditory localization the ability to identify the position and changes in position of sound sources based on acoustic information. When sounds are presented through headphones, the acoustic image usually appears to originate within the head and lacks the three-dimensional quality of real sound sources. The image can be lateralized on a left–right dimension (auditory lateralization)—that is, toward the left or right ear—but not localized in external space. Also called sound localization.

Auditory masking a reduction in the ability to detect, discriminate, or recognize one sound (the signal or target) due to the presence of another sound (the masker), measured as an increase in the detection threshold caused by the masker. The amount of masking is the increase in threshold measured in decibels (dB). For example, if the detection threshold with no masker is 10 dB SPL (decibels sound-pressure level) and the masker raises the threshold to 60 dB SPL, the amount of masking is 50 dB or, equivalently, the masker produces 50 dB of masking. The ability of one sound to mask another has been used extensively to assess the FREQUENCY SELECTIVITY of the auditory system. See also CRITICAL BAND; MASKING.

Auditory memory memory for information obtained by hearing. It may be either SHORT-TERM MEMORY or LONG-TERM MEMORY, and the material retained may be linguistic (e.g., words) or nonlinguistic (e.g., music).

Auditory memory span the number of simple items,
such as words or numbers, that can be repeated in the same order by a person after hearing the series once. The auditory memory span indicates the capacity of a person's working memory. Also called auditory span. See also memory span.

**auditory nerve** the branch of the eighth cranial nerve (see vestibulocochlear nerve) concerned with the sense of hearing. It originates in the cochlea, from which nerve fibers pass through several layers of nuclei in the brainstem to terminate predominantly in the auditory cortex. Also called acoustic nerve; cochlear nerve.

**auditory object** see fission.

**auditory ossicles** see ossicles.

**auditory pathway** the neural route along which auditory information is conveyed from the cochlear hair cells to the auditory cortex. The major structures in the auditory pathway are the cochlear nucleus, superior olivary complex, lateral lemniscus, inferior colliculus, and the medial geniculate nucleus.

**auditory perception** the organization and interpretation of sensory information received through the ear. It is a complex process in which pressure changes in the air are funneled into the middle ear, where motion of the tympanic membrane and the tiny attached bones (ossicles) are transmitted to the inner ear and cause vibrations of membranous structures within the coiled, fluid-filled cochlea. Many specialized cells in the cochlea amplify and filter the movements through a variety of electromechanical mechanisms. Eventually, hair cells convert the mechanical motions to neural stimulation that is transmitted along the auditory pathway to the auditory cortex for processing.

**auditory perceptual disorder** a former name for central auditory processing disorder.

**auditory processing** the processes or mechanisms that underlie hearing.

**auditory processing disorder** see central auditory processing disorder.

**auditory projection area** see auditory cortex.

**auditory sensation** the sensation produced by a sound or other auditory stimulus.

**auditory sensation level** see sensation level.

**auditory sensation unit** the just noticeable difference in sound intensity. See difference threshold.

**auditory sensory memory** see echoic memory.

**auditory skills** the skills related to hearing, including auditory discrimination, auditory attention, and auditory memory. Also called central auditory abilities.

**auditory space perception** perception of the direction, distance, and elevation of a sound source. See auditory localization.

**auditory span** see auditory memory span.

**auditory spectrum** a term sometimes used to denote the audibility range.

**auditory stimulus** a stimulus capable of eliciting auditory sensation. It usually refers to airborne sound but can include vibration produced by bone conduction or by internally generated events.

**auditory system** the biological structures and processes responsible for hearing. The peripheral auditory system, or auditory periphery, includes the external, middle, and inner ears and the auditory nerve. Auditory structures of the brain, including the auditory cortex, constitute the central auditory system.

**auditory threshold** 1. the minimum level of sound that can be detected by an organism. See absolute threshold. 2. any threshold pertaining to hearing, including difference thresholds, pain thresholds, acoustic reflex thresholds, and bone-conduction thresholds.

**auditory thrombosis** a blood clot in the internal auditory artery, resulting in sudden deafness.

**auditory training** helping people with hearing loss to distinguish sounds and understand spoken language better by teaching them how to make the most effective use of their residual hearing and to discern contextual clues related to situations and environments.

**Auditory Verbal Learning Test (AVLT)** see Rey auditory verbal learning test.

**Aufgabe n.** a predisposition toward particular mental operations inherent in the nature of a task or conveyed by the instructions for performing it. Introduced by the Würzburg School in their introspective experiments on mental processes, the concept became a precursor to the later determining tendency and the modern mental set. [German: “assignment”]

**augmentation n.** 1. an increase in the amplitude of average evoked potential, either above background noise in the average-evoked-response technique or by more than would be expected from the increase in the stimulus. 2. more generally, any increase, enlargement, growth, or intensification.

**augmentation principle** see attribution theory.

**augmentation strategy** a mechanism to increase the effectiveness of pharmacological agents by the addition of other agents. Augmentation strategies are most commonly used in the treatment of depression.

**augmentative communication** communication facilitated, aided, or expanded by a resource other than the communicator. An example is provision of an easy-to-access online dictionary or thesaurus to e-mail recipients, or of links to websites for additional information regarding news items. See also facilitated communication.

**augury n.** the divination of future events on the basis of omens, portents, or other signs. In ancient Rome, an augur was a priest whose interpretations of natural phenomena (e.g., meteorological events, the flight of birds) were used to guide public decisions.

**aura n.** 1. a subjective sensation that precedes an epileptic seizure or migraine headache. It may include such phenomena as strange tastes or odors, flashes of light (a visual aura), numbness, and feelings of unreality or déjà vu. 2. in parapsychology, a subtle halo or emanation that purportedly surrounds every person, animal, plant, or object. Some sensitives claim to be able to discern such auras, which can allegedly reveal an individual's personal qualities as well as his or her state of physical health. It is also claimed that auras may be rendered visible by such means as Kirlian photography and the use of Xlina Screens. In spiritualism and theosophy, a person's aura is sometimes identified with his or her astral body (see astral projection); in other traditions, it may be seen as the man-
aural

ifestation of a life force or energy field. See also EFLUVIUM; REICHENBACH PHENOMENON.

aural adj. pertaining to or perceived by the ear.

aural harmonic a distortion product generated within the ear. See HARMONIC.

auricle n. 1. see PINNA. 2. a small ear-shaped pouch that extends from the upper anterior portion of each ATRIUM of the heart.

auscultation n. a diagnostic method in which the examiner listens for sounds within the body either with the aid of a stethoscope (mediate auscultation) or directly by laying the ear on the surface of the body (immediate auscultation).

Austrian school the theoretical developments in psychology associated principally with the universities of Vienna and Graz in Austria at the end of the 19th century. Influenced by Franz BRENTANO and Ernst MACH, the emphasis was on the mental processes that produced whole, organized perceptions, a focus that was a precursor to GESTALT PSYCHOLOGY. See ACT PSYCHOLOGY.

aut- combining form see AUTO-.

autassassinophilia n. a PARAPHILIA in which sexual arousal and the achievement of orgasm are facilitated by the fantasy or belief that one is in danger of being killed.

auricular perturbing or influencing the auricle.

auricular adj. pertaining to or perceived by the ear.

auricle adj. pertaining to or perceived by the ear.

aural harmonic a distortion product generated within the ear. See HARMONIC.

authoritarian personality a personality pattern characterized by strict adherence to highly simplified conventional values, an attitude of great deference to authority figures while demanding subservience from those regarded as lower in status, and hostility toward people who deviate from conventional moral prescriptions.

autocratic leader a leader who is guided by (a) fear of an external authority or (b) the type of conscience that is guided by (a) fear of an external authority or (b) the voice of an internalized external authority, such as the SUPEREGO. Compare HUMANISTIC CONSCIENCE. [defined by Erich FROMM]

authoritarian leader the type of leader who determines policy and makes decisions without seeking input from followers, rejects any suggestions from others, assigns tasks to group members while considering their preferences, and dominates interactions through frequent criticism. Also called AUTOCRATIC LEADER. Compare DEMOCRATIC LEADER; LAISSEZ-FAIRE LEADER. [defined by Kurt LEWIN and his colleagues in experimental studies of leadership styles]

authoritarian parenting see PARENTING.

authority n. the capacity to influence others. Formal authority enables an individual to exert influence as a result of either high, legally recognized office (legitimate authority) or high rank in a long-established but not legally codified hierarchy (traditional authority). Informal authority is based on the individual having either attributes that facilitate the achievement of a group’s goals (rational or expert authority) or an attractive and authoritative personality serving to enhance his or her credibility (charismatic authority).

authority and social order maintaining orientation see CONVENTIONAL LEVEL.

authority complex a pattern of emotionally charged concepts of authority that are partially or completely repressed. To satisfy an unconscious need for authority, a person projects power onto certain other people (see PROJECTION) and experiences inferiority in their presence. Therefore, reactions to authority often take the form of oversubmission.

authority relations see STATUS RELATIONS.

autism n. 1. a neurodevelopmental disorder characterized by markedly impaired social interactions and verbal and nonverbal communication; narrow interests; and repetitive behavior. Manifestations and features of the disorder appear before age 3 but vary greatly across children according to developmental level, language skills, and chronological age. They may include a lack of awareness of the feelings of others, impaired ability to imitate, absence of social play, abnormal speech, abnormal nonverbal communication, and a preference for maintaining environmental sameness. Classified in DSM-IV-TR as a PERSISVE DEVELOPMENTAL DISORDER, autism has been subsumed into AUTISM SPECTRUM DISORDER in DSM-5 and is no longer considered a distinct diagnosis. Also called AUTISTIC DISORDER: childhood autism: early infantile autism: infantile autism: KANNER’S SYNDROME. 2. in schizophrenia, an abnormal preoccupation with the self and fantasy such that there is a lack of interest in or ability to focus on external reality. —AUTISTIC adj.

autism spectrum disorder (ASD) any one of a group of disorders with an onset typically occurring during the preschool years and characterized by varying but often marked difficulties in communications and social interaction. ASD was formerly said to include such disorders as the prototype AUTISM, ASPERGER’S DISORDER, CHILDHOOD DISINTEGRATIVE DISORDER, and RETT SYNDROME; it was synonymous with PERSISVE DEVELOPMENTAL DISORDER but more commonly used, given its reflection of symptom overlap among the disorders. It is now the official term used in DSM-5, where it encompasses and subsumes these disorders: Autism, Asperger’s disorder, and childhood disintegrative disorder are no longer considered distinct diagnoses, and medical or genetic disorders that may be as-
associated with ASD, such as Rett syndrome, are identified only as specifiers of the disorder. Also called autistic spectrum disorder.

**autistic-contiguous position** in object relations theory, a primitive, preverbal mode of normal infant experience that emphasizes sensory contact with others. If such surface contact is not soothing and comforting, the infant may react to the world as potentially dangerous, a reaction that could become pathological if it becomes rigidified as a defensive style. The concept was introduced by U.S. psychoanalyst Thomas Ogden to describe a mode of relating to the world that precedes Melanie Klein’s paranoid-schizoid position and depressive position. Also called autistic-contiguous mode.

**autistic disorder** see autism.

**autistic fantasy** a defense mechanism in which a person deals with emotional conflict and stressors by indulging in excessive daydreaming as a substitute for active problem solving.

**autistic savant** see savant.

**autistic thinking** narcissistic, egocentric thought processes, such as fantasizing and daydreaming, that have little or no relation to reality. It is similar to dereistic thinking (see derealism), but the emphasis is on self-absorption rather than disconnection from reality. The term is highly inaccurate and misleading regarding the characteristics of autism.

**auto-** (aut-) combining form 1. self (e.g., autobiography). 2. self-caused (e.g., automasochism).

**autoagonistophilia** n. sexual arousal from being observed or filmed while engaging in sexual activity.

**autoassassinophilia** n. see autoassassinophilia.

**autobiographical memory** 1. a person’s memory for episodes or experiences that occurred in his or her own life. Often the terms autobiographical memory and episodic memory are used interchangeably. However, autobiographical memory can consist of information stored in episodic memory (i.e., of events experienced at a particular time and place), semantic memory (i.e., of knowledge of general facts and concepts that give meaning to information), or a mix of the two. For example, the autobiographical memory of one’s first day at school might contain episodic information, such as meeting the teacher, but it might also contain semantic information, such as knowledge that the teacher’s name was Susan. 2. more broadly, memory for any information about the self, including not only personal experiences but also self-related factual knowledge, the self-schema, and so forth.

**Autobiographical Memory Interview** (AMI) a semistructured interview designed to assess memory for autobiographical information, impairment of which is often indicative of retrograde amnesia (inability to recall previously learned information or past events) and potentially associated with a variety of neurological and psychiatric disorders. The AMI contains an Autobiographical Incidents Schedule, which queries specific, personally experienced events from childhood, early adult life, and the recent past; and a Personal Semantic Memory Schedule, which queries generic or semantic facts about the self, divided into childhood, early adult life, and recent information. (Developed in 1989 by British neuropsychiatrist Michael D. Kopelman, British clinical psychologist Barbara A. Wilson, and British cognitive psychologist Alan D. Baddeley (1934–)).

**autobiography** n. in therapy or counseling, a technique in which a life history, written by the client from his or her own point of view, is used to obtain information regarding the client’s behavioral patterns and feelings. A structured autobiography is based on explicit questions or topic guidelines supplied by the therapist or counselor. An unstructured autobiography contains no guidelines. See also life review.

**autocentric** adj. centered on or within the self. Compare allocentric.

**autochthonous** adj. 1. native, indigenous, or original. 2. denoting endogenous processes and events that originate within the individual, independently of external influences. Compare allochthonous.

**autochthonous gestalt** a perceptual pattern induced by internal factors (autochthonous forces) rather than factors of the external stimulus.

**autoclitic** n. a unit of verbal behavior (a verbal operator) that depends on other verbal behavior and that alters its effect on a listener. For example, in saying “I think that is a cat,” the words I think serve as an autoclitic to indicate to the listener that the speaker is less than certain about the remaining verbal operators in the sentence. The is also an autoclitic, indicating that the same stimulus is occasioning the words that and cat.

**autocorrelation** n. the situation in which successive values of a variable measured over time are correlated with other values of the same series separated from them by a specific interval. This often occurs with economic or demographic data. Autocorrelations are generally assumed to be linear relationships and may be presented graphically in an autocorelogram or formulaically in an autocorrelation function. Also called serial correlation. See time-series analysis.

**autocratic** adj. 1. dictatorial, high-handed, and undemocratic. 2. wielding unlimited power and not permitting opposition.—autocrat n.

**autocratic leader** see authoritarian leader.

**autocrine** adj. describing or relating to a type of cellular signaling in which a chemical messenger is secreted by a cell into its environment and feeds back to elicit a response in the same cell. For example, some nerve cells have autoreceptors that are affected by neurotransmitter molecules released by the same cell. Compare endocrine: paracrine.

**autodysomophobia** n. see olfactory reference syndrome.

**autoenucleation** n. an act of self-mutilation in which an individual excises an organ or tumor from his or her own body, as, for example, when a person with a psychotic disorder removes an eyeball (see enucleation). Also called self-enucleation.

**autoerotic asphyxia** sexual pleasure obtained from being unable to breathe during masturbation. It may involve the person hanging himself or herself, a practice that has been found to result in a number of accidental deaths each year when the person is unable to get free of the rope. Also called autoerotic asphyxiation.

**autoeroticism** n. the creation of sexual excitement and gratification by the self, whether through masturbation,
other sexual behaviors (e.g., stimulating nongenital portions of the body), or thoughts (e.g., daydreams, fantasies). Also called autoerotism. Compare ALLOEROTICISM. —autoerotic adj. [defined by British sexologist Havelock Ellis (1859–1939)]

**autophagy**

a relaxation technique in which a quasi-hypnotic state is self-induced and deep relaxation is achieved through mental imagery, breath control, and exercises that focus attention on physical sensations, including warmth and heaviness of the limbs, a regular heartbeat, abdominal warmth, and cooling of the forehead. The aim is to reduce stress by gaining control of autonomic arousal associated with anxiety and to obtain an IDEAL PERFORMANCE STATE. [developed in the early 20th century by German neurologist Johannes Heinrich Schultz (1884–1970)]

**autognosis** n. knowledge of self.

**autographism** n. see DERMATOGRAPHISM.

**autohynosis** n. see SELF-HYPNOSIS. —autohypnotic adj.

**autohypnotic amnesia** a Jungian term for REPRESION, based on the observation that a form of amnesia may be induced in a person under hypnotization (see HYPNOTIC AMNESIA; POSTHYPNOTIC AMNESIA). Repression in this context is seen as a form of systematic amnesia, in which the individual “forgets” certain ideas or memories through a process of autosuggestion.

**autointeraction** n. a condition in which the body’s immune system fails to recognize its own tissues as “self” and attempts to reject its own cells. It is a primary factor in the development of such diseases as rheumatoid arthritis and systemic lupus erythematosus (called autoimmune disorders). —autoimmune adj.

**autokinetic effect** the illusion of seeing a static spot of light moving in a dark room. The autokinetic effect has been used in certain psychological experiments, for example, investigating suggestibility or the establishment of group norms. Also called autokinetic illusion.

**automaintenance** n. a procedure in which stimulus–reinforcer pairings are used to sustain an already established behavior. It is most commonly used with pigeons. Signals are presented, regardless of behaviors, on a response device (e.g., a pecking disk), and reinforcement (e.g., food) is delivered after a specified time period regardless of the pigeons’ pecking activity.

**automasochism** n. sexual pleasure derived from inflicting pain on oneself during masturbation or during sexual activity with a partner. See also SEXUAL MASOCHISM.

**automated assessment** see COMPUTERIZED ASSESSMENT.

**automated desensitization** the use of devices such as digitized media to facilitate the presentation of anxiety-provoking and relaxing stimuli during SYSTEMATIC DESENSITIZATION. It is especially helpful in situations where a client is reluctant to undergo desensitization in the presence of the therapist. See DEVICE FOR AUTOMATED DESENSITIZATION.

**automated natural language understanding** understanding speech or writing through computer-based processes. Understanding in this context means determining the meaning of what is spoken or written, enabling an appropriate response to questions or commands. Compare AUTOMATED SPEECH RECOGNITION.

**automated reasoning** computer-based mathematical reasoning, including geometric theorem proving, algebraic equation solving, and mathematical theorem proving. It is a subdiscipline of ARTIFICIAL INTELLIGENCE.

**automated speech recognition (ASR)** recognition of speech by means of a computer-based process. Recognition in this context usually means the production of a written representation of the words spoken. Unlike AUTOMATED NATURAL LANGUAGE UNDERSTANDING, ASR does not require an understanding of the meanings of the words recognized.

**automatic action** an act that is performed without requiring attention or conscious awareness.

**automatic activation** involuntary processing of stimuli and preparation for associated responses. This activation tends to occur more rapidly than that resulting from voluntary processing.

**automatic activation of attitudes** the spontaneous activation of an attitude from memory on encountering the ATTITUDE OBJECT. The likelihood of automatic activation depends on the ATTITUDE ACCESSIBILITY.

**automatic drawing** the act of drawing images or objects while in a hypnotic trance or in a situation in which attention is distracted. It may be used in HYNOTHERAPY to provide a therapist with access to unconscious material from the client. See also AUTOMATIC WRITING.

**automaticity** n. the quality of a behavior or mental process that can be carried out rapidly and without effort or explicit intention (an AUTOMATIC PROCESS). In brain imaging studies, automatic processes show dramatic decreases in cortical activity. See also DEAUTOMATIZATION HYPOTHESIS; HABIT.

**automatic obedience** excessive, uncritical, or mechanical compliance with the requests, suggestions, or commands of others.

**automatic performance** see ROUTINIZED BEHAVIOR.

**automatic process** see ROUTINIZATION.

**automatic promotion** see SOCIAL PROMOTION.

**automatic reinforcer** a physical or sensory consequence of a behavior that serves to reinforce the behavior, without the influence of another individual. An example is a person continuing to read a book because he or she enjoys it.

**automatic speaker recognition** identification of a speaker by means of an analysis, usually computer-based, of the characteristics of his or her speech. Also called AUTOMATIC SPEAKER IDENTIFICATION.

**automatic speech** 1. speech that erupts involuntarily, or without conscious control. It sometimes occurs as a consequence of dementia, Tourette’s syndrome, or highly emotional states. Automatic speech is not to be confused with synthesized or SYNTHETIC SPEECH. 2. speech that is uttered with little or no conscious consideration of the spoken material, such as the days of the week, numbers, the alphabet, and other well-learned material.
**automatic thoughts** 1. thoughts that are instantaneous, habitual, and nonconscious. Automatic thoughts affect a person’s mood and actions. Helping individuals to become aware of the presence and impact of negative automatic thoughts, and then to test their validity, is a central task of cognitive therapy. 2. thoughts that have been so well learned and habitually repeated that they occur without cognitive effort. Also called routinized thoughts.

**automatic writing** the act of writing while one’s attention is not focused on the task or of writing without conscious awareness, as during a hypnotic trance. It may be used in hypnotherapy to provide a therapist with access to unconscious material from the client. See also automatic drawing.

**automatism** n. nonpurposeful behavior performed mechanically, without intention and without conscious awareness. It may be motor or verbal and ranges from simple repetitive acts, such as lip-smacking or repeatedly using the same phrase (e.g., as it were), to complex activities, such as sleepwalking and automatic writing. Automatism is seen in several disorders, including catatonic schizophrenia and complex partial seizures.

**automatism defense** a legal defense consisting of the claim that criminal intent (see mens rea) is lacking as a result of the defendant’s dissociated state at the time the criminal act was committed. The defense is more common in the United Kingdom and Canada than in the United States.

**automatization** n. 1. the development of a skill or habit to a point at which it becomes routine and requires little if any conscious effort or direction. 2. the state of individuals who respond to compulsive impulses so automatically that they may be described as automata (see automaton).

**automatograph** n. a classic device used to measure movement. It consists of a plate that lies on metal balls and thus follows every impulse of the hand that lies flat on it: The plate has an attachment by which the slightest involuntary movements are registered.

**automaton** n. 1. a machine that simulates human functions (e.g., a mechanized installation device on a conveyor belt) via preprogrammed coded instructions. See also cybernetics; feedback; robotics. 2. a human acting in an autonomous and routine manner, seemingly without an external driving force. See also automatization.

**automotive telematics** technology for delivering information to moving automobiles and other road vehicles. The information can include traffic conditions on routes of interest, alternative routing, hotel accommodation, safety news, and entertainment for passengers.

**automutilation** n. sexual pleasure derived from mutilating parts of one’s body or from fantasy about mutilated parts of one’s body. It usually involves cutting some part of the body during masturbation.

**autonecrophilia** n. sexual pleasure derived from the fantasy that one is dead and that another person is having sexual relations with one’s dead body.

**autonoetic** adj. describing a state of knowledge or memory in which one is aware not only of the known or remembered thing but also of one’s personal experience in relation to that thing. Autonoetic consciousness is a corresponding kind of consciousness in which one’s knowledge of facts, concepts, and meanings is mediated through an awareness of one’s own existence in time. Compare anoetic; nortic; [defined Endel Tulving]

**autonomic** adj. occurring involuntarily, particularly pertaining to the AUTONOMIC NERVOUS SYSTEM or the processes controlled by it. —autonomically adj.

**autonomic apparatus** all the body organs, including the endocrine glands and viscera, that are controlled by the AUTONOMIC NERVOUS SYSTEM.

**autonomic balance** the complementary and reciprocal interactions of the sympathetic and parasympathetic branches of the AUTONOMIC NERVOUS SYSTEM.

**autonomic conditioning** in classical conditioning, a procedure in which the conditioned response measured is an index of physiological arousal, usually an electrophysiological measure such as skin conductance. The conditioned stimulus is usually a simple visual or auditory stimulus presented for 5 to 10 seconds, whereas the unconditioned stimulus is a mildly aversive stimulus such as an electric shock or a loud noise.

**autonomic dysfunction** dysfunction of the AUTONOMIC NERVOUS SYSTEM, including impairment, failure, or overactivity of sympathetic or parasympathetic function. The dysfunction may be local or generalized, acute or chronic, and is associated with a number of disorders. Also called autonomic neuropathy; dysautonomia. See also familial dysautonomia.

**autonomic dysreflexia** exaggerated activity of the AUTONOMIC NERVOUS SYSTEM in an individual with a spinal cord injury at or above the level of the sixth thoracic vertebra. It is caused by irritation, pain, or similar stimulation of the nervous system below the area of the injury and may be fatal. Symptoms include the sudden onset of headache and hypertension; there may also be arrhythmia, sweating, dilated pupils, blurred vision, nasal stuffiness, flushing, and gooseflesh. Also called autonomic hyperreflexia.

**autonomic ganglia** the ganglia of the AUTONOMIC NERVOUS SYSTEM. They include the two chains of sympathetic ganglia (see sympathetic chain) and the more peripheral parasympathetic ganglia (see parasympathetic nervous system).

**autonomic hyperactivity** arousal of the AUTONOMIC NERVOUS SYSTEM, particularly its sympathetic nervous system functions, resulting in the physiological symptoms associated with anxiety and fear (e.g., sweating, palpitations, dry mouth, light-headedness, upset stomach).

**autonomic hyperreflexia** see autonomic dysreflexia.

**autonomic learning** a type of learning in which the responses learned consist of changes in functions involving the AUTONOMIC NERVOUS SYSTEM, such as heart rate or blood pressure. See also conditioned response.

**autonomic motor pool** motor neurons in the brainstem and spinal cord that give rise to nerves that supply AUTONOMIC GANGLIA.

**autonomic nervous system** (ANS) the portion of the nervous system innervating smooth muscle and glands, including the circulatory, digestive, respiratory, and reproductive organs. It is divided into the sympathetic nervous system and parasympathetic nervous system. Autonomic responses typically involve changes in involuntary bodily functions, such as heart rate, salivation, digestion, perspi-
autonomic neuropathy

autonomic neuropathy see AUTONOMIC DYSFUNCTION.

autonomic reactivity 1. the extent to which an organism responds physiologically to a stimulus, such as a stressor. 2. a pattern of responses of the AUTONOMIC NERVOUS SYSTEM that is characteristic of an individual throughout life. Also called autonomous response specificity: individual response stereotypy.

autonomic response see AUTONOMIC NERVOUS SYSTEM.

autonomic restrictors people with GENERALIZED ANXIETY DISORDER, who have lower heart rate, blood pressure, skin conductance, and respiration rate than do people with other anxiety disorders.

autonomous adj. 1. having an independent existence. 2. acting or operating under one’s own direction. 3. having self-government. Compare HETERONOMOUS.

autonomous activity in GENERAL SYSTEMS THEORY, processes or behaviors that occur spontaneously, in the absence of external eliciting stimuli.

autonomous depression 1. a MAJOR DEPRESSIVE EPISODE that does not occur in response to any obvious psychosocial stressor. See also ENDogenous DEPRESSION. 2. less commonly, depression characterized by agitation and self-criticism.

autonomous stage in Jean PIAGET’s theory of moral development, the stage during which the child, typically 10 years of age or older, eventually understands that rules and laws are not permanent, fixed properties of the world but rather are flexible, modifiable entities created by people. The child gradually relies less on parental authority and more on individual and independent morality and learns that intentions, not consequences or the likelihood of punishment, are important in determining the morality of an act. Also called autonomous morality. See MORAL INDEPENDENCE; MORAL RELATIVISM. Compare HETERONOMOUS STAGE; PREMORAL STAGE.

autonomous states of mind the mental processes exhibited by parents or primary caregivers who are able to discuss coherently their thoughts, feelings, and memories about their own childhood ATTACHMENT experiences. Such individuals are said to demonstrate an autonomous or secure sense of attachment, characterized by an understanding of the importance of nurturance. In contrast, parents or primary caregivers who are not coherent in discussing their childhood experiences are said to have insecure, “nonautonomous” states of mind, characterized by dismissive or conflicted feelings about attachments. Studies indicate that those with autonomous states of mind are likely to raise children who are securely attached themselves (e.g., who seek a mother’s comfort when upset or hurt), whereas those with nonautonomous states are likely to raise children who are also insecurely attached (e.g., who do not seek a mother’s comfort when distressed). This construct is one of the components of the ATTACHMENT AND BIOBEHAVIORAL CATCH-UP INTERVENTION. See also INSECURE ATTACHMENT; SECURE ATTACHMENT. [described by U.S. psychologist Mary Dozier (1954–)]

autonomous syntax the theory that SYNTAX is an autonomous component of language that operates independently of meaning (semantics) and function (pragmatics).

Such a view explains how a sentence with no meaningful content or communicative function can nevertheless be recognized as grammatical by native speakers (see GRAMMATICALITY). It also explains why syntactic rules, such as number agreement between subject and verb, operate regardless of the semantic relationship between the sentence elements. For example, in the two sentences The boy is slamming the doors and The doors are being slammed by the boy, the verb takes different forms to agree with the grammatical subject in each case (boy is; doors are), regardless of the fact that in both cases the boy is the AGENT of the action, and the doors are its PATIENT. See CASE GRAMMAR. [introduced by Noam CHOMSKY]

autonomous work groups small, self-regulated, employee-centered units within an organization that are given responsibility for developing procedures, organizing the production process, generating the required product, and maintaining quality.

autonomy n. 1. a state of independence and self-determination in an individual, a group, or a society. According to some theories, an inordinate focus on self-determination and achievement represents a risk factor for the development of MAJOR DEPRESSIVE DISORDER. See also FUNCTIONAL AUTONY. Compare HETEROLOGY. 2. in SELF-DETERMINATION THEORY more specifically, the experience of acting from choice, rather than feeling pressured to act. This form of autonomy is considered a fundamental psychological need that predicts well-being.

autonomy versus shame and doubt the second of ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, between the ages of 1½ and 3 years. During this stage, children acquire a degree of self-reliance and self-confidence if allowed to develop at their own pace but may begin to doubt their ability to control themselves and their world if parents are overcritical, overprotective, or inconsistent.

autopagnosia n. see AUTOPAGNOSIA.

autophagia n. 1. the chewing or eating of one’s own flesh. 2. the body’s maintenance of nutrition by consumption of its own tissues, as in times of excessive fasting. Also called autophagia.

autophony n. the hearing of one’s own voice reverberating inside one’s head. Autophon is usually caused by diseases of the middle ear, such as serious OTITIS MEDIA, a condition called patulous eustachian tube in which the eustachian tube remains open, or SUPERIOR CANAL DEHISCENCE. Also called autophonia: autophonic response.

autoplasty n. 1. adaptation to reality by modifying one’s own behavioral patterns, rather than by altering one’s environment. Autoplastic behavior can be negative and psychologically harmful, as in the development of neurotic behavior, or positive and psychologically healthy, as in the tendency toward more adaptive thinking and action following psychotherapeutic intervention. Also called autoplasic development. 2. surgical repair using tissue from another part of the patient’s body. Compare ALLOPLASTY.

autoplastic adj.

autopoiesis n. a system, often a COGNITIVE ARCHITECTURE, in which the constituent modular components support, nurture, and maintain each other.

autopsy n. a procedure in which the body of a dead person is examined in an effort to determine the exact cause and time of death. For legal, religious, and cultural rea-
sons, an autopsy generally cannot be performed without permission of the next of kin or an order of the public authorities. The procedure usually requires a detailed dissection of body tissues, laboratory tests, and other techniques when the death occurs under suspicious circumstances. Also called postmortem examination. See also PSYCHOLOGICAL AUTOPSY.

autopsychic delusion a delusion about one’s personality. It is thus distinguished from an ALLOPSYCHIC DELUSION, which refers to the outside world, and a SOMATIC DELUSION, which refers to one’s own body. [defined by German neurologist Karl Wernicke (1848–1905)].

autopsy a. a delusional condition in which the individual maintains distorted ideas about himself or herself, such as being the world’s savior, the devil incarnate, or an unrecognized genius. —autopsychic adj.

autoradiography a. a histological technique that reveals the distribution of radioactive chemicals in tissues or in analytical media, such as electrophoretic plates. —auto radiographic adj.

autoreceptor n. a molecule in the membrane of a presynaptic neuron that regulates the synthesis and release of a neurotransmitter by that neuron by monitoring how much transmitter has been released and “telling” the neuron.

autoregression n. a pattern of relationship between repeated measures of a variable taken over time, such that the variable as measured at one point in time is predicted by the variable observed at one or more earlier points in time. See TIME-SERIES ANALYSIS.

autoregressive model (AR model) a model used to represent TIME SERIES that demonstrate AUTOREGRESSION, that is, where each successive observation depends, at least in part, on one or more previously observed values.

autoscope n. a device or instrument that records or magnifies small muscular movements.

autoscopophilia n. sexual pleasure derived from observing oneself disrobing, being nude, or watching oneself during sexual activity. It may involve viewing videos or pictures of these situations.

autopsycopy n. seeing a double of oneself in external space. The image is generally short-lived and hazy, filmy, and colorless. Also called AUTOSCOPIC PHENOMENON. See also DOPPELGÄNGER PHENOMENON; OUT-OF-BODY EXPERIENCE.

autosexuality n. any form of sexual arousal or stimulation that occurs without the participation of another individual, for example, masturbation, sexual dreams, or sexual fantasies.

autoshaping n. a form of conditioning in which a subject that has been given reinforcement following a stimulus, regardless of its response to that stimulus, consistently performs an irrelevant behavior. The classic example is a pigeon that receives food after a light goes on, then conditions itself to peck at the light even though the pecking is not necessary to receive the food.

autosomal adj. denoting a genetic characteristic located on or transmitted by an AUTOSOME.

autosomal aberration any disorder of structure, function, or both that is associated with an alteration in the structure or number of any of the pairs of chromosomes that are not sex chromosomes (see AUTOSOME). An example of such a disorder is DOWN SYNDROME. Also called AUTOSOMAL ABNORMALITY: AUTOSOMAL ANOMALY.

autosomal dominant see DOMINANT ALLELE.

autosomal recessive see RECESSIVE ALLELE.

autosomal trisomy of group G the condition in which either of the chromosome pairs 21 or 22 (known as group G) includes an additional autosome. The most common of these two autosomal abnormalities is trisomy 21; see DOWN SYNDROME.

autosome n. any chromosome that is not a SEX CHROMOSOME. A human normally has a total of 44 autosomes (arranged in 22 HOMOLOGOUS pairs) in the nucleus of each body cell, although irregular numbers may occur through the loss or addition of one or more autosomes. If a homologous pair of autosomes has an extra chromosome, the condition is called TRISOMY. If one member of a homologous pair is absent, the condition is called MONOSOMY.

autostereogram n. a two-dimensional arrangement of repeated elements that produces a perception of three-dimensional depth when viewed correctly. See RANDOM-DOT STEREOPSIS; STEREOSCOPY.

autostereotyping n. incorporating STEREOTYPES about the groups to which one belongs into one’s own SELF-CONCEPT. Also called SELF-STEREOTYPING. See GROUP IDENTIFICATION. —autostereotype vb.

autostimulation theory a widely held supposition that REM SLEEP in newborn infants facilitates early development of the visual system. It is also thought to explain why REM sleep decreases as infants are exposed to more and more interesting visual stimuli while awake.

autosuggestibility n. susceptibility to being influenced by one’s own suggestions, as in SELF-HYPNOSIS.

autosuggestion n. the process of making positive suggestions to oneself for such purposes as improving morale, inducing relaxation, or promoting recovery from illness. Also called SELF-SUGGESTION. See also AUTOGENIC TRAINING; SELF-AFFIRMATION.

autotomy n. 1. in animal behavior, the casting off of a body part, as, for example, when a lizard sheds its tail to escape from a predator; 2. SELF-MUTILATION or the cutting off by an individual of his or her body parts.

autotopagnosia n. a type of AGNOSIA involving loss or impairment of the ability to recognize (i.e., point to) parts of one’s own body. It is generally associated with a left parietal lobe neoplasm. Also called AUTOPAGNOSIA. Compare SOMATOTOPAGNOSIA.

auxiliary 1. adj. subsidiary or supporting. 2. n. a person or thing that provides support, usually in a subsidiary capacity. 3. n. see AUXILIARY VERB.

auxiliary ego in PSYCHODRAMA, a group member, other than the therapist, who assumes the role of a significant figure in the PROTAGONIST’s life.

auxiliary inversion in grammar, the reversal of the usual order of SUBJECT and AUXILIARY VERB in a declarative sentence to create a question so that, for example, The poodle is barking becomes Is the poodle barking? Such constructions are of major interest in GENERATIVE GRAMMAR and PSYCHOLINGUISTICS. See INTERROGATIVE.

auxiliary organ see EXECUTIVE ORGAN.
auxiliary therapist

auxiliary therapist n. a therapist who takes part in COTHERAPY.

auxiliary verb n. a verb that is used to indicate the tense, mood, or voice of another verb, such as have in The ship had sunk, do in Do you pray?, and be in I was met by a friend. Other common auxiliary verbs in English are can, could, shall, should, will, would, may, might, and must. Also called auxiliary.

availability n. the presence of information in memory storage. Availability is not the same as and should be distinguished from accessibility, which refers to the ability of a portion of information to be retrieved from memory storage at any given time.

availability heuristic n. a common strategy for making judgments about likelihood of occurrence in which the individual bases such judgments on the salience of the information held in his or her memory about the particular type of event: The more available and relevant information there is, the more likely the event is judged to be. Use of this strategy may lead to errors of judgment when information that is highly available in memory (e.g., about well-publicized events, such as plane crashes) leads people to believe that those kinds of events are more probable than they actually are, or when the relative unavailability of information (e.g., about less well-publicized causes of death, as from diabetes) leads people to believe that those kinds of events are less probable than they are. The tendency to make such errors is known as the availability bias. Compare REPRESENTATIVENESS HEDICISTIC. [described in 1973 by Amos Tversky and Daniel Kahneman]

available-case analysis see PAIRWISE DELETION.

avalanche conduction the spreading of nerve impulses from a receptor to a number of other neurons, resulting in an effect that is disproportionate to the initial stimulus, as occurs in a seizure.

avatar n. see ALTER EGO.

Aventyl n. a trade name for NORTRIPTYLINE.

average n. see MEAN.

average child see SOCIOMETRIC STATUS.

average deviation see MEAN DEVIATION.

average error the typical degree to which a series of observations are inaccurate with respect to an absolute criterion (e.g., a standard weight or length) or a relative criterion (e.g., the mean of the observations within a given condition).

average evoked potential (AEP) the summated electrical responses of the brain (see EVOKED POTENTIAL) to repeated presentations of the same stimulus. Since any individual potential typically shows considerable random fluctuations, this technique is used to better distinguish the actual response from background “noise.” Also called average evoked response (AER).

aversion n. a physiological or emotional response indicating dislike for a stimulus. It is usually accompanied by withdrawal from or avoidance of the objectionable stimulus (an aversion reaction). —aversive adj.

aversion conditioning the process by which a noxious or unpleasant stimulus is paired with an undesired behavior. This technique may be used therapeutically, for example, in the treatment of substance abuse, in which case it is called aversion therapy. Also called aversive conditioning.

aversion therapy a form of BEHAVIOR THERAPY in which the client is conditioned to change or eliminate undesirable behavior or symptoms by associating them with noxious or unpleasant experiences, such as a bitter taste (for nail biting) or nausea (for alcoholism). Also called aversive therapy: deterrent therapy.

aversive conditioning see AVERSION CONDITIONING.

aversive control the use of an aversive stimulus or consequence, such as punishment or negative reinforcement, to control behavior.

aversive event see AVIATION THERAPY.

aversive racism a form of racial PREJUDICE felt by individuals who outwardly endorse egalitarian attitudes and values but nonetheless experience negative emotions in the presence of members of certain racial groups, particularly in ambiguous circumstances. For example, if a White employer who supports equality nonetheless favors White candidates over Black candidates in job interviews when all the individuals’ qualifications for the position are unclear, then he or she is demonstrating aversive racism. See also MODERN RACISM.

aversive stimulus any stimulus or occurrence that evokes avoidance or escape behavior. Also called aversive event. See also AVOIDANCE CONDITIONING.

aversive system NEUROTICISM as represented by an individual’s relative sensitivity to negative or punishing (i.e., aversive) cues and stimuli and his or her processes for avoiding them. Compare APPETITIVE SYSTEM. See also BEHAVIORAL INHIBITION SYSTEM. [proposed by British psychologist Jeffrey Alan Gray (1934–2004)]

aversive therapy see AVIATION THERAPY.

Aveyron boy see WILD BOY OF AVEYRON.

avian influenza a highly contagious viral disease among domestic fowl and other birds, colloquially known as bird flu. It is usually spread by migratory birds, which can carry the virus asymptomatically. Cross-transmission to humans has been rare (requiring close contact with infected birds), but there is potential for mutation, which could lead to increased bird-to-human transmission and human-to-human transmission. In humans, typical symptoms include fever, cough, sore throat, muscle aches, eye infections, and pneumonia; it can be fatal.

aviation clinical psychology program a program developed at the Aeromedical Research Laboratory at Fort Rucker, Alabama (established in 1962). The Laboratory directs medical research, provides training support to Army aviation and airborne activities, and trains aviation psychologists.

aviation psychology a specialty in APPLIED PSYCHOLOGY that focuses on understanding human behavior, emotions, and mental states as they relate to the operation and control of aviation systems and influence the safety and efficiency of flight.

aviophobia n. see FEAR OF FLYING.

AVLT abbreviation for Auditory Verbal Learning Test. See REY AUDITORY VERBAL LEARNING TEST.

AVM abbreviation for ARTERIOVENOUS MALFORMATION.

avoidance n. the practice or an instance of keeping away
from particular situations, environments, individuals, or things because of either (a) the anticipated negative consequence of such an encounter or (b) anxious or painful feelings associated with them. Psychology brings several theoretical perspectives to the study of avoidance: its use as a means of coping; its use as a response to fear or shame; its existence as a personality style or predisposition; and its existence as a component in anxiety disorders. See approach–avoidance conflict.

avoidance–avoidance conflict a situation involving a choice between two equally objectionable alternatives, for example, when an individual must choose between unemployment and a salary cut. Also called double-avoidance conflict. See also approach–approach conflict; approach–avoidance conflict.

avoidance behavior any act or series of actions that enables an individual to avoid or anticipate unpleasant or painful situations, stimuli, or events, including conditioned aversive stimuli. See avoidance conditioning. Compare escape behavior.

avoidance conditioning the establishment of behavior that prevents or postpones aversive stimulation. In a typical conditioning experiment, a buzzer is sounded, then a shock is applied to the subject (e.g., a dog) until it performs a particular act (e.g., jumping over a fence). After several trials, the dog jumps as soon as the buzzer sounds, avoiding the shock. Also called avoidance learning. See also escape conditioning.

avoidance coping any strategy for managing a stressful situation in which a person does not address the problem directly but instead disengages from the situation and averts attention from it. In other words, the individual turns away from the processing of threatening information. Examples of avoidance coping include escapistism, wishful thinking, self-isolation, undue emotional restraint, and using drugs or alcohol. While generally viewed more unfavorably than the converse approach coping, avoidant strategies may provide some benefit by reducing stress and preventing anxiety from becoming overwhelming. [Identified in 1986 by Susan H. Roth (1948– ), U.S. personality psychologist, and Lawrence J. Cohen (1958– ), U.S. clinical psychologist]

avoidance gradient the variation in the strength of a drive as a function of the organism’s proximity to an aversive stimulus. For example, a rat’s withdrawal behavior increases in intensity as it nears a feared stimulus (e.g., an electric shock). The avoidance gradient appears steeper than the approach gradient. [originally proposed by Neal E. Miller]

avoidance learning see avoidance conditioning.

avoidance of intimacy the tendency of some individuals to shun closeness in interpersonal relations. People who avoid intimacy are reluctant and often fearful to become physically or emotionally close to another person, tend to have superficial relationships, and often report feeling lonely. In attachment theory, avoidance of intimacy is considered the defining characteristic of an avoidant attachment style in adulthood.

avoidance response a response in which an organism anticipates an aversive stimulus and consequently attempts to prevent contact with this stimulus. The avoidance response is a form of abient behavior (see abience). Also called avoidance reaction.

avoidance training see avoidance conditioning.

avoidance without warning signal see Sidman avoidance schedule.

avoidant attachment in the strange situation, a form of insecure attachment in which infants do not seek proximity to their parent after separation. Instead, the infant does not appear distressed by the separation and avoids the returning parent.

avoidant attachment style see anxious–avoidant attachment.

avoidant marriage a long-lasting marriage in which the partners seldom argue because they have “agreed to disagree” and accept their differences of opinions with no apparent rancor.

avoidant paruresis see paruresis.

avoidant personality a personality trait characterized by feeling uncomfortable when psychologically close to others, resulting in a tendency not to form intimate relations.

avoidant personality disorder a personality disorder characterized by (a) hypersensitivity to rejection and criticism, (b) a desire for uncritical acceptance, (c) social withdrawal in spite of a desire for affection and acceptance, and (d) low self-esteem. This pattern is long-standing and severe enough to cause objective distress and seriously impair the ability to work and maintain relationships. It is included in both DSM–IV–TR and DSM–5. [First defined in 1969 by Theodore Millon]

avolution n. failure to engage in goal-directed behavior, occasionally occurring in severe major depressive episodes.

AVP abbreviation for arginine vasopressin.

awareness n. perception or knowledge of something. Accurate reportability of something perceived or known is widely used as a behavioral index of conscious awareness. However, it is possible to be aware of something without being explicitly conscious of it (e.g., see blindsight). See also consciousness; self-awareness.

awareness training an approach in psychology and education that stresses self-awareness, self-realization, exploration, and interpersonal sensitivity. Awareness training is associated with such writers as German-born U.S. psychiatrist Frederick (Fritz) S. Perls (1893–1970) and U.S. psychologist William C. Schutz (1925–2002).

awe n. the experience of admiration and elevation in response to physical beauty, displays of exceptional ability, or moral goodness. The awe-inspiring stimulus is experienced as “vast” and difficult to comprehend.

awfulize vb. see catastrophize. —awfulizing n.

AWOL acronym for absence without leave.

Axenfeld–Rieger syndrome an autosomal dominant, developmental spectrum disorder characterized by cornea and iris defects and glaucoma leading to blindness. Other associated developmental defects commonly involve the teeth and facial bones. Researchers have identified three types of Axenfeld–Rieger syndrome according to genetic cause: Type 1 is caused by mutations in the PITX2 gene, and Type 3 is caused by mutations in the FOXC1 gene. The gene that causes Type 2 has not yet been identified, but it is located on chromosome 13. [Initially reported in 1920 by…]
axial adj. relating to, along, or otherwise involving an AXIS, particularly the long axis or central part of the body.

axial gradient the difference in development or metabolic rate of tissues along a body axis. See also ANTERIOR–POSTERIOR DEVELOPMENT GRADIENT.

axiom n. in logic and philosophy, a universally accepted proposition that is not capable of proof or disproof. An axiom can be used as the starting point for a chain of DEDUCTIVE REASONING. Also called postulate. [from Greek axioma, "worthy thing"] —axiomatic adj.

axis n. (pl. axes) 1. in DSM–IV–TR, any of the dimensions that are helpful for describing individual behavior and thus facilitate CLINICAL ASSESSMENT. DSM–IV–TR (but not DSM–5) uses a MULTIAXIAL CLASSIFICATION based on five axes: clinical disorders (Axis I), personality disorders and mental retardation (Axis II), GENERAL MEDICAL CONDITIONS (Axis III), psychosocial and environmental problems (Axis IV), and global assessment of functioning (Axis V). 2. an imaginary line that bisects the body or an organ in a particular plane. For example, the long (or cephalocaudal) axis runs in the median plane, dividing the body into right and left halves. 3. the second cervical vertebra, on which the skull rotates. 4. see NEURAL AXIS. 5. a system made up of interrelated parts, as in the HYPOTHALAMIC–PITUITARY–ADRENAL AXIS. 6. a fixed reference line in a coordinate system. See also ABSCSISA; ORDAINATE.

axis cylinder the central core of an AXON, consisting of cytoplasm (or axoplasm) surrounded by the plasma membrane (or axolemma).

axo-axonal synapse a SYNAPSE between two nerve cells in which the nerve impulse travels from one AXON to the other axon, rather than between axon and dendrite (axo-dendritic synapse) or axon and cell body (axosomatic synapse).

axolemma n. see AXIS CYLINDER.

axon n. the long, thin, hollow, cylindrical extension of a NEURON that normally carries a nerve impulse away from the CELL BODY. An axon often branches extensively and may be surrounded by a protective MYELIN SHEATH. Each branch of an axon ends in a terminal button (also called synaptic bouton or knob) among numerous other synapses from which an impulse is transmitted, through discharge of a NEUROTRANSMITTER, across a SYNAPSE to a neighboring neuron. Also called nerve fiber. —axonal adj.

axonal bundle a group of parallel AXONS. Also called fasciculus.

axonal myelination see MYELINATION.

axonal transport the transportation of materials along the AXON of a neuron via the flow of the jellylike fluid (axonplasm) it contains. Transport may be directed away from the CELL BODY (anterograde) or back toward the cell body (retrograde). Also called axoplasmic flow: axoplasmic transport.

axon varicosities enlarged areas of an AXON that contain SYNAPTIC VESICLES and release neurotransmitter molecules.

axon collateral a branch of a neuron’s AXON.

axon hillock a cone-shaped part of the CELL BODY of a neuron from which the AXON originates. Depolarization must reach a critical threshold at the axon hillock for the axon to propagate a nerve impulse.

axon reflex a peripheral nerve reflex, often associated with pain, in which stimulation of nerve fibers causes impulses to pass up these fibers to their endings, where substances are released.

axoplasm n. see AXIS CYLINDER: AXONAL TRANSPORT. —axoplasmic adj.

axoplasmic flow (axoplasmic transport) see AXONAL TRANSPORT.

axosomatic synapse see AXO-AXONAL SYNAPSE.

axotomy n. the severing of an AXON. This type of denervation is often used in experimental studies of neurophysiology or as a model of certain diseases of the nervous system.

Ayahuasca n. a powerful hallucinogenic beverage made from the stems of a tropical South American woody vine, Banisteriopsis caapi, often with leaves from the plant Psychotria viridis. Ayahuasca has been used for centuries by indigenous peoples of the Amazon for religious, spiritual, and medicinal purposes and more recently in the United States and Europe for similar reasons. The pharmacologically active ingredients are harmine and harmaline from B. caapi and dimethyltryptamine (see DMT) from P. viridis. In smaller doses, these ingredients have psychedelic and euphoric effects but in larger doses cause nausea, vomiting, and tinnitus. Also called caapi: yage.

Ayurveda n. a holistic Hindu system of traditional healing, originating and practiced primarily in the Indian subcontinent, that has spread to some extent in Western cultures. It includes diet and herbal remedies and emphasizes the use of body, mind, and spirit in disease prevention and treatment.

azapirone n. any of a class of nonbenzodiazepine ANXIOLYTICS of which the prototype is BUSPIRONE. They relieve anxiety by acting as PARTIAL AGONISTS at the 5-HT1a serotonin receptor (see SEROTONIN AGONIST). Azapirones produce less sedation than the BENZODIAZEPINES, and they seem to lack the abuse potential of these drugs. However, their onset of action is 2 to 3 weeks, and they cannot therefore be used to manage acute or paroxysmal anxiety. Also called azapiredecandione.

azathioprine n. a drug used to suppress the immune response. It is the most widely used drug in support of organ transplantation and potentially severe cases of immune reactions. U.S. trade name (among others): Imuran.

azoospermia n. absence of viable sperm in the semen, usually as a failure of spermatogenesis.
baah-ji n. see BAH-TSCHI.
babbling n. prespeech sounds, such as dadada, made by infants from around 6 months of age. Babbling is usually regarded as practice in vocalization, which facilitates later speech development. See BABY TALK; PRESPEECH DEVELOPMENT. —babble vb.

Babinski reflex the reflex occurring in a healthy infant in which the big toe extends upward and the other toes fan out when the sole of the foot is gently stimulated. This reflex is elicited in newborns to monitor central nervous system development. The Babinski reflex is normal up to about 2 years of age; in adults, it is an indication of neurological disorder and called Babinski’s sign. [Joseph F. Babinski (1857–1932), French neurologist]

Babkin reflex a neonatal reflex in which infants open their mouths and twist their heads in response to pressure on their palms. [Boris Petrovich Babkin (1877–1950), Russian-born Canadian neurologist]

Babor’s Type A–Type B distinction a two-part typology used to group substance abusers, particularly those who abuse alcohol, for research purposes and to determine appropriate treatment options for them. Type A substance abusers have fewer childhood risk factors and start drinking or taking drugs later in life than Type B substance abusers, who have more severe problems related to their substance use, worse psychopathological functioning, and more stress. [developed by U.S. psychologist Thomas F. Babor (1944–)]

baby blues a colloquial name for the transient depressive symptoms experienced by many women during the first 10 days after giving birth. It should be distinguished from POSTPARTUM DEPRESSION. Also called maternity blues; postpartum blues.

baby brain a colloquial term for the memory deficits, reasoning and spatial learning difficulties, and other cognitive problems popularly believed to be experienced by pregnant women. Although often attributed to increases in hormone levels and external stressors, baby brain remains controversial among medical professionals, many of whom dispute not just its supposed characteristics but its very existence. Critics contend that the phenomenon actually results from sleep deprivation and inaccurate self-reports of problems. Additionally, empirical research is limited and contradictory. Although some studies provide support for the phenomenon, showing temporarily diminished brain volume in women during pregnancy and a smaller HIPPOCAMPUS in pregnant than in nonpregnant rats, others indicate that pregnancy does not adversely affect cognition and may actually enhance it. Also called pregnancy brain.

babyfacedness n. the attribute of having an adult face with configural features resembling those of an infant, that is, large eyes, full cheeks, a round shape, a protruding forehead, and a small nose and chin. Research has shown that babyfaced adults are often assumed to possess childlike qualities, such as higher levels of innocence and lower levels of competence. This assumption and its influence upon how babylaced people are treated by others is termed the babyface overgeneralization effect.

baby talk 1. the type of speech used by a young child. 2. the type of speech used by adults and older children when talking to infants or very young children. See INFANT-DIRECTED SPEECH.

BAC abbreviation for BLOOD ALCOHOL CONCENTRATION.

backbone n. see SPINAL COLUMN.

back-clipping n. see CLIPPING.

backcrossing n. the process of crossbreeding a HYBRID animal or plant with a member of the genetic line from which the hybrid was originally derived. The offspring of the mating is known as a backcross.

back-formation n. the creation of a new word on the mistaken assumption that an existing word must be derived from it. This usually involves the elimination of an apparent affix or inflection, as in the creation of the verb enthuse from enthusiasm. The term is also applied to a word formed in this way. Also called inverse derivation: regressive formation. See also CLIPPING.

background n. 1. in perception, any aspect of the environment that forms a setting for the primary stimulus or stimuli. See also FIGURE–GROUND. 2. in general, the sum total of a person’s upbringing, education, training, and experience.

background variable see SUBJECT VARIABLE.

back-propagation algorithms (backprop algorithms) see PERCEPTRON.

back-to-back stem-and-leaf plot a variation of a STEM-AND-LEAF PLOT in which the trailing digits (leaves) from two data sets are displayed on either side of the same central column of initial values (stem). The leaf values from one data set are given on the right-hand side while those of the second group are shown on the left-hand side. For example, consider the following hypothetical sets of test scores obtained by participants on two different occasions:

| 79 79 83 83 86 87 92 99 |
and

| 80 81 82 83 87 87 90 99 |

The back-to-back stem-and-leaf plot for these values is

| 7 | 9 9 |
| 0 1 2 3 7 7 | 8 | 3 3 6 7 |
| 0 9 | 9 | 2 9 |

backtrack search a GRAPH search strategy that considers states in a graph recursively. If the present state is not
back-translation

the goal state, then its first child (node) is examined. If this child is not the goal state, then its first child is taken. If there are no children of a state, then the next sibling of the present state is considered. If there are no further siblings of a state, then the sibling of the state’s parent has to be considered. This process continues until either a goal state is found or there are no further states to examine. States, their siblings, and their children are usually (but not necessarily) considered in a left-to-right format.

**back-translation n.** see TRANSLATION AND BACK-TRANSLATION.

**backup reinforcer** in BEHAVIOR MODIFICATION, a reward given to a client or patient in return for tokens he or she has earned. See also TOKEN ECONOMY.

**backward association** the formation of an associative link between one item and an item that precedes it in a series or sequence. Compare FORWARD ASSOCIATION.

**backward chaining** see CHAINING.

**backward conditioning** a procedure in which an UNCONDITIONED STIMULUS is consistently presented before a NEUTRAL STIMULUS. Generally, this arrangement is not thought to produce a change in the effect of a neutral stimulus. Occasionally, however, the neutral stimulus may take on inhibitory functions, presumably because its occurrence signals that the unconditioned stimulus is completed or will not occur at all. It may also take on excitatory functions as a result of PSEUDOCONDITIONING. Also called backward pairing. Compare FORWARD CONDITIONING.

**backward displacement** in parapsychology experiments using ZENER CARDS or similar targets, a result in which the participant’s “call” or guess matches the outcome of the previous trial in the series rather than the current one. If this effect occurs consistently, it may be taken as evidence of RETROCognition. Compare FORWARD DISPLACEMENT.

**backward elimination** a technique used in REGRESSION ANALYSIS in which the goal is to forecast an outcome or response variable according to a subset of predictor variables narrowed down from a large initial set. In background elimination, all available predictors are included originally and then examined one at a time, with any predictors that do not contribute in a statistically meaningful manner systematically dropped until a predetermined criterion is reached. Also called backward deletion; backward selection: stepdown selection. See also STEPWISE REGRESSION.

**backward masking** see MASKING.

**backward pairing** see BACKWARD CONDITIONING.

**backward reading** reading letters or words in reverse order, for example, deb for bed, or Car my is this for This is my car.

**backward search** a problem-solving strategy in which the solver works backward from the end goal of the problem to the beginning. An example would be finding the path through a maze by working from the end of the maze to the beginning. See also WORKING BACKWARD.

**baclofen n.** a skeletal MUSCLE RELAXANT that inhibits transmission of sympathetic reflexes at the spinal cord level. A GABA$_A$ receptor agonist, it is often used in the treatment of reversible spasticity associated with multiple sclerosis or spinal cord injury. Baclofen has also been found to inhibit the rewarding properties of drugs with abuse potential (opiates, cocaine, etc.). U.S. trade name: Lioresal.

**Baconian method** the inductive method of scientific investigation first set out by Francis BACON. The method involves the inference of general laws or principles from particular instances observed under controlled conditions (i.e., in experiments). To make sure that any such generalization is valid, the observer must seek not only positive instances of an association between things in which one event or state brings about another, but also negative instances in which the event or state fails to occur in the absence of the other (see METHOD OF EXCLUSION; MILL’S CANONS). Finally, the observer tries to formulate an explanation for the causal connection so established. See INDUCTIVE REASONING.

**bacteremia n.** see SEPTICEMIA.

**bacterial endocarditis** inflammation of the heart lining (endocardium) due to bacterial infection and causing damage to the heart valves and impaired pumping action of the heart. Fever and other systemic symptoms ensue, including embolism and heart failure. The infection can be acquired by unhygienic intravenous drug administration or abuse.

**bacterial meningitis** inflammation of the MENSES, which form a protective covering for the brain and spinal cord, caused by bacterial infection, most commonly Neisseria meningitidis (the meningococcus), Haemophilus influenzae, or Streptococcus pneumoniae (the pneumococcus). Meningococcal meningitis is highly contagious because the bacteria are present in the throat as well as the cerebrospinal fluid. Common symptoms of bacterial meningitis, which can result in severe morbidity or mortality, include fever, headache, nausea, weakness, and confusion. See also MENINGITIS; TUBERCULOUS MENINGITIS.

**bacterium n.** (pl. bacteria) a unicellular, prokaryotic microorganism, that is, an organism whose chromosome is not contained in a nuclear envelope. Bacteria are considered to represent an earlier stage in the evolution of life than eukaryotes (organisms whose chromosomes are contained in nuclear envelopes, i.e., all organisms except bacteria). In humans, many bacteria cause disease (e.g., tetanus, syphilis, tuberculosis), whereas others are beneficial (e.g., preventing the growth of harmful microbes in the large intestine and enhancing the IMMUNE RESPONSE).—bacterial adj.

**bad breast** in the psychoanalytic theory of Melanie KLEIN, the internalized representation (see INTRODUCTION) of the mother’s breast as absent or unsatisfying. According to Klein, the infant first experiences the mother and the nourishing breast as PART-OBJECTS with positive qualities—the GOOD BREAST—and negative qualities—the bad breast. Klein thought that the development of these internalized representations of the breast was the first manifestation of SPLITTING.

**bad faith** an individual’s denial of his or her freedom as a human being or unwillingness to accept the undetermined and unforced nature of his or her actions. This often entails a denial of responsibility for the consequences of one’s actions and choices or hiding the truth from oneself intentionally. See also EXISTENTIAL PSYCHOTHERAPY. [proposed by French existentialist philosopher Jean-Paul Sartre (1905–1980)]

**bad is stronger than good** the tendency for negative
events, information, or feedback to have significantly more impact or influence on emotions, thoughts, or behavior than an equivalent positive event, information, or feedback. See POSITIVE-NEGATIVE ASYMMETRY; TRAIT NEGATIVITY BIAS.

**bad me** in the SELF-SYSTEM theory of Harry Stack Sullivan, the internalized personification of impulses and behaviors that are considered to be negative by the self and, therefore, need to be hidden or disguised from others or from the self. In a child, for instance, the bad me may arise out of a sense of parental disapproval that in turn gives rise to anxiety and self-doubt. Compare GOOD ME; NOT ME.

**bad object** in the psychoanalytic theory of Melanie Klein, an introjected PART-OBJECT perceived as having negative qualities (see INTRODUCTION). It is an early object representation that derives from SPLITTING of the object into parts containing negative qualities (i.e., the bad object) and positive qualities (i.e., the GOOD OBJECT). The creation of the bad object is understood as a means of managing internal anxiety over destructive impulses arising from frustration. The ego projects these impulses into an object and therefore often feels it to be an external threat or persecutor.

**bad trip** see TRIP.

**bah-itschi** (bah-tsi; baah-ji) n. a CULTURE-BOUND SYNDROME found in Thailand, with symptoms similar to those of LATAH.

**BAL** abbreviation for BECK ANXIETY INVENTORY.

**bait shyness** an alternative but less common name for CONDITIONED TASTE AVERSION.

**BAL** abbreviation for blood alcohol level. See BLOOD ALCOHOL CONCENTRATION.

**balance** 1. n. a harmonious relationship or equilibrium of opposing forces or contrasting elements. See AUTONOMIC BALANCE; BALANCE THEORY; HOMEOSTASIS. 2. n. the sense of EQUILIBRIUM mediated by the VESTIBULAR SYSTEM of the inner ear. 3. v. to adjust forces to maintain something at a level from which it would ordinarily deviate.

**balance control** see BALANCE TRAINING.

**balanced bilingual** a person who has proficiency in two languages such that his or her skills in each language match those of a native speaker of the same age. Compare UNBALANCED BILINGUAL. See BILINGUALISM.

**balanced design** any research design in which the number of observations or measurements obtained in each experimental condition is equal. For example, a health researcher interested in exercise and depression would be using a balanced design if he or she examined 50 people who exercise less than 30 minutes per day, 50 people who exercise between 30 and 60 minutes per day, and 50 people who exercise more than 60 minutes per day.

**balanced Latin square** a type of study design in which multiple conditions or treatments are administered to the same participants over time. It is a form of LATIN SQUARE that must fulfill three criteria: Each treatment must occur once with each participant, each treatment must occur the same number of times for each time period or trial, and each treatment must precede and follow every other treatment an equal number of times. For example, consider the following balanced Latin square for an experimental design involving four treatments (A, B, C, and D) and four people:

<table>
<thead>
<tr>
<th>Participant</th>
<th>Treatment Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A B D C</td>
</tr>
<tr>
<td>2</td>
<td>B C A D</td>
</tr>
<tr>
<td>3</td>
<td>C D B A</td>
</tr>
<tr>
<td>4</td>
<td>D A C B</td>
</tr>
</tbody>
</table>

As shown, one person receives the treatments in the sequence A, B, D, and then C; a second person receives them in the sequence B, C, A, and D; a third person receives them in the sequence C, D, B, and A; and a fourth person receives them in the sequence D, A, C, and B.

**balanced scale** a test or survey in which, for each possible response, there is a response that means the opposite. A rating scale with the four alternatives very poor, poor, good, and very good is an example, as is a set of survey questions in which half of the questions characterize a particular trait (e.g., perceived stress level) in one direction (e.g., low) and the other half characterize the trait in the opposite direction (e.g., high).

**balance theory** a particular COGNITIVE CONSISTENCY THEORY specifying that people prefer elements within a cognitive system to be internally consistent with one another (i.e., balanced). Balanced systems are assumed to be more stable and psychologically pleasant than imbalanced systems. The theory has been primarily specified and tested within the context of systems involving three elements. These systems are sometimes referred to as P-O-X TRIADS, in which P = person (i.e., self), O = other person, and X = some stimulus or event. [first proposed in 1946 by Fritz Heider]

**balance training** a form of physical or occupational therapy for individuals who experience difficulty with balance control (maintaining balance when standing, walking, or performing other activities). It involves a series of exercises designed to enhance muscular control and improve interpretation of information from the senses and may make use of trainer bicycles, tricycles with body supports and foot attachments, stilts, pogo sticks, rocker boards, and a rubber bouncing tube used like a trampoline. Balance training is also used by many athletes to enhance fitness, coordination, and performance.

**Baldwin effect** the influence on intraspecies evolution of behavior change and learning. An individual member of the species acquires a new ability that enables better adaptation to the environment and hence increases probability of survival; the propensity for acquiring this characteristic is conferred in turn on descendants of that species member until a genetic variation occurs and the characteristic itself becomes hereditary. The Baldwin effect was originally called organic selection. [described in 1896 by James Mark Baldwin]

**Baldwin's figure** a horizontal line with a square at each end. Small squares at the ends of the line make the line look longer than when large squares are at the ends of the line. Also called Baldwin's illusion. [James Mark Baldwin]

**Bálint's syndrome** a spatial and attentional disorder resulting from bilateral lesions in the parieto-occipital regions of the brain. It consists of inability to visually guide the hand to an object (OPTIC ATAXIA), inability to change visual gaze (OCULOMOTOR APRAXIA), and inability to recognize multiple stimuli in a scene and understand their na-
Ballet’s disease

a disorder marked by the loss of movements of the eye and pupil while autonomic responses remain normal. The condition is associated with hyperthyroid disorders, such as exophthalmic goiter (see EXOPHTHALMOS). Also called Ballet’s sign: ophthalmoplegia externa. [Gilbert Ballet (1853–1916), French neurologist]

ballet technique a structured form of DANCE THERAPY.

ballismus n. involuntary throwing or flinging movements of the limbs, caused by severe muscle contractions due to neurological damage. It may involve both sides of the body or, in the case of hemibalismus (or hemibalism), one side only. Also called ballism.

ballistic adj. describing a movement (or part of a movement) in which the motion, once initiated, is not altered by feedback-based corrections. Ballistic is sometimes also used, incorrectly, to describe any rapid movement.

Baltimore Longitudinal Study of Aging (BLSA) the intramural scientific study of aging conducted by the National Institute on Aging. Over 1,400 volunteers ranging in age from their 20s to their 90s are tested at regular intervals throughout their lives. The study, which has been ongoing since 1958, examines changes due to age and changes due to disease and other causes.

B and D abbreviation for BONDAGE and DISCIPLINE.

banding n. an approach to setting cutoff scores in PERSONNEL SELECTION. Several ranges of scores known as score bands are identified, usually on the basis of the STANDARD ERROR OF MEASUREMENT for the test or PREDICTOR VARIABLE. Rather than being considered individually, all candidates who score within the same band are considered equally qualified. Consequently, hiring decisions are made from within band ranges, in contrast to traditional approaches that choose the highest scorer first, the next highest scorer second, and so forth.

bandpass filter see FILTER.

band symmetry see SYMMETRY.

bandwagon effect the tendency for people in social and sometimes political situations to align themselves with the majority opinion and do or believe things because many other people appear to be doing or believing the same.

bandwidth n. 1. a range of frequencies, usually expressed in hertz (cycles per second). In INFORMATION THEORY, it is a measure of the amount of information that a communication channel can transmit per unit of time. 2. the range of information available from measuring instruments. Greater bandwidth is generally associated with lower accuracy (fidelity). 3. a window or range of data values that contains a point of interest. The term is often used in NONPARAMETRIC REGRESSION and estimation problems.

bandwidth selectivity see FREQUENCY SELECTIVITY.

bangungut n. a CULTURE-BOUND SYNDROME observed mainly among young, healthy, Filipino males. The individual is often overheard screaming or moaning during sleep, apparently experiencing a terrifying nightmare; this is followed by unexpected death. Also called oriental nightmare-death syndrome.

banner advertisement a relatively small advertisement displayed on a web page, often inducing consumers to click on the advertisement (typically a small graphic) to go to another website to learn more about the product.

baquet n. a large, shallow, covered tub containing water, iron filings, ground glass, and bottles arranged in patterns from which metal rods protrude, used by Franz Anton MÉS- MÉR in his attempts to cure patients with a variety of hysterical symptoms. Mesmer had his patients place the rods on ailing parts of their bodies so that they would experience the supposed healing power of magnetism. See ANIMAL MAGNETISM; MESMERISM.

bar- combining form see BARO-.

baragnosis n. an inability to judge the weights of objects held in the hand. It is usually a result of damage to the primary somatosensory cortex. Compare BAROGNOSIS.

Bárány test a test designed to reveal whether the SEMICIRCULAR CANALS of the inner ear are functioning properly. The patient is rotated in a special chair—the Bárány chair—with his or her head in each of the planes that bring the three canals vertical to the direction of rotation. The resulting Nystagmus (involuntary movements of the eyes) indicates whether the canals are functioning properly. Also called Bárány method. [Robert Bárány (1876–1936), Austrian physician]

barber’s-pole effect the perception that a rotating vertical cylinder with spiral markings (a barber’s pole) appears to be moving up, rather than simply rotating.

barbiturate n. any of a family of drugs derived from barbituric acid that depress activity of the central nervous system (see CNS DEPRESSANT) and were previously widely used as anxio-lytics, sedatives, hypnotics, and general anesthesics. They typically induce profound tolerance and withdrawal symptoms and depress respiration. Moreover, they can depress breathing completely—hence their use by individuals wishing to commit suicide. Barbiturates are commonly categorized according to their rates of action (including onset of effect, absorption, and excretion) as long acting, intermediate acting, short acting, or ultrashort acting. Their use became common in the 1930s, but they were rapidly supplanted in the 1970s by the BENZODIAZEPINES, which lack the lethality associated with overdose of the barbiturates. The group includes AMORARBITAL, BUT- ARBITAL, PENTOBARBITAL, PHENOBARBITAL, PRIMIDONE, and THIOPENTAL, among others. The prototype of the group, barbital, was introduced into medical practice in 1903. See SEDATIVE, HYPNOTIC, AND ANXIOLYTIC DRUG.

Bard–Cannon theory see CANNON–BARD THEORY.

Bardet–Biedl syndrome (BBS) an autosomal recessive genetic disorder characterized by progressive visual impairment due to deterioration of the retina, leading to night blindness, loss of peripheral vision, and blurred central vision. Additional symptoms can include some degree of obesity, polydactyly (extra fingers or toes), hypogonadism (small testicles), intellectual disability or developmental delay, and impaired speech. At least 14 genes are known to be associated with Bardet–Biedl syndrome, with about 45% of cases caused by mutations of either the BBS1 or BBS10 gene. See also LAURENCE–MOON–BARDET–BIEDEL SYNDROME. [described in 1920 by George Bardet (1885–1970), French physician, and in 1922 by Artur Biedl (1869–1933), Romanian-born Austrian physician]

bar display in ergonomics, a machine display in which fluctuating values of a system attribute are indicated by
the length of rectangular bars of equal width. See also OBJECT DISPLAY.

Barefoot v. Estelle a 1983 case resulting in a decision in which the U.S. Supreme Court upheld a death sentence after a psychiatrist testified at trial that the likelihood the defendant would reoffend was 100% and absolute, although the psychiatrist had never examined the defendant. "Though the psychiatrist had never examined the defendant, the likelihood the U.S. Supreme Court upheld a death sentence, it was 100% and absolute, although the psychiatrist had never examined the defendant." The likelihood that the defendant would reoffend was 100% and absolute, although the psychiatrist had never examined the defendant. 

baresthesia n: the sensation of weight or pressure.

bargaining n: the process in which two parties attempt to resolve their conflicting interests by trading resources in return for some benefits. Compare NEGOTIATION. —bar-gain vb.

bargaining stage the third of the five STAGES OF GRIEF described by Elisabeth KÜBLER-ROSS. It is characterized by an attempt to negotiate a deal with God or fate that would delay one’s own death or that of an important other, or that would mitigate or end other great loss or trauma.

bar graph a graph in which bars of varying height with spaces between them are used to display data for variables defined by qualities or categories. For example, to show the political affiliations of Americans, the different parties (e.g., Democrat, Republican, Independent) would be listed on the x-axis, and the height of the bar rising above each party would represent the number or proportion of people in that category. Also called bar chart; bar diagram. See also HISTOGRAM.

bar hustler see MALE HOMOSEXUAL PROSTITUTION.

bariatries n: a field of medicine that focuses on the study of OBESITY: its causes, prevention, and treatment.

barK abbreviation for BETA-ADRENERGIC RECEPTOR KINASE.

Barnum effect the tendency to believe that vague predictions or general personality descriptions, such as those offered by astrology, have specific applications to oneself. Coinage of the term has been attributed to Paul Everett MIYEL, it alludes to a remark allegedly made by U.S. showman Phineas T. Barnum (1810–1891) to the effect that “There’s a sucker born every minute.” The effect was termed the fallacy of personal validation by U.S. psychologist Bertram Robin Forer (1914–2000), who first studied it in 1949.

baro- (bar-): combining form pressure or weight.

barognosis n: the ability to estimate the weights of objects held in the hand. Compare BARAGNOSIS.

Barona equation an equation that uses demographic variables (such as age, education, and occupational history) to estimate IQ prior to brain injury or disease. [Andres Barona (1945– ), U.S. psychologist]

baroreceptor n: a pressure receptor in the heart or a major artery that detects changes in blood pressure and communicates that information to the brain via the automatic nervous system. Also called CAROCEPTOR.

barotitis n: a disorder of the ear due to exposure to differing atmospheric pressures.

Barr body see SEX CHROMATIN. [Murray L. Barr (1908–1995), Canadian anatomist]

bar reflex a pathological phenomenon in which the lateral or vertical movement of one leg of a recumbent individual is followed by a similar movement of the other leg. This is usually a diagnostic sign of damage or disease in the anterior region of the FRONTAL LOBE.

barrier n: something that restricts, impedes, or blocks progress or the achievement of an ultimate objective or end. In psychological contexts, barriers are mental, emotional, or behavioral limitations in individuals and groups.

barrier-free environment a built space that is free of obstacles to individuals with physical and cognitive disabilities and permits safe, uninhibited movements. Environmental barriers can include street curbs, revolving doors or doors too narrow to admit wheelchairs, inaccessible toilets and washbowls, and elevator buttons that cannot be read by people with visual impairment. See also UNIVERSAL DESIGN.

Barron–Welsh Art Scale (BWAS) an assessment of aesthetic preference in which participants indicate like or dislike for each of 86 black-and-white figures selected to differentiate between the judgment of CRITERION GROUPS of artists and nonartists. The figures vary in complexity from simple line drawings of geometric figures to detailed, multilinear abstractions. Although available as a separate instrument, the Barron–Welsh scale is part of the larger WELSH FIGURE PREFERENCE TEST of personality characteristics; indeed, performance on the BWAS has been interpreted variously as an index of creativity and a reflection of underlying personality variables. [originally developed in 1952 by Frank X. Barron (1922–2002) and George S. Welsh (1918–1990), U.S. psychologists]

BARS acronym for BEHAVIORALLY ANCHORED RATING SCALE.

Barthel Index a form of FUNCTIONAL STATUS measurement that includes 10 items assessing an individual’s ability to perform ACTIVITIES OF DAILY LIVING independently. An individual is rated on a point scale regarding the degree of assistance required to perform each item, and the ratings are then combined to yield a total score. [Dorothea W. Barthel, 20th-century U.S. psychologist]

Bartholin’s glands see VESTIGIAL GLANDS. [Caspar Bartholin (1655–1738), Danish anatomist]

Bartlett technique see REPEATED REPRODUCTION. [Frederic C. Bartlett]

Bartlett test for equality of variance a procedure used to determine whether variation across two or more groups is equivalent, this being a critical assumption in ANALYSIS OF VARIANCE and many other parametric methods. The Bartlett test is sensitive to scores that are not from a NORMAL DISTRIBUTION. [Maurice Stevenson Bartlett (1910–2002), British statistician]

Bartley v. Kremens a lawsuit resulting in a Pennsylvania court decision (1976) that extended DUE PROCESS protection and provision of legal counsel to children committed to mental facilities by their parents.

baryphonia n: speech characterized by a thick, heavy voice quality. Also called BARYPHONIA.

BAS abbreviation for BEHAVIORAL APPROACH SYSTEM.

basal age the highest MENTAL AGE level at which a participant can answer all items on a standardized test correctly. The concept of mental ages is used relatively rarely in current testing. Compare CEILING AGE.

basal cell see TYPE IV CELL.

basal dendrite any of several DENDRITES on a PYRAMIDAL CELL that extend horizontally from the CELL BODY. Compare APICAL DENDRITE.
basal forebrain

basal forebrain a region of the ventral FOREBRAIN near the corpus callosum containing CHOLINERGIC neurons that project widely to the cerebral cortex and hippocampus and are thought to be important in aspects of memory, learning, and attention. See BASAL NUCLEUS OF MEYNERT.

basal ganglia a group of nuclei (neuron cell bodies) deep within the cerebral hemispheres of the brain that includes the CAUDATE NUCLEUS, PUTAMEN, GLOBUS PALlidUS, SUBSTANTIA NIGRA, and subthalamIC NUCLEUS. The putamen and globus pallidus are together known as the Lenticular (or lentiform) nucleus, the lenticular nucleus and caudate nucleus are together known as the corpus striatum, and the caudate nucleus and putamen are together called the striatum. The basal ganglia are involved in the generation of goal-directed voluntary movement. Also called basal nuclei.

basal magnocellular nucleus see BASAL NUCLEUS OF MEYNERT.

basal metabolism the minimum energy expenditure required to maintain the vital functions of the body while awake but at rest and not expending energy for thermoregulation. Basal metabolic rate (BMR) is measured in kilojoules (or calories) expended per kilogram of body weight or per square meter of body surface per hour.

basal nuclei see BASAL GANGLIA.

basal nucleus of Meynert a collection of neurons in the BASAL FOREBRAIN that modulates the activity of many areas of the neocortex by providing CHOLINERGIC innervation. It is implicated in Alzheimer’s disease. Also called basal magnocellular nucleus; Meynert’s nucleus; nucleus basalis magnocellularis. [Theodor H. Meynert (1833–1892), Austrian neurologist]

basal reader approach a method of reading instruction through the use of a series of books. The vocabulary, content, and sequence of skills to be taught are thus determined by the authors.

basal skin resistance see SKIN RESISTANCE.

base 1. n. the lowest or most fundamental part of something. 2. adj. elemental, or having a primitive or basic nature.

baseline n. 1. data or information obtained prior to or at the onset of a study (e.g., before introduction of an intervention) that serves as a basis for comparison with data collected at a later point in time so as to assess the effects of particular manipulations or treatments. For example, a memory researcher may measure how many words from a particular list participants remember initially and then compare that figure to the number of words they remember following the use of a new mnemonic technique (i.e., the experimental manipulation). 2. more generally, any stable level of performance used as a yardstick to assess the effects of particular manipulations or changes.

baseline assessment 1. a process of obtaining information about a participant’s status (e.g., ability level, psychological well-being) before exposure to an intervention, treatment, or other study manipulation. The information so obtained is compared to data gathered during the course of the research in order to identify any effects associated with the study conditions. 2. the measurement of characteristics of humans and other animals at a particular point in development in order to evaluate natural changes in these characteristics over time.

baseline characteristic any of various qualities of a participant that are assessed prior to a study or intervention as they may potentially influence outcome measures. For example, a researcher evaluating the effect of a new stress-reduction technique on health status may examine such baseline characteristics as sex, age, and ethnicity.

baseline functioning see PREMORBID FUNCTIONING.

baseline measure an observation of a participant’s response before the administration of any experimental intervention.

baseline performance the measured rate of a behavior before introduction of an intervention, which allows comparison and assessment of the effects of the intervention. For example, a baseline for being off task is established before an intervention aimed at increasing on-task classroom behavior is delivered.

base pair see DNA.

base rate 1. the naturally occurring frequency of a phenomenon in a population. An example is the percentage of students at a particular college who have major depressive disorder. This rate is often contrasted with the rate of the phenomenon under the influence of some changed condition in order to determine the degree to which the change influences the phenomenon. 2. in PERSONNEL PSYCHOLOGY, the percentage of job applicants who would succeed in the job if all were hired. Base rates are used to measure the effectiveness of EMPLOYMENT TESTS.

base-rate fallacy a decision-making error in which information about the rate of occurrence of some trait in a population (the base-rate information) is ignored or not given appropriate weight. For example, given a choice of the two categories, people might categorize a man as an engineer, rather than a lawyer, if they heard that he enjoyed physics at school—even if they knew that he was drawn from a population consisting of 90% lawyers and 10% engineers. See REPRESENTATIVENESS HEURISTIC.

bases of an attitude the types of information from which an attitude is derived. Traditionally, researchers have distinguished between three categories of bases: The affective basis refers to the emotions, feelings, and moods associated with the ATTITUDE OBJECT; the Cognitive basis refers to beliefs about evaluative attributes associated with the attitude object; and the behavioral basis refers to responses, such as past behaviors and future intentions, associated with the attitude object. Also called components of an attitude. See also TRIPARTITE MODEL OF ATTITUDES.

base structure see DEEP STRUCTURE.

bashful bladder syndrome see PARURESIS.

basic anxiety in EGO PSYCHOLOGY, a feeling of being helpless, abandoned, and endangered in a hostile world. According to Karen D. HORNEY, it arises from the infant’s helplessness and dependence on his or her parents or from parental indifference. Defenses against basic anxiety and hostility may produce NEUROTIC NEEDS and NEUROTIC TRENDS, such as a submissive attitude, the need to exert power over others, or withdrawal from relationships. See also BASIC HOSTILITY.

basic category see BASIC-LEVEL CATEGORY.

basic conflict in EGO PSYCHOLOGY, the conflict between a person’s dominant NEUROTIC TENDENCY and his or her incompatible, nondominant NEUROTIC NEEDS, which must be kept repressed. [First described by Karen D. HORNEY]
basic emotion see PRIMARY EMOTION.

basic encounter a meaningful experience in one person’s relating to another that is characterized by mutual trust and empathy. The development and occurrence of such encounters in therapy and counseling contexts are considered to be beneficial to the therapeutic process and outcome for the client. See also CLIENT-CENTERED THERAPY.

basic hostility in EGO PSYCHOLOGY, a feeling of hostility and resentment toward the parents that develops as a result of the BASIC ANXIETY that the infant feels at being dependent on them. To the extent that the infant fears the parents, basic hostility and anxiety are repressed and give rise to NEUROTIC NEEDS and NEUROTIC TRENDS. [defined by Karen D. Horney]

BASIC ID see MULTIMODAL THERAPY.

basic-level category a category formed at the level that people find most natural and appropriate in their own, everyday experience of the things so categorized. A basic-level category (e.g., bird, table) will be broader than the more specific SUBORDINATE CATEGORIES into which it can be divided (e.g., hawk, dining table) but less abstract than the SUPERORDINATE CATEGORY into which it can be subsumed (e.g., animals, furniture). A basic-level category will usually meet the following criteria: (a) It represents a level of CATEGORIZATION at which high resemblance among members of the category co-occurs with low resemblance with members of different categories; (b) it represents the highest level at which members have a similar general shape and is therefore the highest level at which a single mental image can stand for the entire category; and (c) it represents the highest level at which numerous attributes can be listed, most of which will apply to most members of the category (see FAMILY RESEMBLANCE). The name of the basic-level category will generally be the term most frequently applied to the things in question in natural language, the term earliest learned, and the term that is most readily remembered. Also called basic category: natural category.

basic mistake in the psychology of Alfred ADLER, a factor arising in early childhood that affects a person’s lifestyle in later life and that may need to be corrected in order to resolve conflicts.

basic mistrust see BASIC TRUST VERSUS MISTRUST.

basic need see PHYSIOLOGICAL NEED.

Basic Nordic Sleep Questionnaire (BNSQ) a standardized questionnaire that uses a 5-point quantitative scale, ranging from never (1) to every night (5), for measuring the frequency of occurrence during the previous 3 months of various sleep disturbances and complaints. The questionnaire was initially developed in 1988 by the Scandinavian Sleep Research Society for use in Denmark, Norway, Sweden, Finland, and Iceland (i.e., the Nordic countries).

basic personality a distinctive pattern of thought, feeling, and behavior supposedly found in people raised in the same culture, largely as a result of their subjection to the same child-rearing practices. The basic personality is in turn held to be responsible for many of a culture’s distinctive institutions, such as its religion and folklore. Also called basic personality structure: basic personality type. See also CULTURAL DETERMINISM: NATIONAL CHARACTER. [proposed by U.S. psychoanalyst and psychocultural theorist Abram Kardiner (1891–1981)]

basic reflex any of the infant reflexes of sucking, eye movement, grasping, and sound orientation. According to PIAGETIAN THEORY, basic reflexes are a feature of the first substage of the SENSORIMOTOR STAGE, in which infants know the world only in terms of their inherited action patterns.

basic research research conducted to obtain greater understanding of a phenomenon, explore a theory, or advance knowledge, with no consideration of any direct practical application. Also called pure research. Compare APPLIED RESEARCH.

basic rest–activity cycle (BRAC) cyclic alternations between neurophysiological activity and nonactivity during waking and sleep, thought typically to involve a 90-minute cycle. [first described in 1961 by U.S. physiologist and sleep researcher Nathaniel Kleitman (1895–1999)]

basic rule the fundamental rule of psychoanalysis that the patient must attempt to put all spontaneous thoughts, feelings, and memories into words without censorship, so that they can be analyzed to reveal unconscious wishes, conflicts, and emotions. Also called fundamental rule.

basic science scientific research or theory that is concerned with knowledge of fundamental phenomena and the laws that govern them, regardless of the potential applications of such knowledge. Also called fundamental science: pure science. Compare APPLIED SCIENCE.

basic skills in education, reading, writing, and arithmetic. Proficiency in the basic skills has traditionally been viewed as essential for scholastic achievement.

basic-skills testing 1. a standardized, often state-regulated assessment of BASIC SKILLS. 2. an examination of an individual’s ability to perform and understand fundamental tasks.

basic technique (BT) in parapsychology experiments using ZENER CARDS, the basic procedure in which each card is removed from the deck and laid aside after being “called,” or guessed, by the participant. The cards are not checked until the entire pack has been guessed in this way. See SCREEN TOUCH MATCHING. See also DOWN THROUGH; UP THROUGH.

basic trust versus mistrust the first of ERIKSON’S EIGHT STAGES OF PSYCHOSEXUAL DEVELOPMENT, between birth and 18 months of age. During this stage, the infant either comes to view other people and himself or herself as trustworthy or comes to develop a fundamental distrust of his or her environment. The growth of basic trust, considered essential for the later development of self-esteem and healthy interpersonal relationships, is attributed to a primary caregiver who is responsively attuned to the infant’s individual needs while conveying the quality of trustworthiness, whereas the growth of basic mistrust is attributed to neglect, lack of love, or inconsistent treatment. The child must experience both trust and mistrust to know how to truly trust.

basilar artery an artery formed by the union of two vertebral arteries. Its branches supply blood to the brainstem and to posterior portions of the cerebral hemispheres.

basilar membrane a fibrous membrane within the COCHLEA that supports the ORGAN OF CORTI. In response to sound, the basilar membrane vibrates; this leads to stimulation of the HAIR CELLS—the auditory receptors within the organ of Corti. The mechanical properties of the basilar membrane vary over its length (34 mm in humans), giving
rise to a pattern of movement known as a traveling wave, or Békésy traveling wave. The location of the maximum movement depends on the frequency of the sound. This fundamental aspect of mammalian hearing was discovered by Georg von Békésy.

**basket cell** a type of neuron found in the cerebellum.

**basket ending** any of the nerve endings that are found around hair follicles and are responsible for sensations of contact and pressure.

**basking in reflected glory** (BIRGing) the tendency to enhance one’s self-esteem by heightening one’s association with a successful or prestigious group. The opposite of this is cutting off reflected failure (CORFing), or distancing oneself from an unsuccessful or low-status group. For example, fans of a sports team may visit the team’s website after a winning game, whereas the same fans may avoid such contact when the team loses. Similarly, people with yard signs endorsing the successful candidate in a presidential election often display them longer after the election than do people with signs endorsing unsuccessful opponents.

**basolateral group** one of the two main groups of nuclei in the amygdala within the brain and the largest portion of the amygdaloid complex. Its nuclei receive neuromodulatory input from various neurotransmitter systems in the basal forebrain and brainstem, are connected particularly with higher order sensory and limbic association areas, and project to the central amygdala. They are implicated in fear conditioning and emotional learning. Also called basolateral complex. See also corticomedial group.

**BAT** acronym for behavioral approach task.

**Batesian mimicry** a form of mimicry in which a species that is nontoxic or palatable to predators mimics the physical shape or coloration of a toxic species. For example, some species of flies have black and yellow coloration similar to bees and wasps with stingers. When predators learn to avoid noxious prey and form generalizations about similar-looking animals, then nontoxic animals are more likely to survive by mimicking the toxic species. [Henry Walter Bates (1825–1892), British naturalist]

**bath therapy** the use of water immersion in therapy. See also hydrotherapy.

**bathy-** combining form deep.

**bathyesthesia** n. awareness of sensations in the deep (subcutaneous) tissues of the body. Also called deep-pressure sensitivity; deep sensibility.

**Batson v. Kentucky** a legal case resulting in a U.S. Supreme Court ruling that it is unconstitutional to exercise peremptory challenges during voir dire for the purpose of removing jurors on account of their race.

**battered-child syndrome** (BCS) the effects on a child of intentional and repeated physical abuse by parents or other caregivers. In addition to sustaining physical injuries, the child is at increased risk of experiencing longer-term problems, such as depression, posttraumatic stress disorder, substance abuse, decreased self-esteem, and sexual and other behavioral difficulties. See also Child Abuse. [term introduced in 1962 by German-born U.S. pediatrician C. Henry Kempe (1922–1984) and colleagues]

**battered-woman syndrome** (BWS) the psychological effects of being physically abused by a spouse or domestic partner. The syndrome includes learned helplessness in relation to the abusive spouse, as well as symptoms of posttraumatic stress. The incidence of domestic violence toward women played a role in the origins of this term; however, it is now understood that men may be the victims of violence by a domestic partner and may also exhibit the effects of this syndrome. See also cycle of violence. [term introduced in 1979 by U.S. clinical and forensic psychologist Lenore E. Walker (1942–)]

**battered women** women who are physically abused by their spouses or domestic partners. Woman beating is considered to surpass rape as the most underreported act of violent assault in the United States. Current data suggest that domestic violence against women is common and occurs in all social classes and ethnic and religious groups, as well as between same-sex partners. While the gender-based focus of this term reflects the higher incidence of domestic violence toward women, men may also be abused by domestic partners. See also intimate partner violence.

**batterer’s excuses** rationalizations given by individuals who beat their spouses or domestic partners. These may include claims of provocation, or that beating a spouse or partner is acceptable in the batterer’s culture, or that the batterer was angry. The victim of battering may come to believe in the batterer’s excuses, and such self-blame or other justifications for the abuser’s behavior can make it more difficult for the person to leave the relationship without adequate support. See also blaming the victim; cycle of violence.

**battle fatigue** see combat stress reaction.

**battlefield recovery** stressful tasks associated with the aftermath of an armed conflict, such as recovering casualties and bodies and identifying and burying the dead.

**battle/garrison dimensions** the dimensions of the risk (low to high) and types of mission (routine to unique) for a variety of operational settings, ranging from garrison (peacetime) to battlefield (combat). The dimensions are influenced by training, previous exposure, and the cohesiveness of units.

**battle inoculation** training in simulated operational conditions (such as fire from real weapons) to prepare soldiers for deployment in combat. The battlefield performance of a soldier is directly related to the quality and amount of realistic unit and individual training that the soldier has received. Training must be related to the wartime mission of a unit and to the conditions it can expect to face. Live-fire training prepares soldiers for the shock and noise of combat. It not only helps to inoculate soldiers to the stresses of operations (including combat) but also enables them to learn methods for coping with their reactions to these stresses. Previous operational experience (especially in combat) also helps to prepare soldiers for future situations. See also stress training.

**battle of the experts** a scenario in which expert witnesses from opposing sides of a legal dispute disagree over an issue that has to be decided to resolve the dispute. Such contradictory testimony is often of little help to the judge or jury in reaching a decision in the case.

**battle shock** psychological impairment resulting from combat stress reactions. The expression was used in the Israeli Yom Kippur war to describe the condition of a combat stress casualty who was unable to tolerate further military combat.
Bayesian adj. denoting an approach to statistical inference and probability that enables previously known (a priori) information about a population characteristic of interest to be incorporated into the analysis. In Bayesian methods, estimated quantities are based in part on empirical data (i.e., what was actually observed) and in part on collective or individual knowledge about what to expect in the population (as captured in a prior distribution). See also posterior distribution. [Thomas Bayes (1702–1761), British mathematician and theologian]

Bayesian inference a method of drawing conclusions about a characteristic of a population using both sample data and previously known information about that characteristic. It relies on Bayes theorem to derive posterior distributions from obtained observations and prior distributions. Compare frequentist inference. [Thomas Bayes]

Bayesian information criterion (BIC) in Bayesian statistics, a summary value used in comparing the relative fit of one model to another for a given set of data. Although adding to the complexity of a model often will improve fit to a set of data, the Bayesian information criterion adds a penalty for each addition, such that relative model fit also is judged in terms of model parsimony (simplicity). [Thomas Bayes]

Bayes theorem a formula for calculating the probability that an event will occur that allows for the acquisition of new information regarding that event. For example, consider the probability that an individual will have a stroke within the next year. Using Bayes theorem, one could take an estimate of this probability based on general population data for that individual’s age group (i.e., the prior probability) and revise it to account for the results of that person’s stress tests and other cardiological markers, creating what is known as the posterior probability. [Thomas Bayes]

Bayley Scales of Infant and Toddler Development scales for assessing the developmental status of infants and young children ages 1 month to 42 months. Test stimuli, such as form boards, blocks, shapes, household objects (e.g., utensils), and other common items, are used to engage the child in specific tasks of increasing difficulty and elicit particular responses. The Bayley scales currently have five components. Tasks from the Mental scale are designed to evaluate such functions as perception, memory, and learning; those from the Motor scale measure gross and fine motor abilities, such as crawling, sitting, grasping, and object manipulation. The Behavior Rating Scale (formerly called the Infant Behavior Record) contains detailed descriptions of specific categories of behavior that are graded on a 5-point scale. It supplements the Mental and Motor scales and provides an assessment of overall attention and arousal, orientation and engagement, emotion regulation, and motor quality. The final two components, the Social-Emotional scale and the Adaptive Behavior scale, use questionnaires to obtain parent or caregiver perceptions of their child’s development. The Bayley scales were originally published in 1969 and subsequently revised in 1993; the most recent version is the Bayley-III, published in 2005. [developed by Nancy Bayley]

BBB/G syndrome see optitz g/bbb syndrome.

BBS acronym for bardet–biedl syndrome.

B cell see lymphocyte.

BCI abbreviation for brain–computer interface.

Bel-2 n. a family of genes whose protein products regulate programmed cell death.

B coefficient see regression coefficient.

B-cognition n. see BEING COGNITION.

BCS abbreviation for BATTERED-CHILD SYNDROME.

BDAE abbreviation for Boston Diagnostic Aphasia Examination. See BOSTON NAMING TEST.

BDD abbreviation for body dysmorphic disorder.

BDI abbreviation for Beck Depression Inventory.

BDNF abbreviation for brain-derived neurotrophic factor.

BDS abbreviation for Blessed Dementia Scale.

BEAM abbreviation for Blessed Dementia Scale.

BEAM abbreviation for BRACKEAN ELECTRICAL ACTIVITY MAPPING.

beat n. 1. a periodic change in loudness produced by superimposing two tones with similar frequencies. For example, the loudness of a 500 Hz tone and a 503 Hz tone when sounded together will fluctuate three times per second—the beat rate. 2. the periodic change in amplitude produced by superimposing two sinusoidal signals that are relatively close in frequency. See also roughness.

beating fantasy in the classical psychoanalysis of Sigmund Freud, a male or female child’s fantasy of being beaten by his or her father or mother. For both sexes, the fantasy is interpreted as an expression of the child’s oedipal desires toward the father and is said to be based on the child’s belief that the father beats the mother in the primal scene. Thus, the fantasy of being beaten provides sexual arousal.

Bechara Gambling Task see IOWA GAMBLING TASK.

Beck Anxiety Inventory (BAI) a 21-item self-report measure used to assess the severity of anxiety in adults and to discriminate anxiety from depression. [Aaron T. Beck]

Beck Depression Inventory (BDI) a self-report questionnaire designed to assess the severity of depressive symptoms in adolescents and adults. Extensively used in both clinical and research settings, it consists of 21 item groups, each of which includes four statements of increasing severity. Each group reflects a symptom or attitude associated with depression (e.g., loss of energy, self-dislike), and each statement has a numerical value from 0 to 3. Participants choose the statement within each group that most accurately reflects how they have felt within the past 2 weeks. The BDI was originally published in 1961; the most recent version is the BDI-II, published in 1996. [Aaron T. Beck and colleagues]

Beck Hopelessness Scale (BHS) a scale of 20 true–false statements used to predict suicide risk by measuring an individual’s attitudes about the future, loss of motivation, and expectations. [Aaron T. Beck]

Beck Scale for Suicide Ideation (BSS) a measure of the necessity for detailed questioning about a patient’s intentions, administered to patients who are considered to be at risk of suicide. [Aaron T. Beck]

Beck therapy see cognitive therapy. [Aaron T. Beck]

Beckwith–Wiedemann syndrome a growth disorder marked by enlarged tongue, large abdominal hernia, and enlarged viscera. Newborns may be born with an om-
phalacole (an opening in the wall of the abdomen) and develop hypoglycemia (low blood sugar). Although children with this disorder are at increased risk for developing cancer, the majority reach adulthood with normal height and intelligence. The cause is usually unknown, but up to 15% of cases occur in families with more than one affected member. In those cases, it appears to be an autosomal dominant pattern of inheritance and involves genes located on the short arm of chromosome 11 ( locus 11p15).

[described in the 1960s by John Bruce Beckwith (1933— ), U.S. physician, and Hans Rudolf Wiedemann (1915–2006), German pediatrician]

**Bedlam** n. the popular name for the Hospital of Saint Mary of Bethlehem in Bishopsgate, London, founded as a monastery in 1247 and converted into an asylum for the insane by Henry VIII in 1547. Many of the inmates were in a state of frenzy, and as they were shackled, starved, beaten, and exhibited to the public for a penny a look, gen-

insane by Henry VIII in 1547. Many of the inmates were in a state of frenzy, and as they were shackled, starved, beaten, and exhibited to the public for a penny a look, general turmoil prevailed. The word itself thus became synonymous with wild confusion or frenzy. Sometimes the term bedlamism was used for psychotic behavior, and the term bedlamite for a psychotic individual.

**bed-sharing** n. a type of cosleeping in which an infant or young child sleeps with one or both parents in the same bed. Bed-sharing with infants is discouraged by the American Academy of Pediatrics and the U.S. Consumer Product Safety Commission because of the associated safety hazards and increased risk of sudden infant death syndrome. Also called family bed. Compare cosleeping.

**bedsore** n. see pressure ulcer.

**bed-wetting** n. the involuntary discharge of urine during sleep. Bed-wetting is considered problematic if it occurs in children older than 4 or 5 years of age; it is twice as common in boys. Also called sleep enuresis. See also elimination disorder; enuresis.

**bee communication** the use of a set pattern of movements by a bee to communicate to other bees the direction and approximate distance to a source of food or a nest site. It comprises both a round dance and a waggle dance in the form of a figure 8; the intensity of these dances communicates the relative quality of a resource. The direction of the straight portion of the waggle dance with respect to gravity in the hive indicates the direction of the resource with respect to the sun. This dancing language is often cited as an example of bees’ ability to communicate about objects distant in time and space, but alternative explanations suggest that other signals (e.g., odors) are equally important in locating food sources.

**before–after design** see pretest–posttest design.

**begging** n. a series of vocalizations, often accompanied by mouth or bill opening, used by young nonhuman animals to entice their parents to feed them. In some species, each offspring has a distinct, individual form of begging that is used by parents for offspring recognition. Parents often give more food to the offspring with the most intense form of begging. In courtship, some adult females engage in begging, receiving food from a potential mate and in some cases reducing the male’s aggression.

**behavior** n. 1. an organism’s activities in response to external or internal stimuli, including objectively observable activities, introspectively observable activities (see covert behavior), and nonconscious processes. 2. more restrictively, any action or function that can be objectively observed or measured in response to controlled stimuli. Historically, behaviorists contrasted objective behavior with mental activities, which were considered subjective and thus unsuitable for scientific study. See behaviorism. —behavioral adj.

**behavioral activation** an intervention that explicitly aims to increase an individual’s engagement in valued life activities through guided goal setting to bring about improvements in thoughts, mood, and quality of life.

**behavioral approach system (BAS)** in reinforcement sensitivity theory, the physiological mechanism believed to control appetitive motivation. It is theorized to be sensitive to signals of reward, nonpunishment, and escape from punishment. Activity in this system causes the individual to begin (or to increase) movement toward goals. It has also been held that this system is responsible for the experience of positive feelings such as hope, elation, and happiness in response to these signals and that having a strong or chronically active BAS tends to result in extraversion. Also called behavioral activation system. Compare behavioral inhibition system. [described by British psychologist Jeffrey Alan Gray (1934–2004)]

**behavioral approach task** (BAT) an assessment technique that observes an individual approach a feared situation until he or she is unable to go further. The BAT is used to assess levels of avoidance and fear of specific situations associated with phobias. It may also be used to corroborate information obtained in the clinical interview and to measure treatment progress and outcome. Variables that can be measured using the BAT include physical symptoms (e.g., increased heart rate), escape or avoidance strategies, and subjective ratings of fear. Also called behavioral approach test; behavioral avoidance test.

**behavioral assessment** the systematic study and evaluation of an individual’s behavior using a wide variety of techniques, including direct observation, interviews, and self-monitoring. When used to identify patterns indicative of disorder, the procedure is called behavioral diagnosis and is essential in deciding upon the use of specific behavioral or cognitive behavioral interventions.

**behavioral avoidance test** see behavioral approach task.

**behavioral baseline** a steady state of behavior against which the effects of introducing an independent variable may be compared. For example, a child may throw between six and eight tantrums per week over the course of several weeks. This level of tantrums could then serve as a behavioral baseline to assess the effectiveness of a treatment regimen. Also called behavior baseline.

**behavioral cardiology** see cardiac psychology.

**behavioral coaching** the act of assisting an individual to change cognitive or physical behavior, or both, through demonstration, observation, and feedback.

**behavioral confirmation** the process by which the actions of one person (the target) come to reinforce the expectations of another person (the perceiver) during the course of their social interaction. Behavioral confirmation processes are used to explain how expectations and beliefs, including stereotypes, come to affect reality. It is often considered a special case of the self-fulfilling prophecy or expectancy effect, but behavioral confirmation differs from these terms primarily in emphasizing that the target’s actual elicited behavior serves to confirm the perceiver’s in-
behavioral endocrinology

behavioral couples therapy a COUPLES THERAPY that focuses on interrupting negative interaction patterns through instruction, modeling, rehearsal, feedback, positive behavior exchange, and structured problem solving. This therapy can be conducted with individual couples or in a couples group format. When practiced with legally married partners, it is called behavioral marital therapy, though some practitioners use this term interchangeably with behavioral couples therapy. See also COGNITIVE BEHAVIORAL COUPLES THERAPY; COMMUNICATION SKILLS TRAINING; INTEGRATIVE BEHAVIORAL COUPLES THERAPY.

behavioral criterion an aspect of actual (rather than self-reported) behavior that must exist in a person for an accurate diagnosis to be made. Also called behavior criterion.

behavioral deficit the lack of certain age-specific aspects of behavior in an individual, who is therefore not developmentally on target. Also called behavior deficit.

behavioral diagnosis see BEHAVIORAL ASSESSMENT.

behavioral disorder see BEHAVIOR DISORDER.

behavioral dynamics the internal motivational patterns or causes underlying overt behavior.

behavioral ecology the study of the interaction between the environment and the behavior of organisms within that environment. Behavioral ecology is primarily concerned with adaptive aspects of nonhuman ANIMAL BEHAVIOR, especially within a natural environment. Research formerly focused on the acquisition and use of resources, but more recent research has also studied the adaptive significance of SOCIAL INTERACTIONS, blending behavioral ecology with SOCIobiology.

behavioral economics an interdisciplinary field concerned with understanding how HEURISTICS, biases, and other psychological variables influence economic behavior. In contrast to the standard view within traditional economics that people are rational actors who always make choices to maximize their well-being, behavioral economists view human rationality as limited and subject to personal, social, and situational influences (see BOUNDED RATIONALITY). Thus, they seek to devise more realistic, psychologically plausible models of economic behavior to account for a variety of decision-making anomalies and market inconsistencies that have been observed, such as loss aversion (the tendency to go disproportionately great lengths to avoid perceived losses), temporal discounting (the tendency to prefer small rewards received sooner to larger ones received later), the ENDOWMENT EFFECT, the FRAMING effect, the magnitude effect (the tendency to discount smaller gains more rapidly than larger ones), the sign effect (the tendency to discount gains more rapidly than losses), the status-quo bias (the tendency to keep things as they are and avoid making changes), and the sunk-cost effect (the tendency to continue a course of action in which one has already invested money, time, or effort). [derived primarily from the work of Daniel Kahneman and Amos Tversky]

behavioral embryology the study of the behavior of embryos. Embryonic chickens and ducks display sensitivity to different types of sensory stimuli before hatching, and motor movements similar to those needed for feeding can be seen. Embryonic rats also display many sensory and motor capacities, as well as learning, prior to birth.

behavioral endocrinology the study of the relation-
behavioral engineering

ships between the functioning of the endocrine glands and neuroendocrine cells (see NEUROENDOCRINOLOGY) and behavior. A variety of endocrine glands, including the hypothalamus, the pituitary gland, and the adrenal gland, have been shown to affect behavior. For example, gonadal secretion of sex hormones influences sexual behavior, and secretion of corticosteroids by the adrenal glands influences physiological and behavioral responses to stress.

behavioral engineering the use of technology to modify behavior, as in the use of metronomes to reduce stuttering. The term is also used as a synonym for BEHAVIOR MODIFICATION itself.

behavioral family therapy a family treatment that is characterized by behavioral analysis of presenting problems and a focus on overt behavior change through application of learning-based behavioral principles and techniques of BEHAVIOR THERAPY. Techniques used to modify targeted behavior patterns include behavior contracts, instruction, modeling, and rehearsal.

behavioral finance a field, closely related to BEHAVIORAL ECONOMICS, that studies the impact of emotion, cognitive biases, and other psychological factors on financial decision making and hence on financial markets. In particular, behavioral finance emphasizes the role such factors play in irrational investment behavior (e.g., under- or overreaction to financial information) and its consequences in market fluctuations (e.g., financial bubbles, panics). See also MENTAL ACCOUNTING.

behavioral genetics the study of familial or hereditary behavior patterns and of the genetic mechanisms of behavior traits. Also called behavior genetics.

behavioral geography the study of the cognitive processes by which humans form an understanding of their environment and the influence of these processes and this understanding on behavior. Researchers in the field are particularly interested in the analysis of COGNITIVE MAPS, seeking to answer such questions as how well these maps correspond to the environments they represent and how people utilize them in understanding their surroundings and in making decisions about how to behave. For example, some behavioral geographers attempt to explain criminal activity or risk taking (e.g., living in flood plains) in terms of such an approach.

behavioral group therapy a form of GROUP THERAPY that applies learning-based behavioral principles and techniques, including modeling, rehearsal, social reinforcement, SYSTEMATIC DESSENSITIZATION, and other methods of BEHAVIOR THERAPY, in the context of a group. See also COGNITIVE-BEHAVIORAL GROUP THERAPY.

behavioral health an interdisciplinary subspecialty of BEHAVIORAL MEDICINE that promotes a philosophy emphasizing individual responsibility in the maintenance of one’s own health and in the prevention of illness and dysfunction by means of self-initiated activities (jogging, exercising, healthy eating, not smoking, etc.). [proposed by U.S. psychologist Joseph D. Matarazzo (1925–)]

behavioral health care see MENTAL HEALTH CARE.

behavioral hierarchy see BEHAVIOR HIERARCHY.

behavioral homeostasis an organism’s tendency to maintain stability or equilibrium through various behavioral processes. For example, temperature regulation is achieved via shivering, sweating, or panting, and satiety is achieved by the initiation and then cessation of feeding behavior. Also called behavior homeostasis. See also HOMEOSTASIS.

behavioral homology functional similarity (i.e., common behavior) across species, suggestive of a shared ancestral origin. Also called behavior homology.

behavioral immunogen a behavior or lifestyle associated with a decreased risk of illness and with longer life. Examples of behavioral immunogens are moderate consumption of alcohol, regular exercise, adequate sleep, and a healthy diet. Compare BEHAVIORAL PATHOGEN.

behavioral incident a single, separate behavioral event with a clearly defined start and finish (e.g., brushing one’s teeth), which may be combined with other events to form a BEHAVIORAL SEQUENCE (e.g., a morning grooming routine of brushing one’s teeth, washing one’s face, and combing one’s hair).

behavioral inhibition a temperamental predisposition characterized by restraint in engaging with the world combined with a tendency to scrutinize the environment for potential threats and to avoid or withdraw from unfamiliar situations or people. It is often related to SOCIAL ANXIETY and a predisposition for greater physiological reactivity to novel situations. [first described by U.S. psychologists Jerome Kagan and J. Steven Reznick (1951–)]

behavioral inhibition system (BIS) in REINFORCEMENT SENSITIVITY THEORY, the physiological mechanism believed to control aversive motivation. It is theorized to be sensitive to signals of punishment and nonreward. Activity in this system suppresses behavior that may lead to negative or painful outcomes and inhibits movement toward goals. It has also been held that this system is responsible for the experience of negative feelings such as fear, anxiety, frustration, and sadness in response to these signals and that having a strong or chronically active BIS tends to result in introversion. Compare BEHAVIORAL APPROACH SYSTEM. [described by British psychologist Jeffrey Alan Gray (1934–2004)]

behavioral integration 1. the combination of separate individual behaviors into a synchronized or coordinated behavioral unit. 2. a model for environmentally sound behavior that specifies the relevant cognitions and affects and their interactions. Also called behavior integration.

behavioral interview an approach to clinical interviewing that focuses on relating a problem behavior to antecedent stimuli and the consequences of reinforcement.

behaviorally anchored rating scale (BARS) a behavior-based measure used in evaluating job performance. Employees are evaluated on each performance dimension by comparing their job behaviors with specific behavior examples that anchor each level of performance. The task of the rater is to find that point on the scale that is most typical of the employee’s performance on the dimension. BARS can also be used to evaluate the performance of job applicants in a SITUATIONAL INTERVIEW. Compare BEHAVIORAL OBSERVATION SCALE; MIXED-STANDARD SCALE. See also CRITICAL-INCIDENT TECHNIQUE.

behavioral marital therapy see BEHAVIORAL COUPLES THERAPY.

behavioral medicine a field that applies behavioral theories and methods to the prevention and treatment of medical and psychological disorders. Areas of application include chronic illness, lifestyle issues (e.g., substance
abuse, obesity, somatoform disorders, and the like. Behavioral medicine is an interdisciplinary field in which physicians, psychologists, psychiatrists, social workers, and others work together in patient care; it includes strong integration of biological, psychosocial, behavioral, and interpersonal perspectives in developing biopsychosocial models of illnesses and interventions to treat and manage them as well as to promote healthy behaviors. See also behavioral health.

behavioral mimicry see mimicry.

behavioral model a conceptualization of psychological disorders in terms of overt behavior patterns produced by learning and the influence of reinforcement contingencies. Treatment techniques, including systematic desensitization and modeling, focus on modifying ineffective or maladaptive patterns.

behavioral modeling 1. a training technique in which workers are instructed on and then shown a skill or problem-solving method that they then practice using role play or a computer simulation. 2. any conscious or non-conscious imitation of the behavior of another person.

behavioral momentum the resistance to change through time of some activity in the face of manipulations intended to disrupt that activity. The more difficult it is to disrupt an activity, the greater its behavioral momentum.

behavioral neurochemistry the study of the relationships between behavior and biochemical influences, including the effects of drugs on metabolic processes within the brain and the role of different neurotransmitters and neuroregulatory substances.

behavioral neuropsychology a subspecialty of clinical neuropsychology that integrates behavior therapy techniques into the treatment of individuals with brain damage.

behavioral neuroscience a branch of neuroscience and biological psychology that seeks to understand and characterize the specific neural circuitry and mechanisms underlying behavioral propensities or capacities.

behavioral observation scale (BOS) a behavior-based measure used in evaluating job performance. The person carrying out the rating uses one or more scales to gauge the frequency with which the employee has demonstrated effective behaviors in the job. A modified version of this measure also is used in other contexts, such as psychological research and clinical assessment. Compare behaviorally anchored rating scale (BARS) mixed-standard scale. See also critical-incident technique.

behavioral pathogen a behavior or lifestyle that may increase the risk of developing illness or disability and may reduce life expectancy. Examples of behavioral pathogens are smoking, drug abuse, poor diet, unprotected sexual activity, and a sedentary lifestyle. Compare behavioral immunogen.

behavioral pattern see behavioral pattern.

behavioral pediatrics a multidisciplinary specialty that is often part of pediatric psychology, clinical child psychology, and health psychology. Practitioners address such problems as habit disorders, oppositional behavior, sleep and eating disorders, and physical health problems (e.g., traumatic brain injury). In the medical literature, this specialty is also called developmental-behavioral pediatrics.

behavioral pharmacology a branch of pharmacology concerned with the physiological and behavioral mechanisms by which drugs operate, encompassing not only the effects of drugs on behavior but also how behavioral factors contribute to the actions of drugs and the ways in which they are used.

behavioral phenotype a pattern of observable motor, cognitive, linguistic, and social abnormalities that is consistently associated with a disorder. In some cases, the behavioral phenotype may constitute a discrete psychological disorder; in others, the abnormalities are usually not regarded as symptoms of a psychological disorder.

behavioral plasticity the degree to which behavior can be influenced and modified by social experience and learning. High plasticity leaves ample room for change, whereas low plasticity involves inflexible behavior patterns.

behavioral procedure any psychological procedure based on the principles and techniques of behavior theory. It may be used in basic research or in applied settings. See applied behavior analysis.

behavioral psychology an approach to understanding psychological phenomena that focuses on observable aspects of behavior and makes use of behavior theory for explanation. See also behaviorism.

behavioral psychotherapy see behavior therapy.

behavioral rehearsal see behavior rehearsal.

behavioral relaxation training a form of relaxation training and behavior therapy that emphasizes labeling of sensations, modeling, reinforcement, and therapist feedback. See also progressive relaxation.

behavioral repertoire see repertoire.

behavioral risk factor any specific behavior or pattern of behaviors (e.g., overeating or smoking) that increases an individual’s likelihood of developing a disorder, disease, or syndrome.

behavioral science any of various disciplines that use systematic observation and experimentation in the scientific study of human and nonhuman animal actions and reactions. Psychology, sociology, and anthropology are examples.

behavioral segment see behavior segment.

behavioral self-control training a technique in behavior therapy that uses self-monitoring, self-evaluation, self-reinforcement, coaching, behavior contracts, and relapse prevention approaches to help clients achieve active coping strategies, to increase their sense of mastery, and to decrease undesired habits (e.g., nail biting). See also behavioral weight control therapy.

behavioral sequence a combination of behavioral incidents directed toward a particular goal or outcome (e.g., getting ready for work in the morning). Also called behavior episode.

behavioral sex therapy a form of sex therapy that uses behavior therapy methods to bring about changes to behavioral sequences that hinder healthy sexual functioning. Behavioral sequences can include those that are relationship based (e.g., communication behaviors) or specifically sexually based (e.g., avoidance of sexual stimuli).

behavioral sink the destructive behaviors among nonhuman animals that occur with overcrowding; these in-
behavioral sleep medicine

include increased aggression and decreased maternal behavior. This was an unexpected finding of studies in 1962 by U.S. experimental psychologist John B. Calhoun (1917–1995) in which rats were given unlimited food and water and allowed to reproduce without intervention. Population density increased rapidly, and the animals displayed increasingly pathological behavior.

behavioral sleep medicine (BSM) a growing clinical specialty area combining aspects of health psychology and sleep disorders medicine. Practitioners include psychologists, physicians, nurse practitioners, and other health care professionals certified in the discipline who seek to understand the cognitive and behavioral factors that contribute to the development and maintenance of adult and pediatric sleep disorders and who use this knowledge to provide empirically validated, nonpharmacological interventions. For example, a BSM practitioner would help a client with insomnia to fall asleep faster, wake up less frequently, and sleep more efficiently using specialized behavioral and cognitive techniques that normalize the person's sleep schedule and condition him or her to see the bedroom as a restful place.

behavioral specialization in animal behavior, adaptation to the conditions and challenges of a specific environment as applied to the selection of habitats, food, and mates. For example, when foraging for foods in competition with other species, those individuals that specialize in a few types of foods, known as "specialists," are usually more efficient in finding and processing food than are generalists. Finches in the Galápagos Islands have diverged, some specializing on insects, others on seeds. Within each of these broad groupings, some specialize on larger and others on smaller food items. Although behavioral specialization provides a competitive advantage in stable environments, generalists can respond more quickly to changing environments. Highly endangered species tend to show specialization.

behavioral study of obedience the experimental analysis, especially as carried out by Stanley MILGRAM in the 1960s, of individuals' willingness to obey the orders of an authority. In Milgram's experiment, each participant played the role of a teacher who was instructed to deliver painful electric shocks to other "participants" for each failure to answer a question correctly. The latter were in fact CONFEDE RATES who did not actually receive shocks for their many deliberate errors. Milgram found that a substantial number of participants (65%) were completely obedient, delivering what they believed were shocks of increasing intensity despite the protestations and apparent suffering of the victim. See also AGENTIC STATE; DESTRUCTIVE OBEDIENCE.

behavioral technology experimentally established procedures (influenced by scientific behavior analysis) that are designed to produce behavioral change.

behavioral teratology the study of impairments in behavior that are produced by embryonic or fetal exposure to toxic substances that affect the developing organism (see TERATOGEN).

behavioral theory of leadership any of various models that define and explain leadership in terms of the actions leaders take to influence others rather than in terms of their motivations, traits, or past experiences. In these models, leadership is viewed as a behavioral response that can be learned. See also LEADERSHIP THEORIES.

behavioral toxicity an adverse behavioral change produced by psychotropic drugs, for example, insomnia, sedation, impaired psychomotor activity, or changes in mental status.

behavioral toxicology the study of the behavioral impact of toxic exposure. There is increasing evidence that many toxins produce subtle behavioral changes, often in neurosensory functioning, at levels far below thresholds for detectable neurological damage. Perhaps the best known example is lead, which is now banned from gasoline and interior paint in many countries because of its low-level toxicological effects on the behavior of developing children.

behavioral weight control therapy any intervention that uses the principles and techniques of BEHAVIOR THERAPY to help clients change eating and exercise habits to achieve and maintain a healthy weight. Practiced in group or individual sessions, these techniques include self-monitoring, behavior contracts, environmental change (e.g., eating seated and only in a specific room), and reinforcement (e.g., social or monetary). See also BEHAVIORAL SELF-CONTROL TRAINING.

behavior analysis the decomposition of behavior into its component parts or processes. This approach to psychology is based on the EXPERIMENTAL ANALYSIS OF BEHAVIOR, in which behavior is the subject matter for research rather than an indicator of underlying psychological entities or processes. Emphasis is placed on interactions between behavior and the environment. See APPLIED BEHAVIOR ANALYSIS. (originally developed by B.F. SKINNER)

behavior-based safety an approach in SAFETY ENGINEERING based on the premise that human behavior is learned and habitual and can thus be modified to avoid error and accidents. Its main application is in the field of TRAINING SYSTEMS DESIGN, where the aim is to devise training programs that ingrain good safety habits. Additional applications include the design of organizational mechanisms to enhance workers’ involvement in safety programs and the design of machines or equipment to accord with the behaviors and habits of workers or consumers.

behavior baseline see BEHAVIORAL BASELINE.

behavior chaining see CHAINING.

behavior change 1. a systematic approach to changing behavior through the use of OPERANT CONDITIONING. 2. any alteration or adjustment of behavior that affects a patient’s functioning, brought about by psychotherapeutic or other interventions or occurring spontaneously.

behavior checklist a list of actions, responses, or other behaviors that are to be recorded each time they are observed, as by an experimental investigator, study participant, or clinician.

behavior coding a method of recording observations in which defined labels are used by specially trained individuals to denote specific qualities and characteristics of behaviors as they are witnessed. For example, a developmental researcher might use the following coding scheme for infant vocalizations: (a) vowels; (b) syllables (i.e., consonant-vowel transitions); (c) babbling (a sequence of repeated syllables); and (d) other (e.g., crying, laughing, vegetative sounds such as cooing). Behavior coding systems typically are specific to a given study and the behaviors under investigation.

behavior-constraint theory the concept that an in-
individual may acquire LEARNED HELPLESSNESS when repeated efforts fail to gain control over excessive or undesirable environmental stimuli.

behavior contract an agreement between therapist and client in which the client agrees to carry out certain behaviors, usually between sessions but sometimes during the session as well. Also called behavioral contract. See also CONTRACT; CONTINGENCY CONTRACT.

behavior control 1. the use of conditioning, therapeutic techniques, or other methods to steer individual or group behavior in a desired direction. For example, behavior control may be used to help children with conduct problems engage in more appropriate actions at school and at home. In some contexts, the term also refers to the misuse of certain treatments (e.g., drugs) to manage institutionalized individuals, particularly patients with mental illnesses. 2. see FATE CONTROL.

behavior criterion see BEHAVIORAL CRITERION.

behavior deficit see BEHAVIORAL DEFICIT.

behavior determinant any factor that produces a behavioral effect.

behavior diary a detailed log of a person’s activities or responses as recorded by a trained observer or the individual himself or herself, usually on a regular basis over a specified interval of time. For example, a behavior diary might be used to log a study participant’s activities over a 24-hour period.

behavior disorder any persistent and repetitive pattern of behavior that violates societal norms or rules, seriously impairs a person’s functioning, or creates distress in others. The term is used in a very general sense to cover a wide range of disorders or syndromes. Also called behavioral disorder. See also PRIMARY BEHAVIOR DISORDER.

behavior disorders of childhood and adolescence observable behaviors in young people that deviate from the norm. The term is often used in SPECIAL EDUCATION and school placement.

behavior dysfunctions classification the classification of personal problems on the basis of behaviors rather than symptoms or hypothetical constructs. Such a classification leads the clinician to work on helping the patient change behaviors rather than treating syndromes or diseases.

behavior episode see BEHAVIORAL SEQUENCE.

behavior field any set of stimuli or conditions, or accumulation of factors, that produces a behavioral effect.

behavior genetics see BEHAVIORAL GENETICS.

behavior hierarchy a ranking of possible responses based on the relative probabilities of their being elicited, with more probable behaviors ranked higher than less probable behaviors. Also called behavioral hierarchy.

behavior homeostasis see BEHAVIORAL HOMEOSTASIS.

behavior homology see BEHAVIORAL HOMOLOGY.

behavior integration see BEHAVIORAL INTEGRATION.

behaviorism n. an approach to psychology, formulated in 1913 by John B. Watson, based on the study of objective, observable facts rather than subjective, qualitative processes, such as feelings, motives, and consciousness. To make psychology a naturalistic science, Watson proposed to limit it to quantitative events, such as stimulus–response relationships, effects of conditioning, physiological processes, and a study of human and animal behavior, all of which can best be investigated through laboratory experiments that yield objective measures under controlled conditions. Historically, behaviorists held that mind was not a proper topic for scientific study since mental events are subjective and not independently verifiable. With its emphasis on activity as an adaptive function, behaviorism is seen as an outgrowth of FUNCTIONALISM. See DESCRIPTIVE BEHAVIORISM; METHODOLOGICAL BEHAVIORISM; NEOBEHAVIORISM; RADICAL BEHAVIORISM.

behaviorist n. a person who espouses the principles of BEHAVIORISM and whose activities are deliberately guided by those principles. See also BEHAVIOR ANALYSIS; BEHAVIOR MODIFICATION.

behavior management the use of APPLIED BEHAVIOR ANALYSIS to produce significant change in human behavior. See also ORGANIZATIONAL BEHAVIOR MANAGEMENT.

behavior mapping a technique of studying the activities of individuals within a space by noting what happens where. The degree of variability of behavior, as well as its association with certain types of environmental features, is a useful starting point to build or test hypotheses about, for example, architectural design. See also ARCHITECTURAL PROGRAMMING.

behavior modification the use of OPERANT CONDITIONING, BIOFEEDBACK, MODELING, AVERSION CONDITIONING, RECIPROCAL INHIBITION, or other learning techniques as a means of changing human behavior. For example, behavioral modification is used in clinical contexts to improve adaptation and alleviate symptoms and in organizational contexts to encourage employees to adopt safe work practices. The term is often used synonymously with BEHAVIOR THERAPY.

behavior observation the recording or evaluation of the ongoing behavior of one or more research participants by one or more observers. Behavior observation may be carried out live or through video media and often involves the use of rating scales, checklists, or charts.

behavior pattern a complex arrangement of two or more responses that occur in a prescribed order. Behavior patterns are also referred to as chains of behavior, highlighting their nature as a complex linking of simpler segments of behavior. They may be formed via the OPERANT CONDITIONING of various segments presented in the appropriate order. Also called behavioral pattern.

behavior problem a pattern of disruptive behavior that generally falls within social norms and does not seriously impair a person’s functioning.

behavior rating use of a scale to assess the degree to which an individual displays one or more behaviors in a given situation.

Behavior Rating scale see BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT.

behavior record a collection of observations of an organism’s behavior within a specified time frame. In animal studies, this involves documenting all observable actions of an individual within a defined period of time. In educational psychology, a behavioral record is a teacher’s written observations of a student’s behavior and personality (see ANECDOTAL RECORD).
behavior rehearsal

**behavior rehearsal** a technique used in behavior therapy or cognitive behavior therapy for modifying or enhancing social or interpersonal skills. The therapist introduces effective interpersonal strategies or behavior patterns to be practiced and rehearsed by the client until these are ready to be used in a real-life situation. The technique is also commonly used in assertiveness training. Also called **behavioral rehearsal**.

**behavior reversal** a method of behavior modification in which the client, supervised by the therapist, practices desirable responses to interpersonal conflicts that are often opposite to his or her usual behavior.

**behavior sampling** a data collection method in which the behaviors of one or more individuals are observed and recorded during a designated period of time. Observations can be made in either a natural or a research setting, and they may be conducted over multiple time periods with or without the awareness of the individual being observed.

**behavior segment** a distinct response that, when linked with other responses, forms a behavior pattern or chain. Also called **behavioral segment**.

**behavior setting** the geographical, physical, and social situation as it affects relationships and behavior. See also ecological psychology. [Identified by U.S. developmental psychologist Roger G. Barker (1903–1990)]

**behavior shaping** see **shaping**.

**behavior system** 1. the different activities that can be undertaken to reach the same goal or carry out the same function; for example, communication is achieved through writing, speaking, or gestures. 2. the expression of important motives (e.g., hunger, sex, aggression), which varies between cultures and among individuals within the same culture who have had different training and experiences. Also called **activity system**.

**behavior theory** the assumption that behavior, including its acquisition, development, and maintenance, can be adequately explained by stimuli- and response-based principles of learning. Behavior theory attempts to describe environmental influences on behavior, often using controlled studies with laboratory animals. It encompasses historical approaches to formal theorizing, such as those of Clark L. Hull and Kenneth W. Spence, and the operant theory of B. F. Skinner, as well as contemporary approaches to behavior. Also called **general behavior theory**.

**behavior therapy** a form of psychotherapy that applies the principles of learning, *operant conditioning*, and classical conditioning to eliminate symptoms and modify ineffective or maladaptive patterns of behavior. The focus of this therapy is upon the behavior itself and the contingencies and environmental factors that reinforce it, rather than exploration of the underlying psychological causes of the behavior. A wide variety of techniques are used in behavior therapy, such as behavior rehearsal, biofeedback, modeling, and systematic desensitization. Also called **behavioral psychotherapy; conditioning therapy**.

**Behrens-Fisher problem** the problem of comparing the means of two samples drawn from different populations when the variances of these populations are not assumed to be equal. In other words, the problem involves the difficulty of making statistical inferences in the absence of equal population variances. The Behrens-Fisher problem may be addressed in many ways, such as by using a *t* test to estimate a probability level (p value) or by using confidence intervals to estimate the range of uncertainty around the mean difference. [W. U. Behrens; Ronald Aylmer Fisher]

**behavior beyond-the-world** n. in existential psychology, the potential for human beings to transcend the limitations of being-in-the-world, usually through selfless love. See also Dasein. [introduced by Swiss existential psychologist Ludwig Binswanger (1881–1966)]

**behavior cognition** (B-cognition) 1. in the humanistic psychology of Abraham Maslow, an exceptional type of cognition that can be distinguished from one’s everyday perception of reality (deficiency cognition or D-cognition). Being cognition involves a dialectical blending of two ways of experiencing: In the first, a person is aware of the whole universe and the interrelatedness of everything within it, including the perceiver; in the second, a person becomes entirely focused on a single object (e.g., a natural phenomenon, a work of art, or a loved person) to the extent that the rest of the universe, including the perceiver, seems to disappear. According to Maslow, self-actualizers (see **self-actualization**) frequently experience being cognitions. See also peak experience; timeless moment, 2. awareness of the inner core of one’s existence, that is, one’s self or identity.

**behavior beyond-the-world** n. in theories and clinical approaches derived from existentialism, the particular type of being characteristic of humans, in contrast to the type of being of nonhuman animals, inanimate objects, or abstractions. The term is roughly synonymous with Dasein, the term used by German philosopher Martin Heidegger (1889–1976). The word being is meant to emphasize that human existence is an activity more than a state or condition. Similarly, world is meant to convey a much richer and more meaningful ground for human life than would be conveyed by a more sterile term, such as environment. Being-in-the-world is by its very nature oriented toward meaning and growth; while it characterizes the type of being of all humans, it is also unique for every person and can be seen to be offering an explanation of what in other psychological traditions might be called identity of self. Compare **being beyond-the-world**. See also world design.

**behavior love** (B-love) in Abraham Maslow’s humanistic psychology, a form of love characterized by mutuality, genuine concern for another’s welfare and pleasure, and reduced dependency, selfishness, and jealousy. B-love is one of the qualities Maslow ascribes to self-actualizers (see **self-actualization**). Compare **deficiency love**.

**behavior motivation** see **metamotivation**.

**being—not being** the fundamental issue that, according to German philosopher Martin Heidegger (1889–1976), motivates human beings, namely, the question of existence and nonexistence (personhood and mortality). See **Dasein**.

**behavior psychology** a psychological perspective that deals with “persons insofar as they are ends-in-themselves.” It is concerned with acknowledgment of the sacred, the unique, and the incomparable in individual human beings. See also humanistic psychology; self-actualization. [developed by Abraham Maslow]

**behavior value** see metamere.

**Békésy audiometer** the first automatic audiometer with patient-controlled push-button responses and an ink
Békésy traveling wave see BASILAR MEMBRANE.
[Georg von BékÉSy]

Belk–Magendie law the principle that the ventral roots of the spinal cord are motor in function and the dorsal roots are sensory. [Charles Bell (1774–1842), Scottish surgeon and anatomist; François Magendie (1783–1855), French physiologist]

Bell’s mania see LETHAL CATATONIA. [Luther Vose Bell (1806–1862), U.S. physician]

Bell’s palsy paralysis of the facial nerve, causing weakness of the muscles on one side of the face and resulting in a distorted expression, inability to close the eye, and often taste loss and sensitivity to sound. [Charles Bell (1774–1842), Scottish surgeon and anatomist]

Bell’s phenomenon the upward and outward movement of the eye that normally occurs when attempting to close the eye. It is seen most prominently in individuals with Bell’s palsy when they attempt to close the eye on the affected side. [Charles Bell]

belonging n. the feeling of being accepted and approved by a group or by society as a whole. Also called belongingness.

belongingness principle see PRINCIPLE OF BELONGINGNESS.

below average denoting a range of intellectual functioning that is just below the average range, roughly between 80 and 90 on most IQ scales, and is inconsistent with the presence of intellectual disability. Such a range may also be described as low normal or dull normal, but below average is now the preferred term.

below-average effect the tendency of a person to underestimate his or her intellectual and social abilities relative to others. The below-average effect is common when the skill in question is relatively hard (e.g., sculpting human figures from clay), whereas the opposite above-average effect generally occurs when the skill in question is relatively easy (e.g., operating a computer mouse). Also called worse-than-average effect.

Bem Sex Role Inventory (BSRI) a questionnaire listing 20 characteristics considered in American society to be more desirable for men (e.g., leadership ability, forcefulness), 20 characteristics considered more desirable for women (e.g., gentleness, affectionateness), and 20 neutral characteristics considered desirable for either sex (e.g., truthfulness, happiness). Participants indicate how well each of the 60 characteristics describes themselves using a

recorder to graph the audiogram throughout the testing process. It yields tracings for continuous and interrupted tones at controlled frequencies. [George von Békésy]

Behrens effect a change in libidinal makeup that may be associated with a change in the individual’s intellectual or social status. [Walter von Behrens]

behavioural effects the effects on the central nervous system of large doses of belladonna alkaloids, such as atropine and scopolamine. These contain atropine, which paralyzes the parasympathetic nervous system. The symptoms include visual hallucinations, mutism, dilated pupils, unresponsiveness, and disorientation.

bell and pad a device used in treatments aimed at controlling nocturnal enuresis (bed-wetting) in children. If the child begins to lose bladder control while asleep, an electric circuit within a bed pad sets off an alarm upon initial detection of the urine, thus awakening the child before he or she wets the entire bed.

bell curve the characteristic curve obtained by plotting a graph of a normal distribution. With a large rounded central peak tapering off on either side, it resembles a cross-sectional representation of a bell. Also called bell-shaped curve.

belle indifférence see LA BELLE INDIFFÉRENCE.

Bellevue scale see WECHSLER ADULT INTELLIGENCE SCALE.
scale ranging from 1 (neither or almost never true) to 7 (always or almost always true). Responses are scored and individuals subsequently categorized as masculine (high on traits associated with masculinity and low on those associated with femininity), feminine (high on traits associated with femininity and low on those associated with masculinity), androgynous (high on both types of traits), or undifferentiated (low on both types of traits). In measuring a person’s adherence to culturally specified standards of desirable behavior for men and women (see sex role), the BSRI was intended to eschew the traditional dichotomy of masculinity and femininity in favor of a more flexible, situationally responsive conceptualization. See also masculinity–femininity test. [developed in 1974 by Sandra Lipsitz Benveniste (1944–2014), U.S. psychologist]

Benadryl n. a trade name for DIPHENHYDRAMINE.

benchmark n. a measure of best performance for a particular process or outcome, which can be used as a reference to improve performance in other settings.

benchmark job a specific job that is used as a reference point for the purpose of evaluation or comparison. Jobs chosen as benchmarks tend to be well known, remain consistent across diverse organizations and industries, and have readily available external market data. They can therefore be and are used to create job descriptions, set pay levels, and measure performance. See classification method; factor-comparison method.

bench trial a trial in which the judge, not a jury, decides the defendant’s guilt or innocence.

Bender Visual–Motor Gestalt Test a VISUOCONSTRUCTIONAL TEST in which the participant first copies line drawings of 16 geometric figures onto blank pieces of paper (Copy Phase) and then redraws them from memory (Recall Phase). All reproductions are scored on a 5-point scale, ranging from 0 (no resemblance) to 4 (nearly perfect). The test is appropriate for individuals ages 4 years and older and is used to assess visual–motor functioning and constructional ability; it is scored for the number of correct reproductions and for the number and types of errors. Developed originally in 1946 by Arthur L. Benton, the test underwent several revisions and is now in its fifth edition (published in 1991). Also called Benton Revised Visual Retention Test (BVRT).

Benzedrine n. a trade name for racemic AMPHETAMINE, that is, a mixture of levoamphetamine and dextroamphetamine.

benzene n. a volatile solvent that, when chronically inhaled, can cause kidney failure and death. See INHALANT.

benzisoxazole n. a class of ATYPICAL ANTIPSYCHOTICS that include RISPERIDONE and ILOPERIDONE.

benzodiazepine n. any of a family of drugs that depress central nervous system activity (CNS DEPRESSANTS) and also produce sedation and relaxation of skeletal muscles. Benzodiazepines include the prototype CHLORIDAZEPoxide, other anxiolytics such as ALPRAZOLAM, CLONAZEPAM, and DIAZEPAM; and hypnotics such as ESTAZOLAM, FLURAZEPAM, QUAZEPAM, TEMAZEPAM, and TRIAZOLAM. They are commonly used in the treatment of generalized anxiety, panic disorder, and insomnia and are useful in the management of acute withdrawal from alcohol and of seizure disorders. Clinically introduced in the 1960s, they rapidly supplanted the barbiturates, largely due to their significantly lower toxicity in overdose. Members of the group show considerable variation in abuse potential, and prolonged use can lead to tolerance and psychological and physical dependence.

benzodiazepine agonist any drug that facilitates the binding of benzodiazepines to subunits of the benzodiazepine receptor complex (see GABA, RECEPTOR).

benzodiazepine antagonist any agent that prevents the binding of benzodiazepines and related chemicals to the benzodiazepine receptor site on the GABA, RECEPTOR complex. Benzodiazepine antagonists in clinical use include FLUAZAZENIL.

benzo thiadiazide n. see THIAZIDE DIURETIC.

benztropine n. an ANTICHOLINERGIC DRUG used in the management of adverse side effects of conventional antipsychotic drugs and as an adjunct in the treatment of Parkinson’s disease. U.S. trade name: Cogentin.

berdache n. see TWO-SPIRIT.

bereavement n. the condition of having lost a loved one to death. The bereaved person may experience emotional pain and distress (see GRIEF; TRAUMATIC GRIEF) and may or may not express this distress to others (see MOURNING; DISENFRANCHISED GRIEF); individual grief and mourning re-
sponges vary. Bereavement may also signify a change in social status (e.g., from wife to widow). —bereaved adj.

bereavement exclusion in DSM–IV–TR, a statement that rules out, as symptoms of a MAJOR DEPRESSIVE EPISODE, an individual’s responses to the death of a loved one (e.g., sadness) unless they last longer than 2 months after the death, markedly impair function, or are accompanied by such symptoms as suicidal ideation. DSM–5 has replaced this exclusion with a broader statement that characterizes an individual’s normal responses to various types of significant loss (e.g., bereavement, financial ruin, disability) as nonetheless meritting careful clinical consideration of the possibility that they may co-occur with a major depressive episode. See also PERSISTENT COMPLEX BEREAVEMENT DISORDER.

bereavement program any of a variety of treatment services (e.g., support groups, GRIEF COUNSELING) offered to individuals coping with the death of a loved one.

bereavement therapy therapy or counseling provided to individuals who are experiencing loss following the death of a loved one. The therapy may address issues of separation, grieving, and carrying on with life. See also GRIEF COUNSELING.

Bereitschaftspotential (BP) n. see READINESS POTENTIAL.

Berger rhythm see ALPHA WAVE. [Hans Berger (1873–1944), German neuropsychiatrist]

beriberi n. a nutritional disease caused by thiamine (vitamin B₁) deficiency and characterized by neurological symptoms and cardiovascular abnormalities. See also WERNICKE’S ENCEPHALOPATHY.

Berkeley Growth Study a study seeking to understand the mental abilities relevant at different ages of life, as well as their importance. A group of participants was followed beginning at 21 months of age for a period of over 50 years (from 1928 to 1982). [conducted by Nancy Baley]

Bernoulli distribution a theoretical distribution of the number of trials required before the first success is obtained in a Bernoulli process (see BERNOULLI TRIAL). Such a distribution is defined by two values: 0 and 1. Usually a value of 0 is used to denote a failure (i.e., the item of interest does not occur) and a value of 1 is used to denote a success (i.e., the item of interest does occur). On this basis, the likeliness of a success is denoted as θ and the likeliness of a failure is denoted as q = 1 − θ. For example, a single toss of a coin has a Bernoulli distribution with p = 0.5 (where 0 = heads and 1 = tails). A Bernoulli distribution is a special case of a BINOMIAL DISTRIBUTION. [Jacques Bernoulli (1654–1705), Swiss mathematician and scientist]

Bernoulli trial a single experiment in which the only two possible outcomes are success or failure. Usually a value of 0 is used to denote a failure (i.e., the item of interest does not occur) and a value of 1 is used to denote a success (i.e., the item does occur). A sequence of Bernoulli trials is known as a BERNOLLI process. See also BERNOLLI DISTRIBUTION. [Jacques Bernoulli]

Berry syndrome see TREACHER COLLINS SYNDROME. [reported in 1889 by George Andreas Berry (1853–1929), British physician]

berserk 1. adj. destructive or violent. 2. n. one who is destructive or violent. The term is derived from an Old Norse word literally meaning “bearshirt,” used to describe ancient Norse warriors who wore bearskins during battle and fought with great strength and fury. The term is now rather archaic.

Bessel’s correction an adjustment used to reduce bias when calculating the VARIANCE and STANDARD DEVIATION in a sample. Specifically, it is the use of n − 1 instead of n in the denominator of the computational formulas used to compute these values, where n is the number of observations in the sample. [Friedrich Wilhelm Bessel (1784–1846), German-born Russian astronomer and mathematician]

BEST acronym for BIOGRAPHICAL EVALUATION AND SCREENING OF TROOPS.

best-first search a problem-solving strategy in which various possible paths to a solution are evaluated in terms of the likelihood that they will prove successful and the path judged most promising is attempted first. See HEURISTIC SEARCH.

best fit the theoretical pattern that best accounts for the relationships among variables in a data set. For example, a REGRESSION EQUATION having the best fit to sample data is the one that minimizes differences between observed and predicted values. On a SCATTERPLOT, a line of best fit provides a visual depiction of this pattern, allowing extrapolation to values not part of the original data set. It is important to note that the best-fitting pattern is not necessarily the one that generated the observed data, as other patterns not considered may provide a superior fit.

best frequency (BF) see TONOTOPIC ORGANIZATION; TUNING CURVE.

bestiality n. sexual excitement or gratification obtained by a human through anal or genital intercourse or other sexual contact with a nonhuman animal. Also called zooerastia; zooreasty. See also SODOMY; ZOOPHILIA.

best interests of the child a standard used by courts to make child custody decisions, namely, that the potential for the child to lead a happy and successful life should be given greater weight than the rights of either parent or caregiver.

beta (symbol: β) n. 1. the likeliness of committing a TYPE II ERROR in research. 2. the effect of a predictor variable on an outcome variable, such as in REGRESSION ANALYSIS or STRUCTURAL EQUATION MODELING.

beta-adrenergic receptor a receptor that binds NOREPINEPHRINE. There are two main types, designated β₁ and β₂. The former mediate stimulation of heart muscle, causing a faster and stronger heartbeat. The latter are associated with relaxation of smooth muscle, causing (for example) dilation of blood vessels and widening of airways. Also called beta adrenoceptor; beta adrenoreceptor; beta receptor. Compare ALPHA-ADRENERGIC RECEPTOR.

beta-adrenergic receptor kinase (bark) a CYCLIC AMP-dependent enzyme that is responsible for inactivating beta-ADRENERGIC RECEPTORS, thereby inhibiting the ability of these receptors to activate SECOND MESSAGERS within the cell. It is a member of a family of G PROTEIN-coupled receptor kinases that work only when receptors are occupied by an agonist.

beta-adrenoreceptor blocking agent see ADRENERGIC BLOCKING AGENT.

beta alcoholism see JELLINEK’S ALCOHOLISM SPECIES.
beta-amyloid (β-amyloid) n. a protein that accumulates—via aberrant processing of amyloid precursor protein (APP)—in the brains of patients with Alzheimer’s disease, forming AMYLOID PLAQUES and contributing to neuronal impairment and eventual loss. Significant progress has been made toward developing therapies that target this processing pathway, and several promising pharmacological agents are now in advanced-stage clinical trials.

beta blocker see ADRENERGIC BLOCKING AGENT.

beta coefficient the multiplicative constant in a REGRESSION ANALYSIS that indicates the change in an outcome variable associated with the change in a predictor variable after each has been standardized to have a distribution with a mean of 0 and a STANDARD Deviation of 1. A beta coefficient controls for the effect of other predictors included in the analysis and thus allows for direct comparison of the individual variables despite differences in measurement scales (e.g., salary measured in dollars and educational degree measured in years of schooling). Also called beta weight.

beta distribution a family of PROBABILITY DISTRIBUTIONS whose values range from 0 to 1 and whose shape is defined by two quantities (parameters) referred to as α and β. A beta distribution provides the likelihood of obtaining each of the possible values within the 0, 1 range.

beta-endorphin n. a neuropeptide involved in pain and hunger that produces its analgesic effects by binding to opioid receptors and disinhibiting dopamine pathways. It is one of a number of ENDOGENOUS opioids. See ENDORPHIN.

beta error see TYPE II ERROR.

Beta examination see ARMY TESTS.

beta-glucuronidase deficiency deficiency of the enzyme β-glucuronidase, which is involved in the breakdown of complex carbohydrates (see MUCOPOLYSACCHARIDOSIS). This deficiency is characterized by enlarged liver or spleen, dermatan sulphate in the urine, bone malformations, white-cell inclusions, and intellectual disability. The condition occurs because of mutations in the GUSB gene in the short arm of chromosome 7. Also called mucopolysaccharidosis Type VII: Sly syndrome.

beta level the likelihood of failing to reject the NULL HYPOTHESIS when it is in fact false, that is, the probability of making a TYPE II ERROR. The beta level for a given statistical procedure is related to the POWER of that procedure (β level = 1 – power).

beta movement see APPARENT MOVEMENT.

beta receptor see BETA-ADRENERGIC RECEPTOR.

beta rhythm see BETA WAVE.

beta-secretase (β-secretase) n. an enzyme that cleaves amyloid precursor protein forming BETA-AMYLOID, accumulation of which in brain tissue can lead to Alzheimer’s disease.

Beta test see ARMY TESTS.

beta wave in electroencephalography, the type of BRAIN WAVE (frequency 13–30 Hz) associated with alert wakefulness and intense mental activity. Also called beta rhythm.

beta weight see BETA COEFFICIENT.

betel nut the seed of the areca palm (Areca catechu), which is chewed as a stimulant by local populations of India and the islands of the Indian and Pacific Oceans. It contains the drug arecoline.

bethanechol n. a CHolinergic drug used to stimulate the bladder in the management of such conditions as lower MOTOR NEURON disease and postoperative or postpartum urinary retention. U.S. trade name: Urecholine.

betrayal n. any act committed by one relationship partner that violates the other’s expectations of that partner (e.g., that he or she is trustworthy and has regard for the other’s well-being). Although the term betrayal is commonly associated with infidelity, most researchers use it in a broader sense to include such acts as lying, disloyalty, revealing secrets to outsiders, intentionally harmful behavior, lack of support, or broken promises. Betrayals can evoke strong emotions in victims and perpetrators and are usually harmful to relationships, sometimes leading directly to their termination. Alternatively, reparative actions by the perpetrator, such as an apology, can foster forgiveness by the victim, which allows the relationship to continue.

betrayal trauma theory a conceptual model for explaining why some children are unable to access memories of prior sexual or physical abuse. According to the theory, this sort of REPRESSION occurs when the perpetrator of the abuse is an adult on whom the child is emotionally dependent, and it develops out of the child’s need to preserve the ATTACHMENT BOND: hence the child is unable to access the stored memories of the abuse while the need for attachment is still strong. [first proposed in 1991 by U.S. cognitive psychologist Jennifer J. Freyd (1957–)]

better-than-average effect see ABOVE-AVERAGE EFFECT.

between-dimension consistency see CROSS-DIMENSION ATTITUDE CONSISTENCY.

between-groups design see BETWEEN-SUBJECTS DESIGN.

between-groups variance the variation in experimental scores that is attributable only to membership in different groups and exposure to different experimental conditions. It is reflected in the ANALYSIS of VARIANCE by the degree to which the several group means differ from one another and is compared with the WITHIN-GROUPS VARIANCE to obtain an F RATIO. Also called between-subjects variance.

between-subjects analysis of variance an examination of the variance in a set of data obtained from a study in which a different group of participants is randomly assigned to each condition. In this procedure, the researcher determines how much of the variance in the obtained data is due to the influence of the variables under investigation and how much is due to random differences among the group members. For example, a researcher studying how amount of daily walking (e.g., none, 30 minutes, 60 minutes, 90 minutes) affects quality of sleep might divide participants into different groups that each walk for one of the specified lengths of time and then evaluate the results using a between-subjects analysis of variance. Compare WITHIN-SUBJECTS ANALYSIS OF VARIANCE.

between-subjects design a study in which individuals are assigned to only one treatment or experimental condition and each person provides only one score for data analysis. For example, in a between-subjects design investigating the efficacy of three different drugs for treating de-
pression, one group of depressed individuals would receive one of the drugs, a different group would receive another one of the drugs, and yet another group would receive the remaining drug. Thus, the researcher is comparing the effect each medication has on a different set of people. Also called **between-groups design; independent-groups design**. Compare **WITHIN-SUBJECTS DESIGN**.

**between-subjects factor** in an **ANALYSIS OF VARIANCE**. An **INDEPENDENT VARIABLE** with multiple levels, each of which is assigned to or experienced by a distinct group of participants. In a study examining weight loss, for example, the different amounts of daily exercise under investigation would be a between-subjects factor if each was undertaken by a different set of people. Also called **between-subjects variable**.

**between-subjects variance** see **BETWEEN-GROUPS VARIANCE**.

**Betz cell** a type of large **PYRAMIDAL CELL** found in the fifth layer of the cerebral cortex (see **CORTICAL LAYERS**), mainly in **MOTOR CORTEX**. Betz cells are associated with muscle movement and have a low threshold of stimulation. [Vladimir A. Betz (1834–1894), Russian anatomist]

**BEV** abbreviation for **BLACK ENGLISH Vernacular**.

**Bewusstseinslage n.** state of consciousness (German): a term used by followers of the **WEINHEIMERSCH Schule** to denote mental experiences or activities that cannot readily be analyzed into a chain of associations based on images or sensations. See **IMAGELSS THOUGHT**.

**beyondism** n. a secular “religion” devised by Raymond B. **CAITTELL** on the basis of **EVOLUTIONARY THEORY**. Beyondism holds that evolution will lead to the advancement of humanity; therefore, anything that furthers evolution is good, and anything that hinders it is not good. If allowed to operate freely, evolutionary processes will solve many of the world’s problems through evolutionary competition, leading to the survival of some civilizations and the extinction of others. Because of this belief, and its support for voluntary **EUGENICS**, beyondism received much criticism as racist. See **POLITICAL GENETICS**.

**beyond reasonable doubt** the standard of **PROOF** required in a criminal trial. To convict a defendant, a jury must be convinced of the defendant’s guilt “beyond a reasonable doubt.” meaning there is no justifiable, rational cause for jury members to doubt the defendant’s guilt. This standard is considered to be equivalent to a moral certainty but is less than an absolute certainty.

**Bezold–Brücke phenomenon** the perception that bright illumination makes yellowish stimuli appear closer to yellow and bluish stimuli closer to blue. [Johann Friedrich W. von **Bezold** (1837–1907), German physicist; Ernst Wilhelm von **Brücke** (1819–1892), German physiologist]

**BF** abbreviation for best frequency. See **TUNOTOPIC ORGANIZATION; TUNING CURVE**.

**B fiber** a myelinated nerve fiber (axon) of the autonomic nervous system. B fibers are approximately 2 mm or less in diameter and transmit impulses to the **SYMPATHETIC CHAIN**. See also **A FIBER; C FIBER**.

**BFOQ** abbreviation for **BONA FIDE OCCUPATIONAL QUALIFICATION**.

**bhang** n. the mildest preparation of **CANNABIS**, consisting of the whole **Cannabis sativa** plant, dried and powdered.

**BHS abbreviation for BECK HOPELESSNESS SCALE**.

**bi-** **(bin-)** **prefix** two, twice, or double.

**BLA abbreviation for BODY IMAGE ASSESSMENT**.

**bias** *n.*
1. **PARTIALITY**: an inclination or predisposition for or against something. See also **PREJUDICE**. 2. any tendency or preference, such as a **RESPONSE BIAS** or **TEST BIAS**. 3. systematic error arising during **SAMPLING**, data collection, or data analysis. See **BIASED ESTIMATOR**; **BIASED SAMPLING**. 4. any deviation of a measured or calculated quantity from its actual (true) value, such that the measurement or calculation is unrepresentative of the item of interest. **—BIASED** adj.

**bias blind spot** the tendency of people to see themselves as less susceptible to misconceptions and cognitive influences than others. For example, people often consider their own political views to be objective and purely fact-based, whereas they believe those who hold opposing political views are influenced by prejudice and party opinion. This bias stems from the fact that a person generally relies on **INTRUSPECTION** when assessing his or her own biases but relies on overt behavior when assessing bias in others. See also **OBJECTIVITY ILLUSION**. [introduced in 2002 by U.S. psychologists Emily Pronin, Daniel Y. Lin, and Lee Ross]

**biased elaboration** the tendency to generate a particular valence of evaluative responses preferentially when elaborating attitude-relevant information. See also **BIASING FACTOR**; **ELABORATION; OBJECTIVE ELABORATION**.

**biased estimator** a value obtained from sample data that consistently under- or overestimates the true quantity in the larger population of interest. In other words, a biased estimator is one whose value on average differs from the value of the parameter it purports to represent. Also called **BIASED STATISTIC**. Compare **UNBIASED ESTIMATOR**.

**biased sampling** selecting individuals or other study units from a population in such a manner that the resulting sample is not representative of the population. Compare **UNBIASED SAMPLING**. See also **SAMPLING BIAS**.

**biased scanning** a hypothetical process in which people alter or maintain a particular **SELF-CONCEPT** by searching the contents of their memory in a selective manner, focusing on memories that fit a predetermined impression. The theory assumes that people have a wide range of implicit memories, enabling them to support different views of the self by selectively remembering certain events.

**biased statistic** see **BIASED ESTIMATOR**.

**biasing factor** a variable that serves to bias the valence of **ELABORATION** of attitude-relevant information. See also **BIASED ELABORATION; MULTIPLE ROLES IN PERSUASION**.

**biastophilia** n. a **PARAPHILIA** involving sexual arousal and excitement based on surprising or attacking a stranger sexually.

**bias–variance tradeoff** the situation in which increasing the complexity of a model to better account for the observed relationships among a set of variables reduces the precision of any estimated values subsequently derived from that model. That is, the model becomes so specific to the particular sample from which it was derived that it no longer is an accurate representation of the larger population of interest. Researchers therefore tend to seek a balance, opting for either greater intricacy or greater certainty as circumstances warrant.
bibliotherapy n. a form of therapy that uses structured reading material. Bibliotherapy is often used as an adjunct to psychotherapy for such purposes as reinforcing specific in-session concepts or strategies or enhancing lifestyle changes. Carefully chosen readings are also used by some individuals as SELF-HELP tools to foster personal growth and development, for example, by facilitating communication and open discussion of problems or enhancing self-concept.

BIC abbreviation for BAYESIAN INFORMATION CRITERION.

cicalutamide n. see ANTIANDROGEN.

bicameralism n. a highly controversial theory of primitive human mentality (posited to predate the development of consciousness) in which cognitive functions are divided between one hemisphere of the brain that “speaks” or “orders,” specifically through auditory hallucination, and another hemisphere that “listens” or “obeys.” The concept, proposed by U.S. psychologist Julian Jaynes (1920–1997) in his 1976 book *The Origins of Consciousness in the Breakdown of the Bicameral Mind*, has not received significant attention in neuropsychological research, although analogies have been drawn to neurological models describing the differing functions of the right and left hemispheres of the brain. The evolutionary aspect of the hypothesis contradicts current evidence about the origins of brain structures for consciousness and language.

bicuculline n. an alkaloid derived from the plant *Dicentra cucullaria* that acts as a competitive GABA ANTAGONIST at GABA_\text{A}_, RECEPTORS and has strong convulsant effects. It has no modern clinical applications but may be used experimentally in laboratory animals for various research purposes.

bidialectism n. the regular use of two or more DIALECTS of a language by a person or within a SPEECH COMMUNITY. Also called bidialectalism. See also CODE SWITCHING; DIGLOSSIA. —bidialectal adj.

bidirectionality of structure and function the reciprocal interaction during development of some physical characteristic of an organism (e.g., brain cells) and the function emanating from that structure (e.g., the electrical firing of those cells). Such bidirectionality implies that development is not governed simply by a reading-out of the genetic code but is a dynamic process involving interaction at all levels of organization, from the genetic through the cultural.

Bidwell’s ghost a second visual AFTERIMAGE that appears in a hue complementary to the stimulus. Also called Purkinje afterimage. [Shelford Bidwell (1848–1909), British physiologist]

Bielschowsky’s disease a condition marked by temporary loss of the ability to move the eyes in a vertical direction, up or down, in a synchronized manner. [Alfred Bielschowsky (1871–1940), German ophthalmologist]

Biemond syndrome a disorder that combines intellectual disability, obesity, HYPOGONADISM, abnormalities in the iris (a hole, split, or cleft), and excess fingers or toes. [A. Biemond, 20th-century French physician]

bigamy n. the crime of marrying someone when already married to someone else. In cultures that permit individuals to have more than one spouse, this practice should be referred to as POLYGAMY and not bigamy. Compare MONOGAMY. —bigamist n. —bigamous adj.

Big Brothers Big Sisters of America a volunteer association in which individuals act as mentors and positive role models to children typically from single-parent families. The Big Brother and Big Sister programs were created separately, and the two organizations merged in 1977.

Big Five personality model a model of the primary dimensions of individual differences in personality. The dimensions are usually labeled EXTRAVERSION, NEUROTICISM, AGREEABLENESS, CONSCIENTIOUSNESS, and OPENNESS TO EXPERIENCE, though the labels vary somewhat among researchers. See also FIVE-FACTOR PERSONALITY MODEL, [described by (among others) U.S. psychologists Lewis R. Goldberg (1932–) and Gerard T. Saucier]

big lie a PROPAGANDA device in which a false statement of extreme magnitude is constantly repeated to persuade the public. The assumption is that a big lie is less likely to be challenged than a lesser one because people will assume that evidence exists to support a statement of such magnitude. Josef Goebbels, the propaganda minister in Nazi Germany, repeatedly used this technique when he charged the Nazis’ enemies with heinous crimes.

bigorexia n. see MUSCLE DYSMORPHIA.

bigram n. any two-letter combination. In PSYCHOLINGUISTICS research, the term typically refers to a within-word consecutive character sequence (e.g., paper contains the bigrams pa, ap, pe, and er); whereas in learning and memory research, it generally refers to a freestanding nonword (e.g., TL, KE).

Big Sister program see BIG BROTHERS BIG SISTERS OF AMERICA.

BID abbreviation for BODY INTEGRITY IDENTITY DISORDER.

bilabial 1. adj. pertaining to the two lips. 2. adj. denoting a speech sound made with both lips, which stop or modify the airstream, for example, [b], [p], [m], or [w]. 3. n. a bilabial speech sound. See LABIAL.

bilateral adj. denoting or relating to both sides of the body or an organ. For example, bilateral symmetry is the symmetrical arrangement of an organism’s body such that the right and left halves are approximately mirror images of one another; bilateral transfer is the TRANSFER OF TRAINING or patterns of performance for a skill from one side of the body, where the skill (e.g., handwriting) was originally learned and primarily used, to the other side of the body. —bilaterally adv.

bilateral descent in anthropology, a system of descent or inheritance in which both the male and the female lines of descent are recognized. Also called bilineal descent. Compare UNILATERAL DESCENT. See also DESCENT GROUP: MATRIARCHY; PATRIARCHY.

bilateral lesion a lesion that involves both sides of an organ, especially both cerebral hemispheres, which can arise directly through injury or disease or secondarily through such mechanisms as EDENUM.

Bildungsroman n. a type of novel that describes the formation of the leading character’s self in the course of development (usually through a series of stages) from childhood to adulthood. The genre was established in Germany by Johann Wolfgang von Goethe’s *Wilhelm Meister’s Apprenticeship* (1795–1796) and has remained central to the German literary tradition. It was therefore an essential part of the intellectual climate in which the early psychoanalysts were educated and did their work. It might be ar-
gued that the classic "stage theories," such as Sigmund Freud’s psychosexual stages, Erik Erikson’s psychosocial stages, Carl Jung’s process of individuation, and Jean Piaget’s stages of cognitive development, grew out of this tradition. [German, literally: “education novel”; coined by German philosopher Wilhelm Dilthey (1833–1911) in a biography of German philosopher Friedrich Schleiermacher (1768–1834)]

bilineal descent see BILATERAL DESCENT.

bilingual education instruction in two languages, typically in one’s native language and in the dominant language of the country in which one is educated. In transitional bilingual education, as students gain fluency, they shift to instruction solely in their nonnative language, usually within 2 to 3 years. In TOTAL IMMERSION bilingual programs, the emphasis is solely on second-language acquisition for both native and nonnative speakers. For example, in the United States, immersion programs are most often conducted in either French or Spanish and may include ENGLISH AS A SECOND LANGUAGE learners along with native English-speaking students.

bilingualism n. the regular use of two or more languages by a person or within a SPEECH COMMUNITY. See ADDITIVE BILINGUALISM; BILITERACY; EARLY BILINGUALISM; ELITE BILINGUALISM; FOLK BILINGUALISM. —bilingual adj.

bilirubin n. an orange-yellow bile pigment produced from breakdown products of the hemoglobin of red blood cells. Bilirubin is excreted in bile, feces, and urine. An excess of bilirubin is often a sign of a liver disorder (or, in babies, liver immaturity or incompatibility with the mother’s blood group) and may cause deposits of yellowish pigments in the skin and other tissues, a condition known as jaundice. See also HEPATITIS.

bilirubin encephalopathy a degenerative disease of the brain caused by deposition of the bile pigment biliru-bin in the basal ganglia and brainstem nuclei. The condition results from disorders in producing or breaking down bilirubin in the liver. This may be seen in newborns who are unable to metabolize bilirubin adequately.

bilis n. a CULTURE-BOUND SYNDROME found among Latino groups, who attribute it to extremely strong anger or rage. Symptoms include abrupt nervous tension, headache, screaming, stomach disturbances, vomiting, loss of weight, tremors, chronic tiredness, and—in extreme cases—loss of consciousness or death. The extreme anger is said to disturb the center of balance of hot and cold in the body, which upsets the material and spiritual aspects of the person. Also called colera: muina.

biliteracy n. the ability to read and write in two or more languages. See BILINGUALISM. —biliterate adj.

bill of rights in health care, a document stating the entitlements a patient has with respect to providers, institutions, and THIRD-PARTY PAYERS. See PATIENTS’ RIGHTS.

bimanual coordination coordination of the movements of the two hands.

bimanual interference problems encountered when the two hands must each perform different movements or the same movement with different timing (e.g., in piano playing).

bimodal distribution a set of scores with two peaks or modes around which values tend to cluster, such that the frequencies at first increase and then decrease around each peak. For example, when graphing the heights of a sample of adolescents, one would obtain a bimodal distribution if most people were either 5’7” or 5’9” tall. See also MULTIMODAL DISTRIBUTION; UNIMODAL DISTRIBUTION.

bin- prefix see BI-.

binary choice in decision making, a choice in which there are only two alternatives (e.g., yes or no, do or don’t do).

binary feature in linguistics, a feature of the phonemic system of a language that has two mutually exclusive aspects, such as voiced-unvoiced (in English) or aspirated-unaspirated (in Hindi). Such features have a critical contrastive function, working rather like an on-off switch to distinguish one PHONEME from another; in English, for instance, the otherwise very similar sounds [b] and [p] are recognized as distinct phonemes because the former is VOICED and the latter UNVOICED. Binary opposition of this kind is a key concept in the structuralist interpretation of language and in the wider structuralist movement generally (see STRUCTURALISM). See also MINIMAL PAIR. [first described by Russian linguist Roman Jakobson (1896–1982)]

binary hue a hue that appears to be a mixture of two unique hues. Orange is a binary hue composed of red and yellow, which are considered unique because they are not produced by color mixing.

binary system a structure or organization composed of two elements or two kinds of elements. In computer science, it is a logical structure composed of two values, commonly called 0 and 1, based on the "off" and "on" modes of electrical circuits and devices. The principle of binary contrast is also of great importance in STRUCTURALISM, particularly structural linguistics. See BINARY FEATURE; MINIMAL PAIR.

binary trial a single experiment in which there are only two possible outcomes. For example, consider a behavioral researcher observing aggression in a group of schoolchildren during recess. If he or she makes a record every 1 minute, then each such period may be considered a binary trial, with aggression present or aggression absent as its only two possible outcomes.

binary variable see DICOTOMOUS VARIABLE.

binasal hemianopia the loss of vision in both the right half of the left visual field and the left half of the right visual field. It is caused by injury (compression) of the OPTIC CHIASM. See HEMIOPANOA.

binaural adj. pertaining to or perceived by both ears. Compare MONOAURAL.

binaural beat a periodic fluctuation in apparent position or in loudness when two tones differing slightly in frequency are presented to each ear separately but simultaneously. Binaural beats are not present in the stimulus but result from the BINAURAL INTERACTION between the tones that occurs within the auditory system.

binaural cue any difference in the sound arriving at the two ears from a given sound source (INTERAUral difference) that acts as a cue to permit AUDITORY LOCALIZATION. The common cues are interaural level differences (ILD), interaural time differences (ITD), and (closely related to ITD) interaural phase differences (IPD). Also called binaural difference.

binaural fusion see FUSION.
**binaural hearing** see BINAURAL.

**binaural interaction** the interaction in the nervous system of signals from the two ears. It is especially important for localizing auditory stimuli.

**binaural masking level difference** see MASKING LEVEL DIFFERENCE.

**binaural summation effect** see SUMMATION EFFECT.

**binding affinity** the tendency of a particular ligand (e.g., neurotransmitter or drug) to bind to a particular receptor, measured by the percentage of receptors occupied by the ligand.

**binding hypothesis** a theory that offers a solution to the BINDING PROBLEM, proposing that the neural mechanism responsible for drawing together disparate information (e.g., different features of an object) from separate cortical areas and “binding” it into unified percepts is temporal synchrony: that is, the simultaneous firing of action potentials from individual neurons—each coding different properties—is the means by which they are organized into a single representation. Many suggest that feature binding is critical for conscious object perception.

**binding problem** the theoretical issue of how the brain perceives and represents different features, or conjunctions of properties, as one object or event. This is problematic because different attributes of a stimulus (e.g., hue, form, spatial location, motion) are analyzed by different areas of the cerebral cortex and yet are experienced in consciousness as a unity; the binding problem is relevant in all areas of knowledge representation, including such complex cognitive representations as THEORY OF MIND.

**Binet–Simon Scale** see STANFORD–BINET INTELLIGENCE SCALE.

**binge drinking** 1. a single occasion of intense, extremely heavy drinking that results in intoxication. 2. a pattern of alcohol consumption characterized by the setting aside of repeated periods of time for intense, extremely heavy drinking, with or without sobriety in between. 3. for most men, ingesting five or more alcoholic drinks within 2 hours; for most women, four or more.

**binge eating** consuming abnormally large quantities of food in a discrete time period with a concurrent sense of loss of control. Recurrent binge eating is associated with numerous adverse consequences, such as increased risk of obesity and its medical sequelae, as well as depression and other mental health problems. When the behavior is chronic and pervasive, it is diagnosed as a binge-eating disorder. See also BULIMIA NERVOSA.

**binge-eating disorder** a disorder marked by recurring discrete periods of uncontrolled consumption of abnormally large quantities of food and by distress associated with this behavior. There is an absence of inappropriate compensatory behaviors (e.g., vomiting, laxative misuse, excessive exercise, fasting). Compare BULIMIA NERVOSA. See also EATING DISORDER.

**binocular adj.** relating to the two eyes. Compare MONOCULAR.

**binocular cell** a cortical cell that responds to a stimulus presented to either the left or the right eye. *Monocular cells*, in contrast, require stimulation through a specific eye to generate a response.

**binocular cue** see DEPTH CUE.

**binocular deprivation** the deprivation of light to both eyes, as by sealing the eyelids. Compare MONOCULAR DEPRIVATION.

**binocular disparity** the slight difference between the right and left retinal images. When both eyes focus on an object, the different position of the eyes produces a disparity of visual angle, and a slightly different image is received by each retina. The two images are automatically compared and, if sufficiently similar, are fused, providing an important cue to depth perception. Also called RETINAL DISPARITY.

**binocular flicker** an experimental paradigm in which each eye is stimulated separately with an intermittent light. The phase relationships of the illumination of each eye can be varied to investigate binocular interactions. [derived by Charles Scott SHERRINGTON]

**binocular fusion** see FUSION.

**binocular parallax** the differences in the two retinal images due to separation of the eyes.

**binocular perception** any visual experience enabled by stimulation through both eyes.

**binocular rivalry** the failure of the eyes to fuse stimuli (see FUSION). For example, if horizontal bars are viewed through the left eye and vertical bars through the right eye, the perception is a patchy and fluctuating alternation of the two patterns, rather than a superimposition of the patterns to form a stable checkerboard.

**binocular summation** the phenomenon of increased sensation or increased magnitude of perceptual response that results from stimulation through both eyes, as compared to stimulation through one eye.

**binocular suppression** the ability of stimulation through one eye to inhibit the response or sensitivity to stimulation through the other eye. See BINOCULAR RIVALRY.

**binocular vision** the normal coordinated function of the eyes that permits viewing of the surroundings in three dimensions. See STEREOPSIS.

**binomial distribution** the PROBABILITY DISTRIBUTION for each possible sequence of outcomes on a variable that has only two possible outcomes, with the likelihood of obtaining each outcome remaining constant. For example, a binomial distribution of the results of trying to predict the outcomes of 10 coin tosses would display the probability of observing each possible set of results, including one success and nine failures, two successes and eight failures, and so forth. This distribution is often denoted by \( b(n, p) \).

**binomial nomenclature** see BIOLOGICAL TAXONOMY.

**binomial probability** within a series of independent observations, the probability of observing a particular combination of outcomes for a variable that can assume only one of two values (e.g., 0 or 1; pass or fail) where there is a fixed likelihood of each value occurring. For example, consider a group of 10 individuals selected from a population of persons ages 40 to 45, with each selection unrelated to any other selection. A binomial probability could be calculated to determine the likelihood that seven of those individuals are married while three are not, given known information on the probability of persons of that age being married.

**binomial test** a statistical procedure to determine whether an observed data pattern for a variable that can
have only one of two values (often represented as 0 and 1) matches a theoretical or expected pattern. In other words, it tests whether the categorical proportions in the obtained data differ significantly from their proportions in the population from which they are believed to derive. See also BINOMIAL PROBABILITY.

**binomial variable** a variable for which there are only two outcomes, typically designated 0 and 1, with each possible outcome having a specified likelihood of being observed. Flipping a coin is an example, as it may land on either heads or tails. See also BINOMIAL DISTRIBUTION.

**Binswanger's disease** a progressive VASCULAR DEMENTIA characterized by DEMYELINATION and multiple INFARCTIONS of subcortical white matter associated with hypertensin and subsequent arteriosclerosis. Symptoms include loss of cognitive functioning, memory impairment, and changes in mood and behavior. Also called subcortical arteriosclerotic encephalopathy. [Otto Ludwig Binswanger (1852–1929), German neurologist]

**bio-** combining form life or living.

**bioacoustics** n. the study of acoustic communication and related behavior of nonhuman animals. This can involve study of the mechanisms of sound production and perception, the physical structure of animal signals, the alteration of animal sounds as they pass through different environments, and the influence of animal sounds on the behavior of other animals.

**bioavailability** n. the quantity of an administered drug that is available for distribution within the body to the target organ or site after absorption into the bloodstream.

**biochemical approach** 1. the study of behavioral patterns, including mental disorders, from the standpoint of chemical changes. An example of this approach is the view that a mental disorder can be explained in terms of an excess or deficiency of certain substances in the nervous system, such as SEROTONIN. 2. the use of psychotropic drugs in the treatment of mental disorders. See PSYCHOPHARMACOTHERAPY.

**biochemical defect** any of numerous chemical imbalances or aberrations in the brain that may be associated with neurological or psychiatric disorder. Such disorders may be related to the production of specific NEUROTRANSMITTERS or the availability of other biochemical substances necessary for brain function.

**biochemical marker** a variation in the chemical activity of an organism that accompanies a disorder, irrespective of whether it directly causes the disorder; an example is demonstrated in the DEXAMETHASONE SUPPRESSION TEST. See also BIOLOGICAL MARKER: CLINICAL MARKER.

**biochemistry** n. the study of the chemical substances and processes of living organisms. —biochemical adj.

**biocybernetics** n. the study of communication and self-regulatory activities within biological organisms; it represents an attempt to understand the functioning of living bodies in terms derived from information science. —biocybernetic or biocybernetical adj.

**biodata** pl. n. see BIOGRAPHICAL DATA.

**biodynamics** n. the study of dynamic processes within living organisms. See DYNAMIC.

**biocological model** see ECOLOGICAL SYSTEMS THEORY.

**biocological theory of intelligence** a theory postulating that intelligence develops as an interaction between biological dispositions and the environment in which these biological dispositions develop. [proposed by U.S. psychologist Stephen J. Ceci (1950–)]

**bioelectric potential** the electric potential of nerve, muscle, and other living tissue.

**bioenergetics** n. a form of alternative psychotherapy that combines work with the body and the mind in treating emotional problems. Bioenergetics proposes that body and mind are functionally identical: What happens in the mind reflects what is happening in the body, and vice versa. It uses exercises and postural changes in an attempt to relieve chronic muscular tensions and rigidity attributed to emotional stress and unresolved emotional conflicts. The approach was developed by U.S. physician Alexander Lowen (1910–2008) and is based on the work of Austrian psychoanalyst Wilhelm Reich (1897–1957).

**bioengineering** n. the application of engineering principles and science to living organisms and biological processes, particularly in the design, testing, and manufacture of devices that can substitute for impaired body parts or functions. —bioengineer n.

**bioequivalence** n. a measure comparing the relative BIOAVAILABILITY of two forms or preparations of a drug. In bioequivalent drug preparations, the same proportion of unchanged, active drug reaches the systemic circulation. Bioequivalence may be a clinical issue when comparing two preparations of a drug (i.e., immediate-release vs. delayed-release) or when comparing trademarked drugs and their generic counterparts. —bioequivalent adj.

**bioethics** n. the study of ethics and values relevant to the conduct of clinical practice and research in medicine and the life sciences. —bioethical adj.

**biofeedback** n. 1. information about bodily processes and systems provided by an organism's receptors to enable it to maintain a physiologically desirable internal environment and make adjustments as necessary; 2. the use of an external monitoring device (e.g., electrocardiograph) to provide an individual with information regarding his or her physiological state. When used to help a person obtain voluntary control over autonomic body functions, such as heart rate or blood pressure, the technique is called biofeedback training. It may be applied therapeutically to treat various conditions, including chronic pain and hypertension. See also NEUROFEEDBACK.

**biogenesis** n. the origin of living things from other living things. **Biogenetics** is the scientific study of the principles and processes governing the production of living organisms from other living organisms, including the mechanisms of heredity. —biogenic adj.

**biogenic** adj. 1. produced by living organisms or biological processes. 2. necessary for the maintenance of life.

**biogenic amine** any of a group of AMINES that affect bodily processes and nervous system functioning. Biogenic amines are divided into subgroups (e.g., CATECHOLAMINES, INDOLEAMINES) and include the neurotransmitters dopamine, epinephrine, histamine, norepinephrine, and serotonin.

**biogenic amine hypothesis** any of a variety of hypotheses, such as the CATECHOLAMINE HYPOTHESIS and DOPAMINE HYPOTHESIS, that consider abnormalities in the physiology and metabolism of biogenic amines essential to the etiology of certain mental disorders.
biogram n. a pattern of possible events involved in learning a BIOFEEDBACK experience. The biogram may begin as a conscious memory device but through repeated trials eventually becomes subconscious in a manner similar to other learning experiences acquired through repeated trials.

biographical data 1. information about a patient’s history and behavioral patterns, gathered by a therapist or medical professional primarily from the patient but sometimes from others who know or are related to him or her. 2. information on job candidates for use in personnel selection. The data are usually obtained from application forms or special questionnaires (biographical inventories) and include such items as age, sex, education, work experience, and interests. Also called biodata.

Biographical Evaluation and Screening of Troops (BEST) a program used for the selection and classification of military personnel. Formerly called the Air Force Medical Evaluation Test (AFMET), it is used to identify individuals who are unlikely to complete the Air Force basic training or who might find it difficult to function in a military system.

biographical inventory see BIOGRAPHICAL DATA.

biographical method the systematic use of personal histories—gathered through such means as interviews, focus groups, observations, and individual reflections and other narratives—in psychological research and analysis. This method emphasizes the placement of the individual within the context of social connections, historical events, and life experiences.

bioinformatics n. the use of INFORMATICS in medicine and other life sciences, as in the analysis of public health, genomics, and biomedical research data. Also called bio-medical informatics.

bioinformational theory a general theory of emotional–motivational organization, integrating cognitive and psychophysiological levels of analysis. It is concerned with how emotions are elicited and displayed and with how they interact; specifically, information about emotions is contained in associative memory networks that include action information (motor programs) and connections to subcortical motivation circuits. Emotions are viewed as context-specific action or response dispositions activated by input that modifies concepts in the emotion network. The model, originally forwarded in the 1970s as a theory of emotional imagery, was derived from research on fear and anxiety but has since evolved and acquired diverse applications across a variety of behavioral and emotional phenomena.

biological age age as determined by changes in bodily structure and performance that are normative at specific ages. Compare CHRONOLOGICAL AGE.

biological aging see AGING; PRIMARY AGING; SENESCENCE.

biological clock the mechanism within an organism that controls the periodicity of BIOLOGICAL RHYTHMS, including ACTIVITY RHYTHMS, even in the absence of any external cues. For example, a bird housed in constant light will continue to show patterns of activity and rest with approximately 24-hour rhythms due to the action of the biological clock. A biological clock in mammals is located in the SUPRACHIASMATIC NUCLEUS of the hypothalamus. Molecular mechanisms of the CIRCADIAN RHYTHM are the same in insects and mammals. Also called internal clock.

biological determinism the concept that psychological and behavioral characteristics are entirely the result of constitutional and biological factors. Environmental conditions serve only as occasions for the manifestation of such characteristics. Compare ENVIRONMENTAL DETERMINISM. See DETERMINISM; GENETIC DETERMINISM; NATURE–NURTURE.

biological drive an innate motivational state produced by depletion or deprivation of a needed substance (e.g., water, oxygen) in order to impel behavior that will restore physiological equilibrium. See also DRIVE.

biological factor any physical, chemical, genetic, or neurological condition associated with psychological disturbances.

biological fallacy 1. the questionable assumption that all human phenomena, including rationality, culture, and ethics, can be explained with reference to strictly biological processes. In this sense, the biological fallacy is one of naturalistic REDUCTIONISM. 2. in the controversial view of some ecological theorists, the “fallacy” of equating life with the life of individual organisms. The term implies that the vital force referred to as “life” is better understood as inherent in, or as a quality of, the totality of the ecosystem.

biological family a person’s blood relations as opposed to relations acquired through marriage, adoption, or fostering. See CONSANGUINITY.

biological intelligence a level of mental ability of presumed biological origins required primarily for cognitive activity. The term was introduced to differentiate forebrain-functioning ability from traditional concepts of intelligence. Biological intelligence is measured with a battery of tests that also indicate evidence of brain injury. [defined by U.S. psychologist Ward C. Halstead (1908–1969)].

biological life events age-related biological changes, such as PUBERTY or menopause (see CLIMACTERIC).

biologically primary ability an ability, such as language acquisition, that has been selected for in evolution and is acquired universally. Children typically are highly motivated to perform tasks involving these abilities. Compare BIOLOGICALLY SECONDARY ABILITY. [postulated by U.S. psychologist David C. Geary (1957– )]

biologically secondary ability an ability, such as reading, that builds upon a BIOLOGICALLY PRIMARY ABILITY but is principally a cultural invention and often requires repetition and external motivation for its mastery. [postulated by U.S. psychologist David C. Geary (1957– )]

biological marker a variation in the physiological processes of an organism that accompanies a disorder, irrespective of whether it directly causes the disorder. Also called biomarker. See also BIOCHEMICAL MARKER; CLINICAL MARKER.

biological measures assessments or other markers of processes or outcomes that are drawn from bodily activity or other natural biological systems or events. Such measures include assessments of cardiopulmonary, endocrine, nervous-system, and immune-system activity.

biological motion motion performed by a living organism. See LOCOMOTION; TAXIS.

biological perspective an approach to abnormal psychology that emphasizes physiologically based causative factors, such as the AMYLOID PLAQUES in Alzheimer’s disease, and consequently tends to focus primarily upon BIOLOGICAL THERAPIES.
biological psychology the science that deals with the biological basis of behavior, thoughts, and emotions and the reciprocal relations between biological and psychological processes. It also addresses topics such as behavior-changing brain lesions, chemical responses in the brain, and brain-related genetics. It includes such fields as behavioral neuroscience, clinical neuroscience, cognitive neuroscience, behavioral endocrinology, and psycho-neuroimmunology. Also called biopsychology: physiological psychology: psychobiology.

biological rhythm any periodic variation in a living organism’s physiological or psychological function, such as energy level, sexual desire, or menstruation. Such rhythms can be linked to cyclical changes in environmental cues, such as day length or passage of the seasons, and tend to be daily (see circadian rhythm) or annual (see circannual rhythm). They also can vary with individuals and with the period of the individual’s life. Also called biorhythm: endogenous rhythm: internal rhythm: life rhythm. See also infradian rhythm: ultradian rhythm.

biological stress a condition that imposes severe demands on the physical and psychological defenses of the organism. Examples include acute or chronic disease, a congenital or acquired disability or defect, exposure to extreme heat or cold, malnutrition or starvation, and exposure to some drugs (e.g., hallucinogens) or to toxic substances. See also stress.

biological symbiosis see symbiosis.

biological taxonomy the science of the classification of organisms. Traditional classifications group organisms into a hierarchical system of ranks, in ascending order: species, genus, family, order, class, phylum, and kingdom (see also domain). Species are named using binomial nomenclature, devised by Swedish biologist Carolus Linnaeus (1707–1778) in 1758: Each species is given two names, the first for the genus to which it belongs and the second identifying the species itself; thus, human beings are classified as Homo sapiens. Also called systematics. See also cladistics.

biological theory of aging any of various explanations of aging based on either programmed biological changes (genetic senescence) or unpredicted changes (DNA damage).

biological therapy any form of treatment for mental disorders that attempts to alter physiological functioning, including drug therapies, electroconvulsive therapy, and psychosurgery. Also called biomedical therapy.

biological transducing system a biological system that converts energy or information from one form to another. See transduction.

biological warfare the use of agents such as bacteria, viruses, and toxins to incapacitate or destroy humans, nonhuman animals, or crops in war.

biologism n. a predilection to make use of biological determinism and concepts from biology to explain behavior and psychological phenomena and to avoid psychological concepts and principles for such explanation. See also reductionism.

biology n. the study of living organisms and life processes. —biological adj. —biologist n.

biomarker n. see biological marker.

biomechanics n. the application of the principles of mechanics to the study of the structure and function of biological systems, which includes the study of the physical stresses and strains on organisms while at rest and in motion. The discipline includes occupational biomechanics, which examines the physical interaction of workers with their tools, machines, and materials so as to maximize performance while minimizing the risk of musculoskeletal disorders. —biomechanical adj.

biomedical engineering the branch of engineering that specializes in research and development of equipment for medical treatment, rehabilitation, and special needs. Examples of applications include devices to monitor the physiological condition of astronauts in space, the design and creation of artificial limbs and organs, and the development of ultrasound devices. See also bioengineering.

biomedical informatics see bioinformatics.

biomedical therapy see biomedical therapy.

biometrics (biometry) n. see biostatistics.

bionics n. the study of biological systems to learn how aspects of their perceptual and problem-solving behavior might be built into an electronic system, such as a computer. [biology] + (electronics)

biophilia n. a fundamental human attraction to and need for contact with the natural world. This idea was introduced in 1964 by Erich Fromm, who believed that subconscious seeking of connections with nature represents a positive psychological orientation toward life that benefits individuals’ functioning and overall well-being. In 1984, U.S. biologist Edward O. Wilson (1929– ) elaborated on the concept to develop the biophilia hypothesis, stating that humans have genetically based, evolutionarily determined attractions to specific landscapes and natural elements that create a propensity to affiliate with other living organisms. The hypothesis also holds that this enmeshment with nature plays an essential role in human cognitive, social, and emotional processes. Although Fromm contrasted biophilia with necrophilia, now it generally is contrasted with biophobia.

biophobia n. a human fear of certain species (e.g., snakes, spiders) and general aversion to nature that creates an urge to affiliate with technology and other human artifacts, interests, and constructions rather than with animals, landscapes, and other elements of the natural world. Such fear is seen in many populations throughout the world, a pervasiveness that U.S. biologist Edward O. Wilson (1929– ) and others consider indicative of its innateness. U.S. ecologist David W. Orr, however, emphasizes that biophobia is culturally acquired, a product of modern living that distances people from the natural world to such a degree that they become indifferent to other organisms and antagonistic toward the environment. Compare biophilia.

biophysical system 1. any biological system that is described or studied in terms of its physical aspects, based on the application of physical laws and the techniques of physics. 2. the hormonal and genital components of the human sexual response. [defined by U.S. sex researchers William H. Masters (1915–2001) and Virginia E. Johnson (1925–2013)]

biophysics n. the interface of biology and physics, involving the study of biological structures and processes (e.g., vision, hearing) according to the principles and methods of physics.

biopsy n. the surgical removal and microscopic study of a...
biopsychology

small amount of tissue from an organ or body part believed to be diseased or otherwise abnormal. The biopsy specimen is examined for signs of malignancy or other abnormalities that would help determine the proper diagnosis and course of therapy.

biopsychology n. see BIOLOGICAL PSYCHOLOGY.

biopsychosocial adj. denoting a systematic integration of the study of mental health and specific mental disorders. [coined by U.S. psychiatrist George L. Engel (1913–1999)]

biorhythm n. 1. a synonym of BIOLOGICAL RHYTHM. 2. according to pseudoscientific belief, a regular biological cycle that can be charted like a sine wave and with which every individual is said to be programmed at birth. Usually this term is used to refer to any one of three basic cycles—physical, emotional, and intellectual—although other cycles (e.g., aesthetic, spiritual) and combinations of cycles have been proposed. It is maintained that these cycles continue unaltered until death and that good and bad days for various activities can be calculated accordingly. As with astrology, predictions made on this basis do not have a significantly different success rate from those made on a basis of pure chance.

biosocial adj. pertaining to the interplay or mingling of biological and social factors, as with human behavior that is influenced simultaneously by complex neurophysiological processes and social interactions.

biosocial theory any approach that explains personality or human behavior in terms of biological predispositions as influenced by social or environmental factors.

biosphere n. collectively, all parts of the earth and its atmosphere in which living organisms exist.

biostatistics n. 1. data compiled about a population, including rates of birth, disease, and death (see VITAL STATISTICS). See also DEMOGRAPHY. 2. the branch of statistics concerned with collecting and analyzing data that pertain to biological processes or health characteristics, especially in medicine and epidemiology. Also called biometrics: biometry. —biostatistical adj. —biostatistician n.

biosynthesis n. 1. the production of chemical compounds by living organisms from nutrients by means of enzyme-catalyzed reactions. 2. the production of molecules of biological or medical interest, either in the laboratory or commercially, for example, by recombinant DNA technology. —biosynthetic adj.

biotaxis n. 1. the classification of living organisms by their anatomical features and traits. 2. the ability of living cells to orient themselves with respect to their environment. See NEUROBIOTAXIS. —biotactic adj.

biotechnology n. any technique that uses biological organisms, cells, or processes to produce products and services to meet human needs.

bioterrorism n. a form of TERRORISM in which biological agents such as viruses and bacteria are deliberately released into air, water, or food to cause illness and death. Anthrax, for example, has been used in bioterrorism.

biotope n. in ecology, a physical region that can be defined by particular environmental characteristics.

biotransformation n. the metabolic process by which a substance (e.g., a drug) is changed from one chemical to another by means of a chemical reaction within a living system. The metabolites, or products, of this change may be active or inactive within the system.

biotransport n. the transportation of substances within cells or into and out of cells across biological membranes. See ACTIVE TRANSPORT; ION PUMP; PASSIVE TRANSPORT.

biotype n. 1. a group of individuals who are very similar or identical in their GENOTYPE (genetic makeup), although they may vary in PHENOTYPE (visible features). 2. a physiological characteristic that distinguishes a population of organisms adapted to a particular environment and that does not occur in populations of the same species in other environments. —biotypic adj.

biotypeology n. the classification of human beings according to their constitutional, anatomical, physiological, and psychological characteristics. See also CONSTITUTIONAL TYPE.

bipedal locomotion the ability to walk or run on two feet and in an upright position, as in human beings and birds. Great apes and bears engage in short periods of bipedal locomotion, especially when carrying food, traveling over wet ground, or looking for something to eat.

biperiden n. a synthetic ANTICHOLINERGIC DRUG closely related to TRIBEXYPHENIDYL but having greater affinity for NICOTINIC RECEPTORS than for MUSCARINIC RECEPTORS, compared with trihexyphenidyl. It is used to manage symptoms of Parkinson’s disease and parkinsonian symptoms induced by antipsychotic drugs. U.S. trade name: Akineton.

biphasic sleep see POLYPHASIC SLEEP.

biplot n. a multivariate graphic that simultaneously displays information about variables and participants. Data about two or more variables usually are denoted by arrows or vectors, and specific measurements for individual cases usually are denoted by dots. Biplots often are used in PRINCIPAL COMPONENTS ANALYSIS.

bipolar adj. denoting something with two opposites or extremes, such as a BIPOLAR NEURON or the BIPOLAR DISORDERS. —bipolarity n.

bipolar cell see BIPOLAR NEURON.

bipolar disorder any of a group of mood disorders in which symptoms of mania and depression alternate. In DSM–IV–TR and DSM–5, the group includes primarily the following subtypes: bipolar I disorder, in which the individual fluctuates between episodes of mania or hypomania and MAJOR DEPRESSIVE EPISODES or experiences a mix of these; bipolar II disorder, in which the individual fluctuates between major depressive and hypomanic episodes; and CYCLOTHYMIC DISORDER. The former official name for bipolar disorders, manic-depressive illness, is still in frequent use.

bipolar electrode see ELECTRODE.

bipolarity n. a construct of mutual exclusion and, by implication, a strong negative correlation between opposite dimensions. It typically is applied to affect or mood (e.g., happiness vs. sadness: enjoyment vs. irritation), but it also may be used to describe INDIVIDUAL DIFFERENCES (e.g., introversion vs. extraversion). In contrast, the concept of UNIDIMENSIONALITY is characterized by variation of a single attribute, such as a greater or lesser degree of pleasure.

bipolar neuron a neuron with only two extensions—an AXON and a DENDRITE—that run from opposite sides of the
bit n. 1. in computing, a variable that can take only the
values of zero or one. [bi(nary) + (digit)] 2. in information theory, the quantity of information that decreases uncertainty or the germane alternatives of a problem by one half. For example, if a dollar bill has been placed in one of 16 identical books standing side by side on a shelf, and one has to identify this book by asking a minimum number of questions that can be answered only by "yes" or "no," the best way to begin would be to ask if the book is to the right (or to the left) of center. The answer to this question would provide one bit of information.

**bite bar** 1. a device used to immobilize a participant's head during studies of visual perception. A bite bar contains an impression of the participant's teeth, so that when the bar is held between the jaws the head cannot move. 2. in animal research, a bar placed in the mouth to restrain animals during surgery or to immobilize animals that are being tested.

**bitemporal hemianopia** a loss of vision in both the left half of the left visual field and the right half of the right visual field. It is caused by injury (compression) of the optic chiasm. See HEMIANOPAIA.

**bitter adj.** denoting the unpleasant TASTE evoked by most alkaloids, glycosides, vitamins, and some salts. Each bitter chemical is recognized by one or more of a family of about 60 receptor proteins; some 15% of the human TASTE CELLS possess these proteins and therefore the capacity to signal bitterness. Bitter tastes are also associated with toxic chemicals. —bitterness n.

**bivalence** n. in logic, the principle that there are two and only two truth values, so that every proposition is necessarily either true or false. Compare INFINITE-VALUED LOGIC.

**bivariate adj.** characterized by two variables or attributes. For example, a set of height and weight measurements for each participant in a study would be bivariate data. Compare MULTIVARIATE; UNIVARIATE.

**bivariate distribution** a distribution showing each possible combination of values for two random variables according to their probability of occurrence. For example, a bivariate distribution may show the probability of obtaining specific pairs of heights and weights among college students. Also called bivariate probability distribution.

**bivariate frequency distribution** a distribution showing each possible combination of two categorical variables according to their observed frequency. For example, a researcher may use a bivariate frequency distribution to display how many male and female students at a university are majoring in particular fields of study.

**bivariate probability distribution** see BIVARIATE DISTRIBUTION.

**bizarre behavior** behavior that is odd, strange, or unexpected, particularly if it is out of the ordinary for a given person. It may be a symptom of brain damage or a mental disorder, especially a psychotic disorder, such as schizophrenia.

**bizarre delusion** a belief that is clearly fantastic and implausible but is nonetheless maintained with conviction. For example, an individual with schizophrenia may believe that external forces are removing the thoughts from his or her mind (see THOUGHT WITHDRAWAL).

**bizarreness effect** see DISTINCTIVENESS EFFECT.

**blackboard** n. a software architecture consisting of a generally accessible global database (the blackboard) accessed by a number of "knowledge sources." The modular knowledge sources interact independently, posting and consuming information to and from the blackboard. An early use of the blackboard approach was in the development of Hearsay, a program that recognized and interpreted voiced speech.

**black box** a system in which both the input and output are observable but the processes that occur between them are unknown or not observable. Such internal processes must be hypothesized on the basis of known relationships between external factors and the resulting effects. For example, in the relationship between leadership ability (input) and on-the-job performance as a project manager (output), the role of the organizational climate could be considered a black box if it is not understood.

**black box warning** see BOXED WARNING.

**Blacks English** a vernacular of English used by the African American speech community. Its formal and sociolinguistic properties have been the subject of intensive linguistic scholarship, notably by U.S. linguist William Labov (1927– ). Also called African American Vernacular English (AAVE); Black English Vernacular (BEV): Ebonics.

**blacking out** see FALLING OUT.

**blackout** n. 1. total loss of consciousness produced, for example, by sudden lowering of the blood supply to the brain or by decreased oxygen supply. 2. amnesia produced by alcoholic intoxication. Also called alcoholic blackout.

**black sheep effect** the tendency to evaluate a disreputable or disliked person more negatively when that person is a member of one's own group rather than of some other group. Although an apparent contradiction of INGROUP BIAS, the black sheep effect is explained by SOCIAL IDENTITY THEORY: People respond negatively to those who act in ways that threaten their group's identity, particularly when they affiliate strongly with their group.

**bladder reflex** see MICTURITION REFLEX.

**Blake-Mouton managerial grid** a model of leadership in which the behavior of the leader is assessed on two dimensions: concern for production and concern for people. The LEADERSHIP STYLE of a manager is described on 9-point scales on each dimension, giving a total of 81 possible styles. The five most often discussed styles are 9,1 (high concern for production, low concern for people: authoritarian); 1,9 (low production, high people: country club); 5,5 (medium production, medium people: compromiser); 1,1 (low production, low people: laissez faire); and 9,9 (high production, high people: team leadership). Also called two-dimensional leader behavior space. See also GRID ORGANIZATIONAL DEVELOPMENT. [developed in 1964 by Robert R. Blake (1918–2004) and Jane S. Mouton (1930–1987), U.S. psychologists]

**blaming the victim** a social psychological phenomenon in which individuals or groups attempt to cope with the bad things that have happened to others by assigning blame to the victim of the trauma or tragedy. Victim blaming serves to create psychological distance between the blamer and the victim, may rationalize a failure to intervene if the blamer was a bystander, and creates a psychological defense for the blamer against feelings of vulnerability.

**blank screen** in psychoanalysis, according to Sigmund Freud, the metaphorical backdrop onto which the patient...
projects feelings and fantasies during the TRANSFERENCE process. The screen is the psychoanalyst, who must remain neutral (blank) to enable the patient to feel free to give voice to his or her innermost thoughts. Contemporary psychoanalysts no longer believe that the psychoanalyst can be a totally neutral blank screen.

**blank trial** a trial within an experiment that uses irregular or meaningless stimulus conditions to prevent the participant from guessing or giving automatic responses. See also CATCH TRIAL.

**blast noise** excessive acoustic exposure (noise), which may rupture the tympanic membrane (eardrum) or cause damage to the inner ear.

**blastocyst** n. the mammalian EMBRYO at a very early stage of development. It consists of a tiny hollow sphere containing an inner cell mass, enclosed in a thin layer of cells that help implant the blastocyst in the uterine lining. Blastocyst formation in humans generally occurs on the 5th or 6th day following fertilization.

**blast olfactometer** an OlfACTOMETER that pulses an ODORANT into the nasal cavities via a blast of air. Because the blast has tactile as well as odor effects, most olfactometers now have a constant airstream into which odorants are introduced. See also STREAM OlfACTOMETER; ZWAARDEMAKER OlfACTOMETER.

**blastula** n. a roughly spherical group of cells formed by division of the fertilized egg (zygote) during the early stages of embryonic development. It consists of a single layer of cells (the blastoderm) surrounding a fluid-filled cavity (the blastocoele). In mammals, the blastula is called a BLASTOCYST.

**blended family** see STEPFAMILY.

**blending** n. in linguistics, the process of combining the beginning of one word with the end of another to create a wholly new term; for example, *Reaganomics* is a blend of (Ronald) Reagan and *economics*. See FORTMANTEAU NEOLOGY.

**blepharospasm** n. a tonic spasm of the eyelid muscle that is manifested by an involuntary blinking or eye closure.

**Blessed Dementia Scale (BDS)** a behavioral rating scale used in the assessment of DEMENTIA severity. It has subscales measuring changes in the performance of everyday tasks, changes in daily activities and habits, and changes in personality and motivation. [developed in 1968 by Gary Blessed, British psychogeriatrician; Bernard E. Tomlinson, British neuropathologist; and Martin Roth, British psychiatrist]

**Bleuler’s theory** a theory proposing a basic underlying symptomatology for schizophrenia. It defined four FUNDAMENTAL SYMPTOMS required for a diagnosis of the condition; the more obvious manifestations of schizophrenia (e.g., delusions, hallucinations) were regarded as accessory symptoms (see SECONDARY SYMPTOMS) because they are shared with other disorders. [Eugen BLEULER]

**blind adj.** 1. denoting a lack of sight. See BLINDNESS. 2. denoting a lack of awareness. In research, a blind procedure may be employed deliberately to enhance experimental control: A **single blind** is a procedure in which participants are unaware of the experimental conditions under which they are operating; a **double blind** is a procedure in which both the participants and the experimenters interacting with them are unaware of the particular experimental conditions; and a **triple blind** is a procedure in which the participants, experimenters, and data analysts are all unaware of the particular experimental conditions.

**blind alley** a type of MAZE pathway or passage whose only exit is its entrance. Also called **cul-de-sac**.

**blind analysis** an evaluation of data or conditions without specific knowledge or previous information about the topic being examined. For example, a clinical psychologist might diagnose a patient without having information concerning previous psychological diagnoses.

**blind judgment** an evaluation made without knowledge of information that might influence one’s assessment of the situation. Such an approach is used to eliminate conscious or unconscious bias. Blind judgments are often used in clinical experiments, for example, judging patients’ current level of depression in the absence of information about which, if any, treatment they have received; and in scholarly peer review of manuscripts, in which the author’s institutional affiliation is not disclosed to the reviewer.

**blindness** n. 1. profound, near-total, or total impairment of the ability to perceive visual stimuli. According to the World Health Organization’s international classification (1990), blindness is defined as **visual acuity** less than 20/400 in the better eye with best correction or a **visual field** less than 10° in the widest meridian in the better eye. In the United States, the criterion for **legal blindness** is visual acuity of 20/200 or less in the better eye with best correction or a visual field of 20° or less in the widest meridian of the better eye. 2. absence of usable vision with the exception of light perception. Major causes of organic blindness include inoperable CATARACT, uncontrolled GLAUCOMA, RETINITIS PIGMENTOSA, DIABETIC RETINOPATHY, age-related MACULAR DEGENERATION, rubella, and brain injury. See also **CORTICAL BLINDNESS; FUNCTIONAL BLINDNESS; LOW VISION; VISUAL IMPAIRMENT. —blind adj.**

**blind review** an evaluation of a manuscript to assess its suitability for publication or of a grant proposal to assess its suitability for funding, as performed by a person who does not know the identity of the author or proposer.

**blindsight** n. the capacity of some individuals with damage to the STRIATE CORTEX (primary visual cortex or area V1) to detect and even localize visual stimuli presented to the blind portion of the visual field. Discrimination of movement, flicker, wavelength, and orientation may also be present. However, these visual capacities are not accompanied by conscious awareness. The causes of blindsight are the subject of some debate: Because the neural pathway from the LATERAL GENICULATE NUCLEUS to the striate cortex is nonfunctional in blindsighted people, it is thought that these capacities are either based on the visual collicular pathway (see COLLICULUS; SUPERIOR COLLICULUS) or represent RESIDUAL VISION using surviving striate cortex. See also **DEAF HEARING; NUMBSENSE.**

**blind spot** 1. in vision, the area of the monocular visual field in which stimulation cannot be perceived because the image falls on the site of the OPTIC DISK in the eye. 2. a lack of insight or awareness—often persistent—about a specific area of one’s behavior or personality, typically because recognition of one’s true feelings and motives would be painful. In classical psychoanalysis, it is regarded as a defense against recognition of repressed impulses or memories that would threaten the patient’s EGO. See SCOTOMIZATION.
blind walk

blind walk a trust exercise used in a group setting (e.g., an encounter group) to help members develop mutual trust. Half of the group close their eyes; the other half become their partners and lead the “blind” people through various experiences. Roles are then reversed, and finally all members discuss their reactions to the experience.

blink response abrupt closure of the eyelids in response to bright light, shifting attention, or irritation of the eye. Also called blink reflex.

BLM (BLMS) abbreviation for buccolingual mastectomy syndrome.

bloating n. a feeling of distension in the abdomen that may have organic or psychogenic causes. It may be a feature of irritable bowel syndrome and is frequently encountered as a symptom of somatization disorder. Also called abdominal bloating.

blob n. see cytochrome oxidase blob.

Bloch’s law a rule of temporal summation stating that visual threshold is reached when luminance × duration reaches a constant. If the brightness of a stimulus is halved, the stimulus can still be detected if its duration is doubled. Bloch’s law only holds for relatively brief (∼100 ms), dim stimuli. Also called Bunsen–Roscoe law.

block n. 1. an abrupt, involuntary interruption in the flow of thought or speech in which the individual is suddenly aware of not being able to perform a particular mental act, such as finding the words to express something he or she wishes to say. Also called mental block. See retrieval block; tip-of-the-tongue phenomenon. 2. in psychotherapy, an obstacle to progress that is perceived as a barrier that cannot be crossed. 3. any physical, biochemical, or psychological barrier or obstacle that obstructs or impedes a process, function, or activity. 4. a group or subset of study participants who share a certain characteristic and are treated as a unit in an experimental design. 5. a set of variables entered as a single entity into a regression analysis or similar statistical procedure.

block design a type of research study in which participants are divided into relatively homogeneous subsets (blocks) from which they are assigned to the experimental or treatment conditions. For example, in a simple block design to evaluate the efficacy of several antidepressants, participants with similar pretest depression scores might be grouped into homogeneous blocks and then assigned to receive different medications. The purpose of a block design is to ensure that a characteristic of the study participants that is related to the target outcome (i.e., a covariate) is distributed equally across treatment conditions. See complete block design; incomplete block design; randomization block design.

block-design test an intelligence subtest, found most notably on the Wechsler intelligence scales, in which the testee is asked to use colored blocks to match a specified design. The block-design test also is utilized in the diagnosis of mental disorder and mental deterioration. See also kohs block design test.

blocking n. 1. a process in which one’s flow of thought or speech is suddenly interrupted (see block). Also called thought deprivation; thought obstruction. 2. the process of grouping research participants into relatively homogeneous subsets on the basis of a particular characteristic. Such blocking helps adjust for preexisting patterns of variation between experimental units. See block design.

blocking factor in a block design, an attribute or variable used as a basis for subdividing study participants or other sampling units into homogeneous subsets.

block randomization a method for assigning study participants to experimental conditions in which individuals are arbitrarily divided into subsets or blocks and then some random process is used to place individuals from those blocks into the different conditions. For example, a researcher might divide participants into blocks of 10 and then randomly assign half of the people in each to the control group and half to the experimental group. Block randomization is distinct from blocking in that the block does not have any significance other than as an assignment unit.

block sampling a technique, mainly used as part of a multistage procedure, for selecting units for study. A population is divided into groups (blocks) that each have approximately the same number of targets (e.g., adults to be interviewed), a random subset of those blocks is chosen, and a random subset of targets within each selected block is identified. This type of sampling helps to ensure that characteristics of the initial population are well represented in the final sample.

Blocq’s disease see astasia–abasia. [Paul O. Blocq (1860–1896), French physician]

blood alcohol concentration (BAC) the amount of ethanol in the bloodstream after alcohol consumption, measured as a percentage. In the United States, the limit at which it becomes a crime to drive after drinking is generally 0.08% (i.e., 0.08 g of alcohol per 100 mL of blood). Also called blood alcohol level (BAL).

blood–brain barrier a semipermeable barrier formed by cells lining the blood capillaries that supply the brain and other parts of the central nervous system. It prevents large molecules, including many drugs, from passing from the blood to the fluid surrounding brain cells and to the cerebrospinal fluid, and thus it protects the brain from potentially harmful substances. Ions and small molecules, such as water, oxygen, carbon dioxide, and alcohol, can cross relatively freely. Entry is also possible for lipid-soluble compounds, such as anesthetics, which diffuse through plasma membranes.

Several anatomical features contribute to the barrier. Cells lining the capillary walls are joined together by tight junctions, which block the passage of molecules through the intercellular spaces found in capillaries elsewhere. Also, the brain capillaries lack pores, called fenestrations, which normally promote the passage of fluid and solutes. Furthermore, the brain capillaries are tightly enveloped in a sheath formed by star-shaped glial cells, called astrocytes. The barrier formed by these features helps maintain a constant environment in which the brain can function, but it also means that many potentially useful drugs cannot enter the brain from the bloodstream. See also area postrema.

blood glucose see blood sugar.

blood group a category of immunologically distinct, genetically determined traits based on the presence or absence of certain antigens on the surface of red blood cells. The most commonly used method of categorization is the ABO system, in which the basic categories are A, B, AB, and O. There are more than 20 other blood group systems, including the rhesus system (see Rh factor). The major initial work on blood groups and on the nature of blood...
transfusion was done at the beginning of the 20th century by Austrian physician Karl Landsteiner (1868–1943), who received a Nobel Prize for this research in 1930. Also called blood type.

bloodletting n. see phlebotomy.

blood levels the relative amounts of various substances in a measured amount of blood. Blood levels involve comparison of observed levels with an amount or range taken to be normal or toxic. The amount may be expressed as a percentage, in milligrams or micrograms per 100 milliliters, millimoles, or micromoles per liter, or a similar measure. Also called circulating levels.

blood oxygenation level-dependent (BOLD) describing a contrast identified during functional magnetic resonance imaging (fMRI) that signals alterations in blood oxygen levels as a function of increased or decreased brain activity during an fMRI event. The exact meaning of these signals has recently been questioned. Also called blood oxygen level-dependent.

blood phobia a persistent and irrational fear of blood, specifically of seeing blood. Situations in which blood may be encountered are often avoided or else endured with intense anxiety or distress. An individual confronting blood experiences a subjective feeling of disgust and fears the consequences of the situation, such as fainting. In certain diagnostic classifications, such as DSM–IV–TR and DSM–5, blood phobia is identified as a specific phobia, blood-injection-injury type. Blood phobia rarely is called hematophobia or hemophobia.

blood poisoning see sepsisemia.

blood pressure the pressure exerted by the blood against the walls of blood vessels, especially arteries. It varies with the strength of the heartbeat, the elasticity of the artery walls and resistance of the arterioles, and the person’s health, age, and state of activity. Blood pressure is measured using an instrument called a sphygmomanometer. The pressure measured during heart contraction (see systolic blood pressure) is higher than that measured when the heart is relaxed (see diastolic blood pressure). The readings are recorded (in millimeters of mercury) as systolic/diastolic; the normal resting blood pressure for an adult is less than 120/80. See also hypertension.

blood sugar the concentration of glucose in the blood, which is regulated by the pancreatic hormones insulin and glucagon. Glucose is an important source of energy for the body, particularly the brain. The normal level of blood sugar for humans, measured 12 hours after the last meal, generally ranges between 70 and 110 mg glucose per deciliter of blood. Abnormally high or low levels (see hyperglycemia; hypoglycemia) may indicate any of several disease states.

blood type see blood group.

Bloom’s taxonomy one of the first systematic classifications of the three domains—cognitive, affective, and psychomotor—that students use in attaining educational goals. Originally proposed in 1956, the taxonomy states that each domain is divided into levels from least to most complex, representing a cumulative hierarchy. The cognitive domain encompasses intellectual capacity. The remembering level is considered to be the lowest taxonomic category in this domain, since information can be recalled with a minimum of understanding. The highest level, creating, represents the cumulative contributions of the remembering level plus four others arranged in order of cognitive complexity: understanding, applying, analyzing, and evaluating. The affective domain encompasses emotional capacity, feelings, values, and attitudes and consists of five levels: receiving, responding, valuing, organizing, and characterizing. The psychomotor domain includes movement, spatial relationships, and use of motor skills. Its hierarchy was not described in the original taxonomy, but a number of different hierarchies were proposed in the 1970s, generally organized around the degree of learned capacity with reflex, imitation, and perception at the lowest level and the creation or coordination of highly skilled movements at the highest level. Also called taxonomy of educational objectives. [proposed by a committee of college examiners chaired by U.S. educator Benjamin S. Bloom (1913–1999)]

B-love n. see being love.

blow 1. n. slang for cocaine. 2. vb. to inhale cocaine or to smoke marijuana.

blow job slang for oral stimulation of the penis by a partner, which may occur as a part of foreplay or may be continued to the point of orgasm.

BLSA abbreviation for BALTIMORE LONGITUDINAL STUDY OF AGING.

blue n. the color experienced when the eye is stimulated by energy in the short-wavelength portion (c. 500–445 nm) of the visible spectrum.

blue-collar worker an employee, such as a factory worker, who performs manual or technical physical labor. The term derives from the blue shirts traditionally worn by many industrial workers. Compare pink-collar worker; white-collar worker.

blues pl. n. a colloquial name for depressive symptoms, especially sadness or anhedonia. It usually implies that the symptoms are mild or transient. See also baby blues.

blue-sighted adj. having unusual sensitivity to blue stimuli. When a yellowed lens is removed to alleviate a cataract, many patients report heightened sensitivity to blue stimuli.

blue–yellow blindness a rare type of partial color blindness marked by blue and yellow confusion.

blunted affect a disturbance in which emotional responses to situations and events are dulled.

blur n. the quality of an image that causes it to be indistinct, with smeared or vague borders.

blur point the minimum distance from the eye that a stimulus must be placed to appear blurred.

blurred vision see visual blurring.

blushing n. an involuntary reddening of the face, sometimes associated with feelings of embarrassment, self-consciousness, modesty, or shame.

B lymphocyte see lymphocyte.

BMLD abbreviation for binaural masking level difference.

B-motivation n. see metamotivation.
BMR abbreviation for basal metabolic rate. See basal metabolism.

BNSQ abbreviation for Basic Nordic Sleep Questionnaire.

BNT abbreviation for Boston Naming Test.

board certified denoting a physician or other health care professional who has passed an examination set by a specialty board and has been certified as a specialist in that area. A board-certified (or boarded) individual is known as a diplomate.

boarding home see adult home; group home; halfway house.

Bobo doll an inflatable plastic clown. In his studies of observational learning, Albert Bandura demonstrated that children who had watched a videotape of an adult being violent with a Bobo doll were more likely to behave aggressively toward the doll than were children who had watched an adult being nonviolent toward it.

bodily-kinesthetic intelligence in the multiple-intelligences theory, the skills involved in forming and coordinating bodily movements, such as dancing, playing a violin, or playing basketball.

body n. 1. the entire physical structure of an organism, such as the human body. 2. the physical body as opposed to the mental processes of a human being. See mind–body problem. 3. the trunk or torso of a human or nonhuman animal. 4. the main part of a structure or organ, such as the body of the penis. 5. a discrete anatomical or cytological structure, such as the Barr body (see sex chromatin).

body awareness the perception of one’s physical self or body at any particular time.

body boundaries the definitiveness or indefiniteness of the outlines of a body. Barrier responses in Rorschach inkblot tests, such as “turtle with shell” and “man in armor,” indicate definite body boundaries, whereas penetration responses, such as “person bleeding” and “torn coat,” indicate indefinite boundaries.

body buffer zone the physical distance a person prefers to maintain between him- or herself and one or more other individuals to avoid feeling uncomfortable. This zone varies depending on the relationship with the others; it is smaller, for example, when there is a close relationship. It also varies according to culture. See also bubble concept of personal space; interpersonal distance.

body build a general measure of the body in terms of trunk, limb length, and girth.

body-build index an index of constitutional types. Individuals are grouped according to the formula (height × 100)/(transverse chest diameter × 6). Mesomorphs, who are muscular, fall within one standard deviation of the mean; narrowly built leptomorphs one standard deviation or more above the mean; and broadly built eurymorphs one standard deviation or more below the mean. [proposed by Hans Eysenck]

bodybuilding the use of a weight-lifting program to build muscle bulk and to acquire muscle definition.

body cell any tissue cell that is not a germ cell. It normally has the diploid number of chromosomes. Also called somatic cell.

body cognitions beliefs or attitudes about the features of one’s appearance. Characteristically negative and self-defeating thoughts are related to subjective dissatisfaction.

body concept the thoughts and feelings that constitute the way an individual views his or her body characteristics: that is, the conceptual image of one’s body. Compare body percept. See body image.

body disfigurement an objective defect of appearance related to a congenital malformation, physical injury, or any disease process that modifies the physical integrity of the individual.

body distortion see body-image distortion; body-size overestimation.

body dysmorphia an extreme disparagement of some aspect of appearance that is not supported by the objective evidence. There may be only a mild defect in the body feature or, in extreme cases, there may be no objective evidence of any malformation or oddity of appearance. See also body dysmorphic disorder; muscle dysmorphia.

body dysmorphic disorder (BDD) a disorder characterized by excessive preoccupation with an imagined defect in physical appearance or markedly excessive concern with a slight physical anomaly. The preoccupation is typically accompanied by frequent checking of the defect. BDD is classified in DSM–IV–TR as a somatoform disorder, but because it shares features with obsessive-compulsive disorder, such as obsessions with appearance and associated compulsions (e.g., mirror-checking), it has been reclassified in DSM–5 under a category labeled obsessive-compulsive and related disorders.

body ego in psychoanalytic theory, the part of the ego that develops out of self-perceptions of the body. It is the first manifestation of the core of the ego around which all perceptions of the self are grouped, including individual memories, sensations, ideas, wishes, strivings, and fantasies.

body electrode placement the pattern or location of individual electrodes used to measure electrical properties of the heart, brain, skin, or other organ or system.

body esteem the degree of positiveness with which individuals regard the various parts of their body and the appearance of those parts.

body ideal the body type promoted within a culture and its media as most attractive or most appropriate to a person’s age, gender, and race. This is variously internalized, imposed, and resisted by individuals and groups.

body image the mental picture one forms of one’s body as a whole, including its physical characteristics (body percept) and one’s attitudes toward these characteristics (body concept). Also called body identity. See also body schema.

Body Image Assessment (BIA) a measure of body image in which a participant is shown silhouettes of figures that increase incrementally in size from very thin to very overweight and is asked to choose the one that represents his or her actual figure and the one that represents his or her ideal figure. In addition to the BIA for adults, there are three other forms of the instrument: BIA–O for obese adults, BIA–C for younger children, and BIA–P for preadolescents. [originally developed in 1985 by U.S. psychologist Donald A. Williamson (1950– ) and colleagues]

body-image avoidance behavioral manifestations of excessive concern with one’s appearance, evidenced by
such behaviors as avoiding social functions and engaging in cover-up activities (e.g., wearing bulky and loose-fitting clothing) to obscure and hide aspects of the body with which one is dissatisfied.

**body-image distortion** distortion in the subjective image or mental representation of one’s own body appearance, size, or movement. The term is usually applied to overestimation of body size or used to define the perceptual experiences of individuals with psychoses. Also called **body-image disturbance**. See also **ANOREXIA NERVOSA; BODY-SIZE OVERESTIMATION**.

**body-image ideals** personal standards of optimal appearance for various body features: idealized features as opposed to actual attributes of appearance.

**body integrity identity disorder (BIID)** a rare disorder characterized by a person’s belief that his or her body is marred by the presence of a particular (although healthy) body part, usually an arm or leg. The condition is associated with marked distress, leading the individual with BIID to wish that the limb was paralyzed, to seek elective surgery to have it removed, to attempt to remove the limb himself or herself, or to injure the limb so badly that doctors are forced to amputate it. Also called **amputee identity disorder; apotemnophilia**.

**body language** the expression of feelings and thoughts, which may or may not be verbalized, through posture, gesture, facial expression, or other movements. For example, anger is usually indicated by a facial expression in which there are downward lines in the forehead, cheeks, and mouth, and the hands may be clenched. Body language is often called **NONVERBAL COMMUNICATION**.

**body mass index (BMI)** a widely used measure of adiposity or obesity based on the following formula: weight (kg) divided by height squared (m²).

**body memory** a sensory recollection of trauma in the form of pain, arousal, tension, or discomfort, usually unaccompanied by words or images. Body memory is frequently the result of trauma occurring during the period of **CHILDHOOD AMNESIA**, leading to a sensorimotor, rather than cognitive, encoding of the traumatic event. See also **SENSORIMOTOR MEMORY**.

**body–mind problem** see **MIND–BODY PROBLEM**.

**body narcissism** 1. an exaggerated preoccupation or fascination with one’s own body and its endogenous zones. See also **NARCISSISM.** 2. in classical psychoanalytic theory, the **PRIMARY NARCISSISM** of the young infant.

**body odor** the odor produced by the action of bacteria on skin secretions, such as perspiration (which itself is nearly odorless). Attitudes toward body odor vary in different cultures.

**body percept** the mental image one forms of the physical characteristics of one’s own body; that is, whether one is slim or stocky, strong or weak, attractive or unattractive, tall or short. Compare **BODY CONCEPT; BODY CONCEPT.** See **BODY IMAGE**.

**body positioning** the notion that body posture can affect memory. Specific kinesthetic and proprioceptive feedback may provide a context for enhancing learning and recall.

**body rocking** see **ROCKING**.

**body schema** the cognitive organization of one’s appearance, including internal image, thoughts, and feelings. See **BODY PERCEPT**.

**body-size overestimation** the specific tendency to overestimate the size of body features (e.g., width of waist, hips, or thighs) in relation to objective size measurements. It was once thought to be an essential feature of **ANOREXIA NERVOSA**. See **BODY-IMAGE DISTORTION**.

**body temperature** a measure of body heat, which is normally about 98.6 °F (37 °C) in humans. Body temperature affects all metabolic processes, and most cells must remain within the range of 32 °F to 113 °F (0 °C–45 °C). Animals are characterized as **ENDOTHERMS** or **ECTOTHERMS** according to how they regulate body temperature. See also **HEAT EFFECTS; HYPOTHERMIA**.

**body therapies** a group of physical therapies that seek to relieve psychological tensions and other symptoms through body manipulation, relaxation, massage, breathing exercises, and changes in posture and position of body parts. The therapies are based on the theory that the body and its functioning embody an individual’s basic personality and way of life. See also **BODYWORK**.

**body type** a classification of individuals according to body build or physique. Some have theorized an association between aspects of physique and psychological traits, proposing a variety of **CONSTITUTIONAL TYPES** and **SOMATOTYPES**.

**bodywork** n. an **ADJUNCTIVE THERAPY** that may be recommended in addition to psychotherapy. It typically includes massage, movement, and exercises involving touch.

**Bogardus Social Distance Scale** an instrument used to measure individuals’ attitudes toward particular ethnic groups. Respondents are presented with different scenarios (e.g., having someone from a particular group as a work colleague) and must indicate the acceptability of each for the groups listed. It is assumed that individuals who would prefer to keep a greater social distance between themselves and members of a specific group are prejudiced against that group. The Bogardus scale is one of the most commonly used **SOCIAL DISTANCE SCALES**. [Emory Bogardus (1882–1973), U.S. sociologist]

**bogus pipeline** fake apparatus used in attitude research to ascertain attitudes toward controversial or sensitive issues, about which participants would otherwise be tempted to answer dishonestly. The apparatus is attached to the participant, who is then informed, incorrectly, that it can detect whether the attitude he or she reports is a true one. In one study, it was found that use of the bogus pipeline resulted in a greater likelihood of admitting cocaine abuse, excessive drinking, and oral sex.

**boilermaker’s deafness** a high-frequency hearing loss resulting from exposure to high-intensity noise. The condition has been known for many years but is increasingly prevalent due to the increased noise of highly industrialized society. See **ACOUSTIC TRAUMA**.

**BOLD** acronym for **BLOOD OXYGENATION LEVEL-DEPENDENT**.

**boldness** n. the tendency to accept risk, a dimension of **TEMPERAMENT** observed in both humans and nonhuman animals. Thus, a bold preschooler may freely engage with unfamiliar classmates, and a bold rat may explore all available areas during an **OPEN-FIELD TEST**. Individual differences in boldness are presumed to arise from differences in the excitability of areas of the **LIMBIC SYSTEM** that are in-
volved in the evaluation of stimulus saliency. For example, bold adults exhibit more bilateral NUCLEUS ACCUMBENS activation and less bilateral AMYGDALA activation when looking at the faces of strangers than do less bold adults. Compare SHYNESS. See also SHY–BOLD CONTINUUM.

bolstering of an attitude a method of reducing COGNITIVE DISSONANCE by generating new cognitive elements that are consistent with an attitude. This is presumed to offset the dissonance resulting from an inconsistent element.

bombesin n. a NEUROPEPTIDE, originally isolated from the skin of the fire-bellied toad and later found in mammals, that regulates the contraction of smooth muscle cells, suppresses appetite, and has a role in certain cancers. See also NEUROPEPTIDE.

bona fide group see NATURAL GROUP.

bona fide occupational qualification (BFOQ) an attribute or personal characteristic (e.g., age, sex, physical ability) that is genuinely necessary to perform a particular job successfully, as opposed to one that is often associated with the job but not in fact necessary for effective performance. See also ADVERSE IMPACT. AGE DISCRIMINATION IN EMPLOYMENT ACT: AMERICANS WITH DISABILITIES ACT.

bona fide pipeline measure see EVALUATIVE PRIMING MEASURE.

bond n. a relationship between two or more individuals that signifies trust and alliance. In a social context, the existence of bonds between individuals is such that each person feels an attraction toward the other and each expects their association to continue. In psychotherapy, the bond of a THERAPEUTIC ALLIANCE between therapist and client is considered beneficial to the treatment. See also PAIR BOND.

bondage n. physical restraint of one person by another to arouse sexual pleasure in one or both partners.

bondage and discipline (B and D) a phase of sexual BONDAGE that is accompanied by such acts as whipping or spanking. Because of the potential physical danger, the partners usually agree on a signal, called a safe word, to be used when the erotic activity exceeds the pleasurable limits. See also SADEMOANISHISM.

bonding n. the process in which ATTACHMENTS or other close relationships are formed between individuals, especially between mother and infant. An early, positive relationship between a mother and a newborn child is considered by some theorists to be essential in establishing unconditional love on the part of the parent, as well as security and trust on the part of the child. In subsequent development, bonding establishes friendship and trust (see BOND).

bone age a measure of the skeletal maturity of an individual based on the stage of ossification of bone, usually determined from X-rays of the hand and wrist.

bone conduction the transmission of sound waves to the inner ear through vibrations of bones in the skull.

bone-conduction testing an audiological procedure to determine if the hearing loss detected in AIR-CONDUCTION TESTING is a result of conductive or sensorineural factors. It is performed at controlled frequencies with a small bone-conduction vibrator that is attached to a headband and placed on the temporal bone behind the ear. See AIR–BONE GAP.

bone pointing see VOODOO DEATH.

Bonferroni t test see DUNN–BONFERRONI PROCEDURE. [Carlos Emilio Bonferroni. (1892–1960), Italian mathematician]

Bonnet syndrome see CHARLES BONNET SYNDROME.

bony labyrinth see Labyrinth.

Boolean algebra a set of rules that simplify the expression of relatively complex logical statements by describing them in terms of different variables whose outcomes are either true or false. In Boolean algebra, which underlies digital computation systems, words are used to create logical combinations or operators (e.g., and, or, not). [George Boole (1815–1864), British mathematician and logician]

boomerang effect a situation in which a persuasive message produces attitude change in the direction opposite to that intended. Boomerang effects occur when recipients generate counterarguments substantially stronger than the arguments contained in the original message.

booster session in therapy, particularly COGNITIVE BEHAVIOR THERAPY, any occasional periodic session, after the main sessions are officially ended, in order to reinforce progress or troubleshoot obstacles to continuation of positive changes made during the therapy.

bootstrapping n. 1. any process or operation in which a system uses its initial resources to develop more powerful and complex processing routines, which are then used in the same fashion, and so on cumulatively. In LANGUAGE ACQUISITION, for example, the term describes children’s ability to learn complex linguistic rules, which can be endlessly reapplied, from extremely limited data (see QUINIAN BOOTSTRAPPING). 2. a statistical technique to estimate the variance of a parameter when standard assumptions about the shape of the data set are not met. For example, bootstrapping may be used to estimate the variance of a set of scores that do not follow a NORMAL DISTRIBUTION. In this procedure, a subset of values is taken from the data set, a quantity (e.g., the mean) is calculated, and the values are reinserted into the data; this sequence is repeated a given number of times. From the resulting set of calculated values (e.g., the mean of the means), the summary value of interest is calculated (e.g., the standard deviation of the mean). See also JACKKNIFE. —bootstrap vb.

borderline 1. adj. pertaining to any phenomenon difficult to categorize because it straddles two distinct classes, showing characteristics of both. Thus, BORDERLINE INTELLIGENCE is supposed to show characteristics of both the average and subaverage categories. See also BORDERLINE DISORDER; BORDERLINE STATE. 2. n. an informal or shorthand designation for someone with BORDERLINE PERSONALITY DISORDER or its symptoms.

borderline case see CASE.

borderline disorder 1. see BORDERLINE PERSONALITY DISORDER. 2. historically, any psychological condition that lies between normality and psychosis, between normality and psychosis, or between normal intelligence and intellectual disability.

borderline intelligence a level of measured intellectual performance between average and significantly subaverage intelligence. Some researchers define it as an IQ between 68 and 83, others as any IQ in the 70s, but it is most often associated with IQs in the range 70 to 75. IQs in the borderline range, especially above 75, do not justify a basis for diagnosis of intellectual disability. Also called bor-
borderline intellectual functioning: borderline mental retardation.

borderline personality disorder in DSM–IV–TR and DSM–5, a personality disorder characterized by a long-standing pattern of instability in mood, interpersonal relationships, and self-image that is severe enough to cause extreme distress or interfere with social and occupational functioning. Among the manifestations of this disorder are (a) self-damaging behavior (e.g., gambling, overeating, substance abuse); (b) intense but unstable relationships; (c) uncontrollable temper outbursts; (d) uncertainty about self-image, gender, goals, and loyalties; (e) shifting moods; (f) self-defeating behavior, such as fights, suicidal gestures, or self-mutilation; and (g) chronic feelings of emptiness and boredom. See also MENTALIZATION.

borderline psychosis see BORDERLINE STATE.

borderline schizophrenia historically, a condition in which an individual inconsistently displays symptoms of schizophrenia (e.g., only under circumstances of high stress) but is in touch with reality most of the time.

borderline state any condition in which an individual’s presenting symptoms are difficult to classify. Historically, borderline state (or borderline psychosis) more specifically referred to a condition in which an individual may become psychotic if exposed to unfavorable circumstances but has not currently lost touch with reality.

boredom n. a state of weariness or ennui resulting from a lack of engagement with stimuli in the environment. It is generally considered to be one of the least desirable conditions of daily life and is often identified by individuals as a cause of feeling depressed. It can be seen as the opposite of INTEREST and SURPRISE. —bored adj.

Borg scale either of two scales for measuring intensity of sensation and experience, enabling comparisons across people and across tasks. The RPE scale (rating of perceived exertion) is used specifically for measuring perceived effort in physical work. The CR10 scale (categorical rating with a scale from 1 to 10) is a general method that measures the magnitude of different sensations, including pain, loudness and noise, and brightness. These scales are used in psychophysics as well as in fitness training, ergonomics, and rehabilitation. [Gunnar Borg, 20th-century Swedish psychologist]

Börjeson–Forssman–Lehmann syndrome a disorder characterized by MICROCEPHALY, severe intellectual disability, obesity, seizures, HYPOGONADISM, and distinct facial features. Fully expressed primarily in males, it is caused by an X-linked recessive trait mutation in the PHF6 gene. [Mats Gunnar Börjeson (1922– ), Hans Axel Forssman (1912–1994), and J. O. Orla Lehmann (1927– ), Swedish physicians]

borna disease a disease of mammals (especially horses) that is caused by a virus and can be transmitted to humans, typically via intranasal infection. It usually results in ENCEPHALOPATHY, which leads to ATAXIA, blindness, and other neurological disorders.

borstal system a treatment approach for juvenile offenders that emphasizes rehabilitation through hard work and recreation, along with a period of supervision during reentry to society. The approach is named after the prison at Borstal in Kent, England, where it was first introduced in 1908.

BOS abbreviation for BEHAVIORAL OBSERVATION SCALE.

Boston Naming Test (BNT) a fluency test of word retrieval used to evaluate APHASIA. Drawings of objects—ranging in difficulty from the commonly encountered (e.g., tree, bed) to the rarely encountered (e.g., sphinx, abacus)—are presented, and the participant provides the name of each object. The BNT was originally developed in 1978 by U.S. neuropsychologist Edith Kaplan, U.S. clinical psychologist Harold Goodglass (1920–2002), and U.S. neuropsychologist Sandra Weintraub (1946–). It is often administered with the Boston Diagnostic Aphasia Examination (BDAE), a test that Kaplan and Goodglass first developed in 1972 for use in determining the presence and type of aphasia and in assessing its severity by measuring aspects of an individual’s communication ability, including perception (e.g., auditory, visual), processing (e.g., comprehension), and expression (e.g., speech, writing). Both tests remain among the most widely used language-disorder assessment instruments in neuropsychology.

Boston Process Approach see PROCESS APPROACH.

BOT abbreviation for BRUININKS–OSERETSKY TEST OF MOTOR PROFICIENCY.

botany n. the scientific study of plants. —botanical adj. —botanist n.

bottleneck model any model of attention that assumes the existence of a limited-capacity channel (typically with a capacity of one item) at some specific stage of human information processing. In LATE-SELECTION THEORIES, this channel (the “bottleneck”) occurs after stimulus identification.

bottoming out a state of despair characterized by financial ruin, suicide attempts, or shattered family and other intimate interpersonal relationships that is frequently experienced by people with severe depression or addiction disorders (e.g., substance abusers and pathological gamblers).

bottom-up design an inductive approach to the design of a system or product. Such an approach involves identifying basic user requirements and allowing these to drive the design, as opposed to basing it on existing product designs or abstract models. Compare TOP-DOWN DESIGN.

bottom-up processing INFORMATION PROCESSING in which incoming stimulus data initiate and determine the higher level processes involved in their recognition, interpretation, and categorization. For example, in vision, features would be combined into objects, and objects into scenes, recognition of which would be based only on the information in the stimulus input. Typically, perceptual or cognitive mechanisms use bottom-up processing when information is unfamiliar or highly complex. Also called bottom-up analysis: data-driven processing. Compare TOP-DOWN PROCESSING. See also SHALLOW PROCESSING.

bouffée délirante see ACUTE DELUSIONAL PSYCHOSIS.

Boulder model see SCIENTIST-PRACTITIONER MODEL.

boundary n. 1. a psychological demarcation that protects the integrity of an individual or group or that helps the person or group set realistic limits on participation in a relationship or activity. 2. in psychotherapy, an important limit that is usually set by the therapist as part of the GROUND RULES in treatment. Boundaries may involve areas of discussion (e.g., the therapist’s personal life is off limits) or physical limits (e.g., rules about touching), which are guided by ethical codes and standards. Respect for boundaries by both the therapist and client is an important concept in the therapeutic relationship.
boundary ambiguity

uncertainty that arises in a family system when an individual’s status, role, or family membership is brought into question, most often as a result of separation, divorce, and remarriage. See PERMEABLE FAMILY.

boundary detector

1. any of the RETINAL GANGLION CELLS that respond to a sharp edge in a receptive field, regardless of brightness or contrast on either side of the edge. These cells are most common in the retinas of frogs. See also FEATURE DETECTOR.

2. any of a class of computational algorithms designed to detect edges in artificial vision or word segmentation in speech processing.

boundary issues

1. ethical issues relating to the proper limits of a professional relationship between a provider of services (e.g., a physician or a psychotherapist) and his or her patient or client, such that the trust and vulnerability of the latter are not abused (see BOUNDARY). A particular area of concern is PROFESSIONAL–CLIENT SEXUAL RELATIONS.

2. in health care, issues relating to the demarcations between different areas and levels of expertise and questions of who is best qualified to give certain types of treatment or advice.

boundary spanning

in organizational settings, identifying information external to the organization, selectively disseminating that information within the organization, and sending information known within the organization out into the external environment. Individuals who occupy boundary spanning roles, such as sales or account managers, both filter information and facilitate information transmission.

boundary system

in GENERAL SYSTEMS THEORY, the semipermeable boundaries between living systems, permitting information to flow in either direction but posing the question of how much interpenetration and interdependence are feasible in a given social system. See also EGO BOUNDARY.

bounded rationality

decision making in which the processes used are rational within the constraints imposed by (a) limitations in the individual’s knowledge; (b) human cognitive limitations generally; and (c) empirical factors arising from the complex, real-life situations in which decisions have to be made. The concept was introduced by Herbert A. Simon as a corrective to the assumption of classical economic theory that individuals can and will make ideally informed and rational decisions in pursuit of their own self-interest (see RATIONAL–ECONOMIC MAN). See PROCEDURAL RATIONALITY; SUBSTANTIVE RATIONALITY. See also SATISFICER.

bound energy

in psychoanalytic theory, PSYCHIC ENERGY that is located within the ego and focused on the individual’s external reality. Bound energy is associated with the SECONDARY PROCESSES and is contrasted with the FREE ENERGY of the id.

bound morpheme

in linguistics, a MORPHEME that can occur only in combination with other morphemes. For example, the morpheme for the past tense -ed can only occur with a verb stem, as in kissed. Compare FREE MORPHEME.

bourgeoisie

n. see MIDDLE CLASS.

bowel disorder

any disorder of the small or large intestine, which frequently occurs as a response to stress and anxiety (e.g., chronic constipation, IRRITABLE BOWEL SYNDROME).

bowel incontinence

see FECAL INCONTINENCE.

Bowen family systems theory

see FAMILY SYSTEMS THEORY.

box-and-whisker plot

a graphical display of the central value, variance, and extreme values in a data set. A rectangle (box) is drawn along the vertical y-axis of the plot, which shows the range of data values. The length of the box indicates the middle 50% of scores and its two ends indicate the upper and lower hinges. Lines (whiskers) extending outward from the box denote variation in the upper and lower 25% of scores, while a separate line within the box indicates the score that falls in the very middle of the set (i.e., the MEDIAN). Stars or other single points indicate extreme scores. A box-and-whisker plot is useful in EXPLORATORY DATA ANALYSIS for indicating whether a distribution is skewed and whether the data set includes any OUTLIERS; it can also be used to compare data sets when large numbers of observations are involved. Also called BOX PLOT.

Box-Cox transformation

a TRANSFORMATION that enables the relationship between one or more predictor variables and an outcome variable to be described by a summative formula and thus to be plotted by a straight line when graphed. Based on MAXIMUM LIKELIHOOD estimation, the technique transforms the outcome variable to obtain linearity and approximate NORMALITY in a data set. Compare BOX–TIDWELL TRANSFORMATION. [George E. P. Box (1919–2013) and David Roxbee Cox (1924–), British statisticians]

boxed warning

an alert strongly recommended by the U.S. FOOD AND DRUG ADMINISTRATION to be included in the LABELING of medications that have been found to have particularly serious or life-threatening side effects or that should be prescribed only under certain circumstances or to certain patient populations. The warning must be prominently displayed and in bold type. Also called BLACK BOX WARNING.

boxer’s dementia

see DEMENTIA PUGILISTICA.

box-score method

a method of summarizing results from multiple studies of the same general research question that considers both statistically meaningful and non-meaningful results but ignores the magnitude of the research findings (e.g., the size of a treatment effect). META-ANALYSIS generally is preferred over the box-score method.

Box–Tidwell transformation

a TRANSFORMATION used to modify a set of predictor variables so that the relationship between those predictors and the outcome variable resembles a straight line. It is similar to the BOX–COX TRANSFORMATION for correcting nonlinearity but instead is applied to the independent variables (predictors) involved. [George E. P. Box (1919–2013), British statistician; Paul William Tidwell (1926–2013), U.S. chemist and statistician]

BP

equation for Bereitschaftspotential. See READINESS POTENTIAL.

BPA

equation for BISPHENOL A.

BPRS

equation for BRIEF PSYCHIATRIC RATING SCALE.

BPS

equation for BRITISH PSYCHOLOGICAL SOCIETY.

BRAC

equation for BASIC REST–ACTIVITY CYCLE.

brac

equation that supports or maintains the correct positioning of a part of the body, such as a limb, a joint, or
the spine. Braces may be designed to permit flexion and motion and are typically intended for permanent or long-term use. They are distinct from splints, which are used to temporarily immobilize or protect a part of the body.

**brachial plexus** a network of nerves that carries signals from the spinal cord to the shoulder, arm, and hand. Injury to the brachial plexus can impair control of these parts.

**brachium** n. (pl. brachia) 1. the upper arm, extending from the shoulder to the elbow. 2. in anatomy, a structure that resembles an arm, such as the **BRACHIUM CONJUNCTIVUM**. —brachial adj.

**brachium conjunctivum** the superior **CEREBELLAR PEDUNCLE** of fibrous tissue extending from each hemisphere of the cerebellum to the pons.

**Brachmann-de Lange syndrome** see **CORNELIA DE LANGE SYNDROME**. [described in 1916 by Winfried Brachmann (1888–1915), German physician, and in 1933 by Cornelia de Lange (1871–1950), Dutch pediatrician]

**brachy-** combining form short.

**brachyccephalic** adj. see **CEPHALIC INDEX**. —brachycephaly n.

**brachymorph** n. a body type characterized by an abnormally short, broad physique. Also called **brachytype**. —brachymorphic adj.

**brachyskeletal** adj. having abnormally short bones, particularly short leg bones. Also called **brachyskelic**.

**bracketed morality** a temporary suspension of the usual moral obligation to consider equally the needs and desires of all persons that is due to contextual factors in a particular situation. Such a suspension occurs, for example, when participating in sporting events (see **GAME REASONING**).

**brady-** combining form slow.

**bradyarthria** n. see **BRADYLLALIA**.

**bradycardia** n. see **ARRHYTHMIA**.

**bradyesthesi a** n. slowed or dulled sensation.

**bradykinesia** n. abnormal slowness in the execution of voluntary movements. Also called **bradykinesis**. Compare **HYPOKINESIS**. —bradykinetic adj.

**bradyllalialia** n. abnormal slowness or hesitation in speech. Also called **bradyarthria; bradylalia**.

**bradylexia** n. extreme slowness in reading that is not attributable to intellectual impairment. —bradylexic adj.

**bradylalia** n. see **BRADYLLALIA**.

**bradyrhythmia** n. slowness of the rhythms of the heart.

**brahmacarya** n. 1. continence or chastity (Sanskrit). In the Hindu tradition (see **HINDUISM**), the term signifies continence in thought, word, and deed, which is one of the five virtues of the first stage of Raja-Yoga. It is also used to denote an ordination ceremony for novice monks as well as the first of the four stages into which human life is divided according to Vedic tradition. 2. in **BUDDHISM**, holy conduct of life. The term signifies a life lived in harmony with Buddhist rules of discipline and is used to describe the chaste lifestyle of a Buddhist monk.

**braid cutting fetish** a fetish in which a person’s hair is cut as part of sexual activity.

**Braid’s strabismus** a form of **STRABISMUS** in which hypnosis can be induced by causing the eyes to converge and turn upward. [James Braid]

**braille** n. a system of letters, numbers, punctuation marks, and scientific and musical symbols adapted as a written language for people with severe visual impairment, using combinations of raised dots that can be touched. Each character comprises a specific pattern of six dots organized in two parallel vertical columns. Prefix symbols are used to indicate capitalization and numbers, and various other conventions are used to represent more than 200 common words or recurring letter combinations. [introduced in 1829 by Louis Braille (1809–1852), French teacher and inventor]

**brain** n. the enlarged, anterior part of the **CENTRAL NERVOUS SYSTEM** within the skull. The young adult human brain weighs about 1.450 g, and its outer layer (the **CEREBRAL CORTEX**) contains over 10 billion nerve cells. The brain develops by differentiation of the embryonic **NEURAL TUBE** along an anterior–posterior axis to form three main regions—the **FOREBRAIN**, **MIDBRAIN**, and **HINDBRAIN**—that can be further subdivided on the basis of anatomical and functional criteria. The cortical tissue is concentrated in the forebrain, and the midbrain and hindbrain structures are often considered together as the **BRAINSTEM**. The functions of the brain are discussed in entries for the different parts of the brain. Also called **encephalon**. See also **BRAIN LOCALIZATION THEORY; EVOLUTION OF THE BRAIN; SPLIT BRAIN**.

**brain abscess** a circumscribed collection of pus that may occur in any part of the brain and, depending on its location, may produce deficits in any neurological function. Brain abscesses are often secondary to infections.

**brain atlas** a collection of illustrations of details of brain structure.

**brain atrophy** see **CEREBRAL ATROPHY**.

**brain bank** a program in which the brains of deceased people with specific neurological disorders are gathered to enable scientists to conduct intensive postmortem histopathological studies.

**brain-based learning** see **NEUROEDUCATION**.

**brain center** any of various regions of the brain that have specific functions, such as the visual centers and the (alleged) hunger center.

**brain comparator** a theoretical structure in the brain that compares an intended movement with sensory feedback that results from the movement (see **COMPARATOR**). The cerebellum is believed to act as a brain comparator to coordinate and calibrate movements in response to visual and somatosensory feedback. See also **COROLLARY DISCHARGE**.

**brain–computer interface (BCI)** a system that translates the electrical activity of the brain into signals controlling external displays and devices, such as cursors on computer screens, Internet browsers, robotic arms, switches, or prostheses. This muscle-independent arrangement aims to help people with motor functions severely limited by injuries, progressive neurodegenerative diseases, or other conditions (e.g., LOCKED-IN SYNDROME) to communicate, manipulate objects in the environment, and otherwise enhance their independence and quality of life. BCI technology generally relies on changes in particular aspects of user-specific electroencephalographic rhythms, including the **P3 COMPONENT; SENSORIMOTOR RHYTHMS, SLOW CORTI**
brain concussion

CAL. POTENTIALS, and VISUAL EVOKED POTENTIALS. Some interfaces, however, are based on other types of electrophysiological activity that require different measurement techniques (e.g., ELECTROCORTICOGRAPHY, FUNCTIONAL MAGNETIC RESONANCE IMAGING, MAGNETORENCEPHALOGRAPHY). Also called brain-machine interface (BMI).

brain concussion see CONCUSSION.

brain contusion see CEREBRAL CONTUSION.

brain damage injury to the brain. It can have various causes, including prenatal infection, birth injury, head injury, toxic agents, brain tumor, brain inflammation, severe seizures, certain metabolic disorders, vitamin deficiency, intracranial hemorrhage, stroke, and surgical procedures. Brain damage is manifested by impairment of cognitive, motor, or sensory skills mediated by the brain.

brain death a state of extreme and irreversible unconsciousness in which neurological activity and vital physiologic functions have ceased, as opposed to cardiac death, in which cessation of natural cardiac activity and breathing indicates a patient is deceased. Although several professional organizations in neurology and related fields have specified their own guidelines for determining brain death, globally standardized criteria do not yet exist. For example, brain stem death is considered sufficient in the United Kingdom, whereas whole-brain death is required in the United States. Despite such variability, many clinicians (as well as legal statutes) establish brain death through the concurrent presence of the following: nonresponsiveness to noxious or other stimuli, absence of breathing, absence of reflexes and spontaneous movement, and absence of electroencephalogram activity. Exact methods of evaluating these factors differ significantly across facilities—for example, different U.S. hospitals require different ancillary tests for cerebral blood flow and other characteristics, including ANGIOGRAPHY, POSITRON EMISSION TOMOGRAPHY, SENSORY EVOKED POTENTIAL RECORDING, SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY, and sonography (see ULTRASOUND). Additionally, medical conditions and other complicating factors that temporarily depress brain function, such as hypothermia, drug overdose, and hyperglycemia or hypoglycemia, must be excluded before a definitive determination of brain death can be made. It must also be distinguished from the similar conditions of COMA and a VEGETATIVE STATE. Also called cerebral death: irreversible coma.

brain-derived neurotrophic factor (BDNF) a NEUROTROPHIN thought to be important in regulating synaptic plasticity, neurogenesis, and neuronal survival. BDNF acts as a neurostimulatory factor, helping to produce and maintain the complexity of neurons. It has been linked to some psychiatric disorders.

brain disease any degenerative, metabolic, and infectious disease that leads to BRAIN DAMAGE.

brain disorder 1. any condition marked by disruption of the normal functioning of the brain. 2. an older term for an acute or chronic mental disorder caused by or associated with impairment of brain function and characterized by mild to severe impairment of cognition and mood. Also called brain syndrome.

brain electrical activity mapping (BEAM) a system of computerized ELECTROENCEPHALOGRAPHY used to analyze and display electrical activity of the brain.

brain fog a CULTURE-BOUND SYNDROME originating in west Africa and most often experienced by high school or college students. Symptoms typically include difficulties with concentration, memory, and understanding information; feelings of pain, tightness, and burning around the head and neck; blurred vision; and tiredness associated with excessive thinking.

brain fingerprinting a forensic technique that uses neuroimaging (e.g., FUNCTIONAL MAGNETIC RESONANCE IMAGING) to match brain activity of control subjects with that of possible criminal suspects when both are viewing crime-scene details. The technique is based on the theory that certain sensory-perceptual brain activity would be expected to become activated in an individual familiar with the crime’s details but not in an individual unfamiliar with them. [developed by Lawrence A. Farwell, U.S. scientist]

brain graft the surgical transplantation or implantation of brain tissue to replace a damaged part or compensate for a defect.

brain growth the increase in size, mass, and complexity of the brain. In humans, the brain grows very rapidly in the fetus and during the early postnatal years, reaching its maximum mass at about 20 years, after which there is a slow decline. Some regions of the brain grow more rapidly than others, well into the teenage years.

brain imaging study of the anatomy or activity of the brain through the intact skull by noninvasive computerized techniques, such as MAGNETIC RESONANCE IMAGING, COMPUTED TOMOGRAPHY, and POSITRON EMISSION TOMOGRAPHY. See also NUCLEAR IMAGING.

brain injury see BRAIN DAMAGE; BRAIN TRAUMA.

brain lesion any damage to an area of brain tissue caused by injury, disease, surgery, tumor, stroke, or infection. Also called cerebral lesion.

brain localization theory any of various theories that differ in the areas of the brain serve different functions. Since the early 19th century, opinion has varied between notions of highly precise localization and a belief that the brain, or large portions of it, function as a whole. In 1861, Paul BROCA deduced from localized brain lesions that the speech center of the brain is in the left frontal lobe (see BROCA’S AREA). Since then, many techniques, including localized electrical stimulation of the brain, electrical recording from the brain, and BRAIN IMAGING, have added information about localization of function in the brain. For many investigators, however, the concept of extreme parcellation of functions has given way to concepts of distributed control by collective activity of different regions. See also MASS ACTION.

brain–machine interface (BMI) see BRAIN–COMPUTER INTERFACE.

brain mapping the creation of a visual representation of the brain in which different functions are assigned to different brain regions. Mapping may be based on a variety of sources of information, including effects of localized brain lesions, recording electrical activity of the brain, and BRAIN IMAGING during various behavioral states. See also BRAIN LOCALIZATION THEORY.

brain nucleus a cluster of cells within the cerebrum or cerebellum concerned with a specific function or functions. See NUCLEUS.

brain pathology any disorder, disease, or pathological...
condition affecting the brain (e.g., tumor, stroke, traumatic injury). See also NEUROPATHOLOGY.

**brain plasticity** 1. the capacity of the brain to compensate for losses in brain tissue caused by injury or disease. See also RECOVERY OF FUNCTION. 2. the capacity of the brain to change as a function of experience. The term plasticity in this sense was first used by William James in 1890.

**brain potential** the electric potential of brain cells. See ELECTROENCEPHALOGRAPHY.

**brain research** investigation of the structure and functions of the brain, including, for example, (a) the administration of psychological and neurological tests after lesions have occurred in various areas; (b) the observation or measurement of the effects of stimulation or ablation of parts of the brain; (c) the use of gross and microscopic anatomical and histopathological techniques; (d) the study of the nature and functions of chemicals involved in neurotransmission; and (e) the use of ELECTROENCEPHALOGRAPHY and BRAIN IMAGING techniques.

**brain reserve** a hypothesis proposing that some adult brains can tolerate pathological changes without overt signs of disturbance because of the capacity of remaining neurons in the central nervous system to compensate for damaged or destroyed tissue. Thus, a person with a high brain reserve can sustain a greater amount of brain injury or deterioration before manifesting symptoms than a person with low brain reserve can. Implicit to this concept is the notion of a critical threshold level of functioning neurons below which normal activities can no longer be maintained and symptoms of disorder appear.

The validity of this hypothesis has been difficult to establish empirically, but the concept has been influential within neurology and cognitive science since it was first proposed to explain the observation that many individuals with Alzheimer’s disease who had extensive AMYLOID PLAQUES and NEUROFIBRILLARY TANGLES in their brains nonetheless showed few decrements in their intellectual abilities. This same discrepancy has since been observed in non-demented patients with low brain reserve and in neurological disorders such as Parkinson’s disease, and other neurological disorders.

Indeed, the lack of a direct relationship between the degree of brain pathology and the clinical manifestation of that damage makes it difficult to diagnose these conditions at an early stage of progression. In their early stages during which degenerative alterations of cerebral autoregulation have begun accumulating and interplaying with the flow of blood and nutrients into the brain, brain tumors can occur at any age, producing initial symptoms of headache, nausea, or sudden vomiting without apparent cause. As the tumor progresses, the patient may experience disturbances of vision, hearing, and smell, loss of coordination, changes in mental status, weakness, and paralysis. Seizures sometimes are caused by a tumor. See also Glioma; meningioma.

**brainwashing** n. a broad class of intense and often coercive tactics intended to produce profound changes in attitudes, beliefs, and emotions. Targets of such tactics have typically been prisoners of war and members of religious cults. See also PSYCHOLOGICAL KIDNAPPING.

**brainwave entrainment** the natural synchronization of brain waves to a frequency or rhythm presented via music or some other environmental stimulus (e.g., noise). Some researchers believe that brainwave entrainment can be used to induce changes in mood.

**brain waves** spontaneous, rhythmic electrical impulses emanating from different areas of the brain. Electroencephalographic brain-wave recordings are used to study SLEEP STAGES and cognitive processes. According to their frequencies, brain waves are classified as ALPHA
brain-wave therapy

WAVES (8–12 Hz), BETA WAVES (13–30 Hz), DELTA WAVES (1–3 Hz), GAMMA WAVES (31–80 Hz), or THETA WAVES (4–7 Hz). The first substantial account of brain waves was given in 1929 by German neuropsychiatrist Hans Berger (1873–1944).

brain-wave therapy an alternative or adjunctive therapy in which ALPHA WAVES and THETA WAVES are stimulated because they are posited to have a vital role in learning and memory and, hence, in therapeutic INSIGHT.

brain weight the weight of a brain, which is about 1,450 g for a young adult human. Brain weights for elephants and whales may exceed 7,000 g and 9,000 g, respectively. Human brain sizes usually increase until around the age of 20, then gradually diminish. Brain weight correlates significantly (on average, r = 0.4) with intelligence. See also BRAIN GROWTH.

branching n. 1. a form of PROGRAMMED INSTRUCTION that provides additional steps, or branches, to be followed if the standard teaching material has not been adequately mastered to a given level of proficiency. Correct and incorrect answers lead to branches of new material so that students complete different sequences depending on how well they perform. Also called branching program. 2. in linguistics, a method of analyzing the formal structure of a sentence by representing it diagrammatically as a treelike structure with an organized hierarchy of branches and subbranches. In PHRASE-STRUCTURE GRAMMAR, a tree diagram of this kind (also known as a phrase marker) is often used to illustrate the set of phrase-structure rules that generates a particular grammatical sentence: The diagram so produced will also be a CONSTITUENT analysis of the sentence in question. Branches of branching have been used in predicting psycholinguistic phenomena and in creating LINGUISTIC TYPOLOGIES.

Brandeis brief a summary presented to the U.S. Supreme Court in the case of Muller v. Oregon in 1908 that outlined the damaging effects on women of long working hours. It is considered to be one of the first examples of a legal brief that relies on extensive documentation of social science research in its argument. [Louis Dembitz Brandeis (1856–1941), U.S. Supreme Court justice]

branding n. the process of creating a clear identity for a product, service, or organization through marketing strategies that include TRADEMARKS, packaging, and messaging that seek to underscore significant differences between the branded entity and the offerings of competitors. The goal of branding is to attract and retain loyal customers.

brand name the unique identifier that characterizes a product as belonging to a particular manufacturer or distributor. Examples are Starbucks coffee and Nike athletic shoes. Brand names enable consumers to differentiate between many products that serve the same function. A particular brand name may carry expectations of value, reliability, service, and perhaps status for the user. See also GREEN BRAND.

brand-use survey a survey in which consumers are interviewed to determine whether or not they purchased a particular brand of product that was featured in a specific advertising appeal. The brand-use survey may be accompanied by use of the PANTRY-CHECK TECHNIQUE to validate results of the survey.

Brattleboro rat a rat that has a mutation in the gene for VASOPRESSIN that prevents the animal from producing functional hormone. Brattleboro rats show symptoms of DIABETES INSIPIDUS.

bravery n. see COURAGE.

Brawner rule see AMERICAN LAW INSTITUTE MODEL PENAL CODE INSANITY TEST.

Brazelon Neonatal Behavioral Assessment Scale an instrument used in both research and clinical settings to assess the neurological and behavioral status of newborns and infants up to 2 months old, as indicated by their responses to various stimuli (a light directed to the eye, a moving ball, a rattle, etc.). The Brazelton scale currently contains 14 neurologically and 26 behaviorally oriented items; the former are graded on a 4-point scale of intensity of response, and the latter on a 9-point scale. Originally developed in 1973, the scale was revised in 2000. Also called Neonatal Behavioral Assessment Scale (NBAS). [Thomas Berry Brazelon (1918– ), U.S. pediatrician]

BRCA1 and BRCA2 the first two major genes found to be associated with susceptibility to breast and ovarian cancer. Cloned respectively in 1994 and 1995, BRCA1 and BRCA2 were the first major cancer genes for which widespread genetic testing was done; within several years, direct screening became available. The risk of breast cancer in women with mutations in one of these genes ranges from 56% to 85%, and this type of breast cancer tends to occur at a younger age than do most other types. Risk of ovarian cancer is also greatly increased. BRCA2 mutations are also associated with increased rates of male breast cancer, although these rates remain low (around 1% of all breast cancers). Because of incomplete PENETRANCE of these genes, a small percentage of mutation CARRIERS never develop breast, ovarian, or associated cancers. See also RISK PERCEPTION.

breadth-first search a GRAPH search strategy that considers states in a graph recursively: If the present state is not the goal state, then its sibling state is considered. If this sibling is not the goal state, then its sibling is considered. If there are no more siblings, then the first child of the first state is considered. This process continues until either a goal state is found or there are no further states to examine. States, their siblings, and their children are usually considered in a left-to-right format. Breadth-first search is often organized by a "queue" or "first-in-first-out" data structure.

breakthrough n. 1. a significant, sometimes sudden, forward step in therapy, especially after an unproductive plateau. 2. a major or significant advance in knowledge, research, or treatment.

breast n. the human mammary (milk-producing) gland, consisting of milk-secreting cells and their ducts, fat cells, and connective tissue. Enlarged breasts in adult females are a characteristic of the human species that is not shared by other mammals; it may result from SEXUAL SELECTION. Enlarged breasts also may occur in human males (see GYNECOMASTIA).

breast envy in the psychoanalytic theory of Melanie KLEIN, the idea that infants envy the nourishing capacity and creative power of the mother’s breast. Such envy may later be transformed into PENIS ENVY.

breast-feeding see NURSING.

breast-phantom phenomenon the illusion that an amputated breast is still present, often manifested as a tin-
brief group therapy group psychotherapy conducted on a short-term (time- or session-limited) or CRISIS-INTER-

brief intensive group cognitive behavior therapy a form of COGNITIVE BEHAVIOR THERAPY conducted in a

brief psychotic disorder in DSM–IV–TR and DSM–5, a disturbance involving the sudden onset of at least one psychotic symptom (e.g., incoherence, delusions, hallucinations, or grossly disorganized or catatonic behavior). The condition is often accompanied by emotional turmoil and lasts from 1 day to 1 month, with complete remission of all symptoms and a full return to previous levels of functioning. It may develop following a period of extreme stress, such as the loss of a loved one. Formerly called brief reactive psychosis.

brief stimulus therapy (BST) ELECTROCONVULSIVE THERAPY (ECT) in which the electric current is modified

briefing n. the mechanism for ventilating the lungs, consisting of cycles of alternate inhalation and exhalation. See also HYPERVENTILATION; INSPIRATION–EXPIRATION RATIO; RESPIRATION.

breathing-related sleep disorder in DSM–IV–TR, a primary SLEEP DISORDER marked by excessive sleepiness or insomnia arising from sleep disruption due to breathing difficulties during sleep, for example, SLEEP APNEA. In DSM–5, the classification refers to three specific disorders: obstructive sleep apnea hypopnea (characterized by episodes of absent or reduced breathing during sleep and by daytime sleepiness); central sleep apnea (repeated episodes of absent or reduced breathing caused by variability in respiratory control during sleep); and sleep-related hypoventilation (decreased respiration during sleep). See DYSSOMNIA.

breathing retraining a technique used in BEHAVIOR THERAPY and COGNITIVE BEHAVIOR THERAPY, particularly in the treatment of hyperventilation in panic and other anxiety disorders. The technique teaches clients slow diaphragmatic breathing through various methods, including therapist modeling and corrective feedback. See also PROGRESSIVE RELAXATION; STRESS MANAGEMENT.

breathwork n. see REBIRTHING.

breathy voice a type of PHONATION in which the vocal cords vibrate as in normal voicing, but the glottal closure is absent or reduced breathing caused by variability in respiratory control during sleep); and

breeding behavior see MATING BEHAVIOR: SEXUAL BEHAVIOR.

breed n. a subtype within a SPECIES sharing certain characteristics that are distinct from other members of the species. German shepherds and Chihuahuas, for example, are different breeds of dogs. The term is typically used for variations that have been induced through selective breeding, as distinguished from subspecies, which are naturally occurring variations within a species.

breeding behavior see MATING BEHAVIOR: SEXUAL BEHAVIOR.

bregma n. the location on the top of the skull that marks the junction of the sutures (immovable joints) between the FRONTAL bone and the two parietal bones (forming the sides of the skull). It is used as a landmark for stereotactic and other procedures (see STEREOTAXY).

bride price in some cultures, a payment to the bride’s family made by the future husband or his family. Also called bridewealth. Compare Dowry.

bridge to reality see REMOTIVATION.

bridging n. a method used in MULTIMODAL THERAPY in which the therapist first focuses on the client’s preferred aspect of treatment (e.g., cognitions) before moving to another aspect (e.g., sensations) that the therapist believes may be more salient.
Brief Visuospatial Memory Test

...ment than occurs with the standard treatment (see ECT-INDUCED AMNESIA). Also called brief stimuli therapy: brief stimulus technique.

Brief Visuospatial Memory Test a measure designed to assess learning, storage, and retention of repeated visual information. In three successive LEARNING TRIALS, the examinee is shown the same six geometric figures and then asked to draw them from memory. In a 25-minute DELAYED RECALL trial that follows, the examinee is again asked to draw the figures from memory. There are six different forms to enable repeat testing.

bright light therapy see PHOTOTHERAPY.

brightness n. the perceptual correlate of light intensity. The brightness of a stimulus depends on its amplitude (energy), wavelength, the ADAPTATION state of the observer, and the nature of any surrounding or intervening stimuli. See LUMINANCE; BRIGHTNESS CONTRAST.

brightness adaptation an apparent decrease in the intensity of a stimulus after exposure to a high level of incident illumination. For example, the inside of a house appears very dim to someone coming in from a snow-covered garden.

brightness constancy the tendency to perceive a familiar object as having the same brightness under different conditions of illumination. For example, a piece of white paper has a similar brightness in daylight as it does at dusk, even though the energy it reflects may be quite different. Brightness constancy is one of the PERCEPTUAL CONSTANCIES. Also called lightness constancy. See also COLOR CONSTANCY; OBJECT CONSTANCY.

brightness contrast the apparent enhanced difference in brightness resulting from simultaneous stimulation by two stimuli of differing brightness. For example, a gray disk looks darker on a white background than on a black background. Also called lightness contrast.

brightness discrimination the ability to distinguish differences in brightness. This appears to vary according to the wavelength of light.

brightness perception the ability to form impressions about the light intensity of a stimulus. See BRIGHTNESS; BRIGHTNESS ADAPTATION; BRIGHTNESS CONTRAST.

brightness threshold the minimum light intensity of a designated wavelength that can be detected against a surrounding field.

brilliance n. a visual quality related to BRIGHTNESS but with an added dimension of salience (see salient). Brilliant stimuli are not just bright. They seem to radiate brightness. —brilliant adj.

bril scale a decibel (dB) scale used to measure the perceived brightness of stimuli, developed from DIRECT SCALING methods. In which 0 dB approximates the ABSOLUTE THRESHOLD. A bril is a unit of LUMINANCE representing the brightness perceived by a typical observer when the brightness is 40 dB above the 0 dB reference level; it is equivalent to one hundredth of a millilambert.

Briquet’s syndrome a former name for SOMATIZATION DISORDER. [Paul Briquet (1796–1881), French physician, who provided the first systematic description of its characteristics in 1859]

Brisaud’s infantilism a developmental anomaly in which infantile mental and physical characteristics continue past puberty. The condition is due to the result of faulty functioning of the thyroid gland. Also called infantile myxedema. Brissaud–Meige syndrome. [Edouard Brissaud (1852–1909) and Henry Meige (1866–1940), French physicians]

British associationism see ASSOCIATIONISM.

British Manual Alphabet see FINGERSPELLING.

British Museum algorithm a problem-solving strategy in which all possible solutions are tried one by one, beginning with those involving the fewest steps. It is so named from the facetious idea that, given enough time, an army of monkeys banging on typewriters would eventually write all the books in the British Museum. See ALGORITHM. See also BRUTE FORCE; EXHAUSTIVE SEARCH.

British Psychological Society (BPS) a professional organization, founded in 1901, that is the representative body for psychologists and psychology in the United Kingdom. By royal charter, it is charged with national responsibility for the development, promotion, and application of psychology for the public good.

broadband n. any of a number of transmission media with very high bit-rate capacity, including fiber optics, cable modems, and wireless networks, that enable the transmission of multiple signals to computers at rates of tens of millions of bits per second.

broadband noise see NOISE.

Broca’s aphasia one of eight classically identified APHASIAS, characterized by nonfluent conversational speech and slow, halting speech production. Auditory comprehension is relatively good for everyday conversation, but there is considerable difficulty with complex syntax or multistep commands. The ability to write is impaired as well. It is associated with injury to the frontal lobe of the brain (see BROCA’S AREA). Also called expressive aphasia. [Paul Broca]

Broca’s area a region of the posterior portion of the inferior frontal convolution of the cerebral hemisphere that is associated with the production of speech. It is located on the left hemisphere of right-handed and of most left-handed individuals. [discovered in the 1860s and studied and researched by Paul Broca]

Brodmann’s area an area of cerebral cortex characterized by variation in the occurrence and arrangement of cells (see CYTOARCHITECTURE) from that of neighboring areas. These areas are identified by numbers and in many cases have been associated with specific brain functions, such as area 17 (STRIATE CORTEX, or primary visual cortex), areas 18 and 19 (PRESTRIATE CORTEX), area 4 (MOTOR AREA), and area 6 (PREMOTOR AREA). Brodmann’s original map of 1909 identified 47 different cortical areas, but investigators have refined the mapping to identify more than 200 distinctive cortical areas. Also called Brodmann’s cytoarchitectonic area. [Korbinian Brodmann (1868–1918), German neurologist]

brofaromine n. an antidepressant drug that is a reversible MONOAMINE OXIDASE INHIBITOR and relatively selective for MONOAMINE OXIDASE A. It therefore lacks many of the food interactions that limit the use of irreversible, nonselective MAO inhibitors. Brofaromine is not currently available in the United States. European trade name: Consonar.

broken home a single-parent household resulting from the divorce or separation of the parents. The term is now
generally avoided by social scientists as it seems to imply that there is a single standard for families and that those families that do not fit this standard are in some way inadequate or dysfunctional (i.e., broken).

broken sleep see MIDDLE INSOMNIA.

bromazepam n. a BENZODIAZEPINE used for the treatment of anxiety. It has a short to intermediate duration of action (serum HALF-LIFE up to 30 hours) and a slow onset of action due to its low lipid solubility (see BLOOD–BRAIN BARRIER). Bromazepam is not currently available in the United States. Canadian trade name: Lectopam.

bromide n. a class of drugs formerly used as anticonvulsants and as sedatives in the treatment of anxiety. Because of their toxicity and the frequency of adverse side effects, bromides were largely supplanted by phenobarbital in the early 20th century. Bromide intoxication (bromism) was a recognized complication, manifested in early stages by cognitive impairment and emotional disturbances and in later stages by psychosis, coma, and death.

bromocriptine n. a DOPAMINE-RECEPTOR AGONIST used to relieve the symptoms of Parkinson’s disease and, due to its ability to inhibit release of the pituitary hormone PROLACTIN, to treat GALACTORRHEA. It is also used to treat amenorrhea, infertility, prolactin-secreting adenomas, and parkinsonism, including the EXTRAPYRAMIDAL SYMPTOMS induced by conventional antipsychotic agents. U.S. trade name: Parlodel.

bromosis n. see Olfactory reference syndrome.

bronchodilator n. a drug administered to widen the airways in the treatment of asthma, bronchitis, and related respiratory disorders. Bronchodilators include METHYLXANTHINES and SYMPATHOMIMETIC DRUGS.

bronchus n. (pl. bronchi) either one of the two main branches of the windpipe (trachea). —bronchial adj.

brooding compulsion an irresistible drive to mentally review trivial details or ponder abstract concepts as a means of reducing distress or preventing some dreaded event or situation.

brood parasitism a practice in which a female bird lays its eggs in the nest of another species, leaving the other parents to rear its chicks. Both cowbirds and cuckoos display brood parasitism. The parasitic species may eject some of the eggs of the host species, and the young of the parasitic species often hatch earlier and beg more intensively than the surviving host brood, successfully competing for food against the foster parents’ own offspring.

Brooklands experiment an experiment in England that studied the benefits of homelike and family living environments for children with severe intellectual disability, at a time when many such children lived in residential facilities. Sixteen children (average age 7 years; average IQ 25) moved from a residential institution to a large house called Brooklands, together with a staff of nurses, a supervisor, and an educator. A similar group of children stayed at the institution. At follow-up, the children who had moved showed improvement in their ability to use and understand language and in other skills, but the institutional group did not. [reported in 1964 by New Zealand psychologist Jack Tizard (1919–1989), working in England]

brotherliness n. the feeling of human unity or solidarity, as expressed in productive involvement with others, care for their well-being, and concern for society as a whole. According to Erich Fromm, brotherliness represents the ideal resolution of the search for ROOTEDNESS.

brown fat tissue made up of fat cells (see ADIPOCYTE) that is found especially around vital organs in the trunk and around the spinal column in the neck and chest. It is capable of intense metabolic activity to generate heat. See also ADIPOSE TISSUE.

Brown–Forsythe test a statistical method for determining whether there is HOMOGENEITY OF VARIANCE across two or more populations. The test, which uses the absolute values of the deviations of scores from the MEDIAN to calculate variance, is a helpful preliminary step in determining whether the required ASSUMPTIONS have been met for certain statistical procedures, such as ANALYSIS OF VARIANCE. [Morton B. Brown, Canadian-born U.S. statistician; Alan B. Forsythe, U.S. statistician]

Brown–Peterson distractor technique a technique used in memory studies that allows participants a brief period for remembering during which REHEARSAL is minimized. Typically, three items (e.g., words) are presented, after which the participant is asked to count backward for a time (as a DISTRACTOR) before attempting to recall the presented items. It measures forgetting or interference in working memory. [John A. Brown; Lloyd R. Peterson (1922– ) and Margaret Jean Peterson (1930– ), U.S. psychologists]

Brown–Séquard’s syndrome a condition resulting from damage along one side of the spinal cord. It is characterized by a set of symptoms that include loss of the sense of pain and temperature along the opposite side of the body as well as spastic paralysis and loss of vibratory, joint, and tendon sensations on the same side as the lesion. [Charles Brown-Séquard (1817–1894), French neurophysiologist]

Brown–Spearman formula see Spearman–Brown prophecy formula.

Bruce effect the effect of CHEMICAL COMMUNICATION in inducing miscarriage in pregnant females. Exposure to odors from an unfamiliar male within a few days of initial mating can disrupt pregnancy in female rodents. See also Whittcn effect. [described in 1959 by Hilda M. Bruce, 20th-century British endocrinologist]

brucine n. an alkaloid obtained from the Brueca genus of shrubs that is an antagonist at receptor sites for the inhibitory neurotransmitter GLYCINE. Brucine is also found (with strychnine) in NUX VOMICA; it resembles strychnine but is less potent.

Brugsch’s index a system of measuring the chest circumference in anthropometric studies. The procedure involves multiplying the chest circumference by 100 and dividing the result by the height of the individual. [Theodor Brugsch (1827–1894), German physician]

brujeria n. see ROOTWORK.

Brunswick faces simple line drawings of faces in which such parameters as eye separation and height, nose length, and mouth height can be varied. The drawings are used in perceptual research for studies of discrimination and categorization. [Egon Brunswik]

Brunswick ratio a mathematical expression of PERCEPTUAL CONSTANCY as environmental factors vary: \( (P - R)/O - R \), where (in the case of size constancy, for example) \( P = \) perceived size, \( R = \) image size on retina, and \( O = \) objective (i.e., actual) size. [Egon Brunswik]

Brunswik–Wyatt syndrome a familial disorder characterized by intellectual disability and several other anomalies, including an extensive port-wine birthmark, paralysis on the side opposite to the causal lesion, and cerebral tumor. [Thomas Brunswik (1858–1937), British physician]

brute force a problem-solving strategy in which every possible solution to a problem is generated and tested (often by a computer). See ALGORITHM: EXHAUSTIVE SEARCH.

bruxism n. persistent grinding, clenching, or gnashing of teeth, usually during sleep. It can be associated with feelings of tension, anger, frustration, or fear. Also called bruxomania; stridor dentium.

BSM abbreviation for BEHAVIORAL SLEEP MEDICINE.

BSRI abbreviation for BEM SEX ROLE INVENTORY.

BSS abbreviation for BECK SCALE FOR SUICIDE IDEATION.

BST abbreviation for BRIEF STIMULUS THERAPY.

BT abbreviation for BASIC TECHNIQUE.

bubble concept of personal space the theory that an imaginary, private region surrounds a person, serving as a buffer against potential emotional or physical threats and determining the distance to be maintained in communicating with others. The size of the “bubble” varies with different individuals and situations, being smaller, for example, for lovemaking than when conducting business. For most people, it extends from about 0.5 to 1.2 m (18 in to 4 ft) for contact with close friends, from 1.2 to 3.6 m (4 to 12 ft) for business acquaintances, and beyond 3.6 m (12 ft) for strangers. The distance also may vary in different cultures: For example, Americans may back away from Europeans who are perceived as standing too close during conversations. See also BODY BUFFER ZONE; PROXEMICS; TERRITORIALITY.

bubble plot a graphical representation of data that is similar to a SCATTERPLOT but includes an additional third variable whose values are represented by differently sized circles. For example, a researcher might use a bubble plot to show the relationship between income, years of education, and age within a particular profession. The first two variables would be arrayed along the horizontal x-axis and vertical y-axis, respectively, with circles placed in the graph to indicate points of intersecting values; the radius of each circle would correspond to values of age, with larger circles indicating greater age.

buccal adj. relating to the cheeks or the mouth cavity.

buccal intercourse see OROGENTIAL ACTIVITY.

buccal speech a type of PHONATION that does not depend on laryngeal voice generation but rather is produced by shaping an air pocket in the buccal (i.e., oral) cavity.

While the cheeks and upper jaw form a neoglottis (substitute vibrating agent), the tongue remains free to serve as an ARTICULATOR to shape the sound. Compare ESOPHAGEAL SPEECH.

buccinator n. a muscle that compresses the cheek and retracts the angle of the mouth for eating, speaking, and smiling. During mastication, the buccinator helps hold the food between the teeth. In speech, the buccinator compresses air in the mouth and forces it out between the lips.

buccofacial apraxia see APRAXIA.

buccolingual masticatory syndrome (BLM; BLMs) a movement disorder associated with the use of conventional antipsychotic agents and characterized by involuntary movements of the tongue and musculature of the mouth and face. Patients may involuntarily chew, protrude the tongue, or make grimacing or pursing movements of the lips and cheeks. Also called buccal-lingual masticatory syndrome: oral-lingual dyskinesia. See also TARDIVE DYSKINESIA.

BuChE abbreviation for butryrylcholinesterase. See CHOLINESTERASE.

Buddhism n. the nontheistic religion and philosophy founded in India by Siddhartha Gautama (c. 563–c. 483 BCE), known as the Buddha (Sanskrit, Pali, literally: “awakened one”). Buddhism holds that the end toward which one ought to strive is enlightenment, a transformation of consciousness that offers the only escape from the cycle of rebirth. Enlightenment involves the overcoming of desire or craving and is achieved by following an eightfold path: right speech, right action, right livelihood, right effort, right mindfulness, right concentration, right views, and right intentions. The escape from the cycle of rebirth involves the dissolution of individual consciousness into a larger whole, a state referred to as NIRVANA, which represents an end of striving. Sigmund Freud attempted to capture this sense of quiescence in his NIRVANA PRINCIPLE. See also ZEN BUDDHISM. —Buddhist adj., n.

buffer 1. n. an irrelevant item interspersed between others in a test or experiment. For example, a buffer may be a question that is not scored and is introduced only to separate or disguise other items. 2. n. a temporary store in memory. For example, SHORT-TERM MEMORY is a buffer. 3. vb see BUFFERING.

buffering n. 1. the protection against stressful experiences that is afforded by an individual’s social support. 2. in industrial and organizational theory, any practice by which an organization protects its operations from environmental uncertainty, for example, by accruing excess inventory to provide a safety margin. —buffer vb.

bufotenin n. a naturally occurring, mildly hallucinogenic substance found on the skin of a species of toad (genus Bufo) and in plants of the genus Anadenanthera; it is also reported to be a component of the urine of certain patients with schizophrenia. Bufotenin is related chemically to LSD, PSilocin, and DMT. See also HALLUCINOGEN.

buggery n. SODOMY or ANAL INTERCOURSE.

bulb n. 1. a globe-shaped structure, such as the OLFAC TORY BULB, 2. an obsolete name for the MEDULLA OBLONGATA.

bulbar adj. pertaining to a bulb or bulblike structure, such as the eyeball (as in BULBAR RETRACTION REFLEX), but especially the medulla oblongata, as in BULBAR PARALYSIS.
bulbar paralysis a condition arising usually from a defect in the motor portions of the medulla oblongata and involving paralysis of the muscles of the lips, tongue, mouth, pharynx, and larynx, resulting in difficulties in chewing, swallowing, and talking. Causes may include myasthenia gravis, motor neuron disease, or tumor. Also called bulbar palsy: progressive bulbar palsy.

bulbar retraction reflex the reflex retraction of the eyeball and closing of the nictitating membrane in animals when the conjunctiva or cornea is touched.

bulbi xanthomatosis see xanthomatosis.

bulbocavernousus muscle a muscle of the perineum in men and women, which constricts the urethra. It therefore accelerates the passage of urine in both sexes and aids ejaculation in men; in women, it also serves as a weak vaginal sphincter. Also called bulbospongiousus muscle.

bulbocavernous reflex contraction of the bulbocavernousus muscle of the penis in response to stimulation of the head of the penis. Absence of this reflex can indicate spinal shock or impairment of the nerves connecting the penis to the spinal cord.

bulbopontine region the part of the brain consisting of the pons and the portion of the medulla oblongata adjacent to the pons.

bulbospongiousus muscle see bulbocavernousus muscle.

bulbotegmental reticular formation the portion of the reticular formation that passes through the medulla oblongata.

bulbourethral glands a pair of glands in males whose ducts open into the urethra, near the base of the penis. Their secretion contributes to semen. Also called Cowper's glands.

bulimia n. insatiable hunger for food. It may have physiological causes, such as a brain lesion or endocrine disturbance, or be primarily a psychological disorder (see Binge-Eating Disorder; Bulimia Nervosa). See also Hyperbulimia; Hypophagia. —bulimic adj., n.

bulimia nervosa an eating disorder involving recurrent episodes of binge eating (i.e., discrete periods of uncontrolled consumption of abnormally large quantities of food) followed by inappropriate compensatory behaviors (e.g., self-induced vomiting, misuse of laxatives, fasting, excessive exercise). Compare binge-eating disorder.

bulky color the attribute of color when color is a property throughout the volume of the stimulus, as in a colored liquid. Also called volume color. Compare film color; surface color.

bullying n. persistent threatening and aggressive physical behavior or verbal abuse directed toward other people, especially those who are younger, smaller, weaker, or in some other situation of relative disadvantage. Cyberbullying is verbally threatening or harassing behavior conducted through such electronic technology as cell phones, e-mail, and text messaging.

bundle hypothesis the notion that sensory features are “bundled,” or bound together, in conscious experience. [proposed by Max Wertheimer] bundling n. 1. a strategy, often used in marketing and politics, of combining several products or policies in a way that maximizes their appeal. 2. more generally, binding a number of individual items together to form a unit. 3. a former custom, found in various parts of Europe and North America, in which courting couples were permitted to sleep together fully clothed as long as various physical impediments to sexual intercourse were in place.

Bunsen–Roscoe law see BLOCH’S LAW. [Robert Wilhelm Eberhard Bunsen (1811–1899), German chemist; Henry Enfield Roscoe (1833–1915), British chemist]

buphthalmos n. see Congenital Glaucoma.

buprenorphine n. an opioid analgesic that is a partial agonist at mu opioid receptors. It is used for the treatment of moderate to severe pain (U.S. trade name: Buprenex) and also for the management of opioid dependence, for which it is used either alone (U.S. trade name: Subutex) or in combination with naloxone (U.S. trade name: Suboxone).

bupropion n. an amineketone that inhibits reuptake of dopamine, norepinephrine, and serotonin and is commonly prescribed for the treatment of depression. In contrast to SSRIs and SNRIs, bupropion affects dopamine and norepinephrine more than serotonin and is sometimes used in combination with other antidepressants to augment the antidepressant response (see augmentation strategy). It has also been used in the treatment of attention-deficit/hyperactivity disorder and as an adjuvant for behavioral treatment for smoking cessation. U.S. trade names: Wellbutrin; Zypin.

bureaucracy n. 1. a system of administration or organizational structure, often in a government body, that is characterized by standardized rule-bound procedures, specialization of skills, and an elaborate hierarchy. 2. unnecessarily lengthy or complex official procedures resulting in delay, inaction, or inflexibility. —bureaucrat n. —bureaucratic adj.

bureaucratic leader 1. the type of leader whose responsibilities and leadership style are largely determined by the routine procedures required by his or her position in a hierarchical organization, such as a government department. 2. a leader who rigidly adheres to prescribed routine and makes no allowance for extenuating circumstances.

Buridan’s ass an example used to illustrate the difficulty of making decisions based solely on the relative desirability of alternatives. The unfortunate ass in the example starves to death while standing equidistant between two equally appealing haystacks. This image is named for French philosopher Jean Buridan (c. 1300–c. 1358), although he was not the originator of the example. The term may have reference to Buridan’s attempt to find a philosophical middle ground in action theory between strict voluntarism and strict rationalism.

burned out 1. describing an individual who is mentally, emotionally, or physically exhausted or overwhelmed. See burnout. 2. historically describing individuals with chronic schizophrenia who are apathetic and withdrawn and show progressive deterioration, with little hope of significant improvement, personal growth, or adaptive functioning. In this pejorative sense, the term is rarely used today, especially in light of research indicating that individuals with schizophrenia can improve functioning.

burn injuries tissue damage caused by exposure to flame, intense heat without flame (e.g., contact with high-voltage electricity, red-hot metal, or scalding liquids), or ultraviolet radiation. Superficial (or first-degree) burns are
burnout

categorized by redness, swelling, and peeling of the skin; partial-thickness (or second-degree) burns are marked by penetration of damage beyond the skin layer, which can be blistered and dull white to cherry red and streaked with coagulated capillaries; full-thickness (or third-degree) burns damage tissues that are subcutaneous or deeper, including epithelial tissue, nerve endings, and blood vessels; and fourth-degree burns are usually identified by a distinct odor and the appearance of charred flesh. Because of sometimes excruciating pain and cosmetic damage, severe burn injuries are often mentally traumatic, and psychological help is recommended along with medical treatment.

breathe n. physical, emotional, or mental exhaustion accompanied by decreased motivation, lowered performance, and negative attitudes toward oneself and others. It results from performing at a high level until stress and tension, especially from extreme and prolonged physical or mental exertion or an overburdening workload, take their toll. The word was first used in this sense in 1975 by U.S. psychologist Herbert J. Freudenberger (1926–1999) in referring to workers in clinics with heavy caseloads. Burnout is most often observed in professionals who work in service-oriented vocations (e.g., social workers, teachers, correctional officers) and experience chronic high levels of stress, performance, and negative attitudes toward oneself and others. See also burnout syndrome; vital exhaustion.

burnt adj. denoting one of the primary odor qualities in hennings’s odor prism and in the crocker–henderson odor system.

burst n. a series of responses elicited at a relatively high rate, for example, in a neuron or at the onset of extinction (an extinction burst) when conditioned responses are no longer rewarded.

burst–pause firing an oscillating pattern in which neurons in the thalamocortical system fire in unison, 1 to 4 per second, followed by pauses in which they do not fire. This pattern becomes synchronized throughout much of the brain, producing the large-amplitude electroencephalogram waves characteristic of slow-wave sleep.

Buschke–Fuld Selective Reminding Test see selective reminding test. [Herman Buschke, U.S. physician, and Paula A. Fuld, U.S. psychologist]

business game a teaching method employed in business schools and management or executive training in which individuals or teams compete against one another in solving typical but simulated management, financial, or operational problems. Games are usually played in an online environment that offers the opportunity for feedback on the results of decisions as the game is played. Also called business-simulation game; management-simulation game. See also case method; conference method; multiple-role playing; scenario analysis.

business psychology see industrial and organizational psychology.

business-simulation game see business game.

buspirone n. a nonbenzodiazepine anxiolytic of the aza-pirole class that acts as a partial serotonin agonist at 5-HT₁₉ receptors. Both it and its primary metabolic prod-uct, 6-hydroxybuspirone, produce some relief of subjective symptoms of anxiety without the sedation, behavioral disinhibition, and risk of dependence associated with the benzodiazepines. Its use has been limited, however, due to its relative lack of efficacy compared with benzodiazepines. U.S. trade name: BuSpar.

bust-to-waist ratio a ratio of curvaceousness determined by dividing bust circumference by waist circumference.

butobarbital n. an intermediate-acting barbiturate used in the treatment of insomnia and for daytime and preoperative sedation. Like other barbiturates, it is a nonselective CNS depressant and therefore quite toxic in overdose. Because tolerance to its sedative and hypnotic effects accrues much more rapidly than tolerance to its CNS depressant effects, its therapeutic index drops and its potential lethality increases as the dose is increased. These factors, plus its potential for abuse, have caused a decline in its clinical use. U.S. trade name: Butisol Sodium.

butorphanol n. a synthetic opioid that is an agonist at kappa opioid receptors and a partial agonist–antagonist at mu opioid receptors. It is used clinically for the management of moderate to severe pain, including migraine headaches, and as a preoperative medication. It is available in an injectable preparation and an intranasal spray, but the ease of use of the latter has made it a common drug of abuse. As with other opioid agents, butorphanol may cause respiratory depression, nausea, and dependence. U.S. trade name: Stadol.

butterfly effect the tendency of a complex, dynamic system to be sensitive to initial conditions, so that over time a small cause may have large, unpredictable effects (see sensitive dependence). The term refers to an example in which the fluttering of the wings of a butterfly in one part of the world is seen to contribute to the causation of a tornado in another. The term is used more generally to describe nonlinear causal connections.

butyrophenone n. any of a class of high-potency antipsychotics used primarily in the treatment of schizophrenia, mania, and severe agitation. They are associated with numerous extrapyramidal symptoms, as well as neuroleptic malignant syndrome and tardive dyskinesia. The prototype is haloperidol.

butyrylcholinesterase (BuChE) n. see cholinesterase.

buying behavior the sum total of the mental processes and physical activities associated with the purchase of products or services. The decision to buy a particular product can occur in a number of stages. Recognition of a need for the product is followed by searching for information about it, evaluating alternative products, and finally making a choice. Experience of using the product after purchase will become a factor in deciding whether or not to purchase it (or a similar product) in the future.

B-value n. see metaneeed.

BVRT abbreviation for Benton visual retention test.

BWAS abbreviation for barron–welsh art scale.

B wave of electroretinogram a large, positive electrical wave pattern that is recorded from the eye when the retina is stimulated by light. The electrical response is detected by an electrode placed on the anesthetized surface of the eye. See electroretinography.
BWS abbreviation for BATTERED-WOMAN SYNDROME.

**bystander effect** a phenomenon in which people fail to offer needed help in emergencies, especially when other people are present in the same setting. Studies of this tendency, initially described in response to well-publicized failures of bystanders to render aid in emergencies, have identified a number of psychological and interpersonal processes that inhibit helping, including misinterpreting other people’s lack of response as an indication that help is not needed, CONFUSION OF RESPONSIBILITY, and DIFFUSION OF RESPONSIBILITY.
CA 1. abbreviation for COCAINE ANONYMOUS. 2. abbreviation for CHRONOLOGICAL AGE.

CA1, CA2, CA3, and CA4 see HIPPOCAMPUS.

ciaapi n. see AYAHUASCA.

CAB abbreviation for COOLIDGE ASSESSMENT BATTERY.

CABG abbreviation for CORONARY ARTERY BYPASS GRAFT.

cable properties the physical properties of an axon such that a small, nonpropagated electrical disturbance spreads and diminishes exponentially with distance, as along a nonorganic cable. The resistance properties of the conductor determine the rate at which the signal degrades.

cable tensiometry a method of measuring muscular strength in which the participant pulls on a cable and the change in the tension of the cable is measured with a tensiometer. See also ERCOGRAPH.

 cachexia n. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.

cafeína a. an extreme state of poor health, physical wasting, and malnutrition, usually associated with chronic illnesses, such as cancer and pulmonary tuberculosis.

caco- (cac-) combining form bad or unpleasant.

cacoethes n. an irresistible, and sometimes irrational, desire or compulsion.

caesarean section see CESAREAN SECTION.

cafard n. a CULTURE-BOUND SYNDROME found in Polynesia, with symptoms similar to those of amok. Also called ca-thard.

Cafergot n. a trade name for ERGOTAMINE.
calcium-deficiency disorders conditions caused by insufficient levels of calcium in the tissues. Absorption of calcium from food and its deposition in bone is facilitated by vitamin D, and deficiency of this vitamin is the usual cause of rickets, a disease of childhood marked by deformed bones and teeth and lax muscles, and osteomalacia, the adult form of rickets. Osteoporosis, in which the bones become brittle and break easily, is caused by resorption (loss) of calcified bone due to disease or aging (it is common in postmenopausal women). Tetany (muscle spasms) is due to a deficiency of calcium in the blood.

calcium regulation the maintenance of calcium levels in the blood and other extracellular fluids. Secretion of parathyroid hormone by the parathyroid glands causes release of ionic calcium from the bones, whereas calcitonin, produced by the thyroid gland, promotes calcium resorption.

calendar age see chronological age.

calendar calculation the rare ability to identify the day of the week for any given date, such as February 19, 1878, in a matter of seconds. Calendar calculators are frequently savants who usually have no evident mathematical ability but may be able to perform other feats with the calendar, such as correctly answering the question, “In what years did April 16 fall on a Sunday?” No satisfactory explanation has been found for this skill. See also idiot savant.

calibration n. the process of assigning values to a measuring device (instrument, test, or scale) relative to a reference standard. For example, it would be useful to compare the scores on a new test of intelligence with those from an older, well-accepte test to ensure that the new test scores provide comparable ratings or values. To do so, a researcher might select a group of people (the calibration sample), administer each individual both the old and new tests, and then assess the results.

California Achievement Tests (CAT) an achievement test battery developed by the California Test Bureau to assess the basic skills of students in kindergarten through 12th grade. Now in its sixth edition and called Terra Nova CAT, it consists of various multiple-choice subtests across 13 levels (K–12) and six thinking-process categories (gathering information, organizing information, analyzing information, generating ideas, synthesizing elements, evaluating outcomes). Among the academic areas covered (at appropriate levels) are reading, language, spelling, mathematics, study skills, science, and social studies. It was originally published in 1943 as a revision of the now obsolete 1933 Progressive Achievement Tests, which were also developed by the California Test Bureau.

California Psychological Inventory (CPI) a self-report inventory designed to evaluate adult and adolescent personality characteristics, interpersonal behavior, and social interaction. It consists of 434 true–false statements (a 260-statement short form is also available) that produce scores on 20 scales divided into four measurement classes: (a) poise, ascendancy, self-assurance, and interpersonal adequacy; (b) socialization, responsibility, intrapersonal values, and character; (c) achievement potential and intellectual efficacy; and (d) intellectual and interest modes.

Originally published in 1957, the CPI is now in its third edition (published in 1996). Also called California Psychological Inventory Test. [devised by U.S. psychologist Harrison G. Gough (1921– ) at the University of California, Berkeley]
term maintenance has proven difficult to achieve among humans.

calorie (symbol: cal) n. the amount of energy required to raise the temperature of 1 g of water by 1 °C. For most purposes, the calorie (a c.g.s. unit) has been replaced by the SI unit of work and energy, the joule: 1 cal = 4.1868 J. However, the energy values of foods are sometimes still expressed in kilocalories (or Calories [Cal]: 1 Cal = 1,000 cal).

Calvinism n. a form of Protestant Christianity based on the teachings of French-born reformer John Calvin (1509–1564, also known as Jean Cauvin). He taught that God will grant salvation only to those who are predestined to receive it as an unmerited gift, the rest of humanity being predestined to damnation. Humans therefore can do nothing to save themselves and have no free will. See PREDESTINATION.

CAM 1. abbreviation for CELL ADHESION MOLECULE. 2. abbreviation for COMPLEMENTARY AND ALTERNATIVE MEDICINE.

camaraderie n. comradeship: goodwill and light-hearted rapport between friends or members of a social group, especially of a military unit. Camaraderie is an important component of the morale, unit cohesion, and esprit de corps required in forming and sustaining unit dynamics. It can also serve as a buffer in protecting members of a unit.

camisole n. see STRAITJACKET.

camouflage n. the use of cryptic coloration and vocal signals that are difficult to localize in order to conceal one’s location (see CRYPTESIS). Many nonhuman animal species use camouflage to escape the notice of predators or to avoid detection by prey. For example, a stick insect looks like an actual stick in its environment, allowing it to blend in. Camouflage ALARM CALLS have acoustic features that make it difficult to determine the caller’s location. See also COUNTERSHADING. Compare ADVERTISEMENT.

cAMP abbreviation for CYCLIC AMP.

camphoraceous adj. denoting one of the seven classes of odorants in the STEREOCHEMICAL SMELL THEORY.

camphorated tincture of opium n. see PAREGORIC.

Campral n. a trade name for ACAMPROSATE.

camptocormia n. a condition in which the back is bent forward at a sharp angle (30°–90°). In some cases, it may be a rare manifestation of CONVERSION DISORDER and may be accompanied by back pain, tremors, or both. It is also occasionally seen in Parkinson’s disease.

campus crisis center a campus organization created to provide support and advice for students experiencing personal difficulty or trauma in their school, college, or university. Substance abuse, rape, depression, academic failure, and suicidal tendencies are typical of the problems or traumas encountered by students. A campus crisis center may offer such services as counseling, a hotline, or an escort service for students returning to housing late at night.

Canadian Psychological Association (CPA) a professional organization representing psychologists in Canada, organized in 1939 and incorporated in 1950. Its objectives are to lead, advance, and promote psychology as a science and profession for the benefit of humanity; to provide leadership in psychology in Canada; to promote the advancement, dissemination, and application of psychological knowledge; and to develop standards and ethical principles for education, training, science, and practice in psychology.

canalization n. 1. in evolutionary genetics, the containment of variation of certain characters within narrow bounds so that expression of underlying genetic variation is repressed. It is a developmental mechanism that maintains a constant PHENOTYPE over a range of different environments in which the organism might normally occur. 2. in neuroscience, the hypothetical process by which repeated use of a neural pathway leads to greater ease of transmission of impulses and hence its establishment as permanent. 3. in psychology, the channeling by an organism of its needs into fixed patterns of gratification, for example, food or recreational preferences.

cancellation test a test of perceptual and motor speed requiring the participant to cancel out randomly scattered symbols on a page or screen.

cancer n. any one of a group of diseases characterized by the unregulated, abnormal growth of cells to form malignant tumors (see NEOPLASM), which invade neighboring tissues; the abnormal cells are generally capable of spreading via the bloodstream or lymphatic system to other body areas or organs by the process of METASTASIS. Causes of cancer are numerous but commonly include viruses, environmental toxins, diet, and inherited genetic variations. Cancers are generally classified as carcinomas if they involve the EPITHELIUM (e.g., cancers of the lungs, stomach, or skin) and sarcomas if the affected tissues are connective (e.g., bone, muscle, or fat). More than 150 different kinds of cancer have been identified in humans, based on cell types, rate of growth, and other factors. Because cancers can be disfiguring and life threatening, psychological counseling is often helpful for patients. —cancerous adj.

cancer phobia a persistent and irrational fear of cancer, which may be a symptom of OBSESSIVE-COMPULSIVE DISORDER or GENERALIZED ANXIETY DISORDER; it may also be classified as a SPECIFIC PHOBIA, other type. The belief that one actually has cancer based on a misinterpretation of bodily symptoms is classified as HYPOCHONDRIASIS.

candidiasis n. infection caused by yeastlike fungi of the genus Candida, especially the species Candida albicans. These fungi are part of the normal flora of the mouth, skin, intestinal tract, and vagina but under certain circumstances can cause a variety of infections. Candidiasis commonly affects the mouth, skin folds, and vagina. Less commonly, but more seriously, Candida can cause systemic infection leading to septicemia, endocarditis, meningitis, or osteomyelitis. Such serious infections are more common in individuals who are weakened or immunocompromised, such as those with AIDS. Candidiasis was formerly called moniliasis.

can-do factors see WILL-DO FACTORS.

cane n. an aid for sitting, standing, or MOBILITY for people with visual impairment or other disabilities. Canes for individuals with neuromuscular disabilities, often called orthopedic canes, are usually sturdy shafts of solid wood or metal designed for weight bearing, with a curved or horizontal handle at the top, a rubber tip at the bottom, and sometimes three or four feet. Canes for individuals with visual impairment generally are slimmer, lighter, longer, made of metal, and used for orientation. See ORIENTATION AND MOBILITY TRAINING.
cannabinoid (CB) n. a CANNABINOID that lacks the psychoactive properties of delta-9-TETRAHYDROCANNABINOL (THC) but shares its anti-inflammatory and other medical properties. Its potential roles in the management of a wide range of medical conditions are being studied.

cannabinoid n. any of a class of about 60 substances in the CANNABIS plant that includes those responsible for the psychoactive properties of the plant. The most important cannabinoid is TETRAHYDROCANNABINOL.

cannabinoid receptor any of a family of specialized molecules in cell membranes that bind with CANNABIS-based compounds and similar bodily created substances (i.e., with CANNABINOIDS and ENDOGENOUS CANNABINOIDS, respectively). There are two known types: CB1 receptors, first identified in 1988 by U.S. pharmacologists Allyn C. Howlett and William A. Devane and located primarily within the brain and spinal cord; and CB2 receptors, located primarily within the spleen and other tissues of the immune system. Findings from recent research indicate the existence of other types of cannabinoid receptors (e.g., GPR55), but their characteristics have yet to be completely elucidated. Both CB1 and CB2 receptors are coupled to G PROTEINS, which affect levels of SECOND MESSAGERS that act to open or close certain ION CHANNELS.

CB1 receptors are the most prolific G-protein-coupled receptors in the central nervous system and are concentrated particularly within the hippocampus, cerebellum, and basal ganglia, areas of the brain related to motor control, learning and memory, emotional responses, motivated behavior, and homeostasis. Their activation by endogenous cannabinoids causes short- or long-term suppression of NEUROTRANSMITTER release by neighboring neurons, leading to pain reduction, smooth muscle relaxation, suppression of nausea and vomiting, enhanced appetite, reduced intraocular pressure, and a variety of other physiological and behavioral effects. Additionally, the CB1 receptor is responsible for the psychoactive and psychomotor effects of plant-based cannabinoids, and it has been implicated in the rewarding aspects associated with the use of such drugs as alcohol, cocaine, methamphetamine, and heroin.

In contrast, activation of CB2 receptors produces immunosuppressive, anti-inflammatory, and antiinflammatory effects. Given this wide range of activity, efforts are ongoing to develop synthetic cannabinoid receptor agonists and antagonists for therapeutic purposes.

cannabis n. any of three related plant species (Cannabis sativa, C. indica, or C. ruderalis) whose dried flowering or fruiting tops or leaves are widely used as a recreational drug, known as MARIJUANA. The principal psychoactive agent in these plants, delta-9-TETRAHYDROCANNABINOL (THC), is concentrated in the resin, most of which is in the plants’ flowering tops. When smoked, THC is rapidly absorbed into the blood and almost immediately distributed to the brain, causing the rapid onset of subjective effects that last 2 to 3 hours. These effects include a sense of euphoria or well-being, easy laughter, perceptual distortions, impairment of concentration and short-term memory, and craving for food. Adverse effects of anxiety or panic are not uncommon, and hallucinations may occur with high doses (see also CANNABIS-INDUCED PSYCHOTIC DISORDER; CANNABIS INTOXICATION). Tolerance to the effects of THC develops with repeated use, and a withdrawal syndrome has been identified. The most potent marijuana preparation is HASHISH, which consists of pure resin. A less potent preparation is sinsemilla, also called GANJA; it is made from the plants’ flowering tops. The weakest preparation is Bhang. Also called hemp.

cannabis abuse in DSM–IV–TR, a pattern of cannabis use marked by recurrent significant adverse consequences related to its repeated ingestion. This diagnosis is preempted by the diagnosis of CANNABIS DEPENDENCE: If the criteria for cannabis abuse and cannabis dependence are both met, only the latter diagnosis is given. In DSM–5, both have been subsumed into a category labeled cannabis use disorder and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

cannabis dependence in DSM–IV–TR, continued use of cannabis despite significant cannabis-related cognitive, behavioral, and physiological problems and tolerance or withdrawal symptoms (chilidng motior agitation) if use is suspended. The diagnosis, along with that for CANNABIS ABUSE, has been subsumed in DSM–5 under cannabis use disorder, and neither is considered a distinct entity any longer. See also SUBSTANCE DEPENDENCE.

cannabis-induced psychotic disorder a rare disorder marked by persecutory delusions associated with CANNABIS INTOXICATION, sometimes accompanied by marked anxiety, emotional lability, depersonalization, and subsequent amnesia for the episode. The disorder usually remits within a day, although it may persist for a few days. Hallucinations occur rarely. Also called CANNABIS PSYCHOSIS.

cannabis intoxication in DSM–IV–TR and DSM–5, a reversible syndrome that occurs during or shortly after the ingestion or smoking of cannabis. It consists of clinically significant behavioral or psychological changes (e.g., enhanced sense of well-being, intensification of perceptions, a sense of slowed time), as well as one or more signs of physiological involvement (e.g., increased pulse rate, conjunctivitis, dry mouth and throat). See also SUBSTANCE INTOXICATION.

cannabis psychosis see CANNABIS-INDUCED PSYCHOTIC DISORDER.

cannibalism n. 1. the consumption of human flesh by humans. See also KURE. 2. a pathological urge to devour human flesh, occasionally observed in schizophrenia and similar mental disturbances, such as WINDSOCK PSYCHOSIS. In classical psychoanalytic theory, cannibalistic impulses are associated with fixation at the ORAL-BITING PHASE of psychosexual development. 3. the ingestion by a nonhuman animal of a member of its own species. Some female insects kill their mate at the time of copulation and eat it as a source of protein for developing eggs. In some animal species, offspring are eaten, often in times of nutritional stress or when offspring are malformed and unlikely to survive. —cannibalistic adj.

Cannon–Bard theory the theory that emotional states result from the influence of lower brain centers (the hypothalamus and thalamus) on higher ones (the cortex), rather than from sensory feedback to the brain produced by peripheral internal organs and voluntary musculature. According to this theory, the thalamus controls the experience of emotion, and the hypothalamus controls the expression of emotion, both of which occur simultaneously. Also called Bard–Cannon theory: Cannon's theory: hypothalamic theory of Cannon: thalamic theory of Cannon. See also FIGHT-OR-FIGHT RESPONSE. [proposed in the 1920s and early 1930s by Walter B. CANNON and Philip Bard (1898–1977), U.S. physiologist]

cannula n. a tube that can be inserted into a body cavity
to provide a channel for the escape of fluid from the cavity. It can also be inserted into a blood vessel to introduce substances into the body to avoid repeated injections by a hypodermic needle or to take blood samples.

canon n. a fundamental working principle or rule believed to increase the likelihood of making accurate inferences and meaningful discoveries. —canonical adj.

canonical analysis any of a class of statistical procedures that assess the degree of relationship between sets of variables via interpretation of a limited number of linear combinations of specific values of those variables. The overall objective of such procedures is to reduce the dimensionality of the data under investigation. Examples include CANONICAL CORRELATION ANALYSIS, DISCRIMINANT ANALYSIS, MULTIPLE REGRESSION, and MULTIVARIATE ANALYSIS OF VARIANCE, among others.

canonical correlation analysis a method of data analysis that provides a measure of the strength of the relationship between a linear combination of predictor variables and a linear combination of outcome measures. Essentially, it extends a basic CORRELATION ANALYSIS, which relates only one variable with another variable, and it extends MULTIPLE REGRESSION, which relates several independent variables with only one dependent variable. For example, a researcher might use a canonical correlation analysis to investigate whether several measures of attitude toward learning (e.g., confidence, anxiety, interest, enjoyment) are related to several measures of achievement (e.g., grade-point average, the number of math classes taken, the number of memberships in honor societies).

canonical correlation coefficient (symbol: \( R_{c} \)) an index of the magnitude of the linear relationship between a linear combination of one set of variables and a linear combination of a different set of variables, with each linear combination made in such a way as to maximize the strength of the relationship between the two variable sets. It ranges in value from −1 to +1.

capability n. 1. the possession of able qualities. 2. an ability, talent, or facility that a person can put to constructive use. For example, a child may have great musical capability. 3. a characteristic that can be developed for functional use.

capacity n. 1. the maximum ability of an individual to receive or retain information and knowledge or to function in mental or physical tasks. 2. the potential of an individual for intellectual or creative development or accomplishment. 3. inborn potential, as contrasted with developed potential (see ability).

capacity model one of a number of models that characterize attention as a finite resource with limited processing power. Attentional deficits occur when the demands on this resource exceed the supply.

capacity sharing in DUAL-TASK PERFORMANCE, the dividing of attentional resources between the tasks such that they are processed in parallel (see PARALLEL PROCESSING), although the processing efficiency varies with the amount of resources required.

CAPD abbreviation for CENTRAL AUDITORY PROCESSING DISORDER.

Capgras syndrome a condition characterized by an individual’s delusional belief that loved ones (e.g., spouse, children, parents) have been replaced by doubles or impostors. This type of MISIDENTIFICATION SYNDROME may be associated with paranoid schizophrenia, a neurological disorder, or a mood disorder. Also called ILLUSION OF DOUBLES. [first described in 1923 by Jean Marie Joseph Capgras (1873–1950), French psychiatrist]

capitalism n. an economic system emphasizing individual enterprise, free-market principles, profit taking, and private or corporate ownership of capital, rather than state control of the economy as in socialism or communism. —capitalist n., adj.

capitalization n. the process by which people take advantage of and build on positive events in their lives. Capitalization is most often studied in social contexts, in which people share news of their personal good fortune with others for various social purposes, such as to heighten enjoyment of the experience, to create a positive impression in others’ eyes, or to enhance the memorability of the event. It is often contrasted with SOCIAL SUPPORT as a means of coping with negative events.

capitalization on chance drawing a conclusion from data wholly or partly biased in a particular direction by chance. A common example of capitalization on chance is the presentation of all the significant results in a study without considering the number of results examined.

capitation n. a method of payment for health care services in which a provider or health care facility is paid a fixed amount for each person served under a risk contract. Capitation is the characteristic payment method of HMOs. —capitated adj.

caprylic adj. denoting one of the four primary odor qualities in the CROCKER–HENDERSON ODOR SYSTEM. This quality is called hircine in the ZWAARDEMAKER SMELL SYSTEM.

capsaicin n. a compound, synthesized by various plants to deter predators, that elicits the sensation of burning. Capsaicin is responsible for the “hot” taste of chili peppers. It is used medicinally in topical ointments to relieve peripheral neuropathy.

captioning n. the display of the text of spoken words, typically used in theaters, on television (see CLOSED-CAPTIONED TELEVISION), and in films, to allow those with hearing loss to follow verbal presentations or dramatic dialogue and action.

captivity n. 1. the state or period of being confined, detained, incarcerated, imprisoned, or enslaved. See also POSTCAPTIVITY HEALTH PROBLEMS; PRISONER OF WAR. 2. the state of a nonhuman animal that is housed in an environment different from its natural environment and is prevented from returning to its natural environment. Much research is done on animals in captivity in order to have careful experimental control over environmental and social variables. Compare FIELD RESEARCH.

capture–tag–recapture sampling a method of sampling that is used to estimate population size. For example, to estimate the number of fish in a lake, a random sample of fish (e.g., 100) would be drawn and tagged, then returned to the lake. The lake would be resampled, and the results (i.e., the fraction of tagged fish in the new sample) would be used to estimate the total number of fish in the lake. Also called capture–recapture sampling: mark–and-recapture sampling.

CAR abbreviation for CONDITIONED AVOIDANCE RESPONSE.

carbamate n. any of a class of acetylcholinesterase inhibitors (see CHOLINESTERASE) used in the treatment of de-
mentia. Carbamates can delay the progression of certain dementias, slowing declines in cognitive function and in activities of daily living. They are preferred to earlier generations of acetylcholinesterase inhibitors because of their relatively benign side effects, relative lack of liver toxicity, and improved dosing schedule (they need to be administered only once or twice a day). An example is rivastigmine.

carbamazepine (CBZ) n. a drug that is related to the TRICYCLIC ANTIDEPRESSANTS but used mainly as an ANTI-CONVULSANT. It is used also for the relief of symptoms of TRIGEMINAL NEURALGIA and as a MOOD STABILIZER in mania. U.S. trade name (among others): Tegretol.

carbidopa n. see SINEMET.

carbohydrate n. any of a group of organic compounds that have the general formula C_n(H_2O)_y. They range from relatively small molecules, such as simple sugars (e.g., GLUCOSE), to macromolecular substances, such as starch, glycogen, and cellulose. Carbohydrates of plant origin form a major source of energy in the diet of animals.

carbohydrate metabolism the utilization by the body of starches, sugars, and other CARBOHYDRATES, which are broken down by various enzymes to GLUCOSE molecules. Glucose is the ultimate source of cellular energy for the brain and other organs.

carbon dioxide (formula: CO_2) a colorless, odorless, incombustible gas formed during respiration, decomposition of organic substances, and combustion. All life on earth is carbon based. The increasing CO_2 concentration in the atmosphere is considered to be a main cause of global warming.

carbon dioxide therapy a form of inhalation therapy, now no longer in use, that was occasionally applied (in conjunction with psychotherapy) to patients with anxiety, conversion, or psychophysiological symptoms. [first used in the 1920s by Hungarian-born U.S. psychiatrist Ladislaus Joseph Meduna (1896–1964) to induce unconsciousness as a means of interrupting pathological brain circuits]

carbonic anhydrase inhibitor any of a group of drugs that interfere with the action of the enzyme carbonic anhydrase in the body. Although their primary role was originally as diuretics, via their ability to block reabsorption of sodium bicarbonate from the proximal renal tubule, thus improving urine excretion and electrolyte balance, their use has been supplanted by less toxic diuretics. At present, acetazolamide (the prototype; U.S. trade name: Diamox) and other carbonic anhydrase inhibitors are used primarily for the management of glaucoma and acute mountain sickness. The drugs are also used as adjunctive agents in the management of epilepsy. Acetazolamide inhibits epileptic seizures and decreases the rate of cerebrospinal fluid formation.

carbon monoxide poisoning a toxic disorder resulting from inhalation of carbon monoxide, a colorless, odorless gas. Depending on the severity of the exposure, symptoms, which are produced by lack of oxygen, range from headache and light-headedness to an acute, transient state of confusion and delirium to deep coma followed by permanent brain damage and death by asphyxiation. Also called carbon monoxide intoxication.

carbon tetrachloride a volatile industrial solvent that, when inhaled, can produce euphoria, disorientation and depersonalization, and other behavioral effects similar to those produced by the major sedatives. Continued use can lead to the rapid development of persisting dementia, as well as severe physical problems and death. Due to its adverse health effects and because it is known to deplete the ozone layer, carbon tetrachloride is no longer in common use. See also INHALANT.

carcinogen n. any substance that initiates the development of CANCER (carcinogenesis) when exposed to living tissue. Tobacco smoke, which induces lung cancer, is an example. —carcinogenic adj.

carcinoma n. see CANCER.

cardi- combining form see CARDIO-.

cardiac death see BRAIN DEATH.

cardiac index a measure of the cardiac output (i.e., the volume of blood pumped by the heart per minute) per square meter of body surface.

cardiac muscle the specialized muscle tissue of the heart. It consists of striated fibers that branch and interlock and are in electrical continuity with each other. This arrangement permits ACTION POTENTIALS to spread rapidly from cell to cell, allowing large groups of cells to contract in unison. Compare SKELETAL MUSCLE SMOOTH MUSCLE.

cardiac neurosis an anxiety reaction precipitated by a heart condition, the suspicion of having a heart condition, or the fear of developing coronary disease. In some cases, a cardiac neurosis develops when the patient detects a heart murmur, palpitations, or a chest pain due to emotional stress. In other cases, it may be caused or aggravated by a physician’s examination (see IATROGENIC). Cardiac anxiety is a common symptom of PANIC DISORDER; it may also be a focus in HYPochondriasis.

cardiac pacemaker an electrical device that is surgically implanted into the chest to regulate an abnormal heart rhythm. Electrical leads from the device are placed in specific areas of the heart, and transducers can monitor the heart’s rate of contraction and deliver an electric charge only when the organ is not functioning as desired.

cardiac psychology an emerging subspecialty of BEHAVIORAL MEDICINE that studies how behavioral, emotional, and social factors influence the development, progression, and treatment of CORONARY HEART DISEASE (CHD). Among the psychosocial factors that have been linked to the onset and exacerbation of CHD are anger, hostility (see TYPE A PERSONALITY), anxiety, depression, psychological stress, job stress, and social isolation or lack of social support. Contextual factors, including socioeconomic status and ethnicity, may contribute to CHD as well. These variables influence the disease’s development both directly by damaging the cardiovascular system through alterations of physiological functioning (e.g., high levels of stress hormones, exaggerated CARDIOVASCULAR REACTIVITY) and indirectly by facilitating unhealthy practices such as cigarette smoking, lack of exercise, and poor diet. In addition to researching the causal relationships between psychosocial factors and cardiovascular disease, cardiac psychologists design interventions to prevent the disease or improve the prognosis and quality of life of those who already have it. These interventions focus on the nonphysical aspects of adopting and maintaining healthier lifestyles. For example, cardiac psychologists often provide information about CHD, teach constructive coping strategies (e.g., relaxation skills, time management skills, stress management skills), and conduct individual and group therapy to
cardinal

address illness-related and mental health issues. Also called behavioral cardiology: psychocardiology.

cardinal adj. describing a number that indicates a count of a set of items, such as two dogs or three circles, but does not indicate order within the set. A child’s understanding of the concept of cardinal numbers is an area of study in developmental psychology. Compare nominal, ordinal.

cardinal disposition see personal disposition.

cardinal humors see humoral theory.

cardinality n. the number of items in a set. In children, the ability to understand that the last number counted in a set represents the set’s overall cardinal value is evident by the age of 2 or 3.

cardinal virtues in medieval philosophy, the four virtues on which all other virtues were thought to hinge, namely, prudence, courage, temperance, and justice. The cardinal or “natural” virtues were seen as available to all humans without the aid of divine grace; as such they were often contrasted with the “theological” virtues of faith, hope, and charity.

cardio- (cardi-combining form heart.

cardiogram n. a graphic tracing of some aspect of heart activity, usually electrical activity (see electrocardiogram). The tracing is produced by the stylet of a recording instrument called a cardiograph, and the procedure itself is called cardiography.

cardiomyopathy n. any disease involving the heart muscle, particularly when the specific cause is uncertain.

cardiophobia n. an excessive and irrational fear of the heart or, more commonly, of having or developing heart disease. See cardiac neurosis.

cardiopulmonary bypass machine a mechanical device that carries out the functions of the heart and lungs for short periods during surgery involving these organs. The machine collects blood from the veins before it reaches the heart and circulates it through a plastic chamber in which it is freshly oxygenated before being pumped back into the patient’s arteries.

cardiovascular (CV) adj. relating to the heart and blood vessels or to blood circulation.

cardiovascular disease any disease, congenital or acquired, that affects the heart and blood vessels. Cardiovascular diseases include hypertension, congestive heart failure, myocardial infarction, arteriosclerosis, and coronary heart disease.

cardiovascular reactivity the degree of change of cardiovascular responses (e.g., blood pressure, heart rate) to a psychological or physiological challenge or stressor. Exaggerated cardiovascular reactivity may indicate risk for development of cardiovascular conditions, such as hypertension or coronary heart disease.

cardiovascular system the heart and blood vessels, which are responsible for the circulation of blood around the body. Also called circulatory system.

card-sorting test a test in which the participant is asked to sort randomly mixed cards into specific categories. Such tests may be used to determine frontal lobe functioning, learning ability, discriminatory powers, or clerical aptitude. See Wisconsin Card Sorting Test.

card-stacking n. a technique of persuasion that attempts to influence opinion through deliberate distortions, as in suppressing information, overemphasizing selected facts, manipulating statistics, and quoting rigged or questionable research.

CARE acronym for communicated authenticity, regard, empathy.

care-and-protection proceedings court intervention on behalf of a child when the parents or caregivers do not adequately provide for the child’s welfare.

career anchor a pattern of self-perceived work skills, interests, abilities, and values that are developed in the early stages of a person’s career and that guide subsequent career decisions. The nine anchors are technical or functional competence, managerial competence, creativity, security, autonomy, entrepreneurship, challenge, lifestyle, and service or dedication to the cause. [proposed by Swissborn U.S. psychologist Edgar H. Schein (1928— ).]

career choice the selection of a vocation, usually on the basis of such factors as parental guidance, vocational guidance, identification with admired figures, trial or part-time jobs, training opportunities, personal interests, and ability tests.

career conference a vocational meeting provided by many schools in which representatives of a given occupational field meet interested students to provide information and answer questions related to the requirements for, and opportunities available in, that field.

career counseling consultation, advice, or guidance specifically focused on a person’s career opportunities, most often provided in educational, work, and some community settings. It also may have the specific goal of enabling a person to change the direction of his or her career. The counseling will take account of an individual’s preferences, intelligence, skill sets, work values, and experience. Such counseling is offered to groups as well as individuals. Also called career guidance.

career development 1. the manner in which a person manages the progress of his or her career, both within and between organizations. The issues that individuals must confront in their career development differ as a function of whether they are in the early, middle, or late stage of their careers. See also professional development. 2. the ways in which an organization structures the career progress of its employees, typically so that they are rewarded with higher levels of pay, status, responsibility, and satisfaction as they gain skills and experience.

career guidance see career counseling.

career planning a vocational guidance program designed to assist a client in choosing an occupation. A realistic appraisal of the individual’s desires and abilities is formulated in relation to existing occupational opportunities. Various tests may be administered to aid a counselor in assessing a client’s skills and aptitudes.

career workshop a vocational guidance intervention consisting of a study group in which occupational opportunities and requirements are discussed and explored.

caregiver n. 1. a person who attends to the needs of and provides assistance to someone else who is not fully independent, such as an infant or an ill adult. A person who does the majority of the work is called the primary caregiver. 2. in health care, any individual involved in the
process of identifying, preventing, or treating an illness or disability. —caregiving adj.

caregiver burden the stress and other psychological symptoms experienced by family members and other nonprofessional caregivers in response to looking after individuals with mental or physical disabilities, disorders, or diseases. See also BURNOUT; COMPASSION FATIGUE.

care of young a manifestation of PARENTAL BEHAVIOR or ALLOPARENTING in animals, usually stimulated by hormonal and other physiological changes when in the presence of offspring. These include the secretion of PROLACTIN, which induces broodiness and parental feeding of young in birds and milk production in mammals.

caretaking behavior the behavior of parents or alloparents (caretakers) in attending to the needs of infants, responding to them when they approach or vocalize and protecting them from the aggression of others. See ALLOPARENTING; CARE OF YOUNG; PARENTAL BEHAVIOR.

carezza (karezza) n. a form of coitus in which the man does not reach orgasm. It is sometimes used as a means of birth control, but if combined with meditation, it is similar to the COITUS RESERVATIS technique. Carezza techniques are derived from principles of Hindu Tantrism and in this sense were first described by U.S. gynecologist Alice B. Stockham (1833–1912) in 1896. Also called coitus protractus.

cargo cult 1. a system of beliefs found in the South Pacific islands, based on the notion that ritual worship will result in the attainment of modern material goods through supernatural means. It originated in indigenous religious practices in the 19th century and was altered, stimulated, and broadened from contact with Western cultures during World War II, when military forces stationed in the islands received regular deliveries of goods by air. 2. the naive assumption that a superficial imitation of the manners, behavior, or style of influential or prosperous groups in society will bring one comparable wealth or status.

carisoprodol n. a drug belonging to the PROPANE DIOLS, a group originally developed as anxiolytics. Carisoprodol is now used as a MUSCLE RELAXANT and is increasingly seen as an intoxicant drug of abuse. U.S. trade name: Soma.

carnal adj. relating to the physical desires and appetites of the body, particularly sexual ones. Carnal knowledge is a mainly legal term for sexual intercourse.

carotid artery either of the two major arteries that ascend the right and left sides of the neck to the head and brain. The branch that enters the brain is the INTERNAL CAROTID ARTERY, whereas the external carotid artery supplies the face and scalp. Both branches arise from the common carotid artery on each side of the lower neck.

carotid sinus a small dilation in the common CAROTID ARTERY at its bifurcation into the external and internal carotids. It contains BARORECEPTORS that, when stimulated, cause slowing of the heart rate, vasodilation, and a fall in blood pressure. It is innervated primarily by the GLOSSOPHARYNGEAL NERVE.

carotid-sinus syndrome see AURIC ARCH SYNDROME.

carotid stenosis see STENOSIS.

carotodynia n. pain in the cheek, neck, and region of the eyes resulting from pressure on the common carotid artery.

carpal age an individual’s ANATOMICAL AGE as estimated from the degree of ossification of the carpal (wrist) bones.

carpal tunnel syndrome (CTS) an inflammatory disorder of the hand caused by repetitive stress, physical injury, or other conditions that cause the tissues around the median nerve to become swollen. It occurs either when the protective lining of the tendons within the carpal tunnel become inflamed and swell or when the ligament that forms the roof of the tunnel becomes thicker and broader. See REPE TITIVE STRAIN INJURY.

carpentered environment an environment consisting of built structures in which rectangles are predominant. Some hypotheses about DEPTH PERCEPTION and OPTICAL ILLUSIONS have suggested that people in carpentered environments interpret parallelograms (or parts of parallelograms) in two-dimensional drawings in ways that are consistent with perception of three-dimensional objects, such as doors, windows, and corners.

Carpenter’s syndrome an autosomal recessive hereditary disorder marked by a pointed skull, webbing of the fingers and toes, subaverage intelligence, and usually obesity. Also called acrocephalopolysyndactyly. [George Alfred Carpenter (1859–1910), British physician]

carphology n. see FLOCCILLATION.

carrier n. 1. an individual with a gene for a recessive trait that is unexpressed in that individual but that may be expressed in offspring if the individual reproduces with another carrier of the same gene. 2. an individual who is infected with a pathogen for a disease and is capable of infecting others but does not develop the disease. 3. an individual who has a mutation in a gene that conveys either increased susceptibility to a disease or other condition or the certainty that the condition will develop. A BRCA1 mutation carrier, for example, is a person who carries an altered BRCA1 gene (see BRCA1 and BRCA2). This alteration is responsible for significantly raising the likelihood that the person, if female, will develop breast or ovarian cancer. See also OBLIGATE CARRIER.

carrier wave see MODULATION.

carryover effect the effect on the current performance of a research participant of the experimental conditions that preceded the current conditions; where such an effect is significant, it may be difficult to determine the specific influence of the variable under study. For example, in a CROSSOVER DESIGN in which a particular drug is administered to nonhuman animals in the first experimental condition, a carryover effect would be evident if the drug continued to exert an influence on the animals’ performance during a subsequent experimental condition. Also called holdover effect. See WASH-OUT PERIOD.

CART analysis classification and regression tree analysis: a method of classifying data into successively smaller and more homogeneous subgroups according to a set of PREDICTOR VARIABLES. CART analysis is similar to but distinct from REGRESSION ANALYSIS in its homogeneity of case subsets. The results of a CART analysis may be displayed in a diagram resembling a tree—subsets of data, based on values of the outcome variable, are shown to branch off from higher level subsets of data.

Cartesian coordinate system a system for locating a point in an n-dimensional space on a graph by indicating the distance of the point from a common origin along each of n axes. The most common application of the Cartesian
Cartesian dualism

system is one based on two dimensions, represented by two perpendicular lines that intersect at a specific spot called the origin. In such a two-dimensional Cartesian coordinate system, the horizontal line is often referred to as the X-AXIS and the vertical line as the Y-AXIS. For example, the coordinate (3, 4) represents an X value of 3 and a Y value of 4 on the graph; thus, from the origin one would count three units over on the x-axis and four units up on the y-axis to locate the coordinate point. [René Descartes]

Cartesian dualism the position taken by René Descartes that the world comprises two distinct and incompatible classes of substance: RES EXTensa, or extended substance, which extends through space; and RES cogitANS, or thinking substance, which has no extension in space. The body (including the brain) is composed of extended and divisible substance, whereas the mind is not. For Descartes, this means that the mind would continue to exist even if the material body did not. He accepted that there is interaction between mind and body, holding that in some activities the mind operates independently of bodily influences, whereas in others the body exerts an influence. Similarly, in some bodily activities there is influence from the mind, whereas in others there is not. Descartes proposed that the locus for the interaction of the mind and body is the point in the pineal gland in the brain termed the CONium. However, to the question of how such incompatible substances can interact at all, Descartes had no answer. See DUALISM; GHOST IN THE MACHINE; MIND–BODY PROBLEM.

Cartesianism n. the system of philosophy developed by René Descartes. The three fundamental tenets of the system are (a) that all knowledge forms a unity; (b) that the purpose of knowledge is to provide humankind with the means of mastery over the natural world; and (c) that all knowledge must be built up from a foundation of indubitable first principles, the truth of which can be known intuitively (see INNATE IDEAS). Many ideas and assumptions influential in psychology can be traced back to Descartes, including the notion of a rational self capable of knowing truth, the contention that the most trustworthy knowledge is of the contents of one’s own mind, and the idea that the deductive methods that have been successful in producing certainty in mathematics can be applied to produce equally valid knowledge in other fields of human endeavor. Of particular importance to the development of psychology are Descartes’ understanding of the ego (see CARTESIAN SELF) and his attempt to explain the relation of the mind to the body (see CARTESIAN DUALISM). See also MODERNISM; RATIONALISM. —Cartesian adj.

Cartesian self in the system of René Descartes, the knowing subject or ego. The Cartesian self is capable of one fundamental certainty because, even if all else is subject to doubt, one cannot seriously doubt that one is thinking, as to doubt is to think. Thus, Descartes concludes, Cogito ergo sum (“I am thinking, therefore I exist”). From this position, Descartes argues that all ideas intuited by the self with the same clarity and distinctness as the cogito must be equally true: this enables the intuition of further indubitable truths, such as the existence of God and the external world. However, since the ideas clearest to the self are the contents of the mind, the notion of the Cartesian self has led to a radical Dualism between the inner life of the mind (subjectivity) and the outer world of things (objectivity). It has also led to the idea that knowledge is necessarily subjective and has opened the question as to how the outer world, including other human beings, can be known except as an idea. See CARTESIAN DUALISM; EGOCENTRIC PREJUDICED SOLIPSISM.

Cartesian theater a metaphorical conception of CONSCIOUSNESS identified as the traditional view by U.S. philosopher Daniel C. Dennett (1942–), who has challenged its adequacy. Based on the idea of the knowing subject or ego defined by René Descartes, the Cartesian theater is envisioned as a place where all aspects of experience come together to provide a unified phenomenal world. See CARTESIAN DUALISM; CARTESIAN SELF.

Carus typology a classification of individuals into five body types: ATHLETIC TYPE, PHELEMATIC TYPE, PHTHIC TYPE, CEREBRAL TYPE, and sterile type. [Carl Gustav Carus (1789–1868), German physiologist and psychologist]

carve out to eliminate coverage for specific health care services (e.g., mental health or substance abuse) from a health care plan and contract for those services from a separate provider. —carve-out n.

Carver and White's BIS/BAS scales a set of self-report scales used to assess an individual’s dispositional sensitivities within the BEHAVIORAL INHIBITION SYSTEM (BIS) and BEHAVIORAL APPROACH SYSTEM (BAS). It comprises a single scale with statements intended to elicit measures of behavioral inhibition and three scales with statements intended to elicit measures of specific aspects of behavioral activation: that is, reward responsiveness, drive, and fun-seeking. Each item is answered using a 4-point Likert scale, ranging from 1 (very true for me) to 4 (very false for me). [developed in 1994 by U.S. psychologists Charles S. Carver (1947–) and Teri L. White (1963–)]

CAS abbreviation for COGNITIVE ASSESSMENT SYSTEM.

Casanova complex a man’s desire to have a large number of lovers, leading to very active pursuit of women and attempts to seduce or entice women into having sexual intercourse without any emotional relationship or commitment. The complex is named for Giovanni Jacopo Casanova (1725–1798), an Italian memorist and adventurer noted for his sexual conquests.

case n. 1. an instance of a disease or disorder, usually at the level of the individual patient. In a borderline case, the symptoms resemble those of a disease or disorder but do not fully meet the criteria. See also PROBAND. 2. a person who is the recipient of assistance (e.g., from a health care professional or lawyer). 3. a unit or observation to be analyzed, such as a nonhuman animal, a person, a group, an institution, an object, or any other entity from which a researcher gathers data. 4. a feature of certain languages in which the forms of nouns, pronouns, and (sometimes) adjectives are altered to indicate their syntactic relations with other words in a sentence. The role of case is most significant in highly inflected languages, such as German or Latin. In English, case endings are now restricted to the personal and possessive pronouns (I, me, mine, etc.) and to plural and possessive nouns (e.g., dogs, children, girl’s, girls’). See ACCUSATIVE; DATIVE; GENITIVE; NOMINATIVE. 5. one of various categories used in CASE GRAMMAR to classify the elements of a sentence in terms of their semantic relations with the main verb. See AGENT; EXPERIENCER; INSTRUMENTAL; PATIENT.

case advocate see ADVOCACY.

case alternation in reading research, a procedure for stimulus presentation in which the characters of stimulus words switch between upper and lower case. The change is
usually made in one of six ways: (a) to the complete word (APPLE/apple), (b) to alternate letters (APple), (c) after the second letter (APple), (d) after the third letter (APPLE), (e) after the fourth letter (APPLE), or (f) after each pair of letters (APpLE).

case-based reasoning 1. an approach in which information about or obtained from previous similar situations (cases) is applied to the current situation, typically to make a decision or prediction or to solve a problem. See also ANALOGICAL THINKING. 2. in ergonomics, the use of detailed scenarios or cases to elicit users’ knowledge, reasoning patterns, motivations, or assumptions regarding a product or system. See KNOWLEDGE ELICITATION.

case-control study a type of study in which a group of individuals diagnosed with a disease or other condition is compared to a group of individuals without the disease diagnosis, specifically with regard to the proportion of people in each group who were exposed to a certain risk factor. Also called case-control design; case-referent study.

case-finding n. the process of identifying individuals who need treatment for mental disorders by administering screening tests, locating individuals who have contacted social agencies or mental health facilities, obtaining referrals from general practitioners, or via triage after a disaster.

case grammar in linguistics, an analysis of sentences that gives primacy to the semantic relations between words (e.g., whether they are the agent or the patient of the action described) rather than to their syntactic relations (e.g., whether they are the subject or the object of the sentence). In the two sentences The boy hit the ball and The ball was hit by the boy, a case-grammar analysis would focus on the fact that boy is the agent of the action in both sentences, rather than the fact that it is the subject of the first sentence and the object in the second. Psychologists have shown a strong interest in case grammar because of its affinity to psychological categories of meaning. See also EXPERIENCER; INSTRUMENTAL.

case history a record of information relating to a person’s psychological or medical condition. Used as an aid to diagnosis and treatment, a case history usually contains test results, interviews, professional evaluations, and sociological, occupational, and educational data. Also called patient history.

case law a body of law established by a series of court decisions. Case law is distinguished from laws that arise from case decisions. Case law is distinguished from laws that arise from case decisions. Case law is distinguished from laws that arise from case decisions. Case law is distinguished from laws that arise from case decisions. Case law is distinguished from laws that arise from case decisions.

case load the amount of work required of a psychotherapist, psychiatrist, doctor, social worker, or counselor during a particular period, as computed by the number of clients assigned to him or her and the comparative difficulty of their cases.

case management a system of managing and coordinating the delivery of health care in order to improve the continuity and quality of care and to reduce costs. Case management is usually a function of a hospital’s utilization review department.

case manager a health care professional, usually a nurse or social worker, who works with patients, providers, and health insurance plans to coordinate the continuity and cost-effectiveness of services.

case method in industrial and organizational psychology, a personnel training technique in which a group of managers or supervisors are presented with an actual or hypothetical business problem, through written materials, audiovisual media, or live role play, and are required to generate solutions. See also BUSINESS GAME; CONFERENCE METHOD; MULTIPLE-ROLE PLAYING; SCENARIO ANALYSIS.

case report a collection of data relating to a person’s psychological or medical condition.

case study an in-depth investigation of a single individual, family, event, or other entity. Multiple types of data (psychological, physiological, biographical, environmental) are assembled, for example, to understand an individual’s background, relationships, and behavior. Although case studies allow for intensive analysis of an issue, they are limited in the extent to which their findings may be generalized.

casewise deletion see LISTWISE DELETION.

casework n. the tasks carried out by a professional, usually a social worker known as a caseworker, that include identifying and assessing the needs of an individual and his or her family and providing or coordinating and monitoring the provision of such services as private counseling, treatment in a hospital or other institution, or arranging for public assistance, housing, and other aid. Also called social casework.

Caspar Hauser experiment any procedure in which an animal is deprived of its natural environment or sensory stimulation from birth onward. The experiment is named for an early 19th-century German child (c. 1812–1833) who allegedly was raised in this manner.

cassina n. a perennial evergreen shrub, Ilex vomitoria, that grows wild in eastern North America, particularly Virginia and the Carolinas. The leaves contain caffeine and have been used by Native Americans to prepare a tea-like beverage known as the “black drink” for medicinal, ceremonial, and social purposes. Also called yaupon; youpon.

caste n. 1. any of the fixed hereditary classes of the Hindu caste system, which are held to be distinguished by different levels of essential purity. The main classes are (in order of status) brahmans or priests, warriors, merchants, and laborers; outcastes or untouchables are people of no caste. Until recently, mobility or intermarriage between castes was exceptional. See also FIXED CLASS SOCIETY; HINDUISM; SOCIAL IMMOBILITY. 2. any system of social stratification regarded as being comparably rigid. 3. any class of society distinguished by inherited privilege and exclusivity.

castration n. surgical removal of the testes (see ORCHIDECTOMY); less commonly, it can indicate removal of the ovaries (see OVARIECTOMY). In either men or women, inactivation of these glands can also occur from radiation, illness, or drugs (see CHEMICAL CASTRATION).

castration anxiety fear of injury to or loss of the genitals. In the PREGNITAL PHASE posited by Freudian psychoanalytic theory, the various losses and deprivations experienced by the infant boy may give rise to the fear that he will also lose his penis.

castration complex in Freudian psychoanalytic theory, the whole combination of the child’s unconscious feelings and fantasies associated with being deprived of the phallicus, which in boys means the loss of the penis and in girls the belief that it has already been removed. It derives from the discovery that girls have no penis and is closely tied to the OEDIPUS COMPLEX.

casual crowd a group that forms, usually in a public
place, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

CAT 1. abbreviation for CALIFORNIA ACHIEVEMENT TESTS. 2. abbreviation for CHILDREN’S APPRECIATION TEST. 3. abbreviation for the British version of the COGNITIVE ABILITIES TEST. 4. abbreviation for COMPUTER ADAPTIVE TESTING. 5. acronym for computerized axial tomography (see COMPUTED TOMOGRAPHY).

cata- (cat-: kata-: kat-) combining form 1. down or beneath (e.g., catabolism). 2. reversal or degeneration (e.g., CATATONIA).

catabolism n. see METABOLISM. —catabolic adj.

catabolite n. a product of catabolism (see METABOLISM).

catalyzed by a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is often observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

catalepsy n. a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

catalyst n. a substance that increases the rate of a chemical reaction without itself being used up. An enzyme is an organic catalyst.

catatonia n. a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

---

**CAT**

1. abbreviation for CALIFORNIA ACHIEVEMENT TESTS. 2. abbreviation for CHILDREN’S APPRECIATION TEST. 3. abbreviation for the British version of the COGNITIVE ABILITIES TEST. 4. abbreviation for COMPUTER ADAPTIVE TESTING. 5. acronym for computerized axial tomography (see COMPUTED TOMOGRAPHY).

cata- (cat-: kata-: kat-) combining form 1. down or beneath (e.g., catabolism). 2. reversal or degeneration (e.g., CATATONIA).

catabolism n. see METABOLISM. —catabolic adj.

catabolite n. a product of catabolism (see METABOLISM).

catalyzed by a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is often observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

catalepsy n. a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.

catalyst n. a substance that increases the rate of a chemical reaction without itself being used up. An enzyme is an organic catalyst.

catatonia n. a state of sustained unresponsiveness in which a fixed body posture or physical attitude is maintained over a long period of time. It is observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building. It is often observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building. It is observed with catatonic schizophrenia, when circumstances cause those present to share a temporary focus. Examples include passersby pausing to watch two people arguing loudly and spectators gathered behind police barricades around a burning building.
rare subtype of schizophrenia characterized by abnormal motor activity, specifically motor immobility (see CATALEPSY; CATATONIC STUPOR) or excessive motor activity (see CATATONIC EXCITEMENT). Other common features include extreme NEGATIVISM (apparently motiveless resistance to all instructions or maintenance of a rigid posture against attempts to be moved) or MUTISM; peculiarities of voluntary movement, such as POSTURING or stereotyped movements; and ECHOLALLA or ECHOPRAXIA. This subtype has been eliminated from DSM–5.

catatonie state see CATATONIA.

catatonie stupor a state of significantly decreased reactivity to environmental stimuli and events and reduced spontaneous movement, often as a symptom of CATATONIC SCHIZOPHRENIA.

catchment area the geographic area served by a health care program (e.g., a community mental health center).

catch trial a trial within an experiment in which a stimulus is not present but the participants’ responses nonetheless are recorded. For example, in an experiment in which participants identify auditory signals, catch trials are those in which no signal is given. The use of a catch trial may help to estimate the level at which a participant is guessing when no stimulus is present. See also BLANK TRIAL.

cat-cry syndrome see CRI DU CHAT SYNDROME.

catecholamine n. any of a class of BIgenic AMINES formed by a catechol molecule and an amine group. Derived from tyrosine, catecholamines include dopamine, epinephrine, and norepinephrine, which are the predominant neurotransmitters in the SYMPATHETIC NERVOUS SYSTEM.

catecholamine hypothesis the hypothesis that deficiencies in the catecholamine neurotransmitters norepinephrine, epinephrine, and dopamine at receptor sites in the brain lead to a state of physiological and psychological depression, and that an excess of such neurotransmitters at these sites is responsible for the production of mania. The catecholamine hypothesis underlay the development of the early tricyclic antidepressants in the late 1950s, as it had been known that these compounds inhibited the reuptake of norepinephrine into presynaptic neurons. Despite numerous shortcomings, the catecholamine hypothesis, and the related MONOAMINE HYPOTHESIS, became the dominant hypotheses in the biological treatment of depression in the last half of the 20th century.

catecholaminergic adj. responding to, releasing, or otherwise involving CATECHOLAMINES. For example, a catecholaminergic neuron is one that releases norepinephrine or another catecholamine as a neurotransmitter.

catechol-O-methyltransferase (COMT) n. an enzyme, found at synapses of neurons, that deactivates CATECHOLAMINES.

categorical adj. referring to a characteristic that is used to classify units, usually individuals or experimental conditions, for the purposes of study. For example, participants may be classified as males or females in a particular study; in this case, sex is categorical.

categorical attitude see ABSTRACT ATTITUDE.

categorical classification see CONCEPTUAL CLASSIFICATION.

categorical data information that consists of counts or observations in specific categories rather than measurements. Categorical data that have a meaningful order are referred to more specifically as ORDINAL DATA, whereas categorical data without a meaningful order are known as NOMINAL DATA.

categorical data analysis any of several statistical procedures used to model variables that indicate counts or observations in specific categories, often as a function of one or more predictor variables. For example, counts of survival status (e.g., life vs. death) may be compared by treatment condition (e.g., treatment vs. no treatment). Techniques commonly used in categorical data analysis include the CHI-SQUARE TEST, LOGISTIC REGRESSION, and PROBIT ANALYSIS.

categorical imperative the moral directive articulated by Immanuel Kant that one’s behavior should be guided by maxims that one would be comfortable to hold as universal laws governing the actions of all people in the same circumstances. Because it is absolute and unconditional, the categorical imperative contrasts with a HYPOTHETICAL IMPERATIVE of the type “If you would achieve end Y, take action Z.” The categorical imperative has been extremely influential in moral philosophy and in theories of moral behavior in psychology. See also UNIVERSALIZABILITY.

categorical intrusion in a memory recall test, the recall by the participant of one or more items that were not presented for memorization but are from the same semantic category (e.g., names, animals, foods) as the presented items. See CATEGORIZED LIST; DEESE–ROEDGER–MCDERMOTT PARADIGM.

categorical perception in speech perception, the phenomenon in which a continuous acoustic dimension, such as VOICE-ONSET TIME, is perceived as having distinct categories with sharp discontinuities at certain points. Whereas discrimination is much more accurate between categories, individuals tested are often unable to discriminate between acoustically different stimuli that fall within the same categorical boundaries. Categorical perception is crucial in the identification of PHONEMES.

categorical scale a sequence of numbers that identifies items as belonging to mutually exclusive categories. For example, a categorical scale for the political party affiliation of a group of Americans might use 1 to denote Republican, 2 to denote Democrat, and 3 to denote Independent. When the number sequence has a meaningful order a categorical scale is more precisely called an ORDINAL SCALE; when it is devoid of such meaningful order it is known as a NOMINAL SCALE.

categorical thought in PIAGETIAN THEORY, thinking that involves the use of general concepts and classifications (i.e., ABSTRACT THINKING). It is particularly lacking in young children, who tend to think concretely (see CONCRETE THINKING).

categorical variable a variable that is defined by a set of two or more categories. Examples include a person’s sex, marital status, or rankings of particular stimuli (such as the relative loudness of different sounds). Specialized methods of CATEGORICAL DATA ANALYSIS are available for assessing information obtained from the measurement of categorical variables.

categories of thought in the thought of Immanuel Kant, 12 basic concepts of human understanding that are essential to the interpretation of empirical experience. These include such fundamental ideas as unity, plurality, reality, negation, causality, and so on. Although they are
categorization

necessary to the understanding of sense experience, the categories are themselves A PRIORI rather than empirically given. Time and space play a similar role in ordering one’s sense impressions but are classed by Kant as immediate intuitions rather than categories of thought. The categories are applicable only to the world of appearances or PHENOMENA; there is no reason to suppose that they apply to things-in-themselves (see NOUmenON).

categorization n. the process by which objects, events, people, or experiences are grouped into classes on the basis of (a) characteristics shared by members of the same class and (b) features distinguishing the members of one class from those of another. Theories of categorization include the prototype model, exemplar theory, and the family resemblance hypothesis. Also called classification. See also ABSTRACTION; CONCEPTUALIZATION. —categorize vb.

categorized list a list used in memory experiments in which the items come from one or more semantic categories (e.g., names, animals, foods). Categorized lists are often used to test free recall: the category labels (animals, foods, etc.) may be used to prompt recall.

category fluency see SEMANTIC FLUENCY.

category production test a test in which participants are given a category (e.g., types of birds) and asked to list examples of it (e.g., robin, blue jay, ostrich). It is often classified as a verbal CONCEPTUAL TEST of implicit memory. See IMPPLICIT MEMORY TEST.

category-system method any method of measurement or classification assessment that involves sorting data elements into categories according to a set of rules. See also INTERACTION PROCESS ANALYSIS; SYMLOG.

Category Test a nonverbal problem-solving task that requires abstract reasoning, concept formation, and mental flexibility. The participant is presented with six subtests each comprising a different set of stimuli organized according to a specific principle and each stimulus within each set being associated with a particular number. The participant must respond by choosing a number and, using feedback about response accuracy, determine the principle of organization underlying the set of stimuli within a particular subtest. Once the principle is correctly identified, the participant can solve each item correctly within the subtest. A final subtest contains items from the previous six. The Category Test is part of the HALSTEAD–REITAN NEUROPSYCHOLOGICAL BATTERY. Also called Halstead Category Test. [designed in 1947 by U.S. psychologist Ward C. Halstead (1908–1969)]

cathard n. see CAFARD.

catharsis n. 1. in psychoanalytic theory, the discharge of previously repressed affects connected to traumatic events that occurs when these events are brought back into consciousness and reexperienced. See also ABreaction. 2. more generally, the release of strong, pent-up emotions. [from Greek, literally: “purge”] —cathartic adj.

cathected adj. see CATHEXIS.

Cathartic discharge see AFFECTIVE DISCHARGE.

catheter n. any flexible tubular instrument inserted into a body cavity to introduce or remove fluids or to keep a body passage open. A catheter may be indwelling, if required for a long period of time, or temporary.

Cathexis n. in psychoanalytic theory, the investment of psychic energy in an object of any kind, such as a wish, fantasy, person, goal, idea, social group, or the self. Such objects are said to be cathected when an individual attaches emotional significance (positive or negative AFFECT) to them. See also ANTICATHEXIS; DICATHEXIS; HYPERCATHEXIS; OBJECT CATHEXIS.

cathanone n. see KHAT.

cation n. a positively charged ion, such as a potassium ion (K+) or sodium ion (Na+). Compare ANION. —caticonic adj.

catoptrics n. the field of optics concerned with the reflection of light. Compare DIOPTRICS.

Cat’s-eye syndrome a rare genetic disorder caused when an individual inherits extra genetic material from chromosome 22 (see ACROCENTRIC CHROMOSOME), with widely variable features that include structural defects of the iris of the eye that produce a cat’s-eye appearance, skin tags near the ear, narrowing or closure of the anus, defects of the heart or kidneys, and intellectual disability. Also called Schmid–Fraccaro syndrome.

Cattell–Horn theory of intelligence a theory proposing that there are two main kinds of intellectual abilities nested under general intelligence: g-c, or CRYSTALLIZED intelligence (or ability), which is the sum of one’s knowledge and is measured by tests of vocabulary, general information, and so forth; and g-f, or FLUID intelligence (or ability), which is the set of mental processes that is used in dealing with relatively novel tasks and is used in the acquisition of g-c. In later versions of the theory, other abilities were added, such as g-v, or visual intelligence (or ability), which is the set of mental processes used in handling visual-spatial tasks (e.g., mentally rotating a geometric figure or visualizing what pieces of paper would look like if folded). [originated by Raymond B. CATTELL in the 1940s; subsequently developed by U.S. psychologist John L. Horn (1928–2006) beginning in the 1960s]

Cattell’s personality trait theory an approach to personality description based on the identification of traits through FACTOR ANALYSIS and their classification into SURFACE TRAITS and the 16 SOURCE TRAITS that underlie them. [Raymond B. CATTELL]

cauda equina the bundle of nerve roots at the base of the spinal cord, so called because of its resemblance to a horse’s tail.

caudal adj. 1. pertaining to a tail. 2. situated at or toward the tail end of an organism. Compare ROSTRAL.

caudate nucleus one of the BASAL GLANGLIA, so named because it has a long extension, or tail.

causal ambiguity a situation in which it is not known which one (or which set) of several phenomena is the cause of a particular effect. Sometimes the ambiguity attaches to the more complex question of which phenomena are causes and which are effects (see REVERSE CAUSALITY). Controlled empirical research is often used to resolve issues of causal ambiguity.

causal analysis an attempt to draw dependable inferences about cause-and-effect relationships from research data. Encompassing a variety of methods (e.g., PATH ANALYSIS, STRUCTURAL EQUATION MODELING), such analyses differ in the degree to which they are statistically complex and the degree to which causal inferences from them are, in fact, justified.
causal attribution see attribution.

causal chain a sequence of conditions or events, either hypothetical or empirically derived, that results in a particular effect. Explanation in terms of causal chains presumes that causation is transitive (see transitivity). Also called causal path.

causal pathway n. a sensation of intense, burning pain resulting from injury to the peripheral nerves. The condition is most often due to a penetrating wound inflicted by a bullet or knife and involves swelling, redness, and sweating in addition to almost unbearable pain.

causal inference the reasoned process of concluding that change in one variable produced change in another variable. See causal analysis.

causality n. in philosophy, the position that all events have causes, that is, that they are consequences of antecedent events. Traditionally, causality has been seen as an essential assumption of naturalism and all scientific explanation, although some have questioned whether causality is a necessary assumption of science. Others have suggested that, although causality must be assumed, there are different types of causality, each of which makes different metaphysical assumptions about the nature of the world and adopts different criteria about what types of relationships between phenomena can be considered as legitimately causal. See also causation; determinism.
—causal adj.

causal latency 1. the temporal separation of a cause from its effect. Not all causes need have immediate effects; indeed, there may be a lengthy interval between a cause and the effect it produces. Causal latency may be expected to increase when there are other factors in a situation that may influence the cause-and-effect relationship. Some causes studied in psychology and the other social sciences are remote causes, in that they require the presence or activity of other factors or conditions before their effects become manifest. Remote causes may be expected to have large causal latencies. See delayed effect. 2. in the statistical procedure known as path analysis, the quality of a variable that has a measurable statistical effect on prediction only when other predictor variables are also included in the prediction model. Although the statistical relationships identified in such analyses are not, strictly speaking, causal, the language of causality is commonly employed. See causal path.

causal law a statement of a consistent or invariant relationship between phenomena in which the relationship is one of causation. A causal law is thus distinguished from other statements of invariant regularity, such as "In temperate climates, when the seasons change, the leaves turn color." Causal laws may reflect different types of causality, ranging from strict determinism, through probabilism, to teleology. Sometimes, in superficial usage, causal laws are understood not as mere statements of consistent relationships but as metaphysical entities or forces that produce the effects that consistently accrue. In such usage, a causal law becomes indistinguishable from a cause.

causal mechanism the most immediate and physical means by which something is accomplished. For example, the causal mechanism for opening a door is the turning of the knob and the exertion of pressure on the door. The discovery of causal mechanism does not resolve questions of causation, as there may well be other latent or remote causes. Nor does the recognition of a causal mechanism imply that the world is inherently mechanical. For example, although a mechanism is required for opening a door, the ultimate cause may be a nonmechanical intention to leave the room. See also mechanical causality: proximate cause.

causal modeling any procedure used to test for cause-and-effect relationships (as opposed to mere correlation) between multiple variables. Structural equation modeling is the best known example. For a causal model to be a useful evaluative tool, strict conditions concerning the measurement of the variables must be met.

causal nexus a nexus or connection between phenomena that is one of causation. See causal chain.

causal ordering 1. the principle that causes must temporally precede their effects, and never vice versa. See also false cause; reverse causality. 2. in path analysis and similar statistical procedures, the categorizing of causal variables as either more or less direct.

causal pathway 1. see causal chain. 2. in path analysis and similar statistical procedures, a relatively probable causal sequence among a complex set of potential causes and effects. The analysis is based on first-order and partial correlations among variables indicating possible relations of cause and effect. From the pattern of correlations, conclusions are drawn regarding which set of variables, in which order, represents the most likely path from some presumed cause of interest to some presumed effect of interest.

causal texture the very large number of mutually dependent events that make up the fabric of reality. Those philosophers and psychologists who use this term conceive of the interdependencies among events in terms of probability rather than certainty, in part because such interdependencies change and develop over time. [introduced into psychology by Edward C. Tolman and Egon Brunswik]

causal variable see independent variable.

causation n. 1. the empirical relation between two events, states, or variables such that change in one (the cause) brings about change in the other (the effect). See also causality. 2. in Aristotelian and rationalist philosophy, the hypothetical relation between two phenomena (entities or events), such that one (the cause) either constitutes the necessary and sufficient grounds for the existence of the other (the effect), or the one possesses the capacity to bring about the other. —causal adj.

causative verb a verb that expresses the notion of something being caused, such as convince, harmonize, or enliven. Children’s acquisition of causative concepts is a lively area of developmental research at the intersection of linguistic, cognitive, and social development. See also actional verb.

cause n. 1. an event or state that brings about another (its effect). 2. in Aristotelian and rationalist philosophy, an entity or event that is a requirement for another entity or event’s coming to be. Aristotle proposed that there were four types of cause—material, formal, efficient, and final. In the case of a sculpture, for example, the material cause is the stone or metal from which it is made, the final cause is the sculptor’s aim or purpose in making it. —causal adj.

cause-and-effect test an intelligence test to measure causal reasoning that offers alternative causes for different
cautious shift

effects and alternative effects for different causes, requiring the examinee to choose the most logical explanations.

cautious shift a choice shift in which an individual making a decision as part of a group adopts a more cautious approach than the same individual would have adopted had he or she made the decision alone. Studies suggest that such shifts are (a) rarer than the opposite risky shift and (b) most likely to occur when the majority of the members of the group, prior to discussion, favor a cautious rather than a risky choice. See also group polarization.

CAVLT abbreviation for children’s auditory verbal learning test.

CBAS abbreviation for coaching behavior assessment system.

CBCA abbreviation for criterion-based content analysis.

CBCL abbreviation for child behavior checklist.

CBD abbreviation for cannabinoid.

CBGD abbreviation for corticobasal ganglionic degeneration.

CBT abbreviation for cognitive behavior therapy.

CBZ abbreviation for carbamazepine.

CCCC theory abbreviation for cognitive complexity and control theory.

CCK abbreviation for cholecystokinin.

CCRC abbreviation for continuing care retirement community.

CCRT abbreviation for core conflictual relationship theme.

CCTV system abbreviation for closed-circuit television system.

CCU 1. abbreviation for continuing care unit. 2. abbreviation for critical care unit (see intensive care unit).

CD 1. abbreviation for communication deviance. 2. abbreviation for conduct disorder.

CDC abbreviation for centers for disease control and prevention.

CDF abbreviation for cumulative distribution function.

CDI abbreviation for children’s depression inventory.

CDQ abbreviation for choice dilemma questionnaire.

cebocephaly n. a type of congenital defect in which the eyes are abnormally close to each other, the nose may be missing or not fully formed, and the facial features resemble those of a monkey. In some cases, the defect pattern may include cyclopia. Cebocephaly is associated with chromosomal abnormalities, such as trisomy 13.

CEF1 abbreviation for children’s embedded figures test.

ceiling age the lowest mental age level at which a participant on a standardized test answers all the items incorrectly. The concept of mental ages is used relatively rarely in current testing. Compare basal age.

ceiling effect a situation in which the majority of values obtained for a variable approach the upper limit of the scale used in its measurement. For example, a test whose items are too easy for those taking it would show a ceiling effect because most people would achieve or be close to the highest possible score. In other words, the test scores would exhibit skewness and have little variance, thus prohibiting meaningful analysis of the results. Compare floor effect.

Celexa n. a trade name for citalopram.

celiac plexus 1. in the nervous system, a network of fibers lying anterior to the aorta at the level of the 12th thoracic vertebra. Most autonomic and visceral afferent nerves pass through this plexus. Also called celiac nervous plexus. 2. in the lymphatic system, a network of afferent and efferent lymphatic vessels in the abdomen. Also called celiac lymphatic plexus.

celibacy n. 1. the state of being unmarried, especially as the result of a religious vow. 2. abstinence from sexual activity. See also chastity. —celibate adj.; n.

cell n. 1. in biology, the basic unit of organized tissue, consisting of an outer plasma membrane, the nucleus, and various organelles in a watery fluid together comprising the cytoplasm. Bacteria lack a nucleus and most organelles. The term was first applied to biological structure by English physicist Robert Hooke (1635–1703) when describing the microscopic appearance of cork. See also cell theory. 2. a combination of two or more characteristics represented by the intersection of a row and a column in a statistical table. A tabular display resulting from a study of handedness in men and women, for instance, might consist of four cells: left-handed females, left-handed males, right-handed females, and right-handed males.

cell adhesion molecule (CAM) any of various proteins on cell surfaces that bind cells to each other and to the extracellular matrix. Certain CAMs have roles in cell migration or extension during development, including axonal pathfinding.

cell assembly a group of neurons that are repeatedly active at the same time and develop as a single functional unit, which may become active when any of its constituent neurons is stimulated. This enables, for example, a person to form a complete mental image of an object when only a portion is visible or to recall a memory from a partial cue. Cell assembly is influential in biological theories of learning and memory: [proposed in 1949 by Donald O. Hebb]

cell body the part of a neuron (nerve cell) that contains the nucleus and most organelles. Also called perikaryon. soma. See also axon.

cell–cell interactions the general processes during embryological development in which one cell affects the differentiation of other, usually neighboring, cells. Also called cell interactions.

cell death see programmed cell death.

cell differentiation see differentiation.

cell division the division of a cell to form daughter cells. It usually involves division of the nucleus (see mitosis; meiosis) followed by partitioning of the cytoplasm.

cell interactions see cell–cell interactions.

cell-mediated immunity see immune response.

cell migration the movement of cells during development from their site of origin to their final location.

cell nucleus see nucleus.

cell proliferation the multiplication of cells by mitosis.

166
cell theory the principle that all organisms are composed of one or more CELLS. [proposed in 1839 for animals by German physiologist Theodor Schwann (1810–1882) and for plants by German botanist Matthias Jakob Schleiden (1804–1881)]
cellular automata computer programs used in the study of ARTIFICIAL LIFE. Typically, a display is used on a computer screen, split into an array of cells, with an initial pattern of occupied cells. The pattern evolves through a sequence of steps according to certain rules (e.g., whether or not certain numbers of neighboring cells are occupied). Programs of this type have been used in investigations of such phenomena as social behavior and evolutionary development. [developed in the 1940s by Austrian-born U.S. mathematician John von Neumann (1903–1957)]
cellular fluid see INTRACELLULAR FLUID.
cellular respiration see RESPIRATION.
CEM abbreviation for COLLECTIVE EFFORT MODEL.
cenesthesia (coenesthesia) n. the blend of numerous bodily sensations that produces an implicit awareness of being alive and of being in a particular physical condition, for example, well or ill, energetic or tired. —coenesthetic adj.
cenesthopathy n. a general feeling of illness or lack of well-being that is not identified with any particular part of the body.
ceno- combining form see COENO-.
censor n. in psychoanalytic theory, the mental agency, located in the PRECONSCIOUS, that is responsible for REPRESION. The censor is posited to determine which wishes, thoughts, and ideas may enter consciousness and which must be kept unconscious because they violate one’s conscience or society’s standards or are in conflict with other wishes or perceptions, or because the affect associated with them is disturbing or overwhelming. The censor is also posited to be responsible for the distortion of wishes that occurs in dreams (see DREAM CENSORSHIP). The idea was introduced in the early writings of Sigmund FREUD, who later developed it into the concept of the SUPEREGO. —censorship n.
censored data a set of data in which some values are unknown because they are not observed or because they fall below the minimum or above the maximum value that can be measured by the scale used. For example, in a study of survival rates of a group of people with a particular disease, censored data would be obtained if the deaths of some participants occurred after the study ended.
censored observation a score that is missing from a data set, either because the event of interest has not occurred by the end of the study period or because the response falls into an unmeasurable portion of the scale. A response measured by a meter, for instance, may not be recorded because it is too small to be detected or is so large that it exceeds the meter’s capability to record. In such a situation, the minimum value is assigned to an undetectable observation, and the maximum value is assigned to an excessive observation.
censored regression see TOBIT ANALYSIS.
censoring n. the situation in which some observations are missing from a set of data (see CENSORED DATA). Censoring is common in studies of survival time, in which the research often ends before the event of interest occurs for all study units. See also LEFT CENSORING; RIGHT CENSORING.
census n. the complete count of an entire population. A census differs from most experimental studies, which use a sample from a population in hopes of generalizing from that observed subset to the larger group.
census tract a small, generally homogeneous geographic area with boundaries established to facilitate the collection and reporting of census data. Community demographic data are frequently used in the assessment of the area’s characteristics and needs, including mental health needs. See also CATCHMENT AREA.
cent n. in acoustics, a logarithmic unit used to express frequency ratios. There are 1200 cents in an OCTAVE, and successive notes or intervals on the equally tempered musical scale are separated by 100 cents, or one SEMITONE.
center n. in neurophysiology, a structure or region that controls a particular function, for example, the respiratory center of the brain.
centered adj. 1. describing the state of an organism that is perfectly integrated with its environment. [defined by Kurt GOLDSTEIN] 2. denoting a state of mind characterized by having a firm grip on reality, knowing who one is and what one wants out of life, and being prepared to meet most eventualities in an efficient manner. 3. in a posture for defense or attack, with body balanced and crouching forward.
Center for Deployment Psychology an organization established by the U.S. Department of Defense in 2006 to meet the mental health needs of service members and their families. The center’s primary goal is to make mental health care in the military more relevant, available, and effective by educating behavioral health professionals on the psychological issues associated with military deployments and teaching them the latest evidence-based treatment protocols for service members and their families.
Center for Epidemiologic Studies Depression Scale (CES-D) a 20-item self-administered rating scale that provides a quantitative measure of different depressive feelings and behaviors that an individual may have experienced during the previous week. Scores range from 0 to 60, with a score of 16 or greater indicating the presence of depressive symptoms and suggesting the need for further testing for a possible depressive disorder. [published in 1977 by Lenore Sawyer Rudolf (1915— ) while a researcher at the National Institute of Mental Health]
Center for Independent Living (CIL) see INDEPENDENT LIVING.
centering n. a technique whose aim is to increase and focus attention and energy, to provide relief from stress and anxiety, or both. Various practices (e.g., meditation, yoga) emphasize centering as a way of focusing attention on the process of breathing in order to slow it down or regularize it. Sometimes this state of concentration is an end in itself. In other instances, at the point of concentration, negative thoughts and emotions are released and positive thoughts and emotions are encouraged. In sport psychology, the technique is used by athletes to assist them in achieving an IDEAL PERFORMANCE STATE.
center median the largest of the INTRALAMINAR NUCLEI of the THALAMUS in the brain. Unlike other thalamic nuclei, it has no connections with the cerebral cortex and
communications only with the BASAL GANGLIA. Also called centromedian nucleus.

center of gravity a balance point, that is, the location about which the mass of an object is evenly distributed. The position of the center of gravity of the body relative to the legs determines whether, for example, a standing posture is stable.

Centers for Disease Control and Prevention (CDC) an agency founded in 1946 (now one of the 11 major operating components of the U.S. Department of Health and Human Services) that stands at the forefront of public health efforts to prevent and control infectious and chronic diseases, injuries, workplace hazards, disabilities, and environmental health threats. The CDC works with public health partners, both nationally and internationally, to monitor health, detect and investigate health problems, conduct research to enhance and implement prevention, promote healthy behaviors and safe and healthful environments, and develop and advocate sound public health policies.

Centers for Medicare and Medicaid Services (CMS) a federal government agency within the Department of Health and Human Services that is responsible for the administration of the MEDICARE, MEDICAID, and Children’s Health Insurance programs, formerly known as the Health Care Financing Administration (HCFA). In 2007, the 10 field offices of the CMS were reorganized into a consor-tia framework based on the organization’s primary lines of business: Medicare Health Plans Operations, Financial Management and Fee-for-Service Operations, Medicaid and Children’s Health Operations, and Quality Improvement and Survey and Certification Operations.

center–surround antagonism a characteristic of the receptive fields of many visual and somatosensory neurons in which stimulation in the center of the receptive field evokes opposite responses to stimulation in the periphery. Thus, some neurons depolarize with center stimulation and hyperpolarize when the same stimulus appears in the surrounding region of the receptive field, whereas other neurons have the opposite pattern of responses. Center–surround antagonism greatly increases the sensitivity of the nervous system to CONTRAST. See also OFF RESPONSE; ON RESPONSE; SIMPLE CELL.

center–surround receptive field a type of receptive field, common in the visual and somatosensory systems, that exhibits CENTER–SURROUND ANTAGONISM. Most center–surround receptive fields consist of a circular center area and an annular (i.e., ringlike) surrounding area.

centile n. a shortened name for PERCENTILE.

central adj. of or relating to the CENTRAL NERVOUS SYSTEM (CNS), especially to disorders that occur as a result of injury to or dysfunction of the CNS. Compare PERIPHERAL.

central anticholinergic syndrome see ANTICHOLIN-ERGIC SYNDROME.

central aphasia loss of the ability to understand or express language resulting from brain lesions. This term is no longer in common use and was never specifically defined: It has been identified with CONDUCTION APHASIA and WERNICKE’S APHASIA, among other types.

central auditory abilities see AUDITORY SKILLS.

central auditory processing disorder (CAPD) an impaired ability to decode acoustic messages into meaningful information and to discriminate speech, despite only minor changes in auditory sensitivity to sound. In adults, CAPD is typically associated with brain damage caused by stroke, lesions, and neurodegenerative diseases, such as multiple sclerosis; in children, it is most often associated with microscopic pathology in the brain and maturational delays in language acquisition. Also called AUDITORY PROCESSING DISORDER.

central auditory system see AUDITORY SYSTEM.

central canal the channel in the center of the spinal cord, which contains CEREBROSPINAL FLUID.

central coherence theory a theory proposing that human beings have an inherent drive to form coherent wholes by integrating pieces of relevant information. Most people tend to process incoming stimuli in context in order to derive a meaningful gist of the situation, often at the expense of surface details. By contrast, individuals with AUTISM SPECTRUM DISORDER exhibit a tendency toward WEAK CENTRAL COHERENCE, which results in an overreliance on local or piecemeal processing and a failure to integrate information in order to process stimuli in context. Also called WEAK CENTRAL COHERENCE THEORY. [proposed in 1989 by German-born British psychologist Uta Frith (1941– )]

central conceptual structure a theoretical integrated repository of mental operations and network of concepts and relationships relevant to a particular domain of experience (e.g., the domain of numbers) and important to task performance. Central conceptual structures are one of two mechanisms proposed by Canadian developmental psychologist Robbie Case (1944–2000) as guiding learning and thinking processes in children, the other being the EXECUTIVE CONTROL STRUCTURE.

central conflict the intrapsychic struggle between the healthy constructive forces of the real self and the obstructive, neurotic forces of the idealized self-image. [first described by Karen D. Horney]

central deafness loss or absence of hearing caused by damage to or abnormality of the auditory structures of the brain (i.e., the central AUDITORY SYSTEM), rather than the auditory nerve or the ear itself. Compare CONDUCTION DEAFNESS; SENSORINEURAL DEAFNESS.

central disposition see PERSONAL DISPOSITION.

central distribution see NONCENTRAL DISTRIBUTION.

central dyslexia an acquired DYSLEXIA characterized by difficulties with the pronunciation and comprehension of written words. Unlike in VISUAL WORD-FORM DYSLEXIA, the visual analysis system of the brain is intact, and the damage is to other, higher level brain pathways and systems involved in reading (e.g., the semantic system). The major types of central dyslexia include DEEP DYSLEXIA and SURFACE DYSLEXIA.

central executive in the model of WORKING MEMORY proposed in 1974 by British cognitive psychologists Alan D. Baddeley (1934– ) and Graham J. Hitch (1946– ), a component that manages the activities of the PHONOLOGICAL LOOP and VISUOSPATIAL SKETCHPAD. In coordinating the numerous processes of working memory, the central executive thus performs such varied functions as manipulating material held within the loop and sketchpad, focusing attention on and switching attention between different tasks, dividing attention between simultaneous tasks, and initiating long-term memory ENCODING and RETRIEVAL. Despite its crucial role, however, the central executive is of limited ca-
pacity and does not have any storage ability of its own. Its exact structure and operation have yet to be established and remain the focus of much current research.

**central fissure** see CENTRAL SULCUS.

**central gray** see PERIAQUEDUCTAL GRAY.

**central inhibition** a process within the central nervous system that prevents or interrupts the flow of neural impulses that control behavior.

**centralism** n. the concept that behavior is a function of the central nervous system mediated by the brain. Compare PERIPHERALISM.

**centralist psychology** 1. a psychological approach that focuses on behavior as a function of the higher brain centers, as opposed to peripheralist psychology (see PERIPHERALISM), which focuses on the effects of the receptors, glands, and muscles on behavior. Centralist psychology is essentially equivalent to CENTRALISM. 2. more generally, the idea that mental activity or mind occurs in or is a function of the brain alone.

**centrality of an attitude** 1. the extent to which an ATTITUDE OBJECT is thought about, reflected in the amount of time devoted to this thinking over an extended period. 2. the extent to which an attitude is linked to other attitudes in memory. Increased centrality is associated with enhanced ATTITUDE STRENGTH.

**centralized organization** an ORGANIZATIONAL STRUCTURE in which those holding positions of authority at the upper levels of the hierarchy retain control over decision making. Compare DECENTRALIZED ORGANIZATION.

**central limited capacity** the observed constraint on the processing capacity of the cognitive system—that is, the limited number of items or tasks that one can process (e.g., attend to, be aware of) at a given moment. Cognition is particularly subject to narrow capacity limits when items are novel or arbitrarily presented and when a primary task is highly paced or is assessed under an additional task load (see DUAL-TASK COMPETITION). This limited capacity affects voluntary decision making, WORKING MEMORY, effortful cognition, and CHOICE REACTION TIME, among other functions. However, capacity limits can be increased dramatically by way of CHUNKING (organization), LONG-TERM MEMORY, or AUTOMATICITY after habituation.

**central limit theorem** (CLT) the statistical principle that the sum of independent values from any distribution will approach a NORMAL DISTRIBUTION as the number of values in the distribution increases. In other words, the larger the sample size, the more closely the SAMPLING DISTRIBUTION approximates a normal distribution. The central limit theorem is used to justify certain data analysis methods when the appropriateness of a method relies on an assumption of normality.

**central lobe** see INSULA.

**central moment** a MOMENT that describes the shape of a set of scores with regard to its deviation about the mean. Four common central moments that describe a RANDOM VARIABLE are the MEAN (the first central moment), the VARIANCE (the second central moment), the SKEWNESS (the third central moment), and the KURTOSIS (the fourth central moment). Also called moment about the mean.

**central nervous system** (CNS) the entire complex of NEURONS, AXONS, and supporting tissue that constitute the brain and spinal cord. The CNS is primarily involved in mental activities and in coordinating and integrating incoming sensory messages and outgoing motor messages. Compare PERIPHERAL NERVOUS SYSTEM.

**central nervous system disorder** any neurological disorder of the central nervous system (i.e., brain and spinal cord).

**central neuron** a neuron contained entirely within the central nervous system.

**central nucleus** a nucleus forming part of the CORTICO-MESENCEPHALIC GROUP in the AMYGDALA within the brain. It receives input from other amygdaloid nuclei and projects to the hypothalamus and many brainstem structures, including the PERIAQUEDUCTAL GRAY. It is involved (among other things) in fear behavior.

**central pain** pain that is caused by a disorder of the central nervous system, such as a brain tumor or infection or injury of the spinal cord.

**central pattern generator** any of the sets of neurons in the spinal cord capable of producing oscillatory behavior and thought to be involved in the control of locomotion and other tasks. A central pattern generator is the neural substrate responsible for repetitive coordinated movements that can be modeled using COUPLED OSCILLATORS.

**central processes** see EXECUTIVE FUNCTIONS.

**central processing dysfunction** impairment in the analysis, storage, synthesis, and symbolic use of information. Because these processes involve memory tasks, the dysfunction is believed to be related to difficulties in learning.

**central processor** 1. the part of a computer that controls and executes operations on data. 2. in models of cognition based on analogies to INFORMATION PROCESSING in a computer, that part of the system that carries out operations on stored representations. The idea of a single central processor in the human cognitive system has been challenged by models based on DISTRIBUTED PROCESSING, PARALLEL DISTRIBUTED PROCESSING, and PARALLEL PROCESSING.

**central reflex time** the portion of REFLEX LATENCY that is occupied by activity within the central nervous system; it excludes the latency of muscular or endocrine response.

**central route to persuasion** the process by which attitudes are formed or changed as a result of carefully scrutinizing and thinking about the central merits of attitude-relevant information. See also ELABORATION; ELABORATION-LIKELIHOOD MODEL. Compare PERIPHERAL ROUTE TO PERSUASION.

**central scotoma** depressed vision in the central part of the visual field, which may be either absolute (total loss of vision) or relative (partial loss of vision). When caused by unilateral injury to or disease of the peripheral visual system (e.g., the retina or optic nerve), the central visual field of only one eye is affected. When associated with injury to the central visual system (i.e., beyond the optic nerve, in the brain), the central visual fields of both eyes are affected, and patients have great difficulty in guiding their fixation, localizing objects, reading, and recognizing faces.

**central sleep apnea** see BREATHING-RELATED SLEEP DISORDER; SLEEP APNEA.

**central state theory** see IDENTITY THEORY.

**central stimulation** electrical or chemical stimulation of the brain. See INTRACRANIAL STIMULATION.
central sulcus a major cleft (see sulcus) that passes roughly vertically along the lateral surface of each cerebral hemisphere from a point beginning near the top of the cerebrum. It marks the border between the frontal lobe and the parietal lobe. Also called central fissure: fissure of Rolando; Rolandic fissure; Rolandic sulcus; sulcus centralis.

central tendency the middle or center point of a set of scores. The central tendency of a sample data set, for instance, may be estimated by a number of different statistics (e.g., mean, median, mode).

central-tendency bias see end-aversion bias.

central vision the ability to see stimuli in the middle of the visual field, surrounding and including the point of fixation. Central vision is provided by the fovea centralis. Also called foveal vision. Compare peripheral vision.

centration n. in piagetian theory, the tendency of children in the preoperational stage to attend to one aspect of a problem, object, or situation at a time, to the exclusion of others. Compare decentralization.

centrencephalic adj. located in or near the center of the brain.

centrencephalic epilepsy a form of epilepsy marked by generalized seizures (absence seizures and some tonic–clonic seizures) that appear to originate near the center of the brain. It is not associated with any particular local anatomical or functional system but instead radiates outward through both cerebral hemispheres. The term was coined in the 1940s by U.S.-born Canadian neurosurgeon Wilder Penfield (1891–1976) and U.S.-born Canadian neuroscientist Herbert Jasper (1906–1999), and its use is restricted primarily to historic contexts.

centrencephalic system the concept of a central anatomical brain region (the centrencephalon) whose activities provide a coherent unity for mental processes and the seat of free will. [proposed by U.S.-born Canadian neurosurgeon Wilder Penfield (1891–1976)]

centrifugal adj. directed away from the center. For example, a centrifugal nerve carries impulses from the peripheral region of the body to the central nervous system. Compare centripetal.

centripetal adj. 1. directed toward the center. For example, a centripetal nerve carries nerve impulses from the periphery to the central nervous system. Compare centrifugal. 2. characterizing treatment approaches that focus inward on minute changes in feelings and impulses, as in psychoanalysis.

centripetal impulse a nerve impulse that travels from the periphery toward the central nervous system, that is, a sensory or afferent impulse.

centroid n. 1. in geometry, the center point of an object or area in multidimensional space. It may be determined by calculating the intersection of all straight lines or planes that divide the area into two equal parts. 2. the mean of multivariate data. It may be obtained by calculating the average of the vectors for the set of variables.

centromedian nucleus see center median.

centromere n. the part of a chromosome at which the chromatids are joined and that is attached to the equatorial plane of the spindle during cell division. The centromere occasionally becomes a separate body of genetic material, accounting for certain types of anomalies.

cephalalgia n. pain in the head (see headache).

cephalic adj. pertaining to or located in the head.

cephalic index the ratio of the maximum breadth of the head to its maximum length, multiplied by 100. The average, or medium, cephalic index for humans is between 75 and 81 (mesocephalic). A measure below 75 indicates a narrow head that is long in proportion to its width (dolicocephalic); a measure above 81 indicates a head that is wide in proportion to its length (brachycephalic). Also called cranial index. [defined by Swedish anatomist Anders Retzius (1796–1860)]

cephalization n. 1. the evolutionary tendency for important structures (brain, major sense organs, etc.) to develop at the anterior (front) end of organisms. 2. the evolutionary tendency for the brain to increase in size. See encephalization; evolution of the brain.

cephalo- (cephal-) combining form head.

cephalocaudal adj. from head to tail, as in the long axis of the body. The term typically refers to the maturation of an embryo or infant, wherein the greatest development takes place at the top of the body (i.e., the head) before the lower parts (i.e., the arms, trunk, legs). Compare proximodistal.

cephalocaudal axis see axis.

cephalogenesis n. formation of the head in embryonic development.

cephalometry n. the scientific measurement of the dimensions of the head. Cephalometry is used in orthodontics to predict and evaluate craniofacial development. Fetal cephalometry is the in utero measurement of the skull of the fetus, using ultrasound or X-ray techniques.

CER abbreviation for conditioned emotional response.

cereb- combining form see cerebro-.

cerebellar adj. of or relating to the cerebellum.

cerebellar ataxia poor muscular coordination (see ataxia) due to damage in the cerebellum. Individuals cannot integrate voluntary movements and therefore find it difficult to stand or walk, feed themselves, and perform complex activities (e.g., playing the piano).

cerebellar cortex the gray matter, or unmyelinated nerve cells, covering the surface of the cerebellum.

cerebellar folia the pattern of thin folds that subdivide the cerebellar cortex.

cerebellar gait an unsteady, wobbly, wide-based gait, resembling that of an intoxicated individual and associated with cerebellar lesions or dysfunction.

cerebellar hemisphere either of the two main lobes of the cerebellum.

cerebellar nucleus any of the small masses of neurons that lie within the white matter of the cerebellum.

cerebellar peduncle any of the three bundles of nerve fibers that connect each main lobe (hemisphere) of the cerebellum with other parts of the brain. The superior cerebellar peduncle, or brachium conjunctivum, connects the cerebellum with the midbrain; the middle peduncle...
connects the cerebellum with the pons; and the inferior peduncle connects the cerebellum with the midulla oblongata.

cerebellar rigidity see EXTENSOR RIGIDITY.

cerebellar speech a type of speech that is jerky, irregular, and poorly coordinated due to a lesion of the cerebellum. Also called ASYNERGIC SPEECH.

cerebellopontine angle a region of the human brain where the cerebellum touches the pons. The facial nerve and the vestibulocochlear nerve enter the brainstem in this region, and tumors frequently occur in either of these nerves in this region.

cerebellum n. (pl. cerebella) a portion of the hindbrain dorsal to the rest of the brainstem, to which it is connected by the cerebellar peduncles. The cerebellum modulates muscular contractions to produce smooth, accurately timed ballistic movements; it helps maintain equilibrium by predicting body positions ahead of actual body movements, and it is required for some kinds of motor conditioning. [Latin, literally: “little brain,” diminutive of cerebrum]

cerebral adj. referring to the cerebrum of the brain.

cerebral achromatopsia see ACHROMATOSIS.

cerebral angiography a depression of light vision and complete loss of form and color vision in either the left or right half of the visual field (unilateral HEMIAMBLYOPIA) or in both the left and right halves (bilateral hemiambylophia). Movement vision is typically not affected. See also REDDOCH’S PHENOMENON.

cerebral anemia a condition of abnormally low levels of hemoglobin or red blood cells in the blood reaching brain tissues, which may cause CEREBRAL INFARCTION.

cerebral angiography a noninvasive technique for examining brain structure by taking X-rays after special dyes have been injected into cerebral blood vessels. Inferences about adjacent tissue can be made from examination of the principal blood vessels. It has been largely superseded by techniques based on MAGNETIC RESONANCE IMAGING, such as magnetic resonance angiography. Also called CEREBRAL ANGIOGRAPHY.

cerebral angiomatosis a disease characterized by the formation of multiple tumors in the blood vessels that supply brain tissue. A congenital form of the disorder is marked by frequent seizures and muscular weakness on one side of the body as a result of impaired blood flow to the brain.

cerebral aqueduct a passage containing CEREBROSPINAL FLUID that extends through the midbrain to link the third and fourth cerebral ventricles of the brain. Also called aqueduct of Sylvius; Sylvian aqueduct.

cerebral arteriography see CEREBRAL ANGIOGRAPHY.

cerebral arteriosclerosis a hardening of the arteries that supply the brain.

cerebral atrophy degeneration and shrinkage of the brain, usually due to aging, disease, or injury. It is marked by enlargement of the surface clefts (SULCI) and inner cavities (VENTRICLES) of the brain. In normal aging there may be few or no cognitive effects, but cerebral atrophy may be secondary to more serious disorders, such as cerebrovascular disease, encephalitis, Alzheimer’s disease, or head injury. Also called BRAIN ATROPHY.

cerebral embolism 1. the application of low-voltage pulses of direct electrical current to the brain, occasionally used in the treatment of depression, anxiety, and insomnia. See ELECTRONARCOSIS. 2. the presence of a small mass of material in the blood vessels of the brain (see EMBOLISM), which blocks or impedes the flow of blood to a part of the brain. Also called CEREBRAL EMBOLE.

cerebral embolism see WERNICKE’S ENCEPHALOPATHY.

cerebral blindness see CORTICAL BLINDNESS.

cerebral contusion bruising of the brain, in which blood vessels are damaged but not ruptured, resulting from head injury. The effects vary with the severity of the injury, ranging from temporary neurological symptoms to permanent disability. Also called BRAIN CONTUSION.

cerebral cortex the layer of gray matter that covers the outside of the CEREBRAL HEMISPHERES in the brain and is associated with higher cognitive functions, such as language, learning, perception, and planning. It consists mostly of NEOCORTEX, which has six main layers of cells (see CORTICAL LAYERS); regions of cerebral cortex that do not have six layers are known as ALLOCORTEX. Differences in the CYTOARCHITECTURE of the layers led to the recognition of distinct areas, called BROMMANN’S AREAS, many of which are known to serve different functions.

cerebral death see BRAIN DEATH.

cerebral diplopia see DIPLOPIA.

cerebral dominance 1. the control of lower brain centers by the cerebrum or cerebral cortex. 2. the controlling or disproportionate influence on certain aspects of behavior by one CEREBRAL HEMISPHERE (e.g., language is typically left lateralized in right-handed people). See HEMISPHERIC LATERALIZATION.

cerebral dyschromatopsia 1. incomplete cerebral ACHROMATOSIS. 2. a distortion of color vision, as if the individual is seeing through a color filter. See also VISUAL ILLUSION.

cerebral dysfunction any impairment in cerebral processes, including disturbances of memory, language, attention, or executive functioning.

cerebral dysplasia any abnormality in the development of the brain. There are various types of cerebral dysplasia, including ANENCEPHALY, marked by failure of the cerebral hemispheres to develop; PORENCEPHALY, characterized by development of a hemisphere containing abnormal cavities; and callosal AGENESIS.

cerebral dysrhythmia a condition of abnormal brainwave rhythms associated with neurological disease or other pathological conditions, such as a drug overdose.

cerebral edema an abnormal accumulation of fluid in the intercellular or intracellular spaces of brain tissues, which may be caused by injury, disease, CEREBROVASCULAR ACCIDENT, or tumor (see also ACUTE MOUNTAIN SICKNESS). The condition results in swelling and a rise in INTRACRANIAL PRESSURE; if uncorrected, this may be followed by herniation of cerebral tissue through weakened areas. It may be reversible unless the damage extends to the brainstem, where the effects can be fatal. The increase in intracranial pressure may result in headaches and visual disorders. Cerebral edema can also cause cognitive dysfunction that recedes when the defect is corrected.

cerebral electrotherapy (CET) the application of low-voltage pulses of direct electrical current to the brain, occasionally used in the treatment of depression, anxiety, and insomnia. See ELECTRONARCOSIS.

cerebral embolism the presence of a small mass of material in the blood vessels of the brain (see EMBOLISM), which blocks or impedes the flow of blood to a part of the
cerebral gigantism

brain, resulting in an acute or chronic neurological deficit. See EMBOIL STROKE.

cerebral gigantism see SOTOS SYNDROME.

cerebral hemisphere either half (left or right) of the cerebrum. The hemispheres are separated by a deep LONGITUDINAL FISSURE, but they are connected by commissural projection, and association fibers so that each side of the brain normally is linked to functions of tissues on either side of the body. See also HEMISPHERIC LATERALIZATION.

cerebral hemorrhage any bleeding into the brain tissue due to a damaged blood vessel. The cause may be cerebral vascular disease, a ruptured aneurysm, a penetrating injury or blow to the head, or other factors. The neurological effects vary with the extent of the hemorrhage. Also called intracerebral hemorrhage. See HEMORRHAGIC STROKE.

cerebral hyperplasia an abnormal increase in the volume of brain tissue, usually due to a proliferation of new, normal cells. Although neurons do not proliferate after the nervous system has reached maturity, cells of the GLIA do continue to multiply into adulthood; in some cases neuroglial cell growth is associated with HYDROCEPHALUS.

cerebral hypoplasia the incomplete development of the cerebral hemispheres. It may be due to a congenital defect or malnutrition during early childhood.

cerebral infarction the death of brain tissue due to an interruption of blood flow caused by rupture of a blood vessel, blockage of a blood vessel by a clot (see EMBOLISM), or a narrowing (stenosis) of a blood vessel.

cerebral infection the invasion of brain tissues by a pathogenic organism, such as a virus or bacterium. Most cases occur as a complication of a viral infection (see ENCEPHALITIS); the most common bacterial infection is MENINGITIS.

cerebral ischemia a condition in which brain tissue is deprived of an adequate blood supply and thus lacks oxygen and nutrients. It is usually marked by loss of normal function of the affected area and may be accompanied by CEREBRAL EDEMA. A brief interruption in blood supply—a TRANSIENT ISCHEMIC ATTACK (TIA)—usually causes no serious damage. An interruption lasting more than several minutes may result in CEREBRAL INFARCTION. See CEREBRAL INFARCTION; STROKE.

cerebral lateralization see HEMISPHERIC LATERALIZATION.

cerebral lesion see BRAIN LESION.

cerebral pacemaker a hypothetical group of nerve cells in the brain that are believed to regulate the rhythms of BRAIN WAVES in the cerebral hemispheres. The cerebral pacemaker is believed to be located at the base of the brain, in the region of the HYPOTHALAMUS or in the RETICULAR FORMATION.

cerebral palsy (CP) a set of nonprogressive movement and posture disorders that results from trauma to the brain occurring prenatally, during the birth process, or before the age of 5. Symptoms include spasticity, uncontrolled movements (see ATHETOSIS), paralysis, unsteady gait, and speech abnormalities (see DYSARTHRIA) but may be accompanied by disorders of any other brain function, resulting in cognitive changes, seizures, visual defects, tactile impairment, hearing loss, and intellectual disability. CP is commonly classified into the following types: spastic, the most common, resulting from damage to the motor cortex, corticospinal tract, or pyramidal tract; dyskinetic, resulting from damage to the basal ganglia; ataxic, resulting from damage to the cerebellum; and mixed, in which more than one type is evident.

cerebral peduncle either of two cylindrical bundles of nerve fibers that pass through the PONS to form the main connection between the CEREBRAL HEMISPHERES and the spinal cord. Also called CRUS CEREBRI.

cerebral specialization the differential contribution of the two cerebral hemispheres to many functions. See HEMISPHERIC LATERALIZATION.

cerebral stimulation see BRAIN STIMULATION.

cerebral syphilis a condition that results when untreated syphilis involves the cerebral cortex and surrounding meningeal membranes, causing GENERAL PARESIS. The condition, which usually develops about 10 years after the initial infection, is marked by irritability, memory impairment, inability to concentrate, headaches, insomnia, and behavioral deterioration. See NEUROSYPHILIS.

cerebral thrombosis see THROMBOSIS.

cerebral trauma any damage to the brain, which may be temporary or permanent, following a blow to the head of sufficient severity to produce a concussion, contusion, or laceration.

cerebral type a body type in which the central nervous system is thought to have a dominant role, resulting in pronounced intellectual and cognitive abilities. See CARUS TYPOLOGY: ROSTAN TYPES.

cerebral vascular accident see CEREBROVASCULAR ACCIDENT.

cerebral vascular disease see CEREBROVASCULAR DISEASE.

cerebral vascular insufficiency see CEREBROVASCULAR INSUFFICIENCY.

cerebral ventricle see VENTRICLE.

cerebral vesicle an outgrowth of the embryonic NEURAL TUBE that develops into one of the three main regions of the brain: namely, the FOREBRAIN, MIDBRAIN, or HINDBRAIN.

cerebration n. any kind of conscious thinking, such as pondering or problem solving. —cerebrate vb.

cerebritis n. an infection of the brain. See CEREBRAL INFECTION.

cerebro- (cerebr-) combining form brain.

cerebrocranial defect a deformity or dysfunction involving the cerebrum and the eight bones of the skull that form a protective layer around it. An example is the premature closing of the sutures of the skull, resulting in a displacement of cerebral tissues.

cerebrovascular adj. referring to diseases, such as TAY-SACHS DISEASE, that are characterized by impairment of the brain and sometimes also by degeneration of the retina.

cerebroside n. a type of lipid present in the MYELIN SHEATH of nerve fibers.

cerebrospinal fluid (CSF) the fluid within the CENTRAL CANAL of the spinal cord, the four VENTRICLES of the brain, and the SUBARACHNOID SPACE of the brain. It serves as a watery cushion to protect vital tissues of the central ner-
cerebrovascular accident (CVA) a disorder of the brain arising from cerebrovascular disease, such as CEREBRAL HEMORRHAGE, CEREBRAL EMBOLISM, or cerebral THROMBOSIS, resulting in temporary or permanent alterations in cognition, motor and sensory skills, or levels of consciousness. This term is often used interchangeably with STROKE. Also called cerebrovascular accident.

cerebrovascular disease a pathological condition of the blood vessels of the brain. It may manifest itself as symptoms of STROKE or a TRANSIENT ISCHEMIC ATTACK. Also called cerebral vascular disease. See also CEREBROVAScular ACCIDENT.

cerebrovascular insufficiency failure of the cardiovascular system to supply adequate levels of oxygenated blood to the brain tissues. The condition usually arises when one of the four main arteries supplying the brain—namely, the two carotid and two vertebral arteries—is interrupted. It may also result from generalized ARTERIOSCLEROSIS or the inability of the heart to maintain adequate blood flow to the brain. Also called cerebral vascular insufficiency.

cerebellum n. the largest part of the brain, forming most of the FOREBRAIN and lying in front of and above the cerebellum. It consists of two CEREBRAL HEMISPHERES bridged by the CORPUS CALLOSUM. Each hemisphere is divided into four main lobes: the FRONTAL LOBE, OCCIPITAL LOBE, PARietAL LOBE, and TEMPORAL LOBE. The outer layer of the cerebellum—the CEREBRAL CORTEX—is intricately folded and composed of GRAY MATTER. Also called télencéphalon. [Latin, literally: “brain”]

CERQ abbreviation for COGNITIVE EMOTION REGULATION QUESTIONNAIRE.

certainty of an attitude the level of subjective confidence that a person has regarding (a) the extent to which he or she has a clear notion of his or her attitude and (b) the degree to which that attitude is a valid evaluation of the ATTITUDE OBJECT. It is related to ATTITUDE STRENGTH.

certainty of paternity the degree to which a putative parent can be certain that he, she, or it is the parent of an offspring. Because of internal fertilization and gestation, all female mammals are certain of maternity, but no male mammal can be 100% certain of paternity. In birds, BROOD PARASITISM can trick parents of both sexes into caring for chicks unrelated to either parent.

certifiable adj. 1. describing people who, because of mental illness, may be a danger to themselves or others and are therefore eligible to be institutionalized. See CERTIFICATION LAWS; COMMITMENT LAWS. 2. having met the requirements to be formally recognized by the relevant licensing or sanctioning body.

certificate of need (CON) written permission that a health care organization must obtain from a government body before making changes that involve expansion or reconstruction. The purpose of this requirement is to certify that the new services so provided will meet the needs of those for whom they are intended and to prevent excessive or duplicative development.

certification n. 1. the formal process by which an external agency affirms that a person has met predetermined standards and has the requisite knowledge and skills to be considered competent in a particular area. Certification applies to individuals and ACCREDITATION applies to institutions. See also CREDENTIALING. 2. the legal proceedings in which appropriate mental health care professionals formally confirm that a person has a mental disorder, which may result in COMMITMENT of that person. —certificated adj.

certification laws 1. legislation governing the admission of individuals to mental institutions, including commitment proceedings as well as a review of case records to determine whether health care is necessary and whether the institution and type of care are appropriate. 2. state laws governing the right of an individual to describe himself or herself as a psychologist.

certiorari n. a writ issued by a superior court demanding review of the action of a lower court. For example, if the U.S. Supreme Court issues a writ of certiorari (Latin, literally: “to be informed”), it has agreed to review a case that was decided by a lower court and subsequently appealed.

cerumen n. the waxlike secretion normally present in the EXTERNAL AUDITORY MEATUS of the ear. Also called earwax.

cerveau isolé a nonhuman animal whose MIDBRAIN has been transected between the inferior and superior colliculi (see COLliculi) for experimental purposes. See also ENCEPHALE ISOLE. [French, “isolated brain”]

cervical adj. 1. relating to, occurring in, or affecting the neck, for example, the CERVICAL NERVES, 2. pertaining to a necklike structure, especially the CERVIX of the uterus.

cervical angina see PSEUDOANGINA.

cervical ganglion any of the collections of neural cell bodies (ganglia) of the SYMPATHETIC NERVOUS SYSTEM that occur in the neck region. They innervate the pupils, sweat glands of the head, salivary glands, and heart.

cervical nerve any of the eight SPINAL NERVES in the neck area. Each has a DORSAL ROOT that is sensory in function and a VENTRAL ROOT that has motor function.

cervical plexus a nerve network formed from the VENTRAL ROOTS of the upper four CERVICAL NERVES. This plexus is anesthetized for surgical operations in the region between the jaw and the collarbone.

cervical sprain syndrome see WHIPLASH.

cervix n. in anatomy, any necklike part, especially the neck of the UTERUS, which is the portion of the uterus that projects into the vagina. The cervix of a tooth is the slightly constricted part between the crown and the root.

CES abbreviation for CRANIAL ELECTRICAL STIMULATION. See ELECTROsleep THERAPY.

Cesamet n. a trade name for NabILone.

cesarean section (caesarean section; C-section) a surgical procedure in which incisions are made through a woman’s abdominal and uterine walls to deliver a baby under circumstances in which vaginal delivery is inadvisable. The name derives from the erroneous belief that Gaius Julius Caesar (100–44 BCE) was delivered in this manner.
CES-D 
abbreviation for CENTER FOR EPIDEMIOLOGIC STUDIES DEPRESSION SCALE.

CET 
abbreviation for CEREBRAL ELECTROTHERAPY.

CF 1. abbreviation for characteristic frequency. See TUNING CURVE. 2. abbreviation for CUMULATIVE FREQUENCY.

CFA 
abbreviation for CONFIRMATORY FACTOR ANALYSIS.

CFF 
abbreviation for CRITICAL FLICKER FREQUENCY.

C fiber 
an unmyelinated peripheral nerve fiber (axon) that conducts pain information slowly. C fibers vary from approximately 0.4 to 1.2 μm in diameter. See also A FIBER; B FIBER.

CFS 
abbreviation for CHRONIC FATIGUE SYNDROME.

cGMP 
abbreviation for CYCLIC GMP.

chained schedule 
a SCHEDULE OF REINFORCEMENT for a single response in which a sequence of at least two schedules, each accompanied by a distinctive stimulus, must be completed before primary reinforcement occurs. For example, in a chained fixed-ratio 10, fixed-ratio 50 schedule, 10 responses change the stimulus situation and then 50 more result in primary reinforcement. Chained schedules are often used to study conditioned reinforcement. Also called chained reinforcement. Compare TANDEM REINFORCEMENT.

chaining 
n. an OPERANT CONDITIONING technique in which a complex behavioral sequence is learned. Animals, both human and nonhuman, can be taught to perform relatively elaborate sequences of activities by this method, which makes PRIMARY REINFORCEMENT contingent on the final response in the series. In backward chaining, the final response is taught first. Once established, the stimulus for that response becomes a conditioned reinforcer that is used to reinforce the next-to-last response in the chain; this stimulus is then used to reinforce another response. The chain is thus taught backward, one response at a time. In forward chaining, the chain is taught by reinforcing the first step in the sequence, then the second, and so on until the entire sequence is learned. Also called behavior chaining.

chain of behavior 
see BEHAVIOR PATTERN.

chain reproduction 
in social and cultural psychology, the process by which material (e.g., ideas or stories) is relayed from person to person or group to group and altered slightly at each stage of transmission. In group exercises based on this process, the ultimate product can be compared with the original in order to show, for example, that a description of a cat has gradually become that of a lion. The same type of distortion occurs in the passing on of rumors and gossip through the processes of leveling (simplification), sharpening (emphasis on selected details), and assimilation (altering the accounts to suit attitudes, expectations, and prejudices).

chakra 
n. in Eastern philosophy, one of the seven energy centers in the body. The chakras roughly correspond with the endocrine system. Each chakra symbolizes different, ascending human needs and has a sound (MANTRA) and color associated with it. Focused awareness and contemplation of the chakras may be practiced in YOGA and in other therapeutic approaches and traditions.

challenge 1. 
n. an obstacle appraised as an opportunity rather than a threat. A threat becomes a challenge when the individual judges that his or her coping resources are adequate not only to overcome the stress associated with the obstacle but also to improve the situation in a measurable way. 2. vb. to pose or face with an obstacle or threat. 

challenged 
adj. describing an individual with a disability. The word is often considered to be euphemistic.

challenge for cause 
a request made to the judge during voir dire that a prospective juror be removed for some specific reason. For example, a juror with some relationship to either the prosecution or the defense may be removed as a result of a challenge for cause. Compare PEREMPTORY CHALLENGE.

challenge suggestion 
a suggestion designed to test for and deepen an individual’s HYPNOTIC SUSCEPTIBILITY. It usually consists of a simple physical command. For example, the hypnotist may say, “You want to close your eyes”: If the individual immediately does so, the hypnotist may conclude that this person is highly suggestible and has entered a state of hypnosis. Compliance with the challenge suggestion may also increase the individual’s sense of being without volitional power and reduce his or her ability to reject subsequent suggestions. Also called challenge test. See also HYPNOTIC RIGIDITY; IDEOMOTOR SUGGESTION.

challenging behavior 
behavior that is dangerous or that interferes in participation in preschool, educational, or adult services and often necessitates the design and use of special interventions. The term is used principally in human services in the United Kingdom and within educational services in the United States and most typically refers to behaviors of people with intellectual or developmental disabilities.

CHAMPUS 
acronym for CIVILIAN HEALTH AND MEDICAL PROGRAM OF THE UNIFORMED SERVICES.

chance difference 
a difference between two samples that arises from the nature of sampling itself, rather than from any intervention by a researcher. For example, scores obtained from two groups of research participants might vary because of personal factors affecting some individuals (e.g., financial worries) and not because of the conditions of the study.

chance variation 1. any change in hereditary traits due to unknown factors. 2. see RANDOM VARIATION.

change agent 
a specific causative factor or element or an entire process that results in change, particularly in the sense of improvement. In psychotherapy research, a change agent may be a component or process in therapy that results in improvement in the behavior or psychological adaptation of a patient or client. 2. an individual who instigates or implements change within a social unit or situation (e.g., a family or group) or within an organization by communicating to, managing, and encouraging others in the change.

change blindness 
a failure to notice changes in the visual array appearing in two successive scenes. This is surprisingly common whenever the brief movement (the transient) that usually accompanies a change is somehow masked or interrupted. In experimental investigations, the transient is often blocked by inserting a blank screen between the original image (e.g., a picture of an airplane) and the changed image (e.g., a second picture of the same airplane with an engine missing), or by scattering a few small, high-contrast shapes across the picture simultaneously with the change. Detection failures also occur when changes are made during blinks, SACCADIES, and other nat-
ural occlusions, or when changes happen gradually and thus have no transients. Such failures have also been documented in such real-world situations as automobile accidents, eyewitness identifications, military operations, and everyday interpersonal interactions.

Attention-based explanations for the phenomenon attribute it to diversion of an individual’s focus from the changing object. Other theories postulate that failure to notice changes represents a failure to encode the visual information in working memory, generally because it was not relevant to task demands. Still other theories emphasize a failure to compare prechange and postchange mental representations of the visual environment. See also ATTENTIONAL BLINDNESS; INATTENTIONAL BLINDNESS; MIND-SIGHT; REPETITION BLINDNESS. [Term coined in 1997 by Canadian psychologist and computer scientist Ronald A. Rensink and colleagues]

change effect in parapsychology, a phenomenon in which the physical structure of an object appears to have been altered by paranormal means, as in the alleged structural changes to metal in “spoon-bending” demonstrations. See PSYCHOKINESIS.

change management the process of planning, implementing, and evaluating change within organizations or communities, with the goal of realizing the benefits of change while implementing it as efficiently, smoothly, and cost-effectively as possible. Change management practices include effective communication regarding the change, such as the identification of intended consequences, and the prediction of and preparation for unintended consequences.

change of life see CLIMACTERIC.

change of venue the transfer of a trial to another location if there is evidence that obtaining a fair and unbiased channel capacity if there is evidence that obtaining a fair and unbiased channel capacity of information or messages that a given channel can accommodate.

channel factors characteristics of the mode by which a persuasive message is communicated. For example, presentation of a message via written text (vs. an audio recording) is a channel factor. See also MESSAGE-LEARNING APPROACH.

channels of communication 1. in the social psychology of groups, the paths that are usually available for the transmission of information from one person to one or more other people in the group or organization. For example, in a highly centralized communication structure, all information passes through the individual at the center of the network, who then routes it to other members of the organization. 2. the sensory means by which information is conveyed in face-to-face communication between people, comprising speech (source: vocal track; destination: ear), kinesics (body movement; eye), odor (chemical processes; nose), touch (body surface; skin), observation (body surface; eye), and proxemics (body placement; eye).

chaos theory an area of mathematical theory that deals with nonlinear systems that are profoundly affected by their initial conditions, tiny variations in which can produce complex, unpredictable, and erratic effects. It has been applied by some psychological researchers to the study of human behavior. See BUTTERFLY EFFECT; COMPLEXITY THEORY; DYNAMIC SYSTEMS THEORY; SENSITIVE DEPENDENCE.

character n. the totality of an individual’s attributes and PERSONALITY TRAITS, particularly his or her characteristic moral, social, and religious attitudes. Character is often used synonymously with PERSONALITY. See CHARACTER TYPE.

character analysis 1. the form of psychoanalytic treatment advocated by Austrian psychoanalyst Wilhelm Reich (1897–1957) in 1933 as focusing less on symptoms and more on restructuring patients’ disordered character to enable them to overcome their self-protective ARMORING (i.e., RESISTANCE) against facing their neuroses. 2. see CHARACTEROLOGY.

character development the gradual development of moral concepts, conscience, religious values or views, and social attitudes as an essential aspect of personality development.

character disorder formerly, in psychoanalysis, an alternative name for PERSONALITY DISORDER.

character displacement a divergence in a physical, physiological, or behavioral trait within two or more populations of a species that reduces competition between those populations and, over time, leads to the development of separate species. Charles DARWIN found several types of finches in the Galápagos Islands with different forms of bills for eating seeds of different sizes or capturing insects of different sizes. This differentiation of bill size and shape from a founder species is a classic example of character displacement.

characteristic n. 1. a particular feature or quality of a person, animal, or other unit of interest, especially any of the enduring qualities or traits that define an individual’s nature or personality in relation to others. 2. a PARAMETER that describes a population distribution, such as its mean or STANDARD DEVIATION.

characteristic frequency (CF) see TUNING CURVE.
character neurosis

**character neurosis** in psychoanalysis, a former name, used interchangeably with *neurotic character*, for PERSONALITY DISORDER.

**characterology** n. 1. formerly, the branch of psychology concerned with character and personality. Also called **character analysis**. 2. a pseudoscience in which character is “read” by external signs, such as hair color or facial type.

**character strength** a positive trait, such as kindness, teamwork, or hope, that is morally valued in its own right and contributes to the fulfillment of the self and others. Also called human strength. See POSITIVE PSYCHOLOGY.

**character structure** the organization of the enduring traits and attributes that make up a person’s CHARACTER.

**character traits** in trait conceptions of personality functioning, dispositional tendencies having to do with values, motives, and the regulation of behavior in accord with moral and ethical standards.

**character type** 1. see PERSONALITY TYPE. 2. in psychoanalytic theory, a personality type defined by the kinds of DEFENSE MECHANISM used (e.g., a PHOBIC CHARACTER) or by fixation at a particular stage in PSYCHOSEXUAL DEVELOPMENT (e.g., an ORAL PERSONALITY).

**Charcot–Marie–Tooth disease** a slowly progressive neuromuscular disorder characterized by muscle wasting (atrophy) and weakness in the arms (from the elbows down) and legs (from the knees down); feeling and movement in these areas may be lost. The disease, which results from degeneration of peripheral motor and sensory nerves, typically does not affect life expectancy. Usually autosomal dominant (see DOMINANT ALLELE), it occasionally has recessive forms resulting in more severe symptoms. Also called **peroneal muscular atrophy**. [Jean-Martin CHARCOT and Pierre Marie (1853–1940), French neurologists; Howard Tooth (1856–1925), British physician]

**charisma** n. the special quality of personality that enables an individual to attract and gain the confidence of large numbers of people. It is exemplified in outstanding political, social, and religious leaders. —**charismatic** adj.

**charismatic authority** see AUTHORITY.

**charismatic leader** the type of political or social leader who commands high levels of devotion, enthusiasm, and commitment from his or her followers. German sociologist Max Weber (1864–1920) defined charismatic leaders as those who are widely admired and respected by their followers (e.g., Napoleon, Churchill), but the term is more popularly used to mean leaders who owe their success to other factors.

**charity** n. any act that benefits other people who lack essential resources or otherwise are in need of assistance. Unlike ALTRUISM, charitable behavior may be carried out with the expectation of benefits in return. For example, a person who volunteers time at an organization that provides food and shelter to those who are homeless may do so primarily to be recognized in the local newspaper.

**charlatan** n. 1. a person who makes a pretense of having knowledge or skills that he or she does not in fact possess, especially in the field of medicine. See also QUACK. 2. in parapsychology, a person who uses conjuring tricks or other forms of deliberate deception to claim paranormal powers.

**Charles Bonnet syndrome** complex visual hallucinations without delusions or the loss of insightful cognition, typically seen in older adults who have severe visual impairment. Such hallucinations are usually nonthreatening and often pleasant and are not indicative of mental illness or psychological disorder. Also called Bonnet syndrome. [Charles Bonnet (1720–1793), Swiss naturalist and philosopher]

**charm** n. 1. the power of pleasing, attracting, or arousing interest in other people through one’s manner or other personal qualities. 2. an amulet often worn for its associative value to bring good luck or to protect from evil. 3. a magic spell, usually consisting of an INCANTATION with associated ritual actions.

**Charpentier’s bands** illusory light and dark bands that appear to follow a moving slit of light in the dark. [Pierre Marie Augustin Charpentier (1852–1916). French experimentalist]

**Charpentier’s illusion** see SIZE–WEIGHT ILLUSION. [Pierre Charpentier]

**chart** 1. n. a graphic or tabular display of data. 2. vb to create such a display.

**chastity** n. the state of abstaining from illicit sexual intercourse or—by extension—from all sexual activity. In religious usage, it also includes the concept of not having sexual urges or impure thoughts. See also CELEBACY.

—**chaste** adj.

**chat** n. see KHAT.

**chauvinism** n. excessive favoritism toward a social, political, or ethnic group. Initially, the word referred to extreme patriotism, as it derives from the name of a French soldier (Nicolas Chauvin) who displayed excessive devotion to Napoleon; now, however, it is often used to mean the mistaken belief that men are superior to women (male chauvinism).

—**chauvinistic** adj. —**chauvinist** n.

**CHD** abbreviation for CORONARY HEART DISEASE.

**ChE** abbreviation for CHOLINESTERASE.

**cheating** n. 1. influencing one’s own or others’ outcomes by deceit, trickery, or other unfair maneuvers. Because cheating is disruptive to maintaining a variety of social relationships, human beings and other animals have developed strategies to detect and punish it. 2. in evolutionary psychology, using asocial strategies to gain an evolutionary advantage. For example, males of some species who have formed an exclusive PAIR BOND with a female may nonetheless seek to mate with other females so as to increase their chances of producing offspring. 3. in RECIPROCAL ALTRUISM, the failure of an individual to aid another individual who has provided assistance in the past. 4. see INFIDELITY.

—**cheat** vb. n.

**checkerboard pattern** a pattern of alternating light and dark squares used in visual psychophysical tests and to stimulate visually responsive cells in the brain.

**checklist** n. a list of items that are to be observed, recorded, corrected, or otherwise considered in some manner. See also BEHAVIOR CHECKLIST.

**check reading** in ergonomics, a machine display that provides information about the particular state of a system and is used by an operator to assess whether that system is operating within normal limits. Compare ANNUNCIATOR.

**ChEI** abbreviation for CHOLINESTERASE INHIBITOR.
cheilophagia (cheilophagia) n. the repeated biting of one’s own lips.
cheiromancy n. see PALMISTRY. —cheiromancer n.
chelation n. the formation of chemical bonds between a metal ion and two or more nonmetallic ions. It can be used to remove certain types of ions from biological reactions or from the body, as in the removal of lead or mercury from the body by use of chelating agents.
chemesthesis n. the sense receptive to chemical stimuli through activation of receptors in the eyes, nose, mouth, and throat other than those associated with the CHEMICAL SENSES, typically those involved in pain, touch, and thermal awareness. An example is the activation of pain receptors deriving from the burn in the taste of a chili pepper. Also called common chemical sense.
chemical antagonism see ANTAGONIST.
chemical brain stimulation the placing of various NEUROTRANSMITTERS or other brain-active chemicals in specific brain locations for therapeutic or experimental purposes.
chemical castration the administration of chemicals (e.g., estrogens or ANTIANDROGENS) that block the effects of androgens and inhibit testicular production to manage advanced prostate cancer or, more controversially, to reduce sexual drive in sex offenders. Research has shown that a minority of sex offenders will offend again after chemical castration, indicating that sex drive is not the only cause of sexual offenses.
chemical communication the use of ODORANTS and other substances (see EXTERNAL CHEMICAL MESSENGER) to transmit information between individuals. Many nonhuman animals have specialized scent glands for scent production and specialized behavior for depositing scents. Chemical signals communicate the identity of species, sub-species, and individuals; reproductive status; dominance status; fear; and territorial boundaries. An advantage of chemical communication is that signals can remain long after the communicator has left.
chemical dependence see SUBSTANCE DEPENDENCE.
chemical senses the senses receptive to chemical stimulation (i.e., through contact with chemical molecules or electrolytes), particularly the senses of SMELL and TASTE. Airborne molecules are inhaled and dissolved in the mucous membrane of the OLFATORY EPITHELIUM to confer odors. Molecules dissolved in liquids are delivered to the TASTE CELLS on the tongue, soft palate, larynx, and pharynx to confer tastes.
chemical stimulation activity or a change of activity generated in olfactory (smell) or gustatory (taste) receptor cells by contact with specific electrolytes or molecules. Both CHEMICAL SENSES have specialized receptor proteins to which stimulating molecules bind to create electrical potentials. These potentials are passed on to peripheral nerves that transmit the message to the central nervous system for interpretation. See CHEMORECEPTOR.
chemical sympathectomy see SYMPATHECTOMY.
chemical synapse a type of specialized junction through which a signal is transmitted from one neuron to another. Across the narrow gap (SYNAPTIC CLEFT) separating them through the release and diffusion of NEUROTRANSMITTER. Though slower than ELECTRICAL SYNAPSES, chemical synapses are more flexible and comprise the majority of neuronal junctions within the body. Because of this prevalence, the qualifier generally is omitted and SYNAPSE used alone to denote a chemical junction.
chemical trail a track of chemical signals left by some nonhuman animals along the ground or another surface that allows group members to follow in the same direction as the trail maker but at a different time. Ants, for example, often leave chemical trails that provide direction toward foraging sites or the home nest.
chemical transmission the transmission of nerve impulses between nerve cells by NEUROTRANSMITTER molecules. See also SYNAPSE.
chemical transmitter see NEUROTRANSMITTER.
chemical warfare combat and associated military operations involving the use of incapacitating agents (e.g., poisons, contaminants, irritants), some of which may be lethal. Chemical weapons conventions prohibit the development, production, stockpiling, and use of such agents.
chemistry n. 1. the composition, attributes, and reactions of substances, particularly at the atomic level. 2. the science of such phenomena. See also NEUROCHEMISTRY.
chemoaffinity hypothesis the notion that each neuron has a chemical identity that directs it to synapse on the proper target cell during development. [developed in the 1940s by U.S. psychologist ROGER SPERRY]
chemoattractant n. a chemical compound that attracts particular classes of GROWTH CONES of neurons and so directs the growth of their axons. Compare CHEMOREPELLANT.
chemoreceptor n. a sensory nerve ending, such as any of those in the TASTE BUDS or OLFATORY EPITHELIUM, that is capable of reacting to certain chemical stimuli. The chemical molecule or electrolyte generally must be in a solution to be detected by the chemoreceptors for taste; it must be volatile to be detected by those involved in smell. In humans, there are hundreds of different taste receptor proteins and a total of about 300,000 TASTE CELLS, with some taste receptors reacting only to certain stimuli, such as those producing a bitter taste. Humans also have about 1,000 types of OLFATORY RECEPTORS and about 1,000 receptors of each type, giving a total of one million olfactory receptors; other mammals (e.g., dogs) may have ten times that number. The relation between specific olfactory stimuli and particular olfactory receptors is still being debated.
chemoreceptor trigger zone (CTZ) a cluster of cells in the medulla oblongata that is sensitive to certain toxic chemicals and reacts by causing vomiting. The trigger zone is particularly sensitive to narcotics and responds by producing dizziness, nausea, and vomiting, the precise effects depending on the agent and the dosage. See also AREA POSTREMA.
chemorepellant n. a chemical compound that repels particular classes of GROWTH CONES of neurons and so directs the growth of their axons. Compare CHEMOTRACTANT.
chemosensory event-related potential (CSERP) an electrical BRAIN POTENTIAL produced by a chemosensory event. This is a more general term than olfactory evoked potential (OEP), which refers specifically to electrical potentials produced by olfactory events rather than trigeminal events (see TRIGEMINAL CHEMORECEPTION) or gustatory events.
chemotaxis

chemotaxis n. see TAXIS.

chemotherapy n. the use of chemical agents to treat diseases, particularly cancer, in which case it is contrasted with RADIATION THERAPY. —chemotherapeutic adj. —chemotherapist n.

Chernoff faces a representation of data in the form of stylized faces, designed to take advantage of the ability of observers to discern subtle changes in facial expressions. Features such as head and eye eccentricity, eyebrow slant, and mouth size represent different values of the variables of interest. [Herman Chernoff (1923–1991), U.S. statistician]

chessboard illusion an illusion of depth that occurs if a systematically distorted checkerboard pattern (known as the Helmholtz chessboard) is viewed close to the retina. The pattern contains small squares in the center, which become progressively larger toward the periphery. The progressive enlargement of the squares compensates for the progressive distortion of the image in the peripheral retina, caused by the optics of the eye. [described by Hermann von Helmholtz]

chest voice the lower reaches, or range, of the speaking or singing voice, in which tone is created by pectoral breathing and chest resonance with little or no nasal resonance. A calm and relaxed normal speaking tone is generally delivered in a chest voice. Compare HEAD VOICE.

Cheyne–Stokes breathing labored breathing that alternates between increasing and decreasing patterns, as in premature infants and individuals in a coma. [John Cheyne (1777–1836), Scottish medical writer; William Stokes (1804–1878), Irish physician]

chi (qi) n. in Eastern philosophy, life-force energy (from Chinese, “energy”). Blockages in chi are believed to create illness. The equivalent Hindu concept is prana (Sanskrit, literally: “breath of life”). See also ACUPUNCTURE.

chiaroscuro n. the illusion of depth or distance in a picture produced by the use of light and shade.

chiasmal syndrome loss of visual acuity and abnormalities of the visual field associated with damage to the OPTIC CHIASM and the adjacent optic nerve or OPTIC TRACT. Typical features are BITEMPORAL HEMIANOPSIS and OPTIC ATROPHY. The majority of cases are caused by brain tumors.

chibih n. see SUSTO.

Chicago school a school of psychology that emerged at the University of Chicago in the early 20th century, associated with psychologists John Dewey, James R. Angell, and Harvey A. Carr. Their approach, called FUNCTIONALISM, was related to the ACT PSYCHOLOGY of Franz Brentano; it was an attempt to modify the subject matter of psychology by introducing the Darwinian idea that mental activities subserve an adaptive biological action function that should be the focus of psychology.

chicken game a type of laboratory game used in experimental investigations of bargaining and competition, in which each party in the interaction can win only by selecting the competitive rather than the cooperative alternative. For example, if two cars traveling in opposite directions are stopped at a narrow intersection without traffic lights and both drivers are in a hurry, each motorist may want to start first across the intersection, pursuing his or her own interest (i.e., choosing the competitive alternative) and hoping that the other will give way (i.e., will adopt the more cooperative strategy). The danger is that if both parties choose the competitive strategy, both lose. This game differs from the PRISONER’S DILEMMA, in which both parties have incentives both to cooperate and compete with their partner. See also GAME THEORY.

chicken pox a highly contagious viral infection characterized by skin eruptions with fever, headache, anorexia, and other mild constitutional symptoms. The varicella-zoster virus, which causes chicken pox in children, also causes shingles in adults, although children or adults may experience both forms (see HERPES INFECTION). A common neurological complication is acute CEREBELLAR ATAXIA. Cranial nerve paralysis also may follow a chicken pox infection. Also called varicella.

child n. a young boy or girl between infancy and adolescence. See CHILDHOOD.

child abuse harm to a child caused by a parent or other caregiver. The harm may be physical (violence), sexual (violation or exploitation), psychological (causing emotional distress), or neglect (failure to provide needed care). See also BATTERED-CHILD SYNDROME.

child advocacy any organized and structured interventions on behalf of children by professionals or institutions, often in relation to such issues as special parenting needs, child abuse, and adoption or foster care.

child analysis the application of psychoanalytic principles (considerably modified from those of CLASSICAL PSYCHOANALYSIS) to the treatment of children. In his first and most famous case, Sigmund Freud analyzed 5-year-old LITTLE HANS by having the child answer questions through his father, but Freud never analyzed a child patient directly. Pioneers in the field are Melanie Klein, who developed the PSYCHOANALYTIC PLAY TECHNIQUE to achieve a deep analysis of the child’s unconscious, and Anna Freud, whose method was more pedagogical and encouraged EGO DEVELOPMENT. See also PLAY THERAPY.

Child Behavior Checklist (CBCL) a standardized instrument used to assess the behavioral problems and competencies of children between the ages of 4 and 18 years (a separate version is available for assessing the behavior of children ages 2 to 3). The CBCL is administered to parents, who describe their children’s behavior by assigning a rating to each of the more than 100 items on the checklist. The items assessed range from internalizing behaviors (e.g., fearful, shy, anxious, inhibited) to externalizing behaviors (e.g., aggressive, antisocial, undercontrolled). See also EXTERNALIZING–INTERNALIZING. [developed in 1983 by U.S. psychologists Thomas M. Achenbach (1940– ) and Craig S. Edelbrock (1951– )]

child care 1. the daytime care of children by a person or organization while parents are at work. 2. the full-time residential care of children who have no other home or whose home life is seriously troubled. 3. broadly, the care of children of any age in any setting.

child care facilities facilities licensed to provide regular out-of-home care to children during the working day. Child care facilities may be privately run but may also be associated with firms, churches, or social agencies. Such a facility is often referred to as a day care center.

child care worker an individual trained to attend to children on a day-to-day basis in a variety of group settings, including child care centers, schools, businesses, private households, and health care institutions. Child care
workers perform such tasks as dressing, feeding, bathing, and overseeing play.

**child-centered** adj. focused on the needs, interests, safety, and well-being of children, as in child-centered home or child-centered education. See also CHILD-FOCUSED.

c**hild custody** the care, protection, and supervision of a child. In certain legal proceedings, such as divorce or separation, the court may grant custody to one or both parents following a CHILD CUSTODY EVALUATION.

**child custody evaluation** a procedure, often conducted by clinical psychologists, that involves evaluating parenting behavior, analyzing parental capacity to address a child’s needs, and providing the court with a recommendation regarding CHILD CUSTODY arrangements. See PRIMARY CREATIVITY STANDARD.

**child day care** see CHILD CARE.

**child development** the sequential changes in the behavior, cognition, and physiology of children as they grow from birth through adolescence. See DEVELOPMENTAL TASK.

**child-directed speech** the specialized register of speech that adults and older children use when talking to young children. It is simplified and often more grammatically correct than adult-directed speech. See also INFANT-DIRECTED SPEECH.

**child find** in the U.S. educational system, an organized screening and identification program, directed by each state’s Department of Education, that identifies preschool children in need of particular services and evaluates their readiness for school entry as well as their risk for developmental disabilities.

**child-focused family** a family in which the needs of one or more children are paramount, sometimes to a point where they dominate the family constellation and the parents’ needs become secondary. Also called child-centered family.

**child guidance** a mental health approach for children that focuses not only on treatment but also on the prevention of possible future disorders by offering instruction, information, and therapeutic aid to the child and his or her family. Child-guidance services and treatment are typically provided by specialized child-guidance clinics. The child-guidance movement emerged in the early 20th century and was at its strongest from the 1940s to 1970s.

**childhood n. 1.** the period between the end of infancy (about 2 years of age) and the onset of puberty, marking the beginning of ADOLESCENCE (10–12 years of age). This period is sometimes divided into (a) early childhood, from 2 years through the preschool age of 5 or 6 years; (b) middle childhood, from 6 to 8–10 years of age; and (c) late childhood or preadolescence, which is identified as the 2-year period before the onset of puberty. 2. the period between 3 or 4 years of age and about 7 years of age. In this context, childhood represents the period after weaning and before children can fend for themselves. Childhood in this more technical sense is unique to humans; other mammals advance directly from infancy to juvenility. See JUVENILE PERIOD. [defined by U.S. anthropologist Barry Bogin (1950–)]

**childhood absence epilepsy** a form of epilepsy in which children below the age of 7 experience frequent ABSENCE SEIZURES. It was formerly called pyknoelepsy.

**childhood amnesia** the commonly experienced inability to recall events from early childhood (see EARLY MEMORY). Childhood amnesia has been attributed to the facts that (a) cognitive abilities necessary for encoding events for the long term have not yet been fully developed and (b) parts of the brain responsible for remembering personal events have not yet matured. Also called infantile amnesia.

**childhood apraxia of speech** see DEVELOPMENTAL APRAXIA OF SPEECH.

**childhood autism** see AUTISM.

**childhood depression** a MAJOR DEPRESSIVE EPISODE that occurs in childhood. Defining symptoms may differ from those of major depressive episodes in adults in that irritable mood is more characteristic than depressed mood, and failure to make expected weight gains often replaces an actual weight loss.

**childhood disintegrative disorder** in DSM–IV–TR, a PERVASIVE DEVELOPMENTAL DISORDER characterized by a significant loss of two or more of the following: previously acquired language skills, social skills or adaptive behavior, bowel or bladder control, play, or motor skills. This regression in functioning follows a period of normal development and occurs between the ages of 2 and 10. Impairments in social interaction and communication are also evident. In DSM–5, childhood disintegrative disorder is subsumed into AUTISM SPECTRUM DISORDER and is no longer considered a distinct entity.

**childhood disorder** any social, emotional, behavioral, or educational disorder of childhood.

**childhood fears** fears occurring at different stages of childhood, such as fear of strangers, which usually develop around 8 months of age, and fear of heights, which emerges after the child learns to crawl. The content of fear changes for children from 2 to 6 years of age, with fears of darkness, animals, doctors, ghosts, monsters, and storms being common occurrences that usually pass in a few months or years without treatment.

**childhood neurosis** in Freudian theory, the development of psychological symptoms in childhood in response to efforts of defense against conflict.

**childhood-onset fluency disorder** in DSM–5, the term for STUTTERING.

**childhood psychosis** a PSYCHOTIC DISORDER with onset in childhood; the defining features (e.g., hallucinations, delusions) are essentially the same as they are for affected individuals in other age groups. Historically, the term has been used much more widely to denote any of a variety of disorders or mental conditions in children that result in severe functional impairment, encompassing, for example, intellectual disability and PERVASIVE DEVELOPMENTAL DISORDERS.

**childhood schizophrenia** schizophrenia with onset prior to age 12; the defining features of schizophrenia are essentially equivalent across all age groups. Historically, the term has been used more widely to denote schizophrenic behavior that appears early in life, encompassing Pervasive Developmental Disorders and Autism in particular.

**childhood sensorineural lesion** see SENSORINEURAL LESION.

**child molestation** child SEXUAL ABUSE: any sexual be-
child neglect

child neglect the denial of attention, care, or affection considered essential for the normal development of a child's physical, emotional, and intellectual qualities, usually due to indifference from, disregard by, or impairment in the child's caregivers. See also PARENTAL REJECTION.

child–parent relationship therapy (CPRT) a PLAY THERAPY-focused intervention for parents of children (ages 3–10) with emotional or behavioral difficulties. The therapy aims to help parents gain empathy for their child, improve their parenting skills, and strengthen their relationship with their child so as to reduce parental stress and decrease the child's emotional or behavioral problems. Also called child–parent relationship training. [introduced in 1991 by U.S. educator Garry L. Landreth]

child pornography pornographic material featuring children. This may include written stories, pictures, or videos of naked children or of children engaging in sexual activity. Child pornography is illegal in the United States, and production or circulation of such materials is usually vigorously prosecuted.

child psychology the branch of psychology concerned with the systematic study of the behavior, adjustment, and growth of individuals from birth through adolescence, as well as with the treatment of their behavioral, mental, and emotional disorders. See also DEVELOPMENTAL PSYCHOLOGY.

child psychotherapy psychotherapy for children up to the age at which they reach puberty. The focus may be on emotions, cognitions, or behavior. The level of parental involvement typically depends on the age of the child, type of problem, or approach used. The child may be treated concurrently in group or family therapy.

child-rearing practice a pattern of raising children that is specific to a particular society, subculture, family, or period in cultural history. Child-rearing practices vary in such areas as methods of discipline, expression of affection, and degree of permissiveness.

children in need of supervision (CHINS) children who commit offenses that may lead the court to act in service to them when they cannot be adequately controlled by parents or guardians. The child will typically appear before the court and receive some form of sanction. The crimes that lead to a CHINS classification are STATUS OFFENSES such as truancy, running away from home, and misbehavior at school.

Children's Apperception Test (CAT) a projective test for children ages 3 to 10 years that is based on the same principles as the THEMATIC APPERCEPTION TEST. A child is shown 10 drawings of animals (another version of the test. CAT-H, presents drawings of humans) and is asked to describe what he or she thinks is happening in each picture. Based on these descriptions, the test aims to measure the child's personality traits, attitudes, and psychodynamic processes. [developed in 1949 by Austrian-born U.S. psychiatrist Leopold Bellak (1916–2002) and Sonya S. Bellak]

Children's Auditory Verbal Learning Test (CAVLT) a measure designed for use with children ages 7 to 17 that assesses learning, storage, and retention of auditory information. In five successive LEARNING TRIALS, a child is read the same list of words and asked to recall the list after each time. After a brief delay, the child is again asked to recall the list from memory.

Children's Complex Figure Test see COMPLEX FIGURE TEST.

Children's Depression Inventory (CDI) a self-report questionnaire, based on the BECK DEPRESSION INVENTORY, designed to assess the severity of depression in children ages 7 to 17 years. Intended primarily as a research tool, the CDI comprises 27 items that each consist of three statements reflecting different levels of severity of a particular symptom. For each item, the participant chooses the statement that best describes himself or herself during the previous 2 weeks. [originally published in 1977 by U.S. clinical psychologist Maria Kovacs (1944– )]

Children's Embedded Figures Test (CEFT) a version of the EMBEDDED FIGURES TEST of cognitive style that is designed for children ages 5 to 12 years. Participants are required to detect a simple shape within 25 increasingly complex figures or colored backgrounds. [developed in 1963 by U.S. clinical psychologist Stephen A. Karp (1928– ) and Norma L. Konstadt]

Children's Manifest Anxiety Scale (CMAS) a 53-item modification of the TAYLOR MANIFEST ANXIETY SCALE that is appropriate for children. Originally developed in 1956 by U.S. psychologists Alfred Castaneda (1923–1981), Boyd R. McCandless (1915–1975), and David S. Palermo (1929–2011), the CMAS was subsequently revised in 1978 by U.S. educational psychologists Cecil R. Reynolds (1952– ) and Bert O. Richmond (1929– ). This Revised Children's Manifest Anxiety Scale (RCMAS) comprises 37 yes–no items measuring the nature and level of anxiety symptoms in children and adolescents ages 6 to 19 years. An updated edition (RCMAS2) was published in 2008.

Children's Personality Questionnaire (CPQ) a 140-item self-report inventory for children ages 8 to 12 years that is based on CATTELL'S PERSONALITY TRAIT THEORY. It assesses 14 dimensions of personality (e.g., shy vs. bold, self-assured vs. apprehensive, sober vs. enthusiastic) conceptualized as useful in evaluating, understanding, and predicting personal adjustment, social development, and academic performance. [originally developed in 1959 by U.S. educator Rutherford Burchard Porter (1909–2002) and Raymond B. Cattell]

child study movement the first organized effort, launched in the late 19th century by G. Stanley HALL, to apply scientific methods to the study of children. The movement focused on child welfare and, among other things, helped to bring about the passage of laws governing child labor and compulsory education.

child support a legally enforceable requirement that parents provide the financial means to meet the economic and educational needs of their children after the parents divorce or separate.

child visitation in the context of divorce or situations in which children have been legally placed in the care of another (e.g., foster care), the permission granted by the court allowing a noncustodial parent, grandparent, or other family member some time to visit the child, provided this contact remains in the best interests of the child. Also called visitation rights.

child welfare the emotional or physical well-being of children, particularly in the context of legal issues or of social programs designed to enrich or intervene in their lives.

child with special needs a child who requires SPECIAL
chlordiazepoxide

EDUCATION. Such children may have learning disabilities, intellectual disabilities, physical disabilities, or emotional difficulties. Also called special child: special needs child. See also EXCEPTIONAL CHILD.

chilophagia n. see CHIROPHAGIA.

chimera n. 1. an organism composed of two or more kinds of genetically dissimilar cells. For example, a chimera may have received a transplant of genetically different tissue, such as bone marrow, or it may have been produced by grafting an embryonic part of one animal onto the embryo of a genetically different animal; the graft may be either from a different species (a xenograft) or from a genetically nonidentical member of the same species (an allograft). 2. an illusion of the imagination, sometimes something desired but impossible to realize. —chimeric adj.

chimeric stimulation a procedure used by Roger Sperry and colleagues to study the functions of the two isolated cerebral hemispheres in split-brain patients. In a typical experiment, participants are presented with an image of a chimeric face, showing the left half of one face joined to the right half of a different face. Both halves are shown in gray scale and are adjusted to fit in an apparently natural way. In patients with a surgically severed corpus callosum, the left hemisphere perceives the left half of visual space, and the right hemisphere perceives the right half. If the patient’s eyes are fixating on the midline of the chimeric face, each hemisphere fills in the missing half by symmetry, yielding two separate percepts of two different faces. Sperry suggested that in split-brain patients there may be two conscious streams in the two hemispheres. See also COMMISSURETOMY; LEFT-HEMISPHERE CONSCIOUSNESS; RIGHT-HEMISPHERE CONSCIOUSNESS.

chimerism n. the presence in an individual of cells with different genotypes, derived from different zygotes. Compare MOSAICISM.

China white see FENTANYL.

Chinese Room argument a philosophical argument claiming that computers or symbol-processing systems can receive and produce only syntactical streams of ordered signs and not semantic information. The name derives from a thought experiment in which a monolingual English speaker in a sealed room attempts to organize streams of Chinese characters into correct sequences, using only a set of rules of Chinese syntax provided by a computer program, and sends these sequences to a Chinese-speaking recipient outside the room. Success at this task produces an exchange that to the recipient is meaningful conversation but that to the English speaker is an exercise in mastering Chinese syntax; like the computer program that generated the syntactical instructions, the English speaker still has no understanding of the meaning of Chinese. The Chinese Room argument is intended as a challenge to conclusions about the significance of passing the TURING TEST: A computer program that successfully simulated intelligent data (such as syntactical rules) would pass this test, but such a simulation is not the same as actual human intelligence and thought. [proposed by U.S. philosopher John R. Searle (1932—).

chin reflex see JAW JERK.

CHINS acronym for CHILDREN IN NEED OF SUPERVISION.

chipper n. 1. someone who smokes five or fewer cigarettes on an average of four days a week with no evidence of withdrawal or addiction. 2. someone who uses opiates occasionally without reaching the point of abuse or dependence.

chiromancy (chiro-mancy) n. see PALMISTRY. —chiromancer n.

chiropractic n. an alternative health care system concerned with the relationship between vertebral alignment within the spine and disease processes. Treatment comprises noninvasive drug-free methods, primarily manipulations and adjustments to the body, theorized to restore proper nerve functioning and to promote health. See also COMPLEMENTARY AND ALTERNATIVE MEDICINE. —chiropractor n.

chiroscopy n. see PALMISTRY. —chiroscoper n.

chi-square (symbol: \( \chi^2 \)) n. a statistic that is the sum of the squared differences between the observed scores in a data set and the EXPECTED VALUE. That is, to obtain the chi-square one finds the difference between each observed score and the expected score, squares that difference, and divides by the expected score; finally, one adds the resulting values for each score in the set. The smaller the chi-square, the more likely it is that the model from which the expected score is obtained provides a legitimate representation of the phenomenon being measured.

chi-square distribution (\( \chi^2 \) distribution) a distribution of the sums of independent squared differences between the observed scores in a data set and the expected score for the set. If a random sample is repeatedly drawn from a normal population and measured on some variable and the obtained scores transformed via STANDARDIZATION, multiplied by themselves, and then added, the result will be a chi-square distribution with DEGREES OF FREEDOM equal to the size of the samples drawn.

chi-square test any of various procedures that use a CHI-SQUARE DISTRIBUTION to evaluate how well a theory fits a set of observed data. Unless otherwise specified, this term usually refers to the chi-square test for independence, used to determine whether there is a relationship between two variables whose values are categories. For example, it may be used to test whether sex (male vs. female) is unrelated to having a household pet (yes vs. no). It compares observed data to the data that would be expected in each cell of a CONTINGENCY TABLE if the two variables were entirely independent. This discrepancy between observed and expected counts is then used to compute the CHI-SQUARE statistic. Also called chi-square procedure.

chloral hydrate a short-acting depressant of the central nervous system, first synthesized in 1832 and once widely used chiefly as a hypnotic. It is occasionally still used to induce sleep, but its use is limited by its potential toxicity: U.S. trade name: Aquachloral. See also KNOCKOUT DROPS.

chlordiazepoxide n. the first commercially available BENZODIAZEPINE anxiolytic. Developed in 1957 and in clinical use in the early 1960s, it became one of the most heavily prescribed medications ever developed. It is characterized by extensive metabolism in the liver and possesses a number of metabolic products, giving it a lengthy HALF-LIFE and a consequent long-acting anxiolytic effect. Its use in the management of anxiety and insomnia has been largely supplanted by benzodiazepines with less complicated metabolism and more predictable half-lives, but it remains in common use to protect against the effects of alcohol withdrawal. It is available in oral and injectable...
chloride channel

form. Because of erratic absorption, intramuscular administration is not advised. U.S. trade name: Librium.

chloride channel see ION CHANNEL.

chloropsia n. see CHROMATOPSIS.

chlorpromazine (CPZ) n. the first synthesized ANTIPSYCHOTIC agent, introduced into clinical use in Europe in 1952 and in Canada and the United States in 1954. It was initially used to reduce presurgical anxiety and deepen conscious sedation during surgical procedures; its antipsychotic effects were discovered serendipitously. This low-potency PHENOTHIAZINE provided a degree of previously unavailable behavioral control and management of positive psychotic symptoms and ushered in the modern era of psychopharmacological treatment. However, although effective in managing the acute symptoms of schizophrenia, acute mania, and other psychoses, chlorpromazine caused a number of unwanted adverse effects, including neuro muscular rigidity and other EXTRAPYRAMIDAL SYMPTOMS, sedation, orthostatic hypotension, cognitive slowing, and long-term association with TARDIVE DysKINESIA. Although chlorpromazine has been largely supplanted by newer antipsychotic agents, it is still used as a referent for dose equivalency of other antipsychotics. It has also been used in lower doses to treat nausea, vomiting, and intractable hiccups. U.S. trade name: Thorazine.

chlorprothixene n. a low-potency antipsychotic of the THIOXANTHENE class, similar in its effects to other thioxanthenes. U.S. trade names: Taractan, Taractin.

choice axiom a mathematical model of decision making that assumes, given several alternatives from which to choose, the probability that a particular alternative will be picked is independent of the sequence of decisions. [developed in 1959 by U.S. mathematician and psychologist R. Duncan Luce (1925–2012)]

choice behavior the selection of one of many available options or behavioral alternatives.

Choice Dilemma Questionnaire (CDQ) a research instrument used in studies of the RISKY SHIFT to measure an individual’s willingness to make risky or cautious decisions. Respondents are presented with a series of scenarios involving a course of action that might or might not yield financial, interpersonal, or educational benefits; they then indicate what the odds of success would have to be before they would recommend the course of action. [originally developed by U.S. social psychologists Nathan Kogan (1926–2013) and Michael A. Wallach (1933–)]

choice reaction time the total time that elapses between the presentation of a stimulus and the occurrence of a response in a task that requires a participant to make one of several different responses depending on which one of several different stimuli is presented. The time actually required to decide on a response can be calculated using DONDER'S METHOD. Also called complex reaction time: compound reaction time. Compare SIMPLE REACTION TIME.

choice shift any change in an individual’s choices or decisions that occurs as a result of group discussion, as measured by comparing his or her prediscussion and postdiscussion responses. In many cases, a RISKY SHIFT is seen within the group as a whole. See also CAUTIOUS SHIFT.

choice stimuli in REACTION-TIME tasks, the array of possible stimuli that may occur in a particular trial. Each stimulus or item in the array is mapped to a different response (e.g., a different key to be pressed). Participants must decide which response to make to a particular stimulus.

choked disk see PAPILLEDEMA.

chokes n. see DECOMPRESSION SICKNESS.

choking under pressure a paradoxical effect in which the demands of a situation that calls for good performance—such as a school test, sports competition, or job interview—cause an individual to perform poorly relative to his or her capabilities. Pressure denotes the individual’s desire to perform well: choking refers to the actual decrement in performance that results.

cholecystokinin (CCK) n. a PEPTIDE HORMONE that is released from the duodenum and may be involved in the satiation of hunger. It also serves as a NEUROTRANSMITTER at some locations in the nervous system.

choleric type a type of temperament characterized by irritability and quick temper, as described by GALEN. See HUMORAL THEORY.

cholesterol n. a steroid derivative abundant in animal tissues, found especially in foods rich in animal fats. Cholesterol is a constituent of plasma membranes, the precursor of other steroids (e.g., the sex hormones), and a component of plasma lipoproteins, especially low-density lipoproteins (LDLs), which are believed to play an important role in forming atherosclerotic plaques (see Atherosclerosis).

choline n. a BIOGENIC AMINE, often classed as a B vitamin, that is a constituent of many important compounds, such as ACETYLCHOLINE and lecithin (a component of plasma membranes).

choline acetylase an enzyme that is involved in the production of the neurotransmitter ACETYLCHOLINE from choline and acetyl coenzyme A. Also called choline acetyltransferase.

cholinergic adj. responding to, releasing, or otherwise involving ACETYLCHOLINE. For example, a cholinergic neuron is one that employs acetylcholine as a neurotransmitter.

cholinergic drug any pharmacological agent that stimulates activity in the PARASYMPATHETIC NERVOUS SYSTEM because it potentiates the activity of ACETYLCHOLINE or has effects similar to this neurotransmitter. Cholinergic drugs include such alkaloids as PHYSOSTIGMINE and PILOCARPINE; BETHANECHOL; and anticholinesterases (CHOLINESTERASE inhibitors: e.g., EDROPHONIUM, NEOSTIGMINE, and PYRIDOSTIGMINE). They are used for such purposes as treating myasthenia gravis, glaucoma, and urinary retention. Also called parasympathetic drug: parasympathomimetic drug.

cholinergic receptor another name for an ACETYLCHOLINE RECEPTOR. Also called cholinoreceptor.

cholinergic synapse a SYNAPSE that uses ACETYLCHOLINE as a neurotransmitter. Cholinergic synapses are found in postganglionic parasympathetic fibers, autonomic preganglionic fibers, preganglionic fibers to the adrenal medulla, somatic motor nerves to the skeletal muscles, and fibers to the sweat glands.

cholinergic system the part of the AUTONOMIC NERVOUS SYSTEM that reacts to the neurotransmitter ACETYLCHOLINE and to cholinergic drugs. Activities of this system
are inhibited by ANTICHOLINERGIC DRUGS, such as atropine. Compare ADRENERGIC SYSTEM.

**cholinesterase (ChE)** n. an enzyme that splits ACETYLCHOLINE into choline and acetic acid, thus inactivating the neurotransmitter after its release at a synaptic junction. Cholinesterase occurs in two forms: *acetylcholinesterase* (AChE), found in nerve tissue and red blood cells; and *butyrylcholinesterase* (BuChE, or *pseudocholinesterase* [PChE]), found in blood plasma and other tissues. Drugs that block the ability of this enzyme to degrade acetylcholine are called cholinesterase inhibitors (ChEIs), or acetylcholinesterase inhibitors [AChEIs] or anticholinesterases. Some ChEIs are used clinically to slow the progression of dementia in Alzheimer’s disease. See COGNITIVE ENHANCER.

**chondroectodermal dysplasia** see ELLIS–VAN CREVELD SYNDROME.

**chorda tympani** see GREATER SUPERFICIAL PETROSAL NERVE.

**chord keyboard** a keyboard with a limited number of keys that can be used to enter a wide range of alphanumerical information by pressing various keys in combination. Some can support one-handed entry. See also DVORAK KEYBOARD.

**chorea** n. irregular and involuntary jerky movements of the limbs and facial muscles. Chorea is associated with various disorders, including HUNTINGTON’S DISEASE and Sydenham’s chorea (formerly known as *Saint Vitus’s dance*), which occurs as a complication of a streptococcal infection (e.g., rheumatic fever). —choreal adj. —choreic adj.

**choreiform** adj. involving involuntary movement that resembles CHOREA. Also called choreoid.

**choreoathetosis** n. chorea accompanied by athetosis (involuntary writhing) of the face, tongue, hands, and feet. The condition is characteristic of HUNTINGTON’S DISEASE.

**choreoid** adj. see CHOREIFORM.

**choreomania** n. an uncontrollable urge to dance, especially in a frenzied, convulsive manner. Major outbreaks of choreomania occurred in Europe during the Middle Ages. Also called dancing madness: dancing mania.

**chorion** n. the outermost of the membranes that surround and protect the developing embryo. In most mammals (including humans), a section of it forms the embryonic part of the placenta. —chorionic adj.

**chorionic villus sampling** (CVS) a method of diagnosing diseases and genetic and chromosomal abnormalities in a fetus. Samples of cells from the chorionic villi, the microscopic projections in the protective membrane surrounding the fetus, are obtained for analysis by bacteria, metabolites, or DNA. Unlike amniocentesis, this procedure can be carried out in the first trimester of pregnancy. Compare PERCUTANEOUS UMBILICAL CORD BLOOD SAMPLING.

**choroid layer** the vascular pigmented layer of tissue that covers the back of the eye and is located between the retina and the sclera. In the anterior portion of the eye it is continuous with the pigmented portion of the CILIARY BODY. The pigment in the choroid layer absorbs stray light; the blood vessels include the choriocapillaris, a plexus of capillaries that provides oxygen and sustenance to the photoreceptors of the retina. Also called choroid: choroid coat.

**choroid plexus** a highly vascularized portion of the lining of the cerebral ventricles that is responsible for the production of CEREBROSPINAL FLUID.

**Chotzen’s syndrome** a genetic condition characterized by an abnormally shaped head due to premature closing of one or more of the cranial sutures, usually involving the coronal suture (see CRANIOSYNOSTOSIS SYNDROME), and by webbing of the fingers and toes. Delayed development and learning difficulties can be associated with the disorder, but affected children often have average intelligence. Most cases are caused by mutations in the TWIST1 gene. In a small number of cases, when the cause is a chromosomal deletion instead of a mutation within the TWIST1 gene, affected children are much more likely to have intellectual disability, developmental delay, and learning difficulties. It is thought that a loss of other genes on chromosome 7 may be responsible for these additional features. Also called acrocephalosyndactyly Type III: Saethre–Chotzen syndrome. [F. Chotzen, German physician]

**Christian Science** a Protestant Christian religious denomination founded in 1879 by U.S. spiritual leader Mary Baker Eddy (1821–1910). It is based on the idea that mind has power over matter, enabling MENTAL HEALING, particularly through prayer, of both spiritual ill health (i.e., sin) and physical illness and disease. The reliance of adherents on their beliefs has sparked many controversies regarding refusal of medical and mental health care.

**chrom-** combining form see CHROMO-.

**chroma–brightness coefficient** the relationship between saturation and intensity in the Munsell color system.

**chromatic adj.** 1. in vision, possessing both hue and saturation. Thus, a chromatic color is any color other than black, white, or gray. Compare achromatic. 2. in music, pertaining to an octave scale in which each note differs from the preceding note by one semitone. Compare diatonic.

**chromatic aberration** a defect in the image formed by a simple glass lens resulting from the fact that light of short wavelength is refracted to a greater extent than light of long wavelength. It causes different colors to be focused at different distances, so that the image has colored fringes. Chromatic aberration can be corrected by the use of an achromatic lens. Also called chromatic error.

**chromatic adaptation** decreased sensitivity to a particular color as a result of prolonged exposure to a colored stimulus. Also called color adaptation.

**chromatic audition** a type of SYNESTHESIA in which color sensations are experienced when sounds are heard. Also called phonopsis. See chromesthesia.

**chromacity** n. a color-stimulus quality determined by the purity and wavelength of the stimulus, independent of its LUMINANCE. Chromaticity and luminance together provide a description of a colored stimulus that is independent of an observer’s perceptions. Also called chromaticness.

**chromatics** n. in optics, the study of color and the sensation of color.

**chromatid** n. in cell division, one of the two duplicate, filamentlike subunits, joined at the CENTROMERE, that make up a chromosome and then separate, each going to a different pole of the dividing cell to become a new chromosome in one of the daughter cells.
chromatin  

**chromatin** n. a substance present in chromosomes and cell nuclei that consists of nucleic acids (mainly DNA) combined with protein (i.e., nucleoprotein). It readily stains with certain identifying dyes.

**chromatin negative** denoting the absence of SEX CHROMATIN in the nucleus of a human somatic cell; this absence identifies the cell as being from a male.

**chromatin positive** denoting the presence of SEX CHROMATIN in a human somatic cell; this presence identifies the cell as being from a female.

**chromatopsia** n. an aberration in color vision in which there is excessive visual sensitivity to one color, such that objects appear tinged with that color. Chromatopsia is caused by drugs, intense stimulation, or SNOW BLINDNESS, and it can occur after eye hemorrhages, cataract extraction, electric shock, or optic atrophy. There are several forms: erythropsia (red vision), chloropsia (green vision), xanthopsia (yellow vision), and cyanopsia (blue vision). Also called chromopsia.

**chromesthesia** n. a type of SYNESTHESIA in which perception of nonvisual stimuli (e.g., sounds, tastes, odors) is accompanied by color sensations. Strictly speaking, chromesthesia is not a conscious juxtaposition of two different sense perceptions: The two perceptions coincide as responses to the same stimulus (e.g., the musical note G may be consistently experienced as blue). Also called pseudochromesthesia.

**chronic myopia** see MYOPIA.

**chromo-** (chrom-: chromato-) combining form color.

**chromoprotein** n. see CHROMOPHORE.

**chromosomal aberration** 1. an abnormal change in the structure of a chromosome. 2. a congenital defect that can be attributed to an abnormal chromosome. See AUTOSOMAL ABBERRATION; SEX-CHROMOSOMAL ABBERRATION.

**chromosomal map** the appearance of a stained chromosome when observed under a microscope. Visually distinct light and dark bands give each chromosome a unique pattern, which enables KARYOTYPE testing to be carried out.

**chromosomal mutation** see MUTATION.

**chromosome** n. a strand or filament composed of nucleic acid (mainly DNA in humans) and proteins (see CHROMATIN) that carries the genetic, or hereditary, traits of an individual. Located in the cell nucleus, chromosomes are visible, through a microscope, only during cell division. The normal human complement of chromosomes total 46, or 23 pairs (44 AUTOSOMES and 2 SEX CHROMOSOMES), which are believed to contain a total of 20,000 to 25,000 genes (see GENOME). Each parent contributes one chromosome to each pair, so a child receives half its chromosomes from its mother and half from its father. —chromosomal adj.

**chromosome 4, deletion of short arm** a chromosomal disorder involving absence of a portion of chromosome 4, resulting in MICROCEPHALY, delayed growth, visual defects, intellectual disability, and seizures. The size of the deleted genetic material varies, and studies suggest that larger deletions tend to result in more severe intellectual disability and physical abnormalities than do smaller deletions. Although sometimes the disorder is passed on from an unaffected parent, most cases are not inherited. Also called Wolf–Hirschhorn syndrome.

**chromosome 5, deletion of short arm** see CRI DU CHAT SYNDROME.

**chromosome 18, deletion of long arm** a chromosomal disorder involving absence of a portion of chromosome 18 and resulting in MICROCEPHALY, short stature, hypotonia, hearing impairment, foot deformities, and intellectual disability. Also called distal 18q-.

**chromosome abnormality** an abnormality that is evidenced by either an abnormal number of chromosomes or some alteration in the structure of one or more chromosomes.

**chromosome disorder** any disorder caused by a defect in the structure or number of one or more chromosomes. Such disorders can result from AUTOSOMAL ABBERRATIONS or SEX-CHROMOSOMAL ABBERRATIONS.

**chromosome mosaicism** a condition resulting from an error in the distribution of chromosomes between daughter cells during an early embryonic cell division, producing two and sometimes three populations of cells with different chromosome numbers in the same individual. Mosaicism involving the sex chromosomes is not uncommon (see HERMAPHRODITISM).

**chromosome number** the number of chromosomes present in the tissue cells of an individual. All members of a species normally have the same number of chromosomes. The normal number for humans is 46. In most mammals, the chromosome number of a gamete, or reproductive cell, is half the somatic chromosome number; for example, in humans, it is 23. See DELETION.

**chromotherapy** n. see PHOTOTHERAPY.

**chron-** combining form see CHRONO-.

**chronaxie** (chronaxy) n. an index of excitability of a nerve or muscle, measured as how long it takes an electrical current of twice the THRESHOLD intensity to elicit a nerve impulse or a muscular contraction. Also called chronaxia.

**chronesthesia** n. a hypothetical ability or capacity of the human brain or mind, acquired through evolution, that allows humans to be constantly aware of the past and the future. The key feature of this “mental time travel” is to enable people to anticipate the future—that is, to learn what to avoid and how to behave in the future—by recalling past events. For example, chronesthesia enables people over time to “distinguish friends from foes” in social relationships and to develop tools that work well (and discard those that do not) in occupational activities. [introduced by Endel TULVING]

**chronic** adj. denoting conditions or symptoms that persist or progress over a long period of time and are resistant to cure. Compare ACUTE.

**chronic adjustment disorder** see ADJUSTMENT DISORDER.

**chronic alcoholism** habitual, long-term dependence on alcohol (see ALCOHOL DEPENDENCE).

**chronically accessible constructs** mental contents (e.g., ideas or categories) that are frequently used and therefore come to mind particularly readily.

**chronically suicidal** describing an individual with a history of multiple suicide attempts or episodes that include serious thoughts about or plans for committing sui-
cide. Such a history often occurs in individuals with borderline personality disorder.

**chronic anxiety** a persistent, pervasive state of apprehension that may be associated with aspects of a number of anxiety disorders. These include uncontrollable worries in generalized anxiety disorder, fear of a panic attack in panic disorder, and obsessions in obsessive-compulsive disorder.

**chronic brain disorder** any disorder caused by or associated with brain damage and producing permanent impairment in one or more areas of brain function (cognitive, motor, sensory, and emotional). Such disorders may arise from trauma, stroke, infection, degenerative diseases, or many other conditions. In older literature, these disorders are also referred to as chronic brain syndromes.

**chronic care** long-term care and treatment of patients with long-standing health problems.

**chronic fatigue syndrome (CFS)** an illness characterized by ongoing disabling fatigue, decrease in physical activity, and flu-like symptoms, such as muscle weakness, swelling of the lymph nodes, headache, sore throat, and sometimes depression. The condition is typically not diagnosed until symptoms have been ongoing for several months, and it can last for years. The cause is unknown, although certain viral infections can set off the illness.

**chronic illness** illness that persists for a long period. Chronic illnesses include many major diseases and conditions, such as heart disease, cancer, diabetes, and arthritis. Disease management is important when dealing with chronic illness: this includes ensuring adherence to treatment and maintaining quality of life.

chronicity n. 1. the state of being chronic. 2. see social breakdown syndrome.

**chronic mood disorder** see mood disorder.

**chronic motor or vocal tic disorder** in DSM–IV–TR, a tic disorder characterized by motor or vocal tics (but not both) for a period of more than 1 year, during which any period without tics lasts for no more than 3 months. The disorder has an onset before the age of 18. It is identified as persistent (chronic) motor or vocal tic disorder in DSM–5. Compare Tourette's disorder.

**chronic myofascial pain** (CMP) a musculoskeletal disorder characterized by pain and stiffness that is restricted to certain locations on the body, called trigger points. It is nonprogressive, nondegenerative, and noninflammatory. Chronic myofascial pain is sometimes referred to as myofascial pain syndrome (MPS), especially in older literature.

**chronic obstructive pulmonary disease (COPD)** any of a group of lung diseases, most commonly chronic bronchitis and emphysema, that are characterized by limited airflow with varying degrees of lung-tissue damage and alveolar (air-sac) enlargement. Marked by coughing, wheezing, and shortness of breath, COPD is caused by cigarette smoking, exposure to other irritants and pollutants, lung infections, or genetic factors. Individuals with COPD frequently experience depression, anxiety, and problems with sexual function; they also sometimes have cognitive and neuropsychological difficulties that may be associated with chronic deficiencies of oxygen to the brain. In addition to medical treatments, behavioral interventions (e.g., those that promote smoking cessation and exercise), psychotherapy, and treatment with psychoactive drugs can benefit patients with this condition. Also called chronic obstructive lung disease.

**chronic pain** pain that continues to occur despite all medical and pharmacological efforts at treatment. In many cases, the pain is initially caused by tissue damage or disease. The continuation of the pain is often the result of pathological changes in the central nervous system.

**chronic posttraumatic stress disorder** a form of posttraumatic stress disorder that is diagnosed when the symptoms persist over a period of more than 3 months.

**chronic preparation** the process by which a research animal undergoes an experimental procedure, often surgical in nature, and is then allowed to recover so that it can be observed over an extended period of time. Compare acute preparation.

**chronic psychosis** 1. a delusional or hallucinatory state that persists indefinitely. 2. a former name for chronic schizophrenia. 3. historically, any irreversible disorder of cognition, mood or affect, and behavior.

**chronic schizophrenia** schizophrenia in which the symptoms persist for an extended period. It is contrasted with acute schizophrenic episodes, in which the symptoms are more transient.

**chronic stress** the physiological or psychological response to a prolonged internal or external stressful event (i.e., a stressor). The stressor need not remain physically present to have its effects; recollections of it can substitute for its presence and sustain chronic stress.

**chronic traumatic encephalopathy** see dementia pugilistica.

chrono- (chron-) combining form time.

**chronobiology** n. the branch of biology concerned with biological rhythms, such as the sleep–wake cycle.

**chronograph** n. an instrument that records time sequences graphically. —chronographic adj.

**chronological age (CA)** the amount of time elapsed since an individual’s birth, typically expressed in terms of months and years. Also called calendar age. Compare biological age.

**chronometer** n. a precise clock that runs continuously and is designed to maintain its accuracy under all conditions of temperature, pressure, and the like.

**chronometric analysis** a method for studying a mental process that involves varying stimulus input conditions and measuring participants’ reaction times to those stimuli. The relations between the stimulus variables and reaction times are then used to make inferences about the underlying mental processes. Also called mental chronometry. See donder’s method.

**chronometry** n. the measurement of time. —chronometric adj.

**chronopsychology** n. the scientific study of the way in which changes to daily sleep–wake cycles can affect the ability to function.

**chronosystem** n. in ecological systems theory, changes and continuities occurring over time that influence an individual’s development. These influences include normative life transitions (e.g., school entry, marriage, retirement), nonnormative life transitions (e.g., divorce, winning the lottery, relocation), and the cumulative effects of
chronotaraxis

the entire sequence of transitions over the life course. Compare EXOSYSTEM; MESOSYSTEM; MACROSYSTEM. [introduced by Urie Bronfenbrenner]

chronotaraxis n. a condition of time confusion in which the individual tends to underestimate or overestimate the passage of time or is confused about the time of day or day of the week.

chronotherapy n. a treatment for CIRCADIAN RHYTHM SLEEP DISORDERS that systematically moves bedtime progressively later by intervals (phase delays) until it approaches the desired bedtime.

chronotropic constraints the limitations imposed by the development of the brain on the timing of maturational events, such as the acquisition of language-processing ability. See also ARCHITECTURAL CONSTRAINTS; REPRESENTATIONAL CONSTRAINTS.

chunking n. 1. the process by which the mind divides large pieces of information into smaller units (chunks) that are easier to retain in SHORT-TERM MEMORY. As a result of this RECORDING, one item in memory (e.g., a keyword or key idea) can stand for multiple other items (e.g., a short list of associated points). The capacity of short-term memory is believed to be constant for the number of individual units it can store (see SEVEN PLUS OR MINUS TWO), but the units themselves can range from simple chunks (e.g., individual letters or numbers) to complex chunks (e.g., words or phrases). The exact number of chunks remembered depends on the size of each chunk or the subunits contained within each chunk. 2. the associated principle that effective communication between humans depends on sorting information into units that do not exceed the mind’s capacity to chunk them (the chunking limit). This has implications for the content and layout of written documents, diagrams and visual aids, websites, and so on. For example, any list of more than nine bullet points should normally be subdivided into two or more shorter lists. [coined by George Armitage Miller in 1956]

Cl abbreviation for CONFIDENCE INTERVAL.

cicatrization n. 1. the formation of a scar, or cicatrix, after a wound has healed. 2. the deliberate scarring of some part of the body for cosmetic or religious purposes. —cicatrize vb.

cichlid n. a tropical spiny-finned freshwater fish that is commonly the subject of behavioral studies.

-cide suffix killer or killing (e.g., INFANTICIDE).

CIE XYZ color space see XYZ SYSTEM.

CIL abbreviation for Center for Independent Living. See INDEPENDENT LIVING.

cilia pl. n. see CILIUM.

ciliary body a part of the eye located behind the iris and consisting of the CILIARY PROCESSES and the CILIARY MUSCLES.

ciliary muscle smooth muscle in the CILIARY BODY of the eye that changes the shape of the lens to bring objects into focus on the retina. The ciliary muscle regulates the tension of the ZONULES, causing the lens to flatten (which lessens the power of the lens and allows focus of distant objects) or become more curved (which increases the power of the lens and allows focus of near objects). The action of the ciliary muscle is a large component of ACCOMMODATION.

ciliary processes the extensions of the CILIARY BODY that project into the posterior chamber of the eye. The ciliary processes are covered by epithelial cells that produce the AQUEOUS HUMOR and are connected by the ZONULES to the capsule of the lens.

cilium n. (pl. cilia) 1. an eyelash. 2. a hairlike extension of a cell, usually occurring in tufts or tracts, as in the stereocilia of HAIR CELLS in the cochlea of the inner ear. —ciliary adj.

Cinderella syndrome behavior in childhood based on the child’s belief of being a “Cinderella,” or a victim of parental rejection, neglect, or abuse.

cingulate cortex a long strip of CEREBRAL CORTEX on the medial surface of each cerebral hemisphere in the prefrontal lobe. The cingulate cortex arches over and generally outlines the location of the CORPUS CALLOSUM, from which it is separated by the CALLOSAL SULCUS. It is a component of the LIMBIC SYSTEM and has a role in emotion and memory; it also has a role in motor planning. Also called callosal gyrus: cingulate gyrus; gyrus cinguli. See also ANTERIOR CINGULATE CORTEX; POSTERIOR CINGULATE CORTEX.

cingulate sulcus the fissure that separates the CINGULATE CORTEX from the superior frontal gyrus on the medial surface of each cerebral hemisphere.

cingulotomy n. a procedure used in the treatment of chronic pain in which electrodes are used to destroy portions of the CINGULUM BUNDLE. It is also, albeit rarely, used in the treatment of some chronic mental disorders (e.g., OBSESSIVE-COMPULSIVE DISORDER) that have not responded to other, nonsurgical forms of treatment. Also called cingulotomy.

cingulum bundle a longitudinal tract of nerve fibers, lying beneath the CINGULATE CORTEX, that connects the frontal lobe with the PARAHIPPOCAMPAL GYRUS and adjacent regions in the temporal lobe.

CIPS abbreviation for Clance Impostor Phenomenon Scale. See IMPOSTOR PHENOMENON.

circadian dysrhythmia a disruption of the normal cycles of wakefulness and sleep. See CIRCADIAN RHYTHM SLEEP DISORDER.

circadian oscillator a neural circuit with an output that repeats about once per day. A circadian oscillator is located in the SUPERCHIASMATIC NUCLEUS of the hypothalamus and is thought to be important in sleep–wake cycles.

circadian rhythm any periodic variation in physiological or behavioral activity that repeats at approximately 24-hour intervals, such as the SLEEP–WAKE CYCLE. Also called diurnal rhythm. Compare INFRADIAN RHYTHM; ULTRADIAN RHYTHM. See also BIOLOGICAL RHYTHM.

circadian rhythm sleep disorder in DSM–IV–TR, a sleep disorder that is due to a mismatch between the sleep–wake schedule required by a person’s environment or occupational circumstances (e.g., shift work) and his or her circadian sleep–wake pattern, resulting in excessive sleepiness or insomnia. This disorder was formerly called SLEEP–WAKE SCHEDULE DISORDER. DSM–5 calls it circadian rhythm sleep–wake disorder. See DYSSOMNIA. See also DISORDERS OF THE SLEEP–WAKE CYCLE SCHEDULE.

circular annual a BIOLOGICAL RHYTHM of behavior, growth, or some other physiological variable that recurs yearly.
**Circumstantiality**

**Circle of Security** a 20-week ATTACHMENT-BASED INTERVENTION that aims to reduce the long-term risks associated with INSECURE ATTACHMENT in children. It is individualized for a particular caregiver–child dyad on the basis of the child’s insecure attachment classification (e.g., anxious–resistant) and the caregiver’s behavior and INTERNAL WORKING MODEL OF ATTACHMENT. It is delivered in a systematic week-by-week, video-based group model and consists of both educational and therapeutic components. [developed by U.S. developmental psychologist Robert S. Marvin (1944–)]

**circle of support** a group of people who provide support for an individual. For a person with a developmental disability, the circle often includes family members, friends, acquaintances, coworkers, and sometimes service providers or coordinators, who meet on a regular basis and help the individual accomplish personal goals. These goals are selected based on extensive and recurrent review of the person’s past and current preferences and interests; they are addressed one stage at a time.

**circle of Willis** a ring of blood vessels on the underside of the brain, formed by links between branches of several major arteries—the BASILAR ARTERY, INTERNAL CAROTID ARTERY, ANTERIOR CEREBRAL ARTERY, ANTERIOR COMMUNICATING ARTERY, MIDDLE CEREBRAL ARTERY, POSTERIOR CEREBRAL ARTERY, and POSTERIOR COMMUNICATING ARTERY. By providing multiple pathways for blood circulation, this arrangement ensures the continuous flow of oxygenated blood to the brain in the event a supplying artery becomes blocked or constricted as a result of an injury, disease, or other condition. Also called arterial circle. [Thomas Willis (1621–1675), English anatomist and physician who was the first to illustrate this area definitively and provide a description of its function]

**circuit resistance training** a series of different exercises set out in a specific order, with a specific time or number of repetitions for each exercise. The type and order of exercises will be set according to their use as rehabilitation—health-related exercise for individuals with spinal cord injuries, diabetes, obesity, and other conditions—or as fitness training for athletes.

**circular behavior** any action that stimulates a similar action in others, such as yawning or laughing. Also called **behavioural contagion**. A technique used in some meth-od of family therapy to yield information about the dynamics and relationships in a family. For example, one family member may be asked to answer a question about who in the family is most depressed: subsequent family members each respond to the same question. This method of questioning everyone in the “circle” is intended to elicit the various perspectives within the group.

**circular reaction** 1. any action that generates a response that provides the stimulation for the action, often such that responses increase in intensity and duration. An example is the contraction of a muscle that sends a nerve impulse toward the brain or spinal cord, which in turn sends a nerve impulse back to the muscle to maintain the contraction. Also called circular reflex. 2. in PIAGETIAN THEORY, repetitive behavior observed in children during the SENSORIMOTOR STAGE, characterized as primary, secondary, or tertiary circular reactions. The primary phase involves ineffective repetitive behaviors; the secondary phase involves repetition of actions that are followed by reinforcement, typically without understanding causation; and the tertiary phase involves repetitive object manipulation, typically with slight variations among subsequent behaviors. 3. in the analysis of crowds and collectives, repetitive behavior that produces BEHAVIORAL CONTAGION as individuals imitate others’ actions without considering the meaning or consequences of those actions.

**circular reasoning** a type of informal FALLACY in which a conclusion is reached that is not materially different from something that was assumed as a premise of the argument. In other words, the argument assumes what it is supposed to prove. Circular reasoning is sometimes difficult to detect because the premise and conclusion are not articulated in precisely the same terms, obscuring the fact that they are really the same proposition.

**circulating levels** see BLOOD LEVELS.

**circular system** see CARDIOVASCULAR SYSTEM.

**circumcision** n. the surgical removal of the foreskin of the penis, typically for religious, cultural, or medical reasons. Circumcision is often performed in infancy but may be performed at any age.

**circumlocution** n. 1. a mode of speaking characterized by difficulty or inability in finding the right words to identify or explain an object that has been perceived and recognized. It involves the use of a variety of words or phrases that indirectly communicate the individual’s meaning. Circumlocution can be a manifestation of ANOMIC APHASIA caused by damage to the left posterior temporal lobe of the brain, but in some cases it is an indication of disorganized thought processes, as in schizophrenia. See CIRCUMSTANTI ALITY. 2. a style of speaking used consciously by healthy individuals to convey meaning indirectly, so that the meaning is inferred by the listener.

**circumplex** n. a circular depiction of the similarities among multiple variables. For example, a researcher studying emotions might focus on certain core affects and create a circumplex representation of them, with variables having opposite values or characteristics (i.e., tranquility–frenzy; sadness–enthusiasm; sluggishness–excitement) displayed at opposite points on the circumplex, whereas variables having highly similar characteristics are displayed adjacent to one another on the circumplex. In other words, the similarity (and correlation) between elements declines as the distance between them on the circle increases.

**circumscribed amnesia** see LOCALIZED AMNESIA.

**circumscribed belief** a narrowly defined delusional belief that is internally consistent and highly resistant to disproof and appears to function separately from other beliefs held by the same person.

**circumstantial bilingualism** see FOLK BILINGUALISM.

**circumstantial evidence** evidence from which the existence of a fact may be inferred but that does not constitute direct proof of that fact.

**circumstantiality** n. circuitous, indirect speech in which the individual digresses to give unnecessary and
circumstriate cortex

often irrelevant details before arriving at the main point. An extreme form, arising from disorganized associative processes, may occur in schizophrenia, obsessive disorders, and certain types of dementia. Circumstantiality differs from TANGENTIALITY in that the main point is never lost but rather accompanied by a large amount of nonessential information. **circumstriate cortex** see **PRESTRIATE CORTEX**.

**circumthanatology** n. the study of NEAR-DEATH EXPERIENCES.

circumvallate papillae | swellings on the posterior portion (back) of the tongue, each surrounded by a trench. In humans, there are 7 to 11 circumvallate papillae, arranged in a chevron; each PAPILLA contains about 250 TASTE BUDS, lining the trench and oriented horizontally. Receptors in circumvallate papillae are particularly sensitive to bitter chemicals.

circumventricular organs | four small structures located along the third and fourth ventricles at the base of the brain, outside the **BLOOD–BRAIN BARRIER**, that are believed to influence body fluid homeostasis, thirst, vomiting, and other physiological functions. Also called **circumventricular system**. See also **AREA POSTERIUM; ORGANUM VASCULOSUM OF THE LAMINA TERMINALIS; SUBCOMMISSURAL ORGAN; SUBFORNICAL ORGAN**.

cirrhosis | n. a result of chronic liver disease marked by widespread formation of fibrous tissue and loss of normal liver function. In most cases, it is a consequence of alcohol abuse, although it may also be due to congenital defects involving metabolic deficiencies, exposure to toxic chemicals, or infections (e.g., hepatitis). — **cirrhotic** adj.

**CISD** abbreviation for **CRITICAL-INCIDENT STRESS DEBRIEFING**.

cisgender | adj. having or relating to a GENDER IDENTITY that corresponds to the culturally determined gender roles for one’s birth sex (i.e., the biological sex one was born with). A cisgender man or **cisgender woman** is thus one whose internal gender identity matches, and presents itself in accordance with, the externally determined cultural expectations of the behavior and roles considered appropriate for one’s sex as male or female. Also called **cissgendered**. Compare **TRANSgend**. — **cisgenderism** n.

ciss | n. a craving for unusual foods or nonnutritive substances while pregnant. See also **PICA**.

cisterna | n. (pl. **cisternae**) 1. in anatomy, an enlarged space, such as the CISTerna MAGNA in the brain. 2. in cell biology, a flattened membranous sac within the GOLGI APPARATUS of a cell. — **cisternal adj**.

cisterna magna | an enlarged space between the lower surface of the **CEREBELLUM** and the dorsal surface of the **MEDULLA OBLONGATA**, which serves as a reservoir of **CEREBROSPINAL FLUID**. Also called **cisterna cerebellomedullaris**.

cistern puncture | see **SUBOCcipITAL PUNCTURE**.

**CIT** abbreviation for **CRITICAL-INCIDENT TECHNIQUE**.

citalopram | n. an antidepressant of the **SSRI** class. It exerts its action by blocking the presynaptic serotonin TRANSPORTER, preventing reabsorption of serotonin into the presynaptic neuron and thereby increasing levels of available serotonin in the SYNAPTIC CLEFT without increas-
ing overall levels of serotonin in the brain. U.S. trade name: **Celexa**.

citation analysis | a form of research that examines the history, frequency, and distribution of citations of particular writers or particular books, articles, or other sources. It now mostly involves the automated search of online or electronic databases.

citizen | n. one who is a formal member of a particular political community, such as a country or state, and is therefore entitled to full **CIVIL RIGHTS** as defined, guaranteed, and protected by that political entity. — **citizenship** n.

cittosis | n. an abnormal desire for unusual foods or nonnutritive substances. See also **CISSA; PICA**.

civil commitment | a legal procedure that permits a person who is not charged with criminal conduct to be certified as mentally ill and to be institutionalized involuntarily.

civil disobedience | public, nonviolent opposition or protest, usually on the grounds of conscience, to a government or its policies that takes the form of refusing to obey certain laws or to pay taxes. See also **PASSIVE RESISTANCE**.

civil emergency | a disastrous event, either natural or caused by human activities, that threatens civilian populations. Such emergencies often require the cooperative effort of both civilian and military authorities to provide civil defense and crisis and disaster management.

**Civilian Health and Medical Program of the Uniformed Services** (CHAMPUS) the medical insurer since 1967 has provided and paid for health care to U.S. military retirees and families and surviving family members of deceased military sponsors. Many new benefits have been added since the program was first established. The current program is called **TRICARE**.

**civilization** | n. 1. a highly developed society, advanced in such areas as arts, sciences, technology, law, religion, and moral and social values. 2. human society as a whole in its present highly advanced state of cultural, intellectual, and technical development. 3. the process of attaining this level of development. — **civilized** adj.

civil rights | the rights of personal liberty and equality guaranteed to citizens by law. Also called **civil liberties**.

civil rights movement | any collective effort to gain political or social rights denied by government, usually by such means as demonstrations, lobbying, and **CIVIL DISOBEDIENCE**. When capitalized, the term usually refers to the struggle for full constitutional rights by African Americans as it originated and developed in the United States in the 1950s and 1960s.

cCL | abbreviation for **CREUTZFELDT–JAKOB DISEASE**.

**CK** abbreviation for **CREATINE KINASE**.

CL | 1. abbreviation for drug **CLEARANCE**. 2. abbreviation for **COMPARISON LEVEL**.

cladistics | n. a method for classifying organisms on the basis of their evolutionary relationships, which are expressed in treelike diagrams called **cladograms**. — **cladism** n. — **cladist** n.

claims review | an evaluation of the appropriateness of a claim for payment for a medical or mental health service rendered. It will consider whether the claimant is eligible for reimbursement, whether the charges are consistent
with customary fees or published institutional rules, and whether the service was necessary.

clairaudience n. in parapsychology, the alleged ability to hear voices or sounds beyond the normal range of hearing, including supposed messages from spirit guides or the dead. This may involve messages heard from or attributed to an “inner voice” or voices separate from thought. It is the auditory equivalent of clairvoyance. See also extrasensory perception. —clairaudient n., adj.

clairvoyance n. in parapsychology, the alleged ability to see things beyond the normal range of sight, such as distant or hidden objects or events in the past or future. Clairvoyance is supposedly an organic ability, whereas remote viewing is a planned activity, with rules and standards, in which clairvoyance may be used to see or sense things (events, thoughts, locations, etc.) from a distance. Compare clairaudience. See also extrasensory perception; second sight.—clairvoyant n., adj.

clairvoyant dream in parapsychology, a dream depicting events that appear to be confirmed by later happenings or knowledge. See clairvoyance; premonitory dream.

Clallm abbreviation for comparison level for alternatives.

clamminess n. a sensory blend that consists of coldness, moistness, and stickiness. —clammy adj.

clan n. 1. in anthropology, a major social division of many traditional societies consisting of a group of families that claim common ancestry. Clans often prohibit marriage between members and are often associated with reverence for a particular totem. See also descent group; phratry. 2. in Scotland and Ireland, a kinship group and former social unit based on traditional patterns of land tenure and the concept of loyalty to a clan chief. Clan members often took the name of the supposed clan founder prefixed by Mac (Scotland) or O’ (Ireland) but were not necessarily linked by common ancestry.

Clance Impostor Phenomenon Scale (CIPS) see impostor phenomenon.

clang association an association of words by similarity of sound rather than meaning. Clang association occurs as a pathological disturbance in manic states and schizophrenia. Also called clanging.

clarification n. a therapist’s formulation, in clear terms and without indicating approval or disapproval, of a client’s statement or expression of feelings. Clarification goes beyond restatement and reflection of feeling but stops short of interpretation.

class n. 1. a group, category, or division. See categorization. 2. in sociology and political theory, see social class. 3. in biological taxonomy, a main subdivision of a phylum, consisting of a group of similar, related orders. 4. in logic and philosophy, a collection of entities that have a specified property or properties in common: that is, a set defined by a condition.

class advocate see advocacy.

class consciousness awareness of belonging to a particular economic or social group, especially one regarded as being exploited or victimized. Karl Marx viewed class consciousness as a necessary condition for a revolution of industrial workers against the capitalist owners’ class. The concept was extended in the late 20th century to include gender, race, ethnicity, and sexual orientation, with similar implications. Here, the sense of “consciousness” derives from German philosophy and implies a social belief system or worldview (see Weltanschauung) rather than perceptual or waking consciousness.

classical adj. denoting a style, mode of operation, or function that was typical or standard at some time in the past. In psychology, for instance, the term classical conditioning was used to contrast Pavlovian conditioning with newly recognized operant conditioning when the distinction between the two forms of learning was pointed out by B. F. Skinner in 1938.

classical conditioning a type of learning in which an initially neutral stimulus—the conditioned stimulus (CS)—when paired with a stimulus that elicits a reflex response—the unconditioned stimulus (US)—results in a learned, or conditioned, response (CR) when the CS is presented. For example, the sound of a tone may be used as a CS, and food in a dog’s mouth as a US. After repeated pairings, namely, the tone followed immediately by food, the tone, which initially had no effect on salivation (was neutral with respect to it), will elicit salivation even if the food is not presented. Also called Pavlovian conditioning; respondent conditioning; Type I conditioning; Type S conditioning. [discovered in the early 20th century by Ivan Pavlov]

classical humors see humoral theory.

classical inference see frequentist inference.

classical paranoia as conceptualized in the 19th century by German physician Karl Ludwig Kahlbaum (1828–1899) and later refined by Emil Kraepelin, a rare disorder characterized by elaborate, fixed, and systematic delusions, usually of a persecutory, grandiose, or jealous character, that develop insidiously, cannot be accounted for by any psychiatric disorder, and exist in the context of preserved logical and orderly thinking.

classical probability an approach to the understanding of probability based on the assumptions that any random process has a given set of possible outcomes and that each possible outcome is equally likely to occur. An example often used is rolling a die, in which there are six possible outcomes and each outcome is assumed to be equally likely.

classical psychoanalysis 1. psychoanalytic theory in which major emphasis is placed on the libido, the stages of psychosexual development, and the id instincts or drives. The prototypical theory of this kind is that of Sigmund Freud. Also called classical theory; drive theory. 2. psychoanalytic treatment that adheres to Sigmund Freud’s basic procedures, using dream interpretation, free association, and analysis of resistance, and to his basic aim of developing insight into the patient’s unconscious life as a way to restructure personality. Also called orthodox psychoanalysis.

classical test theory (CTT) the theory that an observed score (e.g., a test result) that is held to represent an underlying attribute (e.g., intelligence) may be divided into two quantities—the true value of the underlying attribute and the error inherent to the process of obtaining the observed score. CTT may be represented mathematically as \( X = T + \epsilon \), where \( X \) is the observed score for respondent \( p \), \( T \) is the respondent’s true score for the construct or characteristic being measured, and \( \epsilon \) is random error that dilutes the expression of respondent \( p \)’s true score. The theory serves as the basis for models of test reliability and assumes that individuals possess stable characteristics or
traits that persist through time. See also GENERALIZABILITY
THEORY. Compare ITEM RESPONSE THEORY.

classical theory see CLASSICAL PSYCHOANALYSIS.

classic categorical approach a method for classifying

disorders founded on the assumption that there are
clear-cut differences between disorders.

classicism factor in psychological aesthetics, a dimen-
sion of artistic style that emphasizes traditional aesthetic
values, particularly those associated with the art and
architecture of ancient Greece and Rome. The classicism fac-
tor is also used to distinguish more polished and formal art
works from those that emphasize novelty and imagination
(the romanticism factor).

classification n. 1. in cognitive psychology, see CATAC
GORIZATION. 2. in clinical psychology and psychiatry, the
grouping of mental disorders on the basis of their charac-
teristics or symptoms. See also DSM–IV–TR; DSM–5; INTER
ATIONAL CLASSIFICATION OF DISEASES; NOSOLOGY. 3. in
biology, see BIOLOGICAL TAXONOMY. —classify vb.

classification and regression tree analysis see CART ANALYSIS.

classification method in industrial and organizational
psychology, a method of evaluating jobs for the purpose of
setting wages or salaries in which jobs are assigned to pre-
defined classes or categories, usually on the basis of job title
and job description. This usually involves comparison with
one or more HENCHMARK JOBS. An example of such a
method is the General Schedule system of the United States
Civil Service. Compare FACTOR-COMPARISON METHOD; JOB-
COMPONENT METHOD; POINT METHOD; RANKING METHOD.

classification rule a mathematical formula for placing
units into groups (e.g., within DISCRIMINANT ANALYSIS) so
as to maximize the similarities among group members
with regard to a set of characteristics. Also called alloca-
tion rule.

classification table a table showing the number or per-
centage of cases correctly categorized by a given model,
rule, or algorithm derived for that purpose. Columns rep-
represent the model predictions and rows represent the actual
classes to which the items in a sample data set belong. For
example, a researcher might use a classification table to
display the results of a DISCRIMINANT ANALYSIS of college
attendance for a group of high school students so as to
evaluate the general accuracy of the model used. Also called
classification matrix: confusion matrix.

classification test 1. a test in which participants are
required to sort objects, people, events, or stimuli into spe-
cific categories. See CATEGORIZATION. 2. a test in which par-
ticipants are themselves sorted into categories (e.g., of
ability or psychological type) according to the responses
given.

classifier system a COGNITIVE ARCHITECTURE consisting of
a computational system in which knowledge, in the form of “if
then” classifier rules, is exposed to a reacting
environment and as a result undergoes modification over
time (learning). The entire system is evaluated over time,
with the importance of the individual classifier seen as
minimal. See ADAPTIVE PRODUCTION SYSTEM. [created in
1986 by U.S. computer scientist John Henry Holland
(1929– )]

class inclusion the concept that a subordinate class
e.g., dogs) must always be smaller than the superordinate

class in which it is contained (e.g., animals). Jean PIAGET
believed that understanding the concept of class inclusion
represented an important developmental step. Children
progress from classifications based on personal factors, per-
cipient features, and common function to classifications
based on hierarchical relationships; for example, a monkey
is a primate, a mammal, and a vertebrate animal. See CONCRETE
OPERATION.

class interval a range of scores or numerical values that
constitute one segment or class of a variable of interest.
For example, individual weights can be placed into class in-
tervals such as 100 Ib–120 lb, 121 Ib–140 lb, 141 Ib–160 lb,
and so forth. Class intervals often are used in FREQUENCY
DISTRIBUTIONS and HISTOGRAMS to present a large data set
in a simpler manner that is more easily interpreted.

class limit the uppermost and lowest values between
which lie a range of values constituting a segment or class
of a variable: the upper and lower boundaries of a CLASS
INTERVAL.

classroom-behavior modification an instructor’s
use of basic learning techniques, such as conditioning, to
alter the behavior of the students within a learning envi-
ronment. Specifically, classroom-behavior modification
may utilize such methods as adjusting classroom seating,
providing a flexible time deadline for assignments, or alter-
ing the lesson requirements. Direct intervention, however,
is the most effective modification procedure, using cogni-
tive behavioral techniques to address inappropriate class-
room behavior. Such procedures are most useful for
students with learning disabilities, attention-deficit/hyper-
activity disorder, and other special needs.

classroom discipline 1. traditionally, any form of
compliance with discipline imposed on school pupils in
class. 2. the methods of correction used by teachers or
schools for student behavior that does not comply with the
rules and regulations that have been established for an op-
timal learning environment. 3. any type of training ex-
ected to produce a specific pattern of behavior within a

classroom. In some countries, classroom discipline now ex-
cludes physical punishment.

classroom environment the physical, social, psycho-
logical, and intellectual conditions that characterize an in-
structional setting. Although the physical environment
usually includes classrooms, laboratories, and lecture
halls, it may also include alternative locations, such as a
museum, home, gymnasium, or even the outdoors. Re-
gardless of the setting, the degree of enclosure or open-
ness, noise, seating arrangements, DENSITY, and size have
all been shown to have an effect on student behavior and
learning. See also OPEN-CLASSROOM DESIGN.

classroom test a test devised by a teacher for use in
class, as contrasted with a STANDARDIZED TEST.

class structure the composition, organization, and in-
terrelationship of SOCIAL CLASSES within a society. The
term encompasses the makeup of individual classes as well
as their economic, political, and other roles within the
larger SOCIAL ORDER.

class theory 1. the notion that conflict between social
and economic classes is a fundamental determining force
in human affairs, affecting not only systems of govern-
ment and social organization but also individual psychol-
ology. It is held that one’s perceptions, goals, and expecta-
tions, and even one’s conceptions of psychological health
and illness, are heavily influenced by the class of which one is a member. Most modern manifestations of class theory trace their origins to Karl Marx, although the work of the critical theorists of the Frankfurt school (1930s onward) has also been influential. See Marxism. 2. the branch of set theory that is concerned with the properties of classes. It is particularly interesting in defining the distinction between classes and sets that are not classes.

claudication n. 1. limping. 2. a cramping pain in the muscles (intermittent claudication), occurring especially in the calf muscles. See also MENTAL CLAUDICATION.

clause n. a linguistic unit smaller than a sentence but larger than a PHRASE; in traditional grammar, a clause is defined as having both a subject and a finite verb (i.e., one that agrees with the subject in number and person). Clauses are usually divided into two principal types: main clauses, which make sense by themselves and can constitute a sentence in their own right, and subordinate clauses, which are dependent on a main clause in both respects. In I smiled at Jane, who waved back, for example, the words before the comma constitute a main clause and those after the comma are a subordinate clause. In psycholinguistics, clauses are considered to be an important unit of sentence processing. Sentences that are complex from a syntactic point of view, in that they contain one or more subordinate clauses, are also considered psychologically more complex. See COMPLEX SENTENCE; COORDINATION.

—clausal adj.

claustrophobia n. a persistent and irrational fear of enclosed places (e.g., elevators, closets, tunnels) or of being confined (e.g., in an airplane or the backseat of a car). Situations where enclosure or confinement may be encountered are often avoided or else endured with intense anxiety or distress. The focus of fear is typically on panic symptoms triggered in these situations, such as feelings of being unable to breathe, choking, sweating, and fears of losing control or going crazy. —claustrophobic adj.

claustrum n. (pl. claustra) a thin layer of gray matter in the brain that separates the white matter of the lenticular nucleus from the insula (from Latin, "barrier"). The claustrum forms part of the BASAL GANGLIA and its function is unknown. —clausal adj.

clava n. see GRACILE TUBERCLE. [from Latin, "club"]

clavus n. a sharp sensation as if a nail were being driven into the head.

clay therapy a form of therapy in which children manipulate clay, often used in physical rehabilitation, in stimulating individuals with intellectual disability, and in the assessment and treatment of various disorders. The clay can be a metaphor for feelings, yet at the same time it serves as a tangible item that is visible, changeable, and under the child's control. A child can look at the clay, focus on it, manipulate it, squeeze it, and pound it, which can help reduce anxiety, enable the acting out of hostile emotions, and provide opportunities for gratification, achievement, and acceptance.

clearance (CL) n. the rate of elimination of a drug from the body in relation to its concentration in a body fluid, as expressed by the equation \(CL = \text{rate of elimination} / C\), where \(C\) is the concentration of the drug in the body fluid. Clearance is additive, that is, drugs are eliminated by various mechanisms (renal, hepatic, etc.) at differing rates; thus, total clearance is the sum of clearance from each individual organ system.

clearance requirement 1. in the design of security systems, the requirement that only specifically authorized personnel should have access to certain physical areas or types of information. 2. in SAFETY ENGINEERING, a mandate or guideline specifying the minimal distance or elevation of objects from a potentially hazardous source.

clear sensorium see SENSORIUM.

cleavage n. the first stage of embryonic development, in which a fertilized ovum divides repeatedly to form a mass of smaller and smaller cells (see BLASTULA). Also called SEGMENTATION.

cleft palate a congenital disorder characterized by a fissure in the roof of the mouth caused by failure of bones of the palate to fuse properly during prenatal development. The extent of a cleft palate may vary in different individuals, affecting only the hard palate or both hard and soft palates or extending completely through to the uvula; a cleft lip may or may not co-occur. The condition is typically corrected through surgery between 9 and 18 months of age, and repeated surgeries during childhood may be necessary for complete correction. Also called URANOSCHISIS.

CLEP acronym for COLLEGE LEVEL EXAMINATION PROGRAM.

Clérambault's syndrome a form ofErotic Paranoia in which a person has delusions that someone else, who is typically older and of higher social status, is in love with him or her. The person continues to hold this belief despite having little contact with the other person and no reciprocation of feelings. The condition is more common in females than in males. Also called de Clérambault's syndrome. [first described in 1922 by Gaëtan Galvan de Clérambault (1872–1934), French physician]

clerical aptitude 1. the ability to learn specific skills required for office work, such as perceptual speed (e.g., comparing names or numbers), speed in typing, error location, and vocabulary. 2. the measure of individual abilities in the following areas: vocabulary (understanding words and ideas), arithmetic (handling figures easily and accurately), and checking (recognizing similarities and differences rapidly).

clerical test an examination to assess a person's knowledge or skills needed for office, clerical, or administrative support positions. Also called clerical-aptitude test.

CLES abbreviation for CONSTRUCTIVIST LEARNING ENVIRONMENT SURVEY.

Clever Hans the "thinking horse," reputed to be able to solve mathematical problems, spell words, distinguish colors, and identify coins, that became famous in Berlin around 1900. It signaled its answers by tapping its foot. However, German psychologist Oskar Pfungst (1874–1932), using experimental methods, demonstrated that the horse was responding to minimal cues in the form of involuntary movements on the part of its owner.

click-thru rate the extent to which consumers actually click on BANNER ADVERTISEMENTS to visit a different website. This is viewed as one measure of banner advertising success.

client n. a person receiving treatment or services, especially in the context of counseling or social work. See PATIENT–CLIENT ISSUE.

client abuse see PATIENT ABUSE.
client-centered consultation

**client-centered consultation** see MENTAL HEALTH CONSULTATION.

**client-centered therapy** a form of psychotherapy developed by Carl Rogers in the early 1940s. According to Rogers, an orderly process of client self-discovery and actualization occurs in response to the therapist’s consistent empathic understanding of, acceptance of, and respect for the client’s frame. The therapist sets the stage for personality growth by reflecting and clarifying the ideas of the client, who is able to see himself or herself more clearly and come into closer touch with his or her real self. As therapy progresses, the client resolves conflicts, reorganizes values and approaches to life, and learns how to interpret his or her thoughts and feelings, consequently changing behavior that he or she considers problematic. It was originally known as **nondirective counseling** or **nondirective therapy**, although this term is now used more broadly to denote any approach to psychotherapy in which the therapist establishes an encouraging atmosphere but avoids giving advice, offering interpretations, or engaging in other actions to actively direct the therapeutic process. Also called **client-centered psychotherapy**; **person-centered therapy**; **Rogerian therapy**.

**client characteristics** aspects of a client that define his or her physical and personality attributes as well as the problems and symptoms that the client brings into therapy for resolution and healing.

**client education** an intervention aimed at giving individuals information intended to change their cognitions, beliefs, affect, and behaviors. This educational process can take place in formal groups (psychoeducational groups) or as a routine part of initiating psychotherapy.

**client obligations** see CONTRACT.

**client–patient issue** see PATIENT–CLIENT ISSUE.

**client rights** the rights of patients or clients to be fully informed of the benefits or risks of treatment procedures and to make knowledgeable decisions to accept or reject treatment.

**client satisfaction** the extent to which a person seeking mental health services is content with the results.

**client self-monitoring** see SELF-MONITORING.

**client–treatment matching** the selection of therapeutic components (i.e., specific therapies and therapists) that are most appropriate for a client’s needs and characteristics (e.g., ethnicity, gender, personality traits). There is evidence that client–treatment matching improves therapeutic outcomes.

**climacteric** n. the biological stage of life in which reproductive capacity declines and finally ceases. In women this period, which results from changes in the levels of estrogen and progesterone and is known as **menopause** (popularly, **change of life**), typically occurs between 45 and 55 years of age and lasts 2 to 7 years. During this time, menstrual flow gradually decreases in occurrence, duration, and volume (a transitional phase called **perimenopause**) and finally ceases altogether, and various physical and potentially psychological changes, such as hot flushes, night sweats, joint pain, emotional lability, and depression, may occur in varying combinations and degrees. Some men undergo a similar period about 10 years later than is typical for women (see **male climacteric**). Also called **climacterium**. See also **gonadopause**.

**climate** n. long-term weather conditions in a particular region, such as average temperature, humidity, and sunshine. The study of climatic influences on cognition, mood, and behavior is part of **ENVIRONMENTAL PSYCHOLOGY**.

**climactic adj.**

**climax** n. see ORGASM.

**clinging behavior** a form of **attachment behavior** in which a child 6 months of age or older clings to the primary caregiver and becomes acutely distressed when left alone. Clinging behavior reaches a maximum in the 2nd and 3rd years and then slowly subsides. The behavior is also observed in the young of other primates and of some rodents.

**clinic** n. 1. a health care facility for the diagnosis and treatment of emergency and ambulatory patients. 2. a brief instructional program or session with diagnostic, therapeutic, or remedial purpose in the areas of mental or physical health or education.

**clinical adj.** 1. of or relating to the diagnosis and treatment of psychological, medical, or other disorders. Originally involving only direct observation of patients, clinical methods have now broadened to take into account biological and statistical factors in treating patients and diagnosing disorders. 2. relating to or occurring in a clinic.

**clinical assessment** the systematic evaluation and measurement of psychological, biological, and social factors in a person presenting with a possible psychological disorder. See also **DYNAMIC ASSESSMENT**.

**clinical counseling** counseling that addresses a client’s personal or emotional difficulties. The counseling encompasses general goals for the client, for example, greater self-acceptance, better reality orientation, improved decision-making ability, and greater effectiveness in interpersonal relationships. The counselor’s responsibilities include gathering and interpreting data, identifying the client’s major problems, and formulating and (sometimes) implementing a treatment plan.

**clinical depression** among mental health professionals, a synonym for **major depressive disorder**. Within the general public, however, the term is often more broadly used to encompass any **depressive disorder** requiring therapeutic intervention.

**clinical diagnosis** the process of identifying and determining the nature of a disorder through the study of the symptom pattern, review of medical and other records, investigation of background factors, and, where indicated, administration of psychological tests.

**clinical efficacy** the effectiveness of clinical interventions based on the evidence of controlled studies. Such studies typically include random assignment to control groups and treatment manuals that guide therapist actions.

**clinical evidence** information about clients or patients that is relevant to clinical diagnosis and therapy, obtained either directly, through questioning (see **CLINICAL INTERVIEW; PSYCHOLOGICAL TEST**), or indirectly, through observation of their behavior in a clinical setting, their **CASE HISTORIES**, and the like.

**clinical geropsychology** an interdisciplinary field of research and practice that utilizes a **LIFESPAN PERSPECTIVE** as a conceptual basis to address the mental health needs and services of older adults.
clinical health psychology a specialty field in health psychology that applies biopsychosocial theory, research, and practice principles to promote physical health and to help resolve the immediate problems of patients with medical conditions and related family difficulties. Biofeedback, relaxation training, hypnotherapy, and coping skills are among the many methods used by clinical health psychologists, who are also active in health policy and in developing and implementing models of preventive intervention.

clinical hypnosis see hypnotherapy.

clinical interview a type of directed conversation initially used with children but now applied in a variety of contexts, including human factors research, psychological, and treatment planning for patients by mental health professionals. In a clinical interview, the investigator may utilize certain standard material but essentially determines which questions to ask based on the responses given by the patient to previous ones. This technique is largely spontaneous and enables the interviewer to adapt questions to the patient’s comprehension and ask additional questions to clarify ambiguities and enhance understanding. See also diagnostic interview.

clinical investigation 1. examination of a patient by means of interviews, testing, behavioral observation, or document analysis, 2. an in-depth analysis of an individual’s life experiences and personal history.

clinical judgment analysis, evaluation, or prediction of the presenting signs and symptoms in an individual with a disease, disorder, dysfunction, or impairment. It includes assessing the appropriateness of particular treatments and the degree or likelihood of clinical improvement. These conclusions are derived from expert knowledge of health or mental health professionals, as opposed to conclusions drawn from actuarial tables or statistical methods.

clinical judgment research empirical studies of the factors influencing the judgments mental health practitioners make with regard to assessment, treatment, predictions (e.g., dangerousness, suicidality), and prognosis in therapeutic and legal settings. Factors researched include individual differences of the practitioner (e.g., values, gender, sexual orientation), social contexts, and complex cognitive thought processes involved in judgment.

clinically relevant behavior (CRB) see functional analytic psychotherapy.

clinical marker an observable sign indicative of disorder. See also biochemical marker; biological marker.

clinical method the process by which a health or mental health professional arrives at a conclusion, judgment, or diagnosis about a client or patient in a clinical situation.

clinical neurology see neurology.

clinical neuropsychology a specialty of clinical psychology that represents the applied practice of neuropsychology and is concerned with assessment of and rehabilitation from brain injury that impairs an individual’s ability to function.

clinical neuroscience an emerging field in which basic neuroscience data and the scientific method are coupled to such fields as clinical psychology, psychiatry, and neurology in order to better understand the neural underpinnings of mental and nervous system disorders and to improve their diagnosis and treatment.

clinical pediatric neuropsychology see pediatric neuropsychology.

clinical practice providing health or mental health services to patients or clients. In mental health, clinical practice includes services (e.g. psychological assessment, diagnosis, treatment) provided by a clinical psychologist, psychiatrist, or other mental health care provider who works directly with clients or patients to relieve distress or dysfunction caused by emotional and behavioral problems. Clinical practice typically refers to work in health and mental health clinics or in group or independent practices.

clinical practice guidelines systematically developed statements to assist providers, as well as clients or patients, in making decisions about appropriate medical or mental health care for specific clinical conditions.

clinical prediction the process of examining such factors as signs, symptoms, and case histories to determine the clinical diagnosis and likely progress of patients. Clinical prediction can be contrasted with actuarial prediction, in which formal statistical methods combine numerical information for the same purposes. See clinical judgment.

clinical psychology the branch of psychology that specializes in the research, assessment, diagnosis, evaluation, prevention, and treatment of emotional and behavioral disorders. Clinical psychologists are doctorate-level professionals who have received training in research methods and techniques for the diagnosis and treatment of various psychological disorders. They work primarily in health and mental health clinics, in research, in academic settings, or in group and independent practices. They also serve as consultants to other professionals in the medical, legal, social-work, and community-relations fields. Clinical psychologists comprise approximately one third of the psychologists working in the United States and are governed by the code of practice of the American Psychological Association and by state licensing requirements.

clinical psychopharmacology a branch of pharmacology concerned with how drugs affect the brain and behavior and specifically with the clinical evaluation and management of drugs developed for the treatment of mental disorders. See also psychopharmacotherapy.

clinical psychophysiology the therapeutic use of the theories and principles of psychophysiology through such techniques as biofeedback, meditation, and hypnosis. See also applied psychophysiology.

clinical risk assessment a clinician-based prediction of the likelihood that an individual will pose a threat to others or engage in a certain behavior (e.g., violence) within a given period. Unlike actuarial risk assessment, a specific formula or weighting system using empirically derived predictors is not applied. Instead, clinicians make predictions of dangerousness or violent behavior primarily on the basis of their own experience, reasoning, and judgment; their observations, examination, and psychological testing of the individual; and information obtained from his or her life history.

clinical significance the extent to which a study result is judged to be meaningful in relation to the diagnosis or treatment of disorders. An example of a clinically significant result would be an outcome indicating that a new intervention strategy is effective in reducing symptoms of...
clinical social work

a field devoted to providing individual, family, and group treatment from a psychosocial perspective in such areas as health, mental health, family and child welfare, and correction. Clinical social work also involves client-centered advocacy that assists clients with information and referral and in dealing with local, state, and federal agencies.

clinical sociology see public sociology.

clinical sport psychology a specialty within clinical psychology focused on individuals involved in sport. Clinical sport psychologists perform much the same services for athletes as do professionals in educational sport psychology (i.e., helping with performance enhancement and consistency), but they also assist athletes with clinical issues that typically extend beyond the training of educational sport psychologists (e.g., depression, eating disorders).

clinical trial a research study designed to compare a new treatment or drug with an existing standard of care or other control condition (see control group). Trials generally are designed to answer scientific questions and to find better ways to treat individuals who have a specific disease or disorder. Also called clinical study. See also randomized clinical trial.

clinical type an individual whose pattern of symptoms or behaviors is consistent with a recognizable disorder of clinical psychology and psychiatry.

clinical utility 1. the extent to which diagnostic testing (e.g., genetic testing) is useful in facilitating beneficial health outcomes (e.g., preventing mortality, ameliorating morbidity and disability) from interventions that are initiated based on test results. 2. the extent to which the interventions themselves can be applied successfully and cost-effectively.

clinical utility research see effectiveness research.

clinical validation the act of acquiring evidence to support the utility of specific procedures for diagnosis or treatment.

clinical vampirism see vampirism.

clinician n. a medical or mental health care professional who is directly involved in the care and treatment of patients, as distinguished from one working in other areas, such as research or administration.

clindamycin n. a permanent deflection of one or more of the fingers. This is a common physical anomaly but is also associated with many genetic or chromosomal disorders, including down syndrome.

clipping n. the shortening of a word in such a way that the new word is used with exactly the same meaning, for example, exam from examination. In general, adults prefer back-dipping, for example, prof for professor, whereas children prefer front-dipping, for example, fessor for professor. Unlike a back-formation, the clipped word has the same part of speech as the full form.

clique n. a status- or friendship-based subgroup within a larger group or organization. Cliques are particularly common during adolescence, when they are often used to raise social standing, strengthen friendship ties, and reduce feelings of isolation and exclusion.

clitoral circumcision see female genital mutilation.

clitoral hood a fold of skin that covers the clitoris when it is flaccid. It is homologous to the foreskin of the penis. See also prepuce.

clitoridectomy n. the surgical removal of all or part of the clitoris, usually performed on girls as an ethnic or religious rite. It is a highly controversial practice and the most common form of female genital mutilation.

clitoris n. a small body of erectile tissue situated anterior to the vaginal opening. It is homologous to the penis but usually much smaller. —clitoral adj.

clomipramine n. a tricyclic antidepressant drug used for the treatment of obsessive-compulsive disorder (OCD) as well as depression and panic disorder. Clomipramine is a more potent inhibitor of serotonin reuptake than other tricyclic antidepressants, and its active metabolite, desmethylclomipramine, inhibits norepinephrine reuptake; it thus is classified as a mixed serotonin–norepinephrine reuptake inhibitor. Because of its tricyclic structure, it has the same adverse side effects and toxicity as other tricyclic antidepressants, and it has been largely supplanted by the SSRIs, one of which—fluoxetine—is also used for the treatment of OCD. U.S. trade name: Anafranil.

clonazepam n. a highly potent benzodiazepine originally developed to treat absence seizures but now used for the treatment of panic disorder and other anxiety disorders and as a mood stabilizer. Because it has a slow onset of action, long half-life, and slow rate of clearance, it needs to be taken less frequently (twice a day) than some other benzodiazepines. U.S. trade name: Klonopin.

clone n. an organism that is genetically identical to another, whether because both organisms originate from a single common parent as a result of asexual reproduction or because one is derived from genetic material taken from the other, as in reproductive cloning. Differences in characteristics between cloned individuals are assumed to be the result of environmental factors. 2. n. a group of genetically identical organisms. 3. n. a group of cells derived from a single parent cell. 4. vb. to produce genetically identical copies of a particular organism or cell. —clonal adj.

clonic adj. of, relating to, or characterized by clonus.

clonic phase see tonic–clonic seizure.

clonic spasm see spasm.

clonidine n. a drug used for the treatment of hypertension. It functions by direct stimulation of alpha-2-adrenergic receptors in the brainstem to restrict the flow of impulses in peripheral sympathetic nerves supplying the arteries, thus causing them to relax (widens); most of the other commonly prescribed antihypertensive drugs act as beta blockers or as diuretics. Clonidine has been used as an adjunctive agent in the management of alcohol and opioid withdrawal, as a nonstimulant treatment for attention-deficit/hyperactivity disorder, and in the management of clo-
U.S. psychiatrist and geneticist C. Robert Cloninger's psychobiological model of personality includes harm avoidance, novelty seeking, persistence, self-directedness, cooperativeness, and self-transcendence. These dimensions are related to the behavioral approach system and behavioral inhibition system.

Cloninger's alcoholism typology is a two-part classification for distinguishing different types of persons with alcohol dependence. Type 1 individuals tend to start problem drinking after age 25, experience alcohol dependence that is more psychological than physiological, and feel guilty for drinking. Type 2 individuals start problem drinking at a younger age, are more likely to have family members with substance abuse problems, and tend to have more behavioral problems. The two types have also been found to differ in personality traits; for example, Type 1 alcoholics are more often harm avoidant (see Cloninger's psychobiological model of personality). These types are sometimes considered representative of either end of a continuum rather than as discrete groups.

Cloning n. 1. the process of making copies of a specific piece of DNA, usually a gene. This uses the techniques of genetic engineering to isolate the desired gene and transfer it to a suitable host cell, such as a bacterium, inside which it will undergo replication. Cloning facilitates investigation of gene structure and function and enables identification and analysis of particular gene products. Also called gene cloning. 2. the process of making genetically identical copies (i.e., clones) of an entire organism. The potential cloning of human beings raises major ethical and social questions.

Cloninger's psychobiological model of personality is a seven-factor model that includes four dimensions of temperament and three dimensions of character. The temperament dimensions include harm avoidance (sensitivity to, and avoidance of, punishment stimuli), novelty seeking (a tendency toward exhilaration or excitement in response to cues of potential reward or relief of punishment), reward dependence (a tendency to respond to positive signals such as social approval and to maintain rewarded behavior), and persistence (a tendency to continue a task or activity regardless of frustration, dissatisfaction, or fatigue). The character dimensions include self-directedness (the extent to which individuals are goal-oriented and resourceful), cooperativeness (the extent to which individuals relate to others), and self-transcendence (the extent to which individuals are transpersonal, spiritual, and idealistic). The model suggests that dimensions of temperament are heritable and that novelty seeking and harm avoidance are closely related to the behavioral approach system and behavioral inhibition system.

Closed call system a system of vocal communication in which there is a limited number of vocalizations that can be used by an organism or in which the vocalizations are not modifiable after a certain age. For example, in some bird species there is little evidence of environmentally induced change in calls after hatching, and in others there is little or no change in vocalizations after a critical period for learning has ended. Compare open call system.

Closed-captioned television television programs supplemented with printed captions, usually placed at the bottom of the screen, that provide a visual representation of the speech on the audio channel. Closed captioning is used for the benefit of viewers with hearing loss.

Closed-circuit television system (CCTV system) a type of print enlargement system for individuals with low vision that uses a video camera to magnify and project printed or handwritten text onto a video monitor or television screen.

closed-class words n. in a language, a category of words that does not readily admit new members, consisting mainly of words that serve key grammatical functions, such as pronouns, prepositions, and determiners (see function word). Compare open-class words.

Closed economy an experimental design used in instrumental- or operant-conditioning procedures in which all arranged reinforcement (e.g., food) is obtained within experimental tests, with no supplements occurring outside the experimental context. Compare open economy.

Closed group a group consisting of only those members who constitute the original group. In counseling or therapy, the term refers to a group that excludes new members during the course of therapy. Compare open group.

Closed head injury a head injury, such as a concussion or acceleration–deceleration injury, in which the skull is not broken open or pierced. Compare open head injury.

Closed-loop system 1. a system that recirculates materials, information, or energy without external input. 2. a self-regulating system in which feedback from sensors enables a control mechanism to maintain a set of operating conditions. An example would be a central heating or air-conditioning system that is set to maintain an environment at a particular temperature. Compare open-loop system.

Closed marriage a marriage that changes little over the years and that involves relatively little change in the individual partners. A closed marriage relies on the legal bond between the parties to enforce permanence and sexual ex-
closedmindedness

clusivity. Also called static marriage. Compare OPEN MARRIAGE.
closedmindedness n. a personality trait reflecting a relatively high level of DOGMATISM. Compare OPENMINDNESS. —closedminded adj.
closed question see FIXED-ALTERNATIVE QUESTION.
closed scenario an experiment in which the participant is required to choose between a limited number of options for solving an assigned problem.
closed shop a work arrangement in which union membership is a precondition for hiring. In the United States, the LABOR MANAGEMENT RELATIONS ACT prohibits such a precondition but does allow UNION SHOPS and AGENCY SHOPS. Compare OPEN SHOP.
closed skill any motor skill that is performed under the same conditions on every occasion, as in making a free-throw shot in a game of basketball. Compare OPEN SKILL.
closed society see OPEN SOCIETY.
closed system 1. an isolated, self-contained system having no contact with the environment, such as the vascular system or a space module. 2. by analogy, a social system that is resistant to new information or change. Compare OPEN SYSTEM.
closet homosexual a gay man or lesbian who does not reveal his or her sexual orientation to others, particularly to family members, parents, or employers. Compare COMING OUT.
closing n. ending a session in psychotherapy or counseling. Approaches to closing vary among therapists: Some allow the client to initiate the end of the session; others initiate it themselves.
closure n. 1. the act, achievement, or sense of completing or resolving something. In psychotherapy, for example, a client achieves closure with the recognition that he or she has reached a resolution to a particular psychological issue or relationship problem. 2. one of the GESTALT PRINCIPLES OF ORGANIZATION. It states that people tend to perceive incomplete forms (e.g., images, sounds) as complete, synthesizing the missing units so as to perceive the image or sound as a whole—in effect closing the gap in the incomplete forms to create complete forms. Also called law of closure: principle of closure. See also AUDITORY CLOSURE; GOODNESS OF CONFIGURATION; PRÄGNANZ; VISUAL CLOSURE. 3. more generally, the act of closing or the state of being closed.
Closure Flexibility Test a perceptual test in which each item consists of one simple geometrical figure and four complex figures: The participant is asked to identify which one of the complex figures has the simple figure embedded within it. The test, which was developed from the earlier GOTTSCALD Figures Test, is considered to be an index of perceptual flexibility. Also called Concealed Figures Test. [originally developed by German psychologist Kurt Gottschaldt (1902–1991)]
clouded sensorium see SENSORIUM.
clouding of consciousness a mental state involving a reduced awareness of the environment, inability to concentrate, and confusion. Also called mental fog.
cloverleaf skull see KLEEBLATTSKÄDEL SYNDROME.
clozapine n. an ATYPICAL ANTIPSYCHOTIC agent of the DIBENZODIAZEPINE class: the first of the atypical antipsycho-

otics to be used clinically and released into the U.S. market in 1990. Although regarded by some as the most effective of all antipsychotic drugs, clozapine has problematic side effects that have limited its use. Among others, these adverse effects may include weight gain, sedation, and—importantly—AGANERUCYTOSIS, which may occur in 1% to 2% of patients treated with the drug. Use of clozapine therefore requires frequent monitoring of white blood cell counts in patients and is generally reserved for patients who have responded suboptimally to other antipsychotic agents. U.S. trade name: Clozaril.
close procedure a technique used in both testing and teaching reading and comprehension, in which words are deleted from a text, leaving blank spaces. The number of blanks that students fill in correctly is used as a measure of progress in these subjects. The close procedure is based on the Gestalt principle of closure. [introduced in 1953 by Wilson L. Taylor]

CLT abbreviation for CENTRAL LIMIT THEOREM.
club drug a substance used by teenagers and young adults at bars, dance clubs, or all-night parties known as raves. Club drugs include MDMA (Ecstasy); GHIB, FLUNITRAZEPAM, and KETAMINE (see also DATE-RAPE DRUG; METHAMPHETAMINE; and LSD). Chronic abuse can have severe physiological or psychological repercussions (or both) and, when combined with the intake of alcohol, might also prove fatal.
clubfoot n. a type of deformity in which the foot is twisted out of normal position, resulting—in most cases—in more than one positional distortion (e.g., the foot may be turned inward and downward, outward and upward, or in some other variation). Clubfoot may be congenital, or the condition may be due to injury or disease, such as polioelitis. Clubfoot often is associated with another anomaly, such as MENINGOMYELOCLE. Also called talipes.
clumsy automation in ergonomics, any reallocation of system functions from humans to machines that does not lead to the expected gains in safety and efficiency. This is usually because automation alters the human operator’s task, resulting in increased workload or UNDERLOAD. Similarly, machine functions may be misallocated to humans. See also ADAPTIVE TASK ALLOCATION; FUNCTION ALLOCATION. [defined in 1989 by U.S. management scientist Earl Wiener (1949– )]
cluster analysis a method of multivariate data analysis in which individuals or units are placed into distinct subgroups based on their strong similarity with regard to specific attributes. For example, one might use cluster analysis to form groups of individual children on the basis of their levels of anxiety, aggression, delinquency, and cognitive difficulties so as to identify useful typologies that could increase understanding of co-occurring mental disorders and lead to more appropriate treatments for specific individuals. There are several different forms of cluster analysis—including HIERARCHICAL CLUSTERING and LATENT CLASS ANALYSIS—and each is appropriate for use with different types of data. Results of a cluster analysis often are presented in a DENDROGRAM. Also called clustering.
clustered data a set of observations or scores that can be grouped into multiple subsets (clusters), such that the items in each subset are similar to one another with respect to certain attributes and the distinctions between subsets help explain the overall variation among the values as a whole. See CLUSTER ANALYSIS.
cluster evaluation 1. a type of PROGRAM EVALUATION, either a FORMATIVE EVALUATION or a SUMMATIVE EVALUATION, carried out at several sites. Each site has the same EVALUATION OBJECTIVES, which are assessed in a coordinated effort by different evaluators in a continuous process. Information so obtained is then shared to enable common PROGRAM OUTCOMES to be assessed and to identify elements that contributed to the failures or successes of the program. 2. a strategy for accumulating information in evaluation research that involves combining and reconciling studies with somewhat different conclusions. This approach suggests criteria for determining when data from dissimilar studies can be pooled. 3. an approach in which individual evaluators of separate projects collaborate with an overarching evaluator. See also META-EVALUATION.

cluster headache an extremely severe unilateral headache, typically limited to the area around one eye, that lasts between 15 minutes and 3 hours and occurs in bouts, or “clusters,” every day (sometimes twice or more a day or every other day) for a period of up to 3 months, followed by a headache-free period of months or years. The exact cause is not known but may include vascular dilation, trigeminal nerve activity, or HISTAMINE release. Also called histamine headache.

clustering n. 1. the tendency for items to be consistently grouped together in the course of recall. This grouping typically occurs for related items. It is readily apparent in memory tasks in which items from the same category, such as nonhuman animals, are recalled together. 2. in statistics, see CLUSTER ANALYSIS. 3. in ergonomics, a method of KNOWLEDGE ELICITATION in which a researcher interviewing users of a product or system sorts data into key ideas or words as they occur and then groups together linked ideas and meanings. The clusters so formed are then used to create taxonomies, task hierarchies, or menu structures. —cluster n. vb.

cluster randomization a process in which preexisting groups are assigned randomly to specific experimental conditions, as occurs in GROUP EXPERIMENTS, GROUP-RANDOMIZED TRIALS, and other designs in which collective entities form the UNIT OF ANALYSIS. When such a process is applied to single individuals it is called RANDOM ASSIGNMENT.

cluster-randomized trial see GROUP-RANDOMIZED TRIAL.

cluster sampling a tiered method of obtaining units for a study. A population is first subdivided into smaller groups or clusters (often administrative or geographical), and a random sample of these clusters is drawn. The process is then repeated for each sample cluster until the required level is reached. An example would be sampling voters in a large jurisdiction (e.g., a state) by randomly choosing subgroups (e.g., counties) and then further subgroups (e.g., towns and cities) until individual participants are obtained for a study.

cluster suicide a statistically high occurrence of suicides within a circumscribed geographic area, social group, or time period. Cluster suicides have been identified involving adolescents, factory workers, and dispersed individuals who imitated the suicide of an admired role model as described by the media (see WEATHER SYNDROME). Compare MASS SUICIDE.

cluttering n. 1. a language disorder characterized by rapid speech that is confused, jumbled, and imprecise. Compare STUTTERING. 2. a tendency to collect items without any intention to do so. It is distinct from the clinically diagnosable condition of HOARDING in that the saved articles do not include trash or other unsanitary items and the individual is able to make rational decisions about and periodically discard materials.

CM abbreviation for COCHLEAR MICROPHONIC.

CMAS abbreviation for CHILDREN’S MANIFEST ANXIETY SCALE.

CME abbreviation for CONTINUING MEDICAL EDUCATION.

CMHC abbreviation for COMMUNITY MENTAL HEALTH CENTER.

CMI abbreviation for CORNELL MEDICAL INDEX.

CMP abbreviation for CHRONIC MYOFASCIAL PAIN.

CMS abbreviation for CENTERS FOR MEDICARE AND MEDICAID SERVICES.

CNS abbreviation for CENTRAL NERVOUS SYSTEM.

CNS abnormality any defect in structure or function of the tissues of the brain and spinal cord, that is, the central nervous system (CNS).

CNS depressant any of a group of drugs that, at low doses, depress the inhibitory centers of the brain. At somewhat higher doses, they depress other neural functions, slow reaction times, and lower respiration and heart rate. At still higher doses, they can induce unconsciousness, coma, and death. Examples of CNS depressants are ALCOHOL, BARBITURATES, BENZODIAZEPINES, INHALANTS, and MEPROBAMATE. See also SEDATIVE, HYPNOTIC, AND ANXIOLYTIC DRUG.

CNS stimulant any of a group of drugs that, at low to moderate doses, heighten wakefulness and alertness, diminish fatigue, and provoke feelings of energy and well-being. At higher doses, the more powerful stimulants can produce agitation, panicked excitement, hallucinations, and paranoia. In general, stimulants exert their effects by enhancing CATECHOLAMINE neurotransmission and increasing activity in the SYMPATHETIC NERVOUS SYSTEM. COCAINE and the AMPHETAMINES are examples of stimulants thought to activate the reward system (nucleus accumbens, limbic, and frontal cortex) by potentiating dopaminergic neurotransmission. CAFFEINE and NICOTINE are CNS stimulants with different mechanisms of action at ADENOSINE receptors and NICOTINIC RECEPTORS, respectively. In non-Western cultures, BETEL NUT, COCA leaves, GUARANA, KAIHAT, and numerous other substances are used as stimulants. Some stimulants are used clinically in mental health, and in psychiatric contexts, they are often referred to as psychostimulants. These drugs include the amphetamines and related or similarly acting compounds (e.g., METHYLPHENIDATE, PEMOLINE, MODAFINIL), used for the treatment of attention-deficit/hyperactivity disorder, narcolepsy, depression, and brain dysfunction and as appetite suppressants. Caffeine and ephedrine are ingredients of over-the-counter “alertness” medications.

CNS vasodilation dilation of cerebral blood vessels leading to increased cerebral blood flow. It can be caused by various agents, such as nitrous oxide.

CNV abbreviation for CONTINGENT NEGATIVE VARIATION.

Co abbreviation for COMPARISON STIMULUS.

coaching n. specialized instruction and training provided
to enable individuals to acquire or enhance particular skills, as in EXECUTIVE COACHING or LIFE COACHING, or to improve performance, as in athletic or academic coaching.

Coaching Behavior Assessment System (CBAS) an observation system, developed in the 1970s, for determining the frequency of 12 specific coaching behaviors and their effect on athletes. The behaviors may be exhibited by the coach in anticipation of or in reaction to an athlete’s or a team’s performance and include correcting, rewarding, giving negative feedback, instructing, and disciplining. A 2-hour instructional program, Coach Effectiveness Training, was later developed to teach coaches how to monitor their behavior, offer technical instruction, avoid expressing frustration, and praise good performance and effort. [originally developed by U.S. psychologists Ronald E. Smith (1940– ) and Frank L. Smoll (1941– )]

coacting group a group consisting of two or more individuals working in one another’s presence on tasks and activities that require little or no interaction or communication (COACTION TASKS), such as clerical staff working at individual desks in an open-design office. Researchers often create coacting groups in laboratory studies to determine the effect of the mere presence of others on performance. See also SOCIAL FACILITATION.

coaction effect the positive or negative change in an individual’s performance sometimes seen when other individuals are present and engaged in the same task. See also AUDIENCE EFFECT.

coaction task any performance, competition, work assignment, or other goal-oriented activity that individuals execute in the presence of one or more other individuals who are performing a similar type of task. Examples include an aerobics exercise session and students taking a written test in a classroom. Compare AUDIENCE TASK.

coactivation n. the activation of the same response at the same time by two different stimuli.

coactive sport a sport in which participants perform the same task without the need for interaction or for coordination of their actions with those of other players. Bowling and golf are examples of coactive sports. Compare INTERACTIVE SPORT.

coadaptation n. the development of interdependent behavioral adaptations between species. For example, a type of fruit tree may depend on a specific mammal to disperse its seeds and that mammal may depend on the tree’s fruit as part of its diet. See also SYMBIOSIS.

coalition n. an alliance of two or more individuals or groups, often formed to gain a better outcome (e.g., power and influence) than can be achieved by each alone. Coalitions tend to be adversarial, in that they seek outcomes that will benefit the coalition members at the expense of nonmembers. They also tend to be unstable because (a) they include individuals who would not naturally form an alliance but are obliged or encouraged to do so by circumstancenstances and (b) members frequently abandon one alliance to form a more profitable one. Such alliances are also formed among nonhuman animals. In chimpanzees, for example, a coalition of two or more lower-ranking chimps can subdue the dominant male in the troop. See also MINIMUM POWER THEORY; MINIMUM RESOURCE THEORY.

coarse tremor see TREMOR.

coartication n. a phenomenon in which the performance of one or more actions in a sequence varies according to the other actions in the sequence. This is particularly important in speech, where the formation of certain PHONEMES varies according to the speech sounds that immediately precede or follow: For example, the aspirated [p] sound in pin differs slightly from the unaspirated [p] in spin (see ASPIRATION). Coarticulation also occurs in keyboarding, where the movements used to type a particular key are different when the preceding or following keys are different. See also ALLOMORPHIC ALLOPHONE.

cobedding n. the practice of placing sibling infants, such as twins, in the same crib, bed, or incubator. There is some evidence of improved outcomes for infants born prematurely and those with LOW BIRTH WEIGHT who are cobedded in neonatal intensive care units. However, the practice of cobedding infants at home remains controversial as it is assumed to present an increased risk of SUDDEN INFANT DEATH SYNDROME. Compare BED-ShARING.

CO blob abbreviation for CYTOCHROME OXIDASE BLOB.

coca n. a shrub, Erythroxylum coca, that is indigenous to Peru, Bolivia, and other South American countries and cultivated in India, Sri Lanka, and Indonesia. The leaves have been used for centuries as the source of cocaine.

cocaine n. a drug, obtained from leaves of the COCA shrub, that stimulates the central nervous system (see CNS STIMULANT), with the effects of reducing fatigue and increasing well-being, followed by a period of depression as the initial effects diminish. The drug acts by blocking the reuptake of the neurotransmitters dopamine, serotonin, and norepinephrine. The psychoactive properties of the coca plant were recognized by the Peruvian Incas before 4000 BCE, and in the 1880s the possible therapeutic uses of cocaine were investigated. Sigmund FREUD observed that the drug functioned as a topical anesthetic. See also CRACK; FREEBASE.

cocaine abuse in DSM–IV–TR, a pattern of cocaine use marked by recurrent significant adverse consequences related to the repeated ingestion of the substance. This diagnosis is preempted by the diagnosis of COCAINE DEPENDENCE: If the criteria for cocaine abuse and cocaine dependence are both met, only the latter diagnosis is given. In DSM–5, however, both have been combined into one category, STIMULANT USE DISORDER, and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

Cocaine Anonymous (CA) a voluntary organization of men and women who seek to recover from cocaine addiction by using a TWELVE-STEP PROGRAM. See also SELF-HELP GROUP.

cocaine dependence in DSM–IV–TR, repeated or continued use of cocaine despite significant cocaine-related behavioral, physiological, and psychosocial problems and tolerance or characteristic withdrawal symptoms if use is suspended. In DSM–5, cocaine dependence has been combined with COCAINE ABUSE into a single disorder, and neither is considered a distinct diagnosis any longer (see STIMULANT USE DISORDER). See also SUBSTANCE DEPENDENCE.

cocaine intoxication in DSM–IV–TR, a reversible syndrome due to the recent ingestion of cocaine. It includes clinically significant behavioral or psychological changes (e.g., agitation, aggressive behavior, elation, grandiosity, impaired judgment, talkativeness, hypervigilance), as well as two or more physiologic signs (e.g., rapid heartbeat, elevated blood pressure, perspiration or chills, nausea and vomiting). Large doses, especially when taken intrave-
nously, may produce confusion, incoherence, apprehension, transient paranoid ideas, increased sexual interest, and perceptual disturbances (e.g., a sensation of insects crawling on the skin). An hour or so after these effects subside, the user may experience tremulousness, anxiety, irritability, fatigue, and depression. The equivalent term in DSM–5 is stimulant intoxication. See also SUBSTANCE INTOXICATION.

cocaine intoxication delirium in DSM–IV–TR and DSM–5, a reversible syndrome that develops over a short period of time (usually hours to days) following the heavy ingestion of cocaine. It includes disturbances of consciousness (e.g., reduced ability to focus, sustain, or shift attention), accompanied by changes in cognition (e.g., memory deficit, disorientation, or language disturbance) in excess of those usually associated with COCAINE INTOXICATION. See also SUBSTANCE INTOXICATION DELIRIUM.

cocaine withdrawal in DSM–IV–TR, a characteristic withdrawal syndrome that develops after cessation of (or reduction in) prolonged, heavy consumption of cocaine. The essential characteristic is depressed mood, sometimes transient, and there may also be fatigue, disturbed sleep, incontinence, and unpleasant dreams, or severe, and there may also be fatigue, disturbed sleep, incontinence, coexistence of those usually associated with COCAINE INTOXICATION. See also SUBSTANCE INTOXICATION DELIRIUM.

cocaine withdrawal delirium in DSM–IV–TR and DSM–5, a reversible syndrome that develops over a short period of time (usually hours to days) following the heavy ingestion of cocaine. It includes disturbances of consciousness (e.g., reduced ability to focus, sustain, or shift attention), accompanied by changes in cognition (e.g., memory deficit, disorientation, or language disturbance) in excess of those usually associated with COCAINE INTOXICATION. See also SUBSTANCE INTOXICATION DELIRIUM.

coccyx n. (pl. coccyges) the last bone of the SPINAL COLUMN in apes and humans; it is formed by fusion of the caudal vertebrae. —coccygeal adj.

cochlea n. the bony fluid-filled part of the inner ear that is concerned with hearing. Shaped like a snail shell, it forms part of the bony LABYRINTH. Along its length run three canals: the SCALA VESTIBULI, SCALA TYMPANI, and SCALA MEDIA, or cochlear duct. The floor of the scala media is formed by the BASILAR MEMBRANE; the ORGAN OF CORTI, which rests on the basilar membrane, contains the hair cells that act as auditory receptor organs. —cochlear adj.

cochlear aplasia the clinical absence or defective development of the cochlea in the inner ear.

cochlear duct see SCALA MEDIA.

cochlear echo see OTOACOUSTIC EMISSIONS.

cochlear emissions see OTOACOUSTIC EMISSIONS.

cochlear implant an electronic device designed to enable individuals with complete deafness to hear and interpret some sounds, particularly those associated with speech. It consists of a microphone to detect sound, a headpiece to transmit sound, a processor to digitize sound, and a receiver to signal electrodes that are surgically implanted in the cochlea to stimulate the auditory nerve. In contrast to a hearing aid, which amplifies sound, it directly stimulates the auditory nerve.

cochlear microphonic (CM) an alternating-current electric potential generated by hair cells in the inner ear that has a waveform similar to that of the acoustic input. Also called WEVER-BRAY EFFECT. [discovered in 1930 by U.S. psychologist Ernest Glen WEVER and U.S. otologist Charles W. Bray (1904–1982)]

cochlear nerve see AUDITORY NERVE.

cochlear nucleus a mass of cell bodies of second-order auditory neurons in the brainstem. The principal subdivisions are the ventral, dorsal, and anterior cochlear nuclei.

cochlear recruitment the Recruitment of previously unstimulated neurons in the cochlea with an increase in stimulus intensity.

Cochran Q test a nonPARAMETRIC statistical procedure applied when each experimental unit (e.g., an individual participant) is observed under multiple conditions and the data can have only one of two outcomes (e.g., yes or no, pass or fail). The Q test is used to evaluate the equality of the outcomes under the different conditions. [William Gemmell COCHRAN (1909–1980), Scottish-born U.S. statistician]

Cockayne syndrome a hereditary disorder characterized by MICROPHALY, dwarfism, premature aging, severe photosensitivity, hearing loss, and moderate to severe learning delays. There are three types: Type 1 (Type A) is diagnosed during early childhood; Type 2 (Type B) is a more severe form in which growth and developmental abnormalities are present at birth; and Type 3 (Type C) is a milder form of the disorder. Individuals with Type 1 or 2 usually do not survive past childhood, whereas those with Type 3 live into adulthood. [reported in 1936 by Edward Alfred Cockayne (1880–1956), British physician]

cocktail-party effect the ability to attend to one of several speech streams while ignoring others, as when one is at a cocktail party. Research in this area in the early 1950s suggested that the unattended messages are not processed, but later findings indicated that meaning is identified in at least some cases. For example, the mention of one’s name is processed even if it occurs in an unattended speech stream. See also ATTENUATION THEORY.

cocktail-party universal see PSYCHOLOGICAL UNIVERSAL.

cocoa n. a product derived from the cacao plant (Theobroma cacao) by roasting and grinding the beans (seeds) and removing the oils. The pharmacologically active ingredients are THEOBROMINE (typically about 1%–3% of dry weight) and CAFFEINE.

cocoa n. the product derived from the cacao (Theobroma cacao) plant, typically about 1%–3% of dry weight, and a source of caffeine.

cocounseling n. the counseling of peers by each other, as opposed to one-way, professionally led counseling. See REEVALUATION COUNSELING.

COD abbreviation for CHANGE-OVER DELAY.

codability n. the extent to which speakers of a language agree on a name for something. For example, the codability of a color is defined by how much agreement there is about a name for that color. —codable adj.

codeine n. a morphine-derived opiate that is used as an analgesic (alone or in combination with other analgesics, e.g., aspirin) and as a cough suppressant. It also induces...
code of ethics

euphoria; however, its addiction potential is substantially less than that of heroin. See OPIOD ANALGESIC.

**code of ethics** a set of standards and principles of professional conduct, such as the Ethical Principles of Psychologists and Code of Conduct of the AMERICAN PSYCHOLOGICAL ASSOCIATION. See PROFESSIONAL ETHICS; STANDARDS OF PRACTICE.

codependency n. 1. the state of being mutually reliant, for example, a relationship between two individuals who are emotionally dependent on one another. 2. a dysfunctional relationship pattern in which an individual is psychologically dependent on (or controlled by) a person who has a pathological addiction (e.g., alcohol, gambling).

codependency adj.

Co-Dependants Anonymous a self-help group for individuals who seek to improve problematic codependent relationships with others by using a twelve-step program. See CODEPENDENCY.

code switching in sociolinguistics, the practice typical of individuals proficient in two or more registers, dialects, or languages who will switch from one to the other depending on the conversational context or in order to enhance linguistic or social meaning. See also DIGLOSSIA.

code test a test that requires participants to translate one set of symbols into another, for example, by writing California in numbers that stand for letters according to the code A = 3, B = 4, C = 5, and so on. Also called coding test; symbol-substitution test. See CRYPTOARITHMETIC; CRYPTOGRAM. See also SYMBOL–DIGIT TEST.

codification n. 1. the systematic arrangement of items in an organized fashion or the classification of items into identifiable categories. 2. the conversion of data or other information into a code that can be translated by others. Also called coding.

codification-of-rules stage in Jean Piaget’s theory of moral development, the stage at which children of 11 and 12 years of age and older view rules as binding once they are agreed to, and games are seen as a system of interconnecting laws. Although the awareness of rules emerges at an earlier age, systematic adherence is not manifested until the codification-of-rules stage.

coding n. see CODIFICATION.

coding test see CODE TEST.

codominance n. a sharing of high rank in certain non-human animal populations. Wild macaques, baboons, and chimpanzees may control their groups through a few small males exhibiting codominance, rather than through a linear hierarchy of animal dominance. Coalitions may be formed by lower ranking individuals either to counter the influence of more dominant individuals or to overthrow them. Often these coalitions are short-lived as one coalition member assumes dominance over the others.

codon n. a unit of the genetic code consisting of three consecutive bases in a DNA or messenger RNA sequence. Most codons specify a particular amino acid in protein synthesis, although some act as “start” or “stop” signals. Codons on a gene are numbered, and genetic mutations are described as occurring at particular codons or locations on the gene. Thus, a family might be described as having a mutation at codon 630 on exon 11 of chromosome 10.

coefficient n. 1. a quantity or value that serves as a measure of some property. For example, the correlation coefficient is a measure of linear relatedness and a regression coefficient is a measure of the relationship between a predictor and a response variable. 2. in algebra, a scalar that multiplies a variable in an equation. For example, in the equation \( y = bx \), the scalar quantity \( b \) is said to be a coefficient.

coefficient alpha see CRONBACH’S ALPHA.

coefficient of agreement a numerical index that reflects the degree of agreement among a set of raters, judges, or instruments as to which of several categories a case belongs. Coefficients of agreement, such as COHEN’S KAPPA, are often corrected for chance agreement. Also called agreement coefficient.

coefficient of alienation (symbol: k) a numerical index that reflects the amount of unexplained variance between two variables. It is a measure of the lack of relationship between the two variables. Also called alienation coefficient.

coefficient of association any of various quantities that index the relationship between two variables. For example, the Pearson product-moment correlation coefficient might be used to measure a relationship involving linear associations, whereas the Spearman correlation coefficient might be used for one involving nonlinear associations.

coefficient of concordance (symbol: W) a numerical index that reflects the degree to which the rankings of items or objects by \( m \) raters are in agreement. Its value ranges from 0 (no agreement) to 1 (perfect agreement). Also called Kendall’s coefficient of concordance: Kendall’s \( W \).

coefficient of contingency (symbol: \( C \)) a measure of the degree of association between two variables whose values are unordered categories. Its value ranges from 0 to 1, with 0 indicating that the two nominal variables are independent of each other. Examples include Cramer’s \( V \) and Yule’s \( Q \). Also called contingency coefficient.

coefficient of determination (symbol: \( r^2 \)) a numerical index that reflects the proportion of variation in an outcome or response variable that is accounted for by its relationship with a predictor variable. More specifically, it is a measure of the percentage of variance in a dependent variable that is accounted for by its linear relationship with a single independent variable. Obtained by multiplying the value of the correlation coefficient \( r \) by itself, the coefficient of determination ranges in value from 0 to 1. Low values indicate the outcome is relatively unrelated to the predictor, whereas values closer to 1 indicate that the two variables are highly related. For example, if \( r = .30 \), then the squared correlation coefficient is \( .30^2 = .09 \) and interpreted to mean 9% of the variance between the two variables is common or overlapping. Also called determination coefficient; squared correlation coefficient.

coefficient of multiple determination (symbol: \( R^2 \)) a numerical index that reflects the degree to which variation in a response or outcome variable (e.g., workers’ incomes) is accounted for by its relationship with two or more predictor variables (e.g., age, gender, years of education). More specifically, it is a measure of the percentage of variance in a dependent variable that is accounted for by its relationship with a weighted linear combination of a set of independent variables. Obtained by multiplying the value of the multiple correlation coefficient \( R \) by it-
self, the coefficient of multiple determination ranges in value from 0 to 1. Low values indicate that the outcome is relatively unrelated to the predictors, whereas values closer to 1 indicate that the outcome and the predictors are highly related. For example, if $R^2 = .40$, then the coefficient of multiple determination is .40 and interpreted to mean 16% of the variance in outcome is explainable by the set of predictors. Also called multiple correlation coefficient squared: $\text{coefficient squared}$. 

Coefficient of relatedness: the mean number of genes shared between two related individuals. Identical twins share 100% of their genes and have a coefficient of relatedness of 1. Between siblings and between parents and offspring, the coefficient of relatedness is .5; between uncles or aunts and nieces or nephews and between grandparents and grand-offspring, it is .25; and between first cousins, it is .125. Most studies of kin recognition and kin-directed behavior show effects only with coefficients of relatedness of 0.25 and greater. See also inclusive fitness.

Coefficient of reliability: see reliability coefficient.

Coefficient of variation: a measure of variability in a set or distribution of values. It is determined by dividing the distribution’s standard deviation by its mean. Also called variation coefficient.

Coefficient of visibility: a measure of the visibility of light of a particular wavelength. The coefficient of visibility for photopic vision is 1 at 555 nm, the wavelength at which humans have peak photopic sensitivity. Also called luminosity coefficient.

coenesthesia n. see coenesthesia.

coenzyme (co-ene- cene- ceno-): combining form common or general.

coenzyme n.: a nonprotein, organic compound that functions with the protein portion of an enzyme (an apoenzyme). Most enzymes fail to function without a specific coenzyme, which is often a vitamin.

coerced confession: an accused person’s admission of guilt elicited by the use of threat, torture, or promises. Also called involuntary confession.

coercion n.: the process of attempting to influence another person through the use of threats, punishment, force, direct pressure, and other negative forms of power. —coerce vb. —coercive adj.

coercive behavior: behavior designed to force others to do one’s bidding, often masked as filial devotion or as marital or parental concern and sometimes expressed directly (e.g., “If you don’t do what I say, I’ll kill myself”).

coercive persuasion: 1. systematic, intensive indoctrination of political or military prisoners, using such methods as threats, punishments, bribes, isolation, continuous interrogation, and repetitious “instruction.” As a countermeasure, military personnel may be trained in methods of coercive persuasion resistance, which are designed to enable them to function and survive to the best of their ability under such adverse circumstances. Also called thought reform. See brainwashing. 2. broadly, a controlled program of social influence to bring about substantial changes in behavior and attitude in members of a group (e.g., military recruits, cult followers). [coined in 1961 by Swiss-born U.S. psychologist Edgar H. Schein (1928–)]

coercive power: the capacity to compel others’ compliance through the use of force, including punishment or the threat of punishment.

coercive treatment: see forced treatment.

coevolution n.: the concurrent evolution of two or more species that mutually affect each other’s evolution.

coexistence hypothesis: a theoretical explanation of the misinformation effect stating that when misleading information is introduced after a witnessed event, it exists in competition with the original memory of the event. The false information is more accessible due to the recency effect and is more likely to be retrieved upon questioning, leading to erroneous reporting of the event. Compare alteration hypothesis.

cofacilitator n.: a therapist or student in training who assists in leading a therapy group. The cofacilitator may act as an observer or as one who balances the approach of the other group leader.

coffee n.: a product derived from evergreen trees of the genus Coffea, which grow wild or are cultivated in tropical regions worldwide, including Brazil, Columbia, and Ethiopia. Of more than 100 species of Coffea, two are commercially important sources of coffee beans (seeds), used in beverages. They are C. arabica and C. robusta, whose beans contain significant concentrations (about 1% and 2%, respectively) of the stimulant caffeine.

Coffelt decision: see LANTERMAN DEVELOPMENTAL DISABILITIES ACT.

configurative culture: a society or culture in which people learn chiefly from other people in the same age group, so that, for example, children learn mostly from children and young adults from young adults. Compare postfigurative culture; prefigurative culture. [coined by U.S. anthropologist Margaret Mead (1901–1978)].

Cogan’s syndrome: a condition in which keratitis is associated with attacks of vertigo, tinnitus, and deafness. Pain in the eyes and reduced vision are also experienced. As the vertigo subsides (usually within days), the patient may become deaf or, in rare cases, blind. It is believed to be an autoimmune disorder. Also called non-syphilitic interstitial keratitis. [described in 1945 by David Glendenning Cogan (1908–1993). U.S. physician]

CogAT: acronym for COGNITIVE ABILITIES TEST.

cognate adj.: denoting words that have a common etymology, or origin, especially words in different languages that have similar form and meaning. For example, the words picture (English), pintura (Spanish), and pittria (Italian) are said to be cognate.

cognizant adj.: having the capacity to compel others’ compliance through the use of force, including punishment or the threat of punishment.
Cognitive Abilities Test

titled components of mind. 2, an individual percept, idea, memory, or the like.—cognitive adj. —cognitive adv.

Cognitive Abilities Test (CogAT) a group of multiple-choice tests measuring students’ abstract reasoning and problem-solving abilities. It is divided into a primary edition (for kindergarten–Grade 2) and a multilevel edition (for Grades 3–12), which are further divided into three levels (K, 1, and 2) and eight levels (A–H), respectively. Each edition contains various subtests (e.g., sentence completion, equation building, and figure synthesis) in three groups: verbal, quantitative, and nonverbal. The CogAT, a revision of the now obsolete 1954 Lorge–Thorndike Intelligence Tests, was originally published in 1968; the most recent version is the CogAT Form 7, published in 2011. A British version of the Cognitive Abilities Test is also available. Designed for use with students ages 7½ to 17 years and over, it is known as the CAT and is now in its fourth edition (published in 2012). [developed by U.S. psychologists Robert L. Thorndike (1910–1990), Irving D. Lorge (1905–1961), Elizabeth P. Hagen (1915–2008), and David E. Lohman (1949–)].

cognitive ability the skills involved in performing the tasks associated with perception, learning, memory, understanding, awareness, reasoning, judgment, intuition, and language.

cognitive-affective crossfire a state of conflict between a person’s cognitive responses to feedback about the self and his or her affective responses. In particular, an individual’s thoughts (cognitions) may favor information that confirms his or her existing self-concept (see self-verification motive), whereas the same individual’s emotional reactions (affects) may favor pleasant or positive views of the self (see self-enhancement motive).

cognitive-affective personality system a theoretical conception of personality structure as a complex system that features a large number of highly interconnected cognitions and emotional tendencies. [developed by Austrian-born U.S. personality psychologist Walter Mischel (1930–) and Japanese-born U.S. psychologist Yuichi Shoda]

cognitive aging age-related changes in mental functioning (e.g., attention, memory, decision making) that occur across the lifespan.

cognitive aid any external representation that supports a mental process. Examples are reminders, checklists, and other prompts designed to prevent forgetting of critical tasks.

cognitive analytic therapy a time-limited, collaborative psychotherapy that emphasizes schemas and integrates principles and techniques from psychodynamic psychotherapy and cognitive behavior therapy. [developed in the 1980s by British psychiatrist Anthony Ryle (1927–)].

cognitive appraisal theory the theory that cognitive evaluation is involved in the generation of each and every emotion. Evaluation includes both a primary appraisal and a secondary appraisal. This concept is elaborated in the cognitive-motivational–relational theory, which recognizes that cognition is one of three simultaneously operating processes that contribute to the generation of any emotion. See also core relational themes. [proposed by Richard S. Lazarus]

cognitive architecture a hypothesized architecture for human problem solving, usually represented as a component of a computer program. Examples include the production system and SOAR. Empirical testing of cognitive phenomena is often used to establish the validity of aspects of this model.

cognitive arousal theory of emotion see Schachter–Singer theory.

cognitive assessment evaluation of such skills as learning, memory, judgment, and reasoning.

Cognitive Assessment System (CAS) an assessment battery that evaluates cognitive ability according to the PASS model. Applicable to both children and adolescents, the test yields separate scores for planning, attention, simultaneous-processing abilities, and successive-processing abilities, as well as an overall score. Among its uses is the evaluation and assessment of learning disabilities as defined in the Individuals with Disabilities Education Act. [devised in the late 1980s by Canadian psychologist Jaganath Prasad (J. P.) Das (1931–) and U.S. psychologist Jack A. Naglieri (1950–)].

cognitive balance theory see balance theory.

cognitive behavioral couples therapy behavioral couples therapy that specifically focuses on the reciprocal influence of the partners’ idiosyncratic patterns of ideas about each other and about couples in general. Interfering ideas are made conscious and explicit and are then altered to improve the couple’s relationship using techniques modified from cognitive behavior therapy. Compare integrative behavioral couples therapy.

cognitive behavioral group therapy a type of group psychotherapy that uses techniques and methods of cognitive behavior therapy, such as modeling, restructuring thoughts, relaxation training, and communication skills training, to achieve behaviorally defined goals. Groups can include clients with diverse issues or can be limited to clients with specific problems (e.g., agoraphobia, anger).

cognitive behavior modification see cognitive behavior therapy.

cognitive behavior theory any theory deriving from general behavioral theory that considers cognitive or thought processes as significant mediators of behavioral change. A central feature in the theoretical formulations of the process is that people respond primarily to cognitive representations of their environments rather than to the environments themselves. The theory has led to popular therapeutic procedures that incorporate cognitive behavior techniques to effect changes in self-image as well as behaviors.

cognitive behavior therapy (CBT) a form of psychotherapy that integrates theories of cognition and learning with treatment techniques derived from cognitive therapy and behavior therapy. CBT assumes that cognitive, emotional, and behavioral variables are functionally interrelated. Treatment is aimed at identifying and modifying the client’s maladaptive thought processes and problematic behaviors through cognitive restructuring and behavioral techniques to achieve change. Also called cognitive behavior modification: cognitive behavioral therapy.

cognitive click a moment in psychotherapy in which it becomes suddenly clear to the client that his or her thinking is incorrect and therefore that he or she must change his or her attitudes and beliefs.
cognitive closure 1. the state in which an individual recognizes that he or she has achieved understanding of something. 2. the final stage in figuratively seeing the total picture and how all pieces of it fit together.

cognitive complexity the state or quality of a thought process that involves numerous constructs, with many interrelationships among them. Such processing is often experienced as difficult or effortful. See also CONCEPTUAL COMPLEXITY.

cognitive complexity and control theory (CCC theory) the proposal that the ability to follow rules depends on the development of conscious awareness and self-control and is therefore age related. In general, a 4-year-old child can solve problems requiring the application of more complex rules than he or she could at age 3. [proposed by Canadian psychologist Philip D. Zelazo (1966– ) and U.S. psychologist Douglas Frye (1952– )]

cognitive conditioning a process in which a stimulus is repeatedly paired with an imagined or anticipated response or behavior. Cognitive conditioning has been used as a therapeutic technique, in which case the stimulus is typically aversive. For example, the client imagines that he or she is smoking a cigarette and gives himself or herself a pinch; the procedure is repeated until the thought produces the effect of discouraging the behavior. See also COGNITIVE REHEARSAL.

cognitive consistency the extent to which one cognitive element follows from or is implied by another cognitive element. See also COGNITIVE CONSONANCE; COGNITIVE DISSONANCE.

cognitive consistency theory any of a broad class of theories postulating that attitude change is a result of the desire to maintain consistency among elements of a cognitive system. See also BALANCE THEORY; COGNITIVE DISSONANCE THEORY; CONGRUITY THEORY.

cognitive consonance in COGNITIVE DISSONANCE THEORY, a situation in which two cognitive elements are consistent with one another, that is, one cognitive element follows from or is implied by the other.

cognitive construct see CONSTRUCT.

cognitive control the set of processes that organize, plan, and schedule mental operations. See also CONTROL PROCESSES; EXECUTIVE.

cognitive coping any strategy in which a person uses mental activity to manage a stressful event or situation. A variety of different forms exist, such as putting the experience into perspective, seeking to understand the causes of the situation, thinking about steps to resolve the situation, thinking about pleasant experiences instead of the current difficulty (positive refocusing), redefining the situation to emphasize potential benefits (positive reappraisal), exaggerating the negative consequences of the event (catastrophizing), blaming oneself or others for the occurrence of the event, dwelling on the negative emotions associated with the event (ruminating), and minimizing the situation or its impact (cognitive avoidance). Some of these strategies (e.g., positive reappraisal, positive refocusing, putting things into perspective) generally are considered more effective than others, being associated with more positive psychological outcomes. Compare BEHAVIORAL COPING.

cognitive decline reduction in one or more cognitive abilities, such as memory, awareness, judgment, and mental acuity, across the adult lifespan. The presence and degree of decline varies with the cognitive ability being measured; Fluid abilities often show greater declines than crystallized abilities (see CATTELL–HORN THEORY OF INTELLIGENCE). Cognitive decline is a part of normal healthy aging, but a severe decline is not normative and could be symptomatic of disease: It is the primary symptom of disease-induced dementias, such as ALZHEIMER’S DISEASE.

cognitive deconstruction a mental state characterized by lack of emotion, the absence of any sense of future, a concentration on the here and now, and a focus on concrete sensation rather than abstract thought. People may cultivate this state to escape from emotional distress or troublesome thoughts. [first described by U.S. social psychologist Roy Baumeister (1953– )]

cognitive deficit performance on intellectual and other mentally based tasks (e.g., those involving memory), as measured by individually administered standardized assessments (verbal and nonverbal cognitive measures), that is substantially below that expected given the individual’s chronological age and formal educational experience.

cognitive derailment the often abrupt shifting of thoughts or associations so that they do not follow one another in a logical sequence. Cognitive derailment is a symptom of schizophrenia; the term is essentially equivalent to THOUGHT DELIRIUM. See also COGNITIVE SLIPPAGE.

cognitive development the growth and maturation of thinking processes of all kinds, including perceiving, remembering, concept formation, problem solving, imagining, and reasoning. Various cognitive developmental theories exist that attempt to explain the mechanisms underlying such growth and maturation. Explanations may be in terms of stages of development in which the changes in thinking are relatively abrupt and discontinuous, or the changes may be viewed as occurring gradually and continuously over time.

cognitive discrimination the ability to make distinctions between concepts and to distinguish between examples and nonexamples of a particular concept.

cognitive disorder any disorder that involves impairment of the EXECUTIVE FUNCTIONS, such as organization, regulation, and perception. Impairments in these fundamental processes can affect performance in many cognitive areas, including processing speed, reasoning, planning, judgment, decision making, emotional engagement and regulation, perseveration, impulse control, awareness, attention, language, learning, memory, and timing.

cognitive dissonance an unpleasant psychological state resulting from inconsistency between two or more elements in a cognitive system. It is presumed to involve a state of heightened arousal and to have characteristics similar to physiological drives (e.g., hunger). Thus, cognitive dissonance creates a motivational drive in an individual to reduce the dissonance (see DISSONANCE REDUCTION). See also COGNITIVE CONSONANCE. [first described by Leon Festinger]

cognitive dissonance theory a theory proposing that people have a fundamental motivation to maintain consistency among elements in their cognitive systems. When inconsistency occurs, people experience an unpleasant psychological state that motivates them to reduce the dissonance in a variety of ways (see DISSONANCE REDUCTION). Several variants of this theory have also been proposed, including the NEW-LOOK THEORY and SELF-CONSISTENCY PERSPECTIVE. Alternative theories have been
cognitive distortion

proposed as well, such as SELF-AFFIRMATION THEORY and SELF-PERCEPTION THEORY. See also COGNITIVE CONSONANCE. [first proposed by Leon Festinger]

cognitive distortion faulty or inaccurate thinking, perception, or belief. An example is OVERGENERALIZATION. Cognitive distortion is a normal psychological process that can occur in all people to a greater or lesser extent.

cognitive domain see BLOOM’S TAXONOMY.

cognitive dysfunction any disruption in mental activities associated with thinking, knowing, and remembering.

cognitive electrophysiology see ELECTROENCEPHALOGRAPHY.

Cognitive Emotion Regulation Questionnaire (CERQ) a 36-item self-report inventory that measures the extent to which adults and adolescents consciously use COGNITIVE COPING strategies to manage emotions associated with negative life events. On a 5-point LIKERT SCALE ranging from almost never to almost always, participants rate statements that reflect one of nine different cognitive coping strategies (e.g., positive reappraisal, self-blame, rumination). The CERQ is utilized both in research to study relationships between cognitive processes and mental health and in clinical diagnosis to identify individuals with unusual patterns of strategy use that may be indicative of depression and other pathology. A simplified version of the measure for children ages 9 to 11 years (CERQ–k) and an abbreviated 18-item adult version (CERQ–short) also exist. [developed in 2001 by Dutch psychologists Nadia Garnefeld, Vivian Kraaij, and Philip Spinhoven (1954—)]

cognitive enhancer a type of drug used to improve cognitive function, usually in the treatment of progressive dementias such as Alzheimer’s disease but also of cognitive dysfunction due to traumatic brain injury. Cognitive enhancers do not reverse the course of the dementia but are reported to slow its progress in mild to moderate forms. Many of these drugs work by inhibiting the activity of acetylcholinesterase in the central nervous system, thereby counteracting the disruption of cholinergic neurotransmission observed in patients with Alzheimer’s disease. Other drugs use different mechanisms for improving cognitive performance in patients with Alzheimer’s disease, including NMDA RECEPTOR antagonists and potentially the prevention of beta-amyloid plaque formation in the brain. Current cognitive enhancers include DONEPEZIL, RIVASTIGMINE, and GALANTAMINE. Also called memory-enhancing drug; and, formerly, nootropic.

cognitive ergonomics a specialty area of ERGONOMICS that seeks to understand the cognitive processes and representations involved in human performance. Cognitive ergonomics studies the combined effect of information-processing characteristics, task constraints, and task environment on human performance and applies the results of such studies to the design and evaluation of work systems.

cognitive ethology the study of mental experiences, including CONSCIOUSNESS and INTENTIONALITY, in nonhuman animals and of the influence of these experiences on the animals’ behavior as they interact with their natural environment. Whether, and which, animals actually possess consciousness and intentionality remains a subject of controversy. [proposed in 1978 by U.S. zoologist Donald Redfield Griffin (1915–2003)]

cognitive evaluation theory a theory postulating that an individual’s performance will improve or decline depending on his or her attitude about the reward for good performance, that is, about whether it is conferred as a true reward for effective performance or as a means by which the grantor of the reward asserts control over the performer. [posited by Leon Festinger]

cognitive–evaluative consistency the degree to which the cognitive basis of an attitude (see BASIS OF AN ATTITUDE) and the overall attitude are evaluatively consistent with one another. For example, if the cognitive basis is extremely positive and the overall attitude is extremely negative, cognitive–evaluative consistency is low. See also AFFECTIVE–COGNITIVE CONSISTENCY: AFFECTIVE–EVALUATIVE CONSISTENCY.

cognitive faculty a specific aspect or domain of mental function, such as language, object recognition, or face perception. See FACULTY PSYCHOLOGY.

cognitive flexibility the capacity for objective appraisal and appropriately flexible action. Cognitive flexibility also implies adaptability and fair-mindedness.

cognitive flooding a method used in psychotherapy, mainly to treat phobias, in which the client is encouraged to focus on negative or aversive mental images to generate emotional states similar to those experienced when faced with a feared object or situation. The simulated fear is then seen to be manageable and associated with images that will reduce the original fear. See also IMPLOSIVE THERAPY; PROLONGED EXPOSURE THERAPY.

cognitive functioning the performance of the mental processes of perception, learning, memory, understanding, awareness, reasoning, judgment, intuition, and language.

cognitive generalization 1. the ability to apply knowledge, concepts, or cognitive skills acquired in one context or domain to problems in another. See GENERAL TRANSFER. 2. a general principle of human cognition, such as association or categorization, that applies across cognitive faculties or domains. In the theory of COGNITIVE GRAMMAR, such generalities are held to underlie the construction of meaning in language.

cognitive grammar in linguistics and psycholinguistics, a theory of grammar in which the constituent units are derived from general cognitive principles, such as association or categorization, and so on, rather than from autonomous linguistic principles. This assumption that language is an integral part of cognition runs counter to the theory of the TASK SPECIFICITY OF LANGUAGE. [introduced in 1987 by U.S. linguist Ronald W. Langacker (1942—)]

cognitive heuristic see HEURISTIC.

cognitive hypothesis testing problem-solving behavior in which the individual derives a set of rules (hypotheses) that are then sampled and tested until the one rule is discovered that consistently results in correct solutions to the problem.

cognitive impairment any impairment in perceptual, learning, memory, linguistic, or thinking abilities. Multiple significant cognitive impairments in memory plus one or more other cognitive defects are characteristic of DEMENTIA. See also MILD COGNITIVE IMPAIRMENT.

cognitive impenetrability the condition of certain processes (e.g., visual processes, reflexes) that are characterized as free of influence from prior conceptual or intel-
cognitive process

lectural knowledge and are thought to proceed with a minimum of conscious control. Compare cognitive penetrability. [coined by Canadian cognitive scientist and philosopher Zenon W. Pylyshyn (1937–)]

cognitive intelligence one’s abilities to learn, remember, reason, solve problems, and make sound judgments, particularly as contrasted with emotional intelligence.

cognitive interdependence the tendency of individuals in close, committed relationships to think of themselves less in individual terms and more as partners in a dyadic relationship. For example, cognitive interdependence leads people to increase their use of plural pronouns (we, us, our) while decreasing their use of singular pronouns (I, me, my). Cognitive interdependence is thought to reflect mental processes that stem from the meshing of perspectives, goals, and identities that characterizes committed relationships and is most commonly observed in romantic relationships such as marriage.

cognitive interview a structured technique developed for enhancing eyewitness recollection in criminal investigation. It relies on principles of cognition and memory retrieval, such as context reinstatement, reporting everything (however seemingly irrelevant), recalling events in different order, and changing perspectives. See also aided recall. [developed in 1984 by U.S. psychologists R. Edward Geiselman (1949–), Ronald P. Fisher (1947–), and colleagues]

cognitive learning theory any theory postulating that learning requires central constructs and new ways of perceiving events (see S–R learning model). Cognitive learning theories are usually contrasted with behavioral learning theories, which suggest that behaviors or responses are acquired through experience (see S–R psychology).

cognitive load the relative demand imposed by a particular task, in terms of mental resources required. Also called mental load: mental workload. See also cognitive overload; mental effort.

cognitively based persuasion an active attempt to change an attitude primarily by altering beliefs regarding attributes associated with the attitude object. Also called rationally based persuasion. See also bases of an attitude. Compare affectively based persuasion.

cognitively guided instruction an educational approach in which teachers make decisions about their instruction based on the knowledge and performance level of their students. Students are encouraged to create their own solutions to problems rather than rely on a set of preconceived, teacher-directed procedures.

cognitive map a mental understanding of an environment, formed through trial and error as well as observation. The concept is based on the assumption that an individual seeks and collects contextual clues, such as environmental relationships, rather than acting as a passive receptor of information needed to achieve a goal. Human beings and other animals have well-developed cognitive maps that contain spatial information enabling them to orient themselves and find their way in the real world (see spatial cognition); symbolism and meaning are also contained in such maps. See also environmental cognition; landmark; mental map. [introduced by Edward C. Tolman]

cognitive miser anyone who seeks out quick, adequate solutions to problems rather than slow, careful ones. Despite this negative denotation, the term describes a general tendency among all people: That is, as a rule people tend to use mental shortcuts in making judgments and drawing inferences.

cognitive model a theoretical view of thought and mental operations, which provides explanations for observed phenomena and makes predictions about an unknown future. People are continually creating and accessing internal representations (models) of what they are experiencing in the world for the purposes of perception, comprehension, and behavior selection (action).

cognitive-motivational-relational theory an extension of the cognitive appraisal theory that puts equal emphasis on three processes involved in the generation of an emotion: (a) appraisal (the cognitive process); (b) the central role of the individual’s strivings, intentions, and goals (the motivational process); and (c) the relevance of external events to these strivings (the relational process). [proposed by Richard S. Lazarus]

cognitive narrowing focusing on a single aspect of a situation or object rather than on the whole.

cognitive neuropsychology the study of the structure and function of the brain as it relates to perception, reasoning, remembering, and all other forms of knowing and awareness. Cognitive neuropsychology focuses on examining the effects of brain damage on thought processes—typically through the use of single-case or small-group designs—so as to construct models of normal cognitive functioning.

cognitive neuroscience a branch of neuroscience and biological psychology that focuses on the neural mechanisms of cognition. Although overlapping with the study of the mind in cognitive psychology, cognitive neuroscience, with its grounding in such areas as experimental psychology, neurobiology, brain imaging techniques, physics, and mathematics, is more concerned with the specific neural mechanisms by which mental processes occur in the brain; the two perspectives continually exert significant influence on each other. Also called neuroscience.

cognitive operation the manipulation of mental representations, notably by identifying, organizing, and elaborating such representations or retrieving them from memory. See also cognitive process; operation; symbolic process; thinking.

cognitive overload the situation in which the demands placed on a person by mental work (the cognitive load) are greater than the person’s mental abilities can cope with. See also communication overload; information overload; sensory overload.

cognitive penetrability the capacity of a mental process to be influenced by an individual’s knowledge, beliefs, or goals. Compare cognitive impenetrability.

cognitive plasticity the capacity for change (e.g., improved performance) in mental processes such as learning and memory in response to a primary experience (e.g., practice).

cognitive problem-solving skills training see problem-solving skills training.

cognitive process any of the mental functions assumed to be involved in the acquisition, storage, interpretation,
cognitive processing therapy

These processes encompass such activities as attention, perception, learning, and problem solving and are commonly understood through several basic theories, including the SERIAL PROCESSING approach, the PARALLEL PROCESSING approach, and a combination theory, which assumes that cognitive processes are both serial and parallel, depending on the demands of the task. This term is often used synonymously with MENTAL PROCESS.

**cognitive processing therapy (CPT)** a form of COGNITIVE BEHAVIOR THERAPY originally used with victims of rape or sexual trauma and later applied to those with posttraumatic stress disorder resulting from any trauma. CPT emphasizes cognitive strategies to help people alter erroneous thinking that has emerged because of a traumatic event. Practitioners may work with clients on false beliefs that the world is no longer safe, for example, or that they are incompetent because they "let" the traumatic event happen to them. [developed by U.S. psychologists Patricia A. Resick, Candice Monson, and Kathleen Chard]

**cognitive psychology** the branch of psychology that explores the operation of mental processes related to perceiving, attending, thinking, language, and memory. Mainly through inferences from behavior. The cognitive approach, which developed in the 1940s and 1950s, diverged sharply from contemporary BEHAVIORISM in (a) emphasizing unseen knowledge processes instead of directly observable behaviors and (b) arguing that the relationship between stimulus and response was complex and mediated rather than simple and direct. Its concentration on the higher mental processes also contrasted with the focus on instincts and other unconscious forces typical of psychoanalysis. More recently, cognitive psychology has been influenced by approaches to INFORMATION PROCESSING and INFORMATION THEORY developed in computer science and ARTIFICIAL INTELLIGENCE. See also COGNITIVE SCIENCE.

**cognitive rehabilitation** specific REHABILITATION interventions designed to address problems in mental processing that are associated with chronic illness, brain injury, or trauma, such as stroke. Cognitive rehabilitation may include relearning specific mental abilities, strengthening unaffected abilities, or substituting new abilities to compensate for lost ones.

**cognitive rehearsal** a therapeutic technique in which a client imagines those situations that tend to produce anxiety or self-defeating behavior and then repeats positive coping statements or mentally rehearses more appropriate behavior.

**cognitive remediation** an intervention to improve neuropsychological function, such as in attention or memory, that has been impaired due to traumatic brain injury, stroke, severe mental illness (e.g., schizophrenia), or other conditions. See COGNITIVE REHABILITATION.

**cognitive reserve** a capacity of the adult brain to sustain the effects of disease or injury without manifesting clinical symptoms of dysfunction and to draw on the active acquisition and differential use of numerous sophisticated cognitive strategies to process information, solve problems, and perform tasks. In other words, individuals with high cognitive reserve have developed a variety of efficient NEURAL NETWORKS and NEURAL PATHWAYS to cope with brain pathology such that they can have a greater degree of underlying neurological damage than individuals with low cognitive reserve before becoming symptomatic. The size of this hypothesized supply of mental abilities and mechanisms, and thus the degree of protection against dementia and other neurological disorders it conveys, is believed to depend on the intellectual challenges a person experiences throughout life: More mental stimulation creates more reserve.

Possible mechanisms by which this might occur include the following: (a) knowledge can enhance memory in the form of richer and more elaborate encoding and more effective retrieval cues facilitated by a superior organizational structuring of information; (b) knowledge can result in easier access to relevant information and better organized representations of the problem, resulting in enhanced problem-solving skills; (c) knowledge of past consequences of various alternatives can provide an effortless means of making accurate predictions regarding future consequences; (d) knowledge can enable reliance on previously compiled efficient algorithms, rather than on slow and controlled processes; and (e) knowledge of prior solutions to familiar problems can reduce online processing requirements. Commonly used indirect measures of cognitive reserve include number of years of education, literacy level, vocabulary knowledge, occupational complexity, estimated premorbid intelligence, and frequency and range of participation in mentally stimulating leisure activities (e.g., reading, writing, doing crossword puzzles, playing board or card games, playing music) or complex mental activities generally.

It is important to distinguish cognitive reserve from the closely related BRAIN RESERVE, which posits that brain-based anatomical differences among people convey differential abilities to tolerate neuronal damage or loss before developing cognitive impairment. Despite the different phases of the two terms, many researchers use them interchangeably.

**cognitive resource theory** 1. a general theoretical framework that assumes that individuals respond to problems, challenges, and choices by actively encoding, processing, and recalling needed information, but that these mental activities place demands on cognitive capacity such that heavy loads in one cognitive domain will lead to reductions in activity in another. 2. a conceptual analysis of leadership effectiveness that assumes that team performance depends on a combination of the leader's cognitive resources (e.g., intelligence, skills, experience) and the particular group setting, especially with regard to the level of interpersonal conflict and stress in the group. This model was developed from the CONTINGENCY THEORY OF LEADERSHIP to give greater weight to the traits of individual leaders. See LEADERSHIP THEORIES. [developed in 1987 by Fred Fiedler and his colleagues]

**cognitive response theory** a theory postulating that attitude change occurs primarily as a function of people's evaluative responses to attitude-relevant information. Such responses include inferences generated about the information, assessments of its validity, and other evaluative reactions that may or may not be cognitive in nature (e.g., emotional responses). This theory holds that it is primarily the number and valence of these responses, rather than memory for the information itself, that determines the magnitude and duration of attitude change. See also MESSAGE-LEARNING APPROACH.

**cognitive restructuring** a technique used in COGNITIVE THERAPY and COGNITIVE BEHAVIOR THERAPY to help the client identify his or her self-defeating beliefs or cogni-
tive distortions, refute them, and then modify them so that they are adaptive and reasonable.

cognitive schema see SCHEMA.

cognitive science an interdisciplinary approach to understanding the mind and mental processes that combines aspects of cognitive psychology, philosophy of mind, epistemology, neuroscience, anthropology, psycholinguistics, and computer science.

cognitive self-guidance system the use of private, self-directed speech to guide problem-solving behavior. [proposed by Lev Vygotsky]

cognitive self-management the use of SELF-TALK, imagery, or both to direct one’s behavior in demanding or stressful situations.

cognitive set the predetermined way an individual construes a situation, which is based on a group of concepts, related to the self and other things, that determines an individual’s view of the world and influences his or her behavior.

cognitive sign principle the belief that, through learning, stimuli come to signal outcomes or events in the environment (see S–S LEARNING MODEL). Edward C. Tolman offered cognitive sign learning as an alternative to the ideas of other behavioral theorists, such as Clark L. Hull, who postulated that stimuli become directly associated with responses (see S–R LEARNING MODEL).

cognitive slippage a mild form of disconnected thought processes or LOOSENING OF ASSOCIATIONS. Cognitive slippage may be seen in patients with a range of physical and mental disorders; it is a common characteristic of individuals with schizophrenia. [coined by Paul Everett Meehl]

cognitive-social learning theory see SOCIAL-COGNITIVE THEORY.

cognitive specificity hypothesis the proposition that specific feeling states, such as depression and anxiety, are linked to particular kinds of AUTOMATIC THOUGHTS. [proposed by Aaron T. Beck]

cognitive stage in some theories of cognitive development, especially that of Jean Piaget, a plane of cognition that is characterized by a particular, qualitatively different level of thinking than earlier or later stages.

cognitive strategy any predetermined plan to control the process and content of thought. In sport psychology, for example, such strategies involve use of the SELF-TALK dialogue to assist athletes to keep focused, energized, confident, and “in the zone.”

cognitive structure 1. a mental framework, pattern, or SCHEMA that maintains and organizes a body of information relating to a particular topic. When a need arises for the cognitive structure, as in a college test, the individual is thought to engage in a memory search in which the stored cognitive structure is retrieved and applied to the present requirements. 2. a unified structure of facts, beliefs, and attitudes about the world or society. See COGNITIVE MAP; CONCEPTUAL SYSTEM; FRAME.

cognitive style a person’s characteristic mode of perceiving, thinking, remembering, and problem solving. Cognitive styles might differ in preferred elements or activities, such as group work versus working individually, more structured versus less defined activities, or visual versus verbal ENCODING. Other dimensions along which cognitive styles vary include REFLECTION–IMPULSIVITY, ABSTRACT ATTITUDE VERSUS CONCRETE ATTITUDE, and FIELD DEPENDENCE versus FIELD INDEPENDENCE. The term is also commonly used to refer to the idea that people differ with respect to the mode of learning (e.g., instruction, study) that is most effective for them. Indeed, many use the term LEARNING STYLE interchangeably with cognitive style, whereas others use the former more specifically to mean a person’s characteristic cognitive, affective, and psychological behaviors that influence his or her preferred instructional methods and interactions with the learning environment. Also called THINKING STYLE. See also LEARNING TYPES; THEORY OF MENTAL SELF-GOVERNMENT.

cognitive system a set of cognitions that are organized into a meaningful complex with implied or stated relationships between them. See also COMPLEX OF IDEAS.

cognitive task analysis the use of descriptive and analytical techniques to identify the knowledge and decision-making processes required to perform a given task proficiently.

cognitive theory any theory of mind that focuses on mental activities, such as perceiving, attending, thinking, remembering, evaluating, planning, language, and creativity, especially a theory that suggests a model for the various processes involved.

cognitive theory of leadership any of various models that define and explain leadership in terms of the perceptual, intellectual, and mental processes of both leaders and those they lead. See also LEADERSHIP THEORIES.

cognitive therapy (CT) a form of psychotherapy based on the concept that emotional and behavioral problems in an individual are, at least in part, the result of maladaptive or faulty ways of thinking and distorted attitudes toward oneself and others. The objective of the therapy is to identify these faulty cognitions and replace them with more adaptive ones, a process known as COGNITIVE RESTRUCTURING. The therapist takes the role of an active guide who attempts to make the client aware of these distorted thinking patterns and who helps the client correct and revise his or her perceptions and attitudes by citing evidence to the contrary or by eliciting it from the client. See also COGNITIVE BEHAVIOR THERAPY. Also called Beck therapy. [developed by Aaron T. Beck]

cognitive triad a set of three beliefs thought to characterize MAJOR DEPRESSIVE EPISODES. These are negative beliefs about the self, the world, and the future. Also called NEGATIVE TRIAD. [proposed in 1976 by Aaron T. Beck]

cognitive tunneling a psychological state, typical of people concentrating on a demanding task or operating under conditions of stress, in which a single, narrowly defined category of information is attended to and processed. Cognitive tunneling involves the processing of highly critical task-relevant information, with limited or no processing of secondary information that may also be important to the task. For example, cognitive tunneling occurs when a pilot focuses on the HEAD-UP DISPLAYS without also scanning out the windows of the plane. Compare SOCIAL TUNNELING.

cognitive unconscious unreportable mental processes such as implicit perceptions, memories, and thoughts. There are many sources of evidence for a cognitive unconscious, including regularities of behavior due to habit or AUTOMATICITY, inferred grammatical rules, the details of sensori-
cognitive vulnerability

motor control, and implicit knowledge after brain damage. It differs from the psychoanalytic notion of the dynamic unconscious, which involves material that is excluded from consciousness to avoid anxiety, shame, or guilt. Compare emotional unconscious. See also tacit knowledge. [proposed by U.S. cognitive psychologist John F. Kihlstrom (1948– )]

cognitive vulnerability a set of beliefs or attitudes thought to make a person vulnerable to emotional disorders such as depression and anxiety. Examples include perfectionism, dependence, and sociopathy.

cognitive walkthrough method in ergonomics, a method of assessing the usability of a product or design in which several evaluators, representing the targeted user group, perform its various functions while discussing and identifying or anticipating problems arising from flawed design.

cognitive well-being see subjective well-being.

cognitivism n. adherence to the principles of cognitive psychology, especially as opposed to those of behaviorism.

cognitivist 1. n. a theorist concerned primarily with describing either intellectual development (e.g., Jean Piaget, Jerome Seymour Bruner) or early language behavior (e.g., Roger Brown). 2. adj. describing a perspective or approach that is based on cognitivism.

cognize vb. to know or become aware of. —cognizance n. —cognizant adj.

cogwheel rigidity muscular rigidity that produces a ratcheted resistance to passive movement of the limbs of people who have Parkinson’s disease. It may also be seen as the side effect of medication, especially antipsychotic drugs that produce a cogwheeling effect. Compare lead-pipe rigidity.

cohabitation n. 1. the state or condition of living together as sexual and domestic partners without being married. See common-law marriage. 2. broadly, people or nonhuman animals sharing living quarters or a habitat. —cohabit vb. —cohabitee n.

Cohen’s d a measure of effect size based on the standardized difference between two means: It indicates the number of standard deviation units by which the means of two data sets differ. For example, a mentoring intervention associated with a Cohen’s d of +0.25 indicates an increase of 0.25 standard deviation units for the average child who received mentoring relative to the average child who did not receive mentoring. The metric is used to represent effect sizes in meta-analysis as well as in the determination of power, with values of 0.20, 0.50, and 0.80 representing small, medium, and large effect sizes, respectively. See also Glass’s D. [Jacob Cohen (1923–1998), U.S. psychologist and statistician]

Cohen’s kappa (symbol: κ) a numerical index that reflects the degree of agreement between two raters or rating systems classifying data into mutually exclusive categories, corrected for the level of agreement expected by chance alone. Values range from 0 (no agreement) to 1 (perfect agreement), with kappas below .40 generally considered poor, .40 to .75 considered fair to good, and more than .75 considered excellent. In accounting for chance, Cohen’s kappa avoids overestimating the true level of agreement as might occur through simply determining the number of times that two raters agree relative to the total number of ratings. [Jacob Cohen]

cohesion n. see group cohesion.

cohort n. a group of individuals who share a similar characteristic or experience. The term usually refers to an age (or birth) cohort, that is, a group of individuals who are born in the same year and thus of similar age.

cohort analysis a statistical procedure to assess the effects attributed to members of a group sharing a particular characteristic, experience, or event. In other words, it is the evaluation of data obtained from studies involving cohorts, as may be the case in longitudinal designs, for example.

cohort effect any outcome associated with being a member of a group whose members all undergo similar experiences. Cohort effects may be difficult to separate from age effects and period effects in research.

cohort sampling a method of sampling data in which one or more groups sharing a similar characteristic, such as year of birth, are identified and observed.

cohort-sequential design an experimental design in which multiple measures are taken over a period of time from two or more groups of different ages (birth cohorts). If, for instance, individuals ranging in age from 5 to 10 years are sampled and then the members of each age group are studied for a 5-year period, the resulting data would span 15 years of development. Such studies essentially are a combination of longitudinal design and a cross-sectional design. Also called accelerated longitudinal design.

cohort study see longitudinal design.

coit anorgasmia failure of a woman to reach orgasm during penile-vaginal intercourse. Studies show that roughly half of women do not have coital orgasms in the absence of concurrent clitoral stimulation. Sex therapists do not consider this a dysfunction; if the woman can have orgasm with her partner in other ways, and enjoys intercourse, there is no requirement that both happen simultaneously.

coitus n. an act of sexual union, usually the insertion of the penis into the vagina followed by ejaculation. Variations include, among others, coitus a tergo, in which the penis is inserted from the rear, and coitus inter femora (interfemoral sex), in which the penis is inserted between the pressed thighs of the partner. Also called coition; intercourse; sexual intercourse. See also anal intercourse; carezza; copulation. —coital adj.

coitus analisis see anal intercourse.

coitus a tergo see coitus.

coitus in ano see anal intercourse.

coitus inter femora see coitus; interfemoral sex.
**collaborative therapy**

**coitus interruptus** the withdrawal of the penis during intercourse, prior to orgasm, with orgasm occurring external to the vagina. This is done mainly to reduce the likelihood of conception but is not very effective, as some semen is often released prior to orgasm.

**coitus intra mammam** coitus in which the penis is inserted between the breasts of the female.

**coitus prolongatus** see CAREZZA.

**coitus reservatus** sexual intercourse in which the man suppresses the ejaculation of semen. Also called male continence.

**coke** n. a common colloquial term for COCAINE.

**cola nut** see KOLA NUT.

**cold-blooded animal** see ECTOTHERM.

**cold cognition** a mental process or activity that does not involve feelings or emotions. For instance, reading a list of nonsense syllables or factoids (brief pieces of invented or inaccurate information) typically involves cold cognition. Compare HOT COGNITION. [introduced in 1963 by U.S. social psychologist Robert P. Abelson (1928–2005)]

**cold-deck imputation** one of several methods of inserting values for missing data (see IMPUTATION) in which missing observations are replaced by values from a source unrelated to the data set under consideration. Suppose, for example, that a patient questionnaire was administered in a hospital and that five people failed to respond to an item. Substituting responses from a similar item on a survey conducted previously would be an example of cold-deck imputation. Compare HOT-DECK IMPUTATION.

**cold emotion** a reaction to some stimuli (e.g., epinephrine) that entails the physiological responses of emotional arousal without an identifiable affective root.

**coldness** n. 1. a psychological characteristic featuring a relative absence of empathy toward and emotional support of others. 2. a thermal sensation produced by a stimulus that is below skin temperature. Exposure to low temperatures may affect physical and mental health. Research indicates that reaction time, tracking proficiency, tactile discrimination, and other types of performance begin to deteriorate at temperatures of 13 °C (55 °F) or below. Studies of cold effects on social behavior have produced conflicting evidence of both increased and decreased aggression.

**cold pressor pain test** a test of pain produced by immersing a limb in iced water. Also called cold pressor test.

**cold spot** any point on the surface of the skin containing nerve receptors sensitive to low-temperature stimuli.

**cold turkey** a common colloquial term for the abrupt cessation of the use of drugs, particularly opiates, without cushioning the impact by the use of medications (e.g., methadone) that provide some of the same actions as the drug being stopped. The name refers specifically to the chills and gooseflesh experienced during OPIOID WITHDRAWAL.

**coleadership** n. the sharing of the organizational, directive, and motivational duties of leadership between two or more individuals. For example, two therapists or counselors may engage in coleadership during GROUP THERAPY. The leadership role may be deliberately divided, or division may occur spontaneously as the various leadership duties become associated with several individuals (see ROLE DIFFERENTIATION). In some cases, the leaders are equal in status and responsibilities, but in other cases, one leader may have more status than another.

**colera** n. see BILIS.

**colic** n. 1. the condition in an otherwise healthy baby of crying at least 3 hours a day; at least 3 days a week for at least 3 weeks; the cause is not understood. 2. a type of pain marked by abrupt onset and cessation.

**colitis** n. inflammation of the colon, the main part of the large intestine. Colitis may be caused or aggravated by emotional disturbances, such as depression or anxiety.

**collaboration** n. 1. the act or process of two or more people working together to obtain an outcome desired by all, as in COLLABORATIVE CARE and COLLABORATIVE LEARNING. 2. an interpersonal relationship in which the parties show cooperation and sensitivity to the others’ needs. [first described by Henry Stack SULLIVAN] —collaborative adj.

**collaborative care** 1. collaboration between two or more disciplines or practitioners to assess a client’s problem or problems, develop a treatment plan, and monitor progress. Also called split treatment. 2. collaboration across agencies to coordinate services to a particular client or client group.

**collaborative empiricism** an approach to psychotherapy in which the therapist and client work together as equal partners in addressing issues and fostering change through mutual understanding, communication, and respect. The therapist views the client as a peer who is capable of objective analyses and conclusions.

**collaborative evaluation** see PARTICIPATORY EVALUATION.

**collaborative family health care** a form of interdisciplinary practice based on the belief that health events occur simultaneously on biological, psychological, and social levels. Collaborative clinicians share decision making and responsibility with patients and their families and integrate clinical expertise from relevant disciplines to provide patients with comprehensive and coordinated care.

**collaborative filtering** a partially automated decision-making procedure in which a computer recommends certain choices on the basis of choices made by others who are similar to the present chooser.

**collaborative learning** 1. the interaction between two or more people working on a task that allows greater learning to be achieved, particularly by those who are less skilled, than would occur if the participants worked alone. 2. the third stage of CULTURAL LEARNING, in which two or more individuals who are equal in expertise or authority work together to solve a common problem. See also IMITATIVE LEARNING; INSTRUCTED LEARNING. [proposed by U.S. psychologist Michael Tomasello (1950–)] and colleagues]

**collaborative memory** the recall output of a group of individuals working together to remember shared information or events. Also called collaborative remembering. See also COLLECTIVE MEMORY.

**collaborative therapy** 1. any form of therapy employing COLLABORATIVE EMPIRICISM. 2. COUPLES THERAPY conducted by two therapists, each seeing one partner but conferring from time to time. Also called collaborative marriage therapy: collaborative marital therapy.
**collagen** n. the major protein of the white fibers of the body’s connective tissue (e.g., in skin, cartilage, bone, and tendons).

**collapsing** n. the process of combining multiple response options or categories to form a smaller number of responses or categories. For example, a researcher could collect demographic data for students at a particular college by each year of matriculation (i.e., freshman, sophomore, junior, and senior) and then collapse the information from four to two categories (e.g., lower division and upper division).

**collateral** adj. secondary to something else. For example, a collateral fiber is a nerve fiber that branches off the main axon of a neuron, and collateral circulation is an alternative route for blood when the primary vessel is obstructed (see anastomosis). —collaterally adj.

**collateral behavior** behavior that is not required by a reinforcement contingency but occurs in a regular, temporal relation to behavior directly reinforced by the contingency. Compare adjunctive behavior; interim behavior; mediating behavior.

**collateral heredity** descent along different lines but from a common ancestry.

**collateral sulcus** a fissure that runs along the inferior surface of each cerebral hemisphere from approximately the posterior end of the occipital lobe to the anterior end of the temporal lobe.

**collative properties** the structural properties of such stimulus patterns in art forms as complexity and novelty. Studies indicate that people tend to prefer stimuli with moderate levels of collative properties. See also arousal potential.

**collective** n. any aggregate of two or more individuals, especially a larger, spontaneous, and relatively short-lived social grouping such as a crowd or mob. A collective often includes individuals who are dispersed over a wide area and have no direct contact with one another but who nonetheless display common shifts in opinion or action.

**collective bargaining** the process in which unionized employers negotiate with employee representatives on wages, benefits, hours, and other conditions of work, such as seniority, discipline, and discharge procedures. See also good-faith bargaining.

**collective behavior** joint or similar actions performed by members of a collective, especially when these actions would be atypical of the same individuals outside of the collective. Examples of collective behavior by groups or aggregations concentrated in a specific location include lynching, rioting, and panics. Others, such as fads and social movements, involve widely dispersed individuals who nonetheless engage in similar actions (see collective movements).

**collective conscience** the shared values, norms, sentiments, and beliefs that form the basis of moral thinking and action in a cohesive society. Also called common conscience. [introduced by Émile Durkheim]

**collective consciousness** see group mind.

**collective efficacy** the belief that a group is capable of integrating skills, efforts, and the persistence of its members to complete the demands of a task successfully.

**collective effort model** (CEM) an EXPECTANCY-VALUE MODEL of productivity losses in groups that posits that working on a task collectively reduces members’ motivation by lowering their expectations of successful goal attainment and diminishing the value of group goals. See also social loafing; sucker effect. [developed in 1993 by U.S. social psychologist Steven J. Karau (1965–) and U.S.-born Australian social psychologist Kipling D. Williams (1953–)]

**collective guilt** 1. an unpleasant emotional state involving a shared realization that one’s group or social unit has violated ethical or social principles, together with associated feelings of regret. Collective guilt is more likely when members of a group (a) strongly identify with that group, (b) feel a sense of control over or responsibility for the negative actions of other members, and (c) recognize the group’s actions are illegitimate. 2. the idea that members of a group may be held responsible for violations of norms or laws committed by other members of the same group. See group fallacy; guilt by association.

**collective hypnosis** see group hypnosis.

**collective hysteria** the spontaneous outbreak of atypical thoughts, feelings, or actions in a group or social aggregate. Manifestations may include psychogenic illness, collective hallucinations, and bizarre actions. Instances of epidemic manias and panics, such as choreomania in the Middle Ages, tulipmania in 17th-century Holland, and radio listeners’ reactions to the Orson Welles broadcast based on H. G. Wells’s War of the Worlds in 1938, have been attributed to collective hysteria. Also called group hysteria: epidemic hysteria; mass hysteria.

**collective induction** group discussion or problem solving, especially when this involves identifying general principles or rules from a set of specific facts, instances, or evidence.

**collective information-processing model** a general theoretical explanation of group decision making that assumes that group members combine and process information through group discussion to formulate decisions, choices, and judgments.

**collective memory** shared recollection: mental representations of past events that are common to members of a social group. For example, mine workers may collectively remember the accidental death of a coworker differently than the general public, just as younger and older people may remember significant historical events differently. Collective memory is expressed in numerous forms—including oral and written narratives, monuments and other memorials, commemorative rituals, and symbols—and serves a range of functions, such as establishing and maintaining relationships, teaching or entertaining others, and supporting group identity. The memory is common to the group, but it is remembered by individuals, and research suggests that they coordinate their personal memories with those of their groups through a process of attunement: Stimuli assumed to be experienced by one’s social group are more prominent in both cognition and behavior because they receive greater attentional focus or more
elaborated encoding, which in turn increases their accessibility. Also called cultural memory: social memory.

collective mind see group mind.

collective monologue a form of egocentric, unsocialized speech in which children talk among themselves without apparently communicating with each other in a meaningful way; that is, the statements of one child seem unrelated to the statements of the others. Also called pseudoconversation. [first described by Jean Piaget]

collective movements instances of collective behavior in which the number of individuals responding similarly to some event or experience increases over time until numerous people are affected across physically distant locations. Some movements, which include social movements, are organized, deliberate attempts to involve and influence individuals, whereas others (fads, crazes, protests, or instances of collective hysteria) occur spontaneously.

collective psychology 1. the mental and emotional states and processes characteristic of individuals when aggregated in such groups as audiences, crowds, mobs, and social movements. The term is mainly associated with early theorists in this area, such as Gustave le Bon. 2. the scientific study of these phenomena.

collective representations the institutions, laws, symbols, rituals, and stories that embody a society’s key concepts and values and its sense of itself as a distinct community with its own identity and way of life. [introduced by Émile Durkheim]

collective self see social identity.

collective self-esteem individuals’ subjective assessment of that portion of their self-concept that is based on their membership in social groups, such as families, teams, or schools, as well as on categories that have psychological significance for them, such as race, ethnicity, or nationality. Collective self-esteem is often measured using the Collective Self-Esteem Scale (CSES), developed in 1992 by U.S. social psychologists Riaa K. Luhtanen and Jennifer Crocker (1952–). Respondents evaluate their general group memberships across four subscales pertaining to membership in the group (evaluation of their worthiness as members of a group), private collective self-esteem (evaluation of the worthiness of the group), public collective self-esteem (evaluation of others’ perceptions of the group), and the importance of the group to their identity.

collective suicide see mass suicide.

collective unconscious the part of the unconscious that, according to Carl Jung, is common to all humankind and contains the inherited accumulation of primitive human experiences in the form of ideas and images called archetypes and manifested in myths as well as other cultural phenomena (e.g., religion) and in dreams. It is the deepest and least accessible part of the unconscious mind. See also personal unconscious: racial memory.

collectivism n. 1. the tendency to view oneself as a member of a larger (family or social) group, rather than as an isolated, independent being. 2. a social or cultural tradition, ideology, or personal outlook that emphasizes the unity of the group or community rather than each person’s individuality. Most Asian, African, and South American societies tend to put more value on collectivism than do Western societies, insofar as they stress cooperation, communalism, constructive interdependence, and conformity to cultural roles and mores. Compare individualism. —collectivist adj.

college admission tests tests for college applicants, which are used to help determine academic achievement and college readiness. For admission to undergraduate programs, these tests, also called college boards, often include the Scholastic Assessment Test and the ACT Assessment. Depending on the field of study, students applying to graduate programs are usually required to take standardized admissions tests such as the Graduate Record Examinations, Graduate Management Admission Test, Law School Admission Test, or Medical College Admission Test.

College Entrance Examination Board Advanced Placement Program see advanced placement examinations.

College Level Examination Program (CLEP) the most widely accepted credit-by-examination program in the United States, helping students of any age earn college credits by obtaining certified evidence of what they already know. A student can earn from 3 to 12 units of credit toward a college degree for each CLEP examination that is successfully completed.

collegial model any collaborative approach that encourages equal participation by all interactants while minimizing status differences. In research, for example, this approach enjoins researchers to involve participants fully in the research process; in therapeutic settings, the model requires therapists to treat clients as equals.

collculus n. (pl. colliculi) a small elevation. Two pairs of colliculi are found on the dorsal surface of the midbrain. The rostral pair, the superior colliculi, receive and process visual information and help control eye movements; they are also thought to have a role in blindsight. The caudal pair, the inferior colliculi, receive and process auditory information. [from Latin, “small hill”]

collinearity n. in regression analysis, the situation in which two independent variables are so highly associated that one can be closely or perfectly predicted by the other. For example, collinearity likely is present if a researcher examines how height and age contribute to children’s weight, since the two predictors are highly interrelated (i.e., as children grow older they get taller). Collinearity leads to difficulties in interpreting the unique influences of the independent variables and requires the use of partialing procedures to distinguish their separate effects. See also multicollinearity. —collinear adj.

colloid n. 1. a large, gluelike molecule that cannot pass through the plasma membrane of a cell. When injected into the peritoneum, colloids attract and retain water by osmosis. 2. a system consisting of two or more phases in which one phase (the dispersed phase) is distributed throughout the other phase (the continuous phase). A sol, for example, consists of large molecules or small solid particles distributed in a liquid, as when starch is mixed with water. —colloidal adj.

collusion n. in psychotherapy, the process in which a therapist consciously or nonconsciously participates with a client or third party to avoid an issue that needs to be addressed. —collusional adj.

collusional marriage a marriage in which one partner instigates or engages in inordinate, deficient, irregular, or illegal conduct and the other partner covertly endorses it
**color blindness** the inability to discriminate between colors and to perceive color hues. Color blindness may be caused by disease, drugs, or brain injury (see ACQUIRED COLOR BLINDNESS), but most often it is an inherited trait (CONGENITAL COLOR BLINDNESS) that affects about 10% of men (it is rare in women). The most widely used classification of the different types of color blindness is based on the trichromatic nature of normal color perception, using prefixes to indicate the three primary colors: proto- (red), deuter- (green), and trit- (blue). The type of deficiency is indicated by suffixes: anomaly for partial inability to perceive one or more of the primary colors and -anopia for complete inability to do this. The most common form of the disorder involves the green or red receptors of the cone cells in the retina, causing a red–green confusion (see DEUTERANOMA; PROTANOMA). Total color blindness is rare, affecting about 3 individuals out of every 1 million (see ACHROMATISM). See also DICROMATISM; MONOCROMATISM; TRICROMATISM.

**color-blindness test** any task or device that tests the ability to distinguish different colored stimuli, specifically to discover abnormalities in the perception of color. The most common tests involve the detection of colored figures against a colored background under conditions that require the use of hue information, rather than luminous intensity or saturation. See also ISHIIHARA TEST FOR COLOR BLINDNESS.

**color cells** the three types of RETINAL CONES, each of which is sensitive to one of the visual primary colors: red, green, and blue. See PHOTOPIGMEN; TRICROMATISM THERY. See also COLOR BLINDNESS.

**color circle** 1. an array of CHROMATIC colors around the circumference of a circle. The colors are arranged in the order in which they are seen in the spectrum, but nonspectral purples and reds are also included. Complementary colors are opposite each other. 2. the arrangement of color sectors on a disk such that the disk appears gray when the colors are “mixed” by rotation of the disk. [first devised by Isaac NEWTON]

**color cone** a three-dimensional representation of all visible colors that takes into account HUE, SATURATION, and LUMINOUS INTENSITY. Luminous intensity is represented on the vertical axis, hue is represented in polar coordinates around the vertical axis, and saturation is represented radially around the vertical axis. See COLOR SOLID.

**color constancy** the tendency to perceive a familiar object as having the same color under different conditions of illumination. For example, a red apple will be perceived as red in well or poorly illuminated surroundings. Color constancy is an example of PERCEPTUAL CONSTANCY. Compare BRIGHTNESS CONSTANCY; OBJECT CONSTANCY; SHAPE CONSTANCY; SIZE CONSTANCY.

**color contrast** the effect of one color upon another when they are viewed in proximity. In simultaneous contrast, complementary colors, such as yellow and blue, are enhanced by each other: The yellow appears yellower, and the blue appears bluer. In successive contrast, the complement of a color is seen after shifting focus to a neutral surface.

**Colored Progressive Matrices** see RAVEN’S PROGRESSIVE MATRICES.

**color harmony** the extent to which colors are pleasing in combination with one another. At least in isolation,
comas are often progressive, involving the onset of neurological deficits, altered mentation, and loss of consciousness. Causes are numerous but commonly include head injury or other trauma, blockage or rupture of cerebral blood vessels, infection, seizures, strokes, and toxic or metabolic disturbances. The Glasgow Coma Scale is the most commonly used instrument for assessing the severity of consciousness deficits, but others include the Grady Coma Scale, theOutline of Unresponsiveness Score, and the Wessex Head Injury Matrix. Electroencephalography and somatosensory potentials also are regarded as useful tools for exploring residual brain activity and providing information for recovery.

comata stimulation the use of multimodal sensory stimulation in an attempt to speed up the process of recovery from coma or improve arousal level. The efficacy of such approaches remains unestablished.
coma therapy see insulin-shock therapy.

coma vigil an imprecise and obsolescent term generally used to denote a vegetative state. In coma vigil, individuals may appear alert and aware (e.g., by opening and moving their eyes) but do not respond to stimuli in any adaptive, meaningful way.

combat and operational stress control (COSC) as defined by the U.S. Army, programs developed and actions taken by military leadership to prevent, identify, and manage adverse combat stress reactions, with the goal of returning soldiers to duty expeditiously, enhancing unit cohesion, optimizing mission performance, and minimizing the occurrence of posttraumatic stress disorder.

combat stress reaction (CSR) any psychological reaction, ranging from mild to severe, to traumatic events in military operations. In World War I, such reactions were known as shell shock, whereas in World War II, the terms battle fatigue, combat fatigue, and combat neurosis were widely used. Adverse and persistent combat stress reactions are now categorized as posttraumatic stress disorders. Also called combat and operational stress reaction (CSR). See also combat and operational stress control; stress casualty.

combat stress reduction a set of measures designed to develop skills to reduce combat stress reactions. Stress reduction entails remediation procedures, regulatory techniques, and preventive strategies (psychological coping techniques). See also combat and operational stress control.

combination n. the selection of \( r \) objects from among \( n \) objects without regard to the order in which the objects are selected. The number of combinations of \( n \) objects taken \( r \) at a time is often denoted as \( _nC_r \). A combination is similar to a permutation but distinguished by the irrelevance of order.

combination law see law of combination.

combination test a type of test in which the main task is to assemble or combine words or objects into a more complex whole.

combination therapy the application of two or more distinct therapeutic approaches by the same therapist to a client’s presenting problem. It is distinct from adjunctive therapy, which involves multiple practitioners.

combination tone a tone generated in the ear that is produced when two primary tones (i.e., two tones differing in frequency) are presented simultaneously. For example, under certain conditions a 1000 Hz tone and a 1200 Hz tone will produce audible combination tones whose frequencies are 200 Hz (a difference tone) and 800 Hz (a cubic difference tone). Most combination tones are produced by nonlinear distortion that occurs within the cochlea.

combinatorial operation a mental process that generates new representations by merging constituents according to a set of rules. For example, sentences are constructed by combinatorial operations on words and phrases according to the rules of syntax.

combined therapy 1. psychotherapy in which the client is engaged in two or more treatments with the same or different therapists. For example, couples therapy may include group therapy with several other couples in addition to individual therapy or conjoint therapy for each couple.

2. treatment using a combination of psychotherapy and medication. See also adjunctive therapy; adjuvant therapy.

coming out revealing that one is gay, lesbian, bisexual, or transgender. Such a declaration can sometimes lead to problems with the individual’s family, employers, or friends and can therefore be a difficult step, even for those who accept and are comfortable with their sexual orientation. Also called coming out of the closet.

command style in education, a highly structured, traditional instruction method in which the teacher makes all decisions regarding lesson development and implementation and the students’ role is to receive the information passively and perform required tasks. Compare individual program.

commensalism n. an interspecies interaction in which two species live closely together with neither species gaining or losing any benefits from the association. Compare mutualism; parasitism. —commensal adj., n.

commissural fiber an axon from any of various neurons that connect the same or equivalent structures in the left and right cerebral hemispheres. Compare association fiber.

commisurotomy n. a surgical procedure involving a partial cutting of a commissure or fiber bridge, especially the great fiber bridge between the two cerebral hemispheres, the corpus callosum. A complete sectioning of the corpus callosum is called a callosotomy; this also severs its large forward portion, the anterior commissure. Complete commissurotomies are now avoided if possible, in favor of partial transections. This surgery has been used to treat severe and intractable epilepsy, and it has also enabled researchers to study the isolated functions of each hemisphere. Research in this area was pioneered by Roger Sperry (see chimeric stimulation). Also called callosotomy; split-brain procedure; split-brain technique. See split brain.

commitment n. 1. confinement to a mental institution by court order following certification by appropriate mental health authorities. The process may be voluntary but is generally involuntary. See certification laws. See also civil commitment; criminal commitment. 2. obligation or devotion to a person, relationship, task, cause, or other entity or action.

commitment laws legislation governing the holding of a patient in a mental hospital involuntarily upon certification. See certification laws.

commodity theory a theory proposing that the value of a product or service is related to its availability. In general, a product that is in short supply is perceived as having greater value than one that is readily available. However, a product’s value is also related to the demand for it. It may be scarce, but if no one wants it, it will not have a high
value. Commodity theory is used to explain consumer behavior in times of product or service restriction. [formulated in 1968 by Timothy C. Brock]

**commonality analysis** in multiple regression, a technique by which the known variance in an outcome or response variable is separated out into the parts that can be uniquely attributed to each individual predictor variable and the parts that are common to any two or more variables.

**common cause hypothesis** the hypothesis that all changes in sensory ability and intellectual functioning (cognitive aging) in old age are due to a common factor, the deterioration of brain function.

**common chemical sense** see chemesthesism.

**common conscience** see collective conscience.

**common factor** 1. in psychotherapy, any of several variables that are common to various types of therapy, such as the therapeutic alliance, and that promote therapeutic success regardless of the different approaches used; common factors can thus be contrasted with factors that are unique to a particular therapy, such as the use of interpretation. The concept of common factors is a premise underlying integrative psychotherapy. Therapeutic factors are similar but typically apply to therapies with groups. [first articulated by Saul Rosenzweig in a 1936 article, “Some Implicit Common Factors in Diverse Methods of Psychotherapy”] 2. see specific factor.

**common fate** one of the gestalt principles of organization, stating that objects functioning or moving in the same direction appear to belong together, that is, they are perceived as a single unit (e.g., a flock of birds). Also called law of common fate: principle of common fate.

**common knowledge effect** in groups, the tendency for information that is known by more members prior to a discussion to more strongly influence the group’s subsequent discussion and judgment. [proposed in 1993 by U.S. social psychologists Daniel Gigone and Reid Hastie]

**common law** 1. the legal principles deriving from previous decisions of the courts, as opposed to those established by statute. Also called judge-made law. See case law. 2. the legal system originating in England and used in the United States and some other English-speaking countries, especially as opposed to those systems deriving from Roman law used in Continental Europe.

**common-law marriage** a relationship between an unmarried but long-term cohabiting couple that is considered legally equivalent to marriage. Most states in the United States do not recognize common-law marriages, although cohabittees may be regarded as equivalent to married partners for some purposes.

**common metric** a unit or scale of measurement that is applied to data from different sources. In a meta-analysis, for instance, the results from multiple studies may need to be placed on a common metric so that they may be meaningfully compared.

**common region** a recently introduced gestalt principle of organization, stating that objects sharing a common bounded region of space appear to belong together and tend to be perceived as a distinct group. For example, animals in a fenced-in enclosure are more likely to be seen as a group than are the same distribution of animals arrayed in open space. Also called law of common region.

**principle of common region** [proposed in 1992 by U.S. psychologist Stephen E. Palmer (1948– )]

**commons dilemma** see tragedy of the commons.

**common sense 1.** beliefs or propositions that are generally agreed upon to reflect sound judgment and nonesoteric reasoning. 2. see sensus communis.

**commonsense justice** practices and procedures that ordinary people consider to be fair and just, which may differ from legal conceptions of justice and fairness.

**commonsense psychology** ideas about psychological issues derived from common experience and not necessarily from empirical laboratory or clinical studies. See folk psychology; popular psychology.

**common trait** in the personality theory of Gordon W. Allport, any of a number of enduring characteristics that describe or determine an individual’s behavior across a variety of situations and that are common to many people and similarly expressed. Common traits, such as assertiveness, thus serve as a basis for comparison of one person to another and are distinct from personal dispositions.

**communality n.** in factor analysis, the proportion of variance in one variable that is accounted for by an underlying element common to all of the variables in a set. It is given by the communality coefficient (h²), which is scaled such that the closer it is to 1.0 in value the more completely the underlying element accounts for the observed variability. Also called common variance. Compare uniqueness.

**communal nursing** see allonursing.

**communal relationship** a relationship in which interaction is governed primarily by consideration of the other’s needs and wishes. This contrasts with an exchange relationship, in which the people involved are concerned mainly with receiving as much as they give. See also equity theory. [discussed by U.S. social psychologists Margaret Clark and Judson Mills (1932–2008)]

**commune n.** a collective living arrangement among individuals or families, typically involving shared chores, resources, and child rearing, as an alternative to marriage and the nuclear family. Such arrangements were fashionable in the counterculture of the 1960s and 1970s.

**communicated authenticity, regard, empathy (CARE)** qualities of a psychotherapist regarded by some theorists as necessary for therapy to be effective and, ultimately, successful. CARE is considered essential to client-centered therapy.

**communicating hydrocephalus** hydrocephalus in the absence of any blockage in the flow of cerebrospinal fluid in the ventricular system. Cerebrospinal fluid passes freely from the brain into the spinal canal but is overproduced or abnormally or inadequately reabsorbed. Compare noncommunicating hydrocephalus.

**communication n.** the transmission of information, which may be by verbal (oral or written) or nonverbal means (see nonverbal communication). Humans communicate to relate and exchange ideas, knowledge, feelings, and experiences and for many other interpersonal and social purposes. Nonhuman animals likewise communicate vocally or nonvocally for a variety of purposes (see animal communication). Communication is studied by cognitive and experimental psychologists, and communica-
communication analysis

TION DISORDERS are treated by mental and behavioral health therapists and by speech and language therapists. Communications is the discipline that studies the processes and systems involved in communication at both the interpersonal and broadly social levels, in the latter case paying particular attention to the publishing media and telecommunication systems (telephones, radio, television, Internet, etc.).

communication analysis the study of the oral and written communications among people, particularly employees in an organization, with the objective of understanding and improving the process. It can include a determination of the patterns and types of these communications as well as an analysis of breakdowns in the communication process. See COMMUNICATION ERGONOMICS.

communication apprehension anxiety related to initiating or maintaining conversation with others. This is a common feature of SOCIAL PHOBIA. See also PUBLIC-SPEAKING ANXIETY.

communication channels see CHANNELS OF COMMUNICATION.

communication deviance (CD) lack of clarity in communication, making it hard to follow and difficult for the listener to share a common focus of attention and meaning with the speaker. Communication deviance is thought to be a long-term trait within families that may engender inefficient patterns of thinking and information processing. It is also thought to be associated with schizophrenia and other psychological disorders.

communication disorder any of a group of disorders characterized by difficulties with speech and language, such as EXPRESSIVE LANGUAGE DISORDER, MIXED RECEPTIVE-EXPRESSIVE LANGUAGE DISORDER, PHONOLOGICAL DISORDER, and STUTTERING.

communication engineering the application of scientific principles to the development of technical systems for communication, such as telephone, radio, television, and computer networks. The development and proliferation of computer networks have made knowledge of computer technology essential to communication engineering.

communication ergonomics a specialty area of ERGONOMICS that identifies those factors that support or undermine communication in shared tasks. Such factors, including information systems, technical systems, and COMMUNICATION NETWORKS and protocols, may be especially important when participants in a task are widely distributed and safety depends on clear, unambiguous communication (e.g., in air traffic control).

communication network the patterns of information transmission and exchange that occur in a group or organization, showing who communicates most frequently (and to what extent) with whom. Such networks may be either centralized or decentralized and characterized mainly by DOWNWARD COMMUNICATION or UPWARD COMMUNICATION. See also CHANNELS OF COMMUNICATION.

communication overload a condition in which more information is presented to a person or a computer system than can be processed or otherwise effectively utilized by the person or system. See also COGNITIVE OVERLOAD; INFORMATION OVERLOAD; SENSORY OVERLOAD; STIMULUS OVERLOAD.

communication skills the skills required to achieve effective communication. In addition to general language proficiency (adequate vocabulary and knowledge of syntax), effective communication involves the ability to listen and read with comprehension, to present one’s thoughts clearly both in speech and in writing, to accept that the perspectives of others may differ from one’s own, and to anticipate the effect of what one says or writes on listeners or readers.

communication skills training an intervention that teaches individuals to express themselves clearly and directly and to listen in an active and empathic way, using such techniques as feedback and modeling, in group, family, or work contexts. Training sessions typically focus on a specific theme (e.g., active listening, problem solving, or conflict resolution) after which homework is assigned. Initially developed for couples and families, the training is now used with such populations as people with developmental impairment and with teams in industry settings.

communication system an organized scheme or mechanism for transmitting and receiving information for the purposes of communication. The communication may be between people, between machines (usually computers), or between people and machines. Traditional systems include one-way communication (e.g., broadcast radio, television) and two-way communication (e.g., telephone, citizens-band radio). Computers and computer networks provide both one-way communication (e.g., websites) and two-way communication (e.g., e-mail, instant messaging, social media).

communication theory 1. the theoretical treatment of the interchange of signs and signals that constitutes communication. 2. the branch of science concerned with all aspects (technical, physiological, psychological, and social) of the storage and transmission of information. See INFORMATION THEORY.

communicative act any verbal or nonverbal behavior through which one party deliberately or unintentionally transmits information to others. For example, a father may point at an object while helping his daughter clean her room to convey to the child that the object should be put away.

communicative competence a speaker’s knowledge of language and ability to use it appropriately in various communicative settings and with a range of different interlocutors. In contrast to Noam CHOMSKY’s notion of COMPETENCE, which explicitly excludes nonlinguistic factors, the idea of communicative competence stresses the social uses of language and the importance of context. See also COMMUNICATION SKILLS. [first described by U.S. sociolinguist Dell H. Hymes (1927–2009)]

communicology n. an area covering the theory and practice of AUDIOLOGY, speech and language pathology; and improvement in communication by means of exchanging ideas, relating experiences, and giving voice to feelings.

communitas n. a society or social group with a strong sense of unity and shared purpose, especially one bound together by shared rituals and traditions. Communitas (Latin for COMMUNITY) was also the title of the classic 1947 text on city planning by U.S. psychologist Paul Goodman (1911–1972) and his architect brother Percival Goodman, which stressed the relationship between city design and human potential.

community n. 1. a socially organized set of species
members living in a physically defined locality. Human communities are often characterized by (a) commonality of interests, attitudes, and values; (b) a general sense of belonging to a unified, socially integrated group; (c) members’ self-identification as community members; and (d) some system of communication, governance, education, and commerce. In general parlance, “the community” often means society or the general public. A collection of individuals who are not socially connected but do have common interests or shared qualities and are therefore perceived by others or by themselves as distinctive in some way (e.g., the scientific community). A unit comprising all the animal and plant species that coexist and are necessary for each other’s survival. Thus, a community includes predator and prey species as well as the various plants that animals need for food, shelter, and so forth; the plants may benefit from the species as well as the various plants that animals need for survival. Thus, a community includes predator and prey species as well as the various plants that animals need for food, shelter, and so forth; the plants may benefit from the presence of the animals in the community through seed dispersal or interspecies interactions.

Community action group a group of citizens organized to campaign against specific problems within the local community, such as inadequate delivery of health services, homelessness, or crime.

Community care in psychiatry, psychology, and rehabilitation, comprehensive community-based services and supports for people with developmental, psychiatric, or physical disabilities. These facilities or services include halfway houses, group homes, sheltered workshops and supported work arrangements, supervised and supportive residences, special education or integrated education programs for children and young people, in-home treatment and family support, personal-care or home-care assistance, case management or service coordination, cooperative living, and hospital-based or free-standing clinics.

Community-centered approach a concerted, coordinated approach by local agencies and facilities to address such problems in a community or catchment area as mental disorder, delinquency, and substance abuse. This approach holds that since these problems developed in the community, efforts at prevention and treatment should be community-based rather than the province primarily of state institutions or federal agencies.

Community competence the efficacy of a unified, socially organized group of people in producing and regulating its outcomes, or its members’ perceptions of this efficacy.

Community control see Neighborhood control.

Community correction see Alternative sentencing.

Community ergonomics the application of ergonomic principles and practices to address cumulative social trauma in complex societal systems. Community ergonomics focuses on distressed community settings characterized by poverty, social isolation, dependency, and low levels of self-regulation and control. In practice, community ergonomics seeks to identify and implement a community–environment interface to bridge the gap between the disadvantaged residents of a community and the resources defining the social environment within which they function.

Community inclusion the practice of accepting and encouraging the presence and participation of people with disabilities—in particular, intellectual and developmental disabilities—in the full range of social, educational, work, and community activities.

Community integration the practice of assisting people with disabilities, especially developmental disabilities, to participate in community activities. Those with such disabilities are encouraged to attend community functions, engage in social interactions with peers and community members without disabilities, and join informal and formal community groups. One model of community integration has service settings that consist of clusters of houses in which adults with disabilities who can function somewhat independently participate in work and daily routines with people without disabilities. With the help of staff members, these adults manage the houses independently—planning meals, purchasing and preparing food, and participating in household maintenance chores—enjoy leisure activities with their peers. In many instances, staff live in the community as well.

Community mental health activities undertaken in the community, rather than in institutional settings, to promote mental health. The community approach focuses on the total population of a single catchment area and involves overall planning and demographic analyses of the area’s mental health needs. It emphasizes preventive services (e.g., by identifying sources of stress within the community) and seeks to provide a continuous, comprehensive system of services designed to meet the mental health needs in the community. Mental health is approached indirectly through consultation and education, with emphasis on such strategies as brief psychotherapy and crisis intervention and on using such workers as paraprofessionals and indigenous mental health workers.

Community mental health center (CMHC) a community-based facility or group of facilities providing prevention, treatment, and rehabilitation mental health services, sometimes organized as a practical alternative to the largely custodial care given in mental hospitals. Typical services are full diagnostic evaluation; outpatient individual and group psychotherapy; emergency inpatient treatment; specialized clinics for people with substance abuse problems and for disturbed children and families; aftercare (foster homes, halfway houses, home visiting); vocational, educational, and social rehabilitation programs for current and former patients; consultation with physicians, clergy members, courts, schools, health departments, and welfare agencies; and training of mental health personnel. Also called comprehensive mental health center.

Community Notification Act see Megan’s Law.

Community prevention and intervention organized efforts by professionals, indigenous nonprofessionals, and others to implement preventive programs as well as systems for intervention in dealing constructively with problems in the community, such as substance abuse, homelessness, child abuse, juvenile delinquency, cigarette smoking, and a high suicide rate. These efforts are typically most effective where the residents are themselves involved in dealing with such problems through existing community groups, such as neighborhood councils, block committees, service groups, social and fraternal organizations, and community educational and self-help programs. See also Community-centered approach.

Community psychology a branch of psychology that encourages the development of theory, research, and practice relevant to the reciprocal relationships between individuals and the social systems that constitute the community context. It intersects with other branches of psychology (e.g., social psychology) and with other disci-
Community residence

plines, such as sociology and public health. A particular emphasis is on social welfare, community mental health, and prevention. Its research findings and methods are applied with regard to poverty, substance abuse, violence, school failure, and other social issues. See ecological perspective.

Community residence a residential setting, usually serving 3 to 15 people and located in a regular house, with live-in or shift staffing. Community residences—some of which provide clinical services in addition to supervision, personal assistance, and training in everyday living skills—represent the most common out-of-home residential setting for people with intellectual or developmental disabilities.

Community services the complex of community-based services and facilities designed to maintain health and welfare, including mental health clinics, public health and adoption services, family services, vocational training facilities, rehabilitation centers, and living facilities (e.g., halfway houses, home care, and foster-family care). See community care; community-centered approach.

Community social worker a professional who serves as a liaison between local, state, and federal government officials and the public on matters affecting the community. Community social workers may, for example, try to raise awareness among officials about the need for local recreational facilities, about employment problems in the community, and about environmental obstacles in public buildings to residents with physical impairments.

Community speech and hearing center see speech, language, and hearing center.

Comorbid n. the simultaneous presence in an individual of more than one illness, disease, or disorder. —comorbid adj.

Companionate grandparent the type of grandparent who has a warm, loving relationship with his or her grandchildren but does not take on day-to-day responsibility for them. Compare involved grandparent; remote grandparent.

Companionate love a type of love characterized by strong feelings of intimacy and affection for another person rather than strong emotional arousal in the other’s presence. In these respects, companionate love is distinguished from passionate love. From the perspective of Robert J. Sternberg’s triangular theory of love, the relationship is high in intimacy and commitment.

Companionate marriage a marriage of warmth, affection, and trust between spouses, usually one based on equality of the partners and interchangeability of their relationship roles.

Comparable form see alternate form.

Comparable-forms reliability see alternate-forms reliability.

Comparable worth the principle that men and women should be paid equally for work requiring similar skills and responsibilities. In other words, comparable worth advocates equal pay for work of equal value, such as a woman working as a receptionist and a man working as a mailroom clerk. The principle has been invoked as a means of closing the gender pay gap and remedying systematic discrimination in pay for female-dominated occupations in comparison to male-dominated occupations with similar behaviors and demands. Also called pay equity. See equity theory.

Comparative analysis see comparative method.

Comparative cognition a subfield of comparative psychology that investigates the origins and mechanisms of cognition in various species and studies the differences and similarities in cognitive processes (e.g., perception, spatial learning and memory, problem solving, social cognition) across a range of animals, including humans, dolphins, elephants, chimpanzees, parrots, and bees.

Comparative judgment a psychophysical judgment in which two or more stimuli are compared with one another or with a given standard. Also called relative judgment. Compare absolute judgment.

Comparative linguistics the branch of linguistics that studies similarities and differences between languages with the general purpose of understanding the historical relationships between them. See diachronic linguistics; genetic linguistics; philology.

Comparative method an experimental research method of analyzing and comparing the behavior of different species of nonhuman animals, different cultures of humans, and different age groups of humans and other animals so as to identify similarities and dissimilarities and obtain an understanding of a phenomenon of interest. For example, macaques are often used as a model for understanding human mother–infant relationships. However, male macaques rarely become interested in or involved with care of the young, so comparative study of other species is needed to understand when and how male care of the young develops. Also called comparative analysis.

Comparative neuropsychology the study of the relationships between behavior and neural mechanisms in different animal species, including humans, especially in relation to the effects of brain damage.

Comparative psychology the study of nonhuman animal behavior with the dual objective of understanding the behavior for its own sake and furthering the understanding of human behavior. Comparative psychology usually involves laboratory studies (compare ethology) and typically refers to research involving nonhuman species whether or not it utilizes the comparative method. Some comparative psychologists engage in both field and laboratory studies. See also animal–human comparison; comparative cognition.

Comparative trial see controlled trial.

Comparator n. an information-processing unit that compares one variable against a similar variable or standard measure and—based on the difference—may act to bring the variable within desired limits. For example, a thermostat may compare the ambient temperature against a preset temperature, turning the heating system on or off to minimize or eliminate any difference. See also brain comparator; servomechanism.

Comparator hypothesis a theory of classical conditioning proposing that the strength of conditioning is based on a comparison of the likelihood that an unconditioned stimulus will occur following a conditioned stimulus with the likelihood that it will occur in the absence of a conditioned stimulus. It predicts that a response will be observed only if the former probability is higher.
comparison n. any appraisal of two or more groups in order to identify differences, such as that between the mean of a variable in one population and its mean in another. Comparisons may be planned in advance, as in A PRIORI COMPARISONS, or decided upon after data analysis has already begun, as in POST HOC COMPARISONS. Also called contrast.

comparison group 1. see SOCIAL COMPARISON THEORY. 2. see CONTROL GROUP.

comparison level (CL) in INTERDEPENDENCE THEORY, a standard used by individuals making decisions about whether to remain in a relationship. According to this theory, such decisions are based on a comparison of the outcomes (reward-to-cost ratios) of the current relationship with the possible outcomes of available alternative relationships or of no relationship at all. If the reward-to-cost ratio outside of the current relationship is higher, the relationship will become unstable and may not last. [proposed in 1959 by Harold H. KELLEY and John W. THIBAUT]

comparison level for alternatives (CLa) in INTERDEPENDENCE THEORY, a standard used by individuals making decisions about whether to remain in a relationship. According to this theory, such decisions are based on a comparison of the outcomes (reward-to-cost ratios) of the current relationship with the possible outcomes of available alternative relationships or of no relationship at all. If the reward-to-cost ratio outside of the current relationship is higher, the relationship will become unstable and may not last. [proposed in 1959 by Harold H. KELLEY and John W. THIBAUT]

comparison process in self psychology, evaluating one’s abilities, traits, or performances in relation to those of selected other people. Comparisons may be upward, as when weekend golfers compare themselves to professionals, or downward, as when weekend golfers compare themselves to beginners. See also SOCIAL COMPARISON THEORY.

comparison stimulus (Co) in psychophysical testing, one of a set of stimuli to be compared with a standard stimulus.

comparison-wise error rate see TESTWISE ERROR RATE.

compartmentalization n. a DEFENSE MECHANISM in which thoughts and feelings that seem to conflict or to be incompatible are isolated from each other in separate and apparently impermeable psychic compartments. In the classical psychoanalytic tradition, compartmentalization emerges in response to fragmentation of the ego, which ideally should be able to tolerate ambiguity and ambivalence. See also ISOLATION. —compartmentalize vb.

compassion n. a strong feeling of sympathv with another person’s feelings of sorrow or distress, usually involving a desire to help or comfort that person. —compassionate adj.

Compassionate Friends a voluntary organization that offers support, friendship, and understanding to families grieving the death of a child. See SELF-HELP GROUP.

compassionate love a form of love that emphasizes the well-being of another person. Compassionate love is affectionate and giving, focused on reducing the other’s suffering and promoting the other’s flourishing. Originally used to define a type of selfless caring described by several religious traditions, the concept is now applied broadly to romantic partners, family members, social groups, and humanity as a whole. Compassionate love is similar to the Platonic ideal of altruistic love. See also AGAPE; COMPASSIONATE LOVE; PASSIONATE LOVE.

compensation fatigue the BURNOUT and stress-related symptoms experienced by caregivers and other helping professionals in reaction to working with traumatized people over an extended period of time. See also POSTTRAUMATIC STRESS DISORDER. [defined by U.S. psychologist Charles R. Figley (1944–)]

compatibility n. 1. the state in which two or more people relate harmoniously because their attitudes, traits, and desires match or complement those of the other or others. 2. in philosophy, the position that FREE WILL and DETERMINISM are congruent and can, in some sense, coexist. Compare INCOMPATIBILITY. See also SOFT DETERMINISM. —compatible adj.

Compazine n. a trade name for PROCHLORPERAZINE.

compensable job factors the factors used to determine the pay rate of a particular job, commonly including skills, effort, or education required; amount of responsibility entailed; and working conditions. The identification of such factors is the basis of the FACTOR-COMPARISON METHOD and the POINT METHOD of job evaluation.

compensation n. 1. substitution or development of strength or capability in one area to offset real or imagined deficiency in another. This may be referred to as overcompensation when the substitute behavior exceeds what might actually be necessary in terms of level of compensation for the deficiency. Compensation may be a conscious or unconscious process. In his classical psychoanalytic theory, Sigmund FREUD described compensation as a DEFENSE MECHANISM that protects the individual against the conscious realization of such deficiencies. The idea of compensation is central to Alfred ADLER’s theory of personality, which sees all human striving as a response to feelings of inferiority (see also INFERIORITY COMPLEX). However, many psychologists emphasize the positive aspects of compensation in mitigating the effects of a weakness or deficiency (see COMPENSATORY MECHANISM). For example, it can be regarded as an important component of successful aging because it reduces the negative effects of cognitive and physical decline associated with the aging process. See SELECTIVE OPTIMIZATION WITH COMPENSATION. 2. in neuroscience, the recruitment of brain areas to substitute for the loss, due to injury or disease, of neural activity in other areas. See also BRAIN RESERVE. 3. in PIAGETIAN THEORY, a mental process—a form of reversibility—in which one realizes that for any operation there exists another operation that compensates for the effects of the first; that is, a change in one dimension can compensate for changes in another. Also called reciprocity. —compensate vb. —compensatory adj.

compensation effect an increase in group performance that occurs when one or more members work harder to compensate for the real or imagined shortcomings of their fellow members. Compare KOHLER EFFECT; SUCKER EFFECT.

compensatory damages a sum of money awarded in a civil action ideally to restore the injured party to his or her state prior to the injury. Typical losses recoverable in compensatory damages are medical expenses, lost wages,
compensatory education

and compensation for pain and suffering. Compare PUNITIVE DAMAGES.

compensatory education educational programs that are specially designed to enhance the intellectual and social skills of disadvantaged children. An example of such a program is HEAD START.

compensatory eye movements movements of the eyes that counteract movement of the head. An example is the VESTIBULO-OCULAR REFLEX.

compensatory mechanism a cognitive process that is used to offset a cognitive weakness. For example, someone who is weaker in spatial abilities than in verbal abilities might use compensatory mechanisms to attempt to solve spatial problems, such as mentally rotating a geometric figure by using verbal processes. The underlying theory is that intelligence partly consists of finding ways to compensate for the skills that one has lost over time or in which one was not adept in the first place.

compensatory nystagmus see BEKTEREV'S NYSTAGMUS.

compensatory reflex a response that is opposite to, and therefore compensates for, another response. For example, a compensatory response to the suppression of pain by opioid drugs would be an increase in pain sensitivity. Therefore, with extended use, more of the opioid would be needed to achieve the same effect of pain suppression.

compensatory self-enhancement a strategy for maintaining self-esteem or public image in which a person responds to poor performance or feedback in one sphere by focusing on or emphasizing his or her positive traits in an unrelated sphere. This emphasis on the positive is intended to offset the unwelcome implications of the bad feedback.

compensatory task a task or project that a group can complete by averaging individual members’ solutions or recommendations. Groups are more likely to outperform individuals on such tasks when (a) the members are equally proficient at the task and (b) the members do not share common biases that produce systematic tendencies toward overestimation or underestimation. Compare ADDITIVE TASK; CONJUNCTIVE TASK; DISJUNCTIVE TASK. See also WISDOM OF CROWDS.

compensatory tracking in ergonomics, a TRACKING task requiring the operator to use a control (e.g., a joystick) to compensate for the movement of a cursor or other indicator on a display so that it remains within a defined target area. A driver, for example, must control his or her speed so that the needle on the speedometer remains at or below the mark showing the legal speed limit.

competence n. 1. the ability to exert control over one’s life, to cope with specific problems effectively, and to make changes to one’s behavior and one’s environment, as opposed to the mere ability to adjust or adapt to circumstances as they are. Affirming, strengthening, or achieving a client’s competence is often a basic goal in psychotherapy. 2. one’s developed repertoire of skills, especially as it is applied to a task or set of tasks. A distinction is sometimes made between competence and performance, which is the extent to which competence is realized in one’s actual work on a problem or set of problems. 3. in linguistics and psycholinguistics, the nonconscious knowledge of the underlying rules of a language that enables individuals to speak and understand it. In this sense, competence is a rationalist concept that must be kept distinct from the actual linguistic performance of any particular speaker, which may be constrained by such nonlinguistic factors as memory, attention, or fatigue. Both terms were introduced by Noam CHOMSKY, who proposed the study of linguistic competence as the true task of linguistics: in doing so, he effectively declared linguistics to be a branch of cognitive psychology. See GENERATIVE GRAMMAR; GRAMMATICALITY; LANGUAGE ACQUISITION DEVICE. 4. in law, the capacity to comprehend the nature of a transaction and to assume legal responsibility for one’s actions. See COMPETENCY TO STAND TRIAL. Compare INCOMPETENCE. —competent adj.

competence motivation the drive to interact effectively with the environment and develop personal skill and capability in solving problems and performing tasks, such mastery being reinforced by a sense of control and positive self-esteem.

competency-based instruction a teaching method in which students work at their own pace toward individual goals in a noncompetitive setting. The teacher works with students in identifying appropriate goals and monitoring their progress toward those goals.

competency evaluation evaluation of a defendant by a psychologist to determine his or her competency to stand trial.

competency to stand trial the capacity to be tried in court as determined by a person’s ability, at the time of trial, to understand and appreciate the criminal proceedings against him or her, to consult with an attorney with a reasonable degree of understanding, and to make and express choices among available options. It is a component of ADJUDICATIVE COMPETENCE. See DUSKY STANDARD. See also INCOMPETENCY PLEA.

competent reservoir see DILUTION EFFECT.

competing response training a technique in BEHAVIOR THERAPY that involves two sequential stages: (a) identification of habit occurrence, including antecedents and warning signs; and (b) creation and practice, in session and through homework, of a competing (i.e., alternative) response to the problem behavior. The competing response should be physically incompatible with the behavioral habit, inconspicuous, and easy to practice. This technique is typically used with habit disorders and is also used in ANGER MANAGEMENT training. See also ALTERNATIVE BEHAVIOR COMPLETION.

competition n. any performance situation structured in such a way that success depends on performing better than others. Interpersonal competition involves individuals striving to outperform each other; intergroup competition involves groups competing against each other, with such groups including both small, face-to-face gatherings and very large groups, such as nations; intragroup competition involves individuals within a group trying to best each other. Because competing individuals sometimes increase their chances of success by actively undermining others’ performances, such goal structures can lead to conflict. Compare COOPERATION. —compete vb. —competitive adj.

competition by resource defense the use of territory or other defended space to exclude others from access to resources. The resources are defended indirectly rather than by direct aggression or competition. A special case is RESOURCE DEFENSE POLYGYNY, in which a male can acquire additional mates if it is able to defend a larger than average set of resources.
competition for resources in ecology, the use of the same resource by individuals of the same species (intraspecific competition) or of different species (interspecific competition) when the supply of the resource is insufficient for the combined needs of all individuals. It is a major factor in natural selection. Also called struggle for existence. See also Darwinism; survival of the fittest.

competition routine a predetermined pattern of behavior, self-talk, and imagery used during competition to enhance performance.

competition tolerance 1. acceptance of goal structures that require interactants to compete with one another. 2. a positive, healthy reaction when one must perform competitively.

competitive bargaining see distributive bargaining.

competitive goals 1. goals that can only be attained by outperforming or outmaneuvering other individuals or groups who are also seeking to attain them. 2. in sports, standards of excellence to be achieved during competition rather than during practice or training. Also called competition goals. 3. established goals that cannot be achieved simultaneously—in effect, they compete or conflict with one another. By spending time and effort to achieve one goal, an individual cannot achieve another goal.

competitive goal structure a performance situation structured in such a way that an interactant can reach his or her goals only by outperforming others or preventing others from reaching their goals. When goal structures are purely competitive, individual success requires that all others fail. Because competition creates incompatibility between people, such goal structures can generate interpersonal conflict. Compare cooperative goal structure.

competitive motive the drive or dispositional tendency to respond competitively in interpersonal and performance settings by maximizing one’s own outcomes and impeding the progress of others. Compare cooperative motive.

competitiveness n. a disposition to seek out objective competitive situations and to compare one’s performance against a standard or another person of comparable ability. —competitive adj.

competitive reward structure a performance setting in which rewards are assigned on the basis of individual rather than group achievement and which is structured in such a way that the success of any one individual decreases the rewards received by the other group members. Compare cooperative reward structure; individualistic reward structure.

Competitive State Anxiety Inventory (CSAI) an instrument that assesses self-confidence and physical and cognitive elements of anxiety that are associated with an immediately upcoming competition (see state anxiety). In its revised edition (CSAI-2), it consists of 27 statements (e.g., “I am concerned about performing poorly”) to which participants respond using a 4-point Likert scale, ranging from not at all to very much so. [originally developed by sport psychologist Rainer Martens (1942-)] and colleagues

complement n. in linguistics, a word, phrase, or clause added to a verb to complete the sense of the predicate. The term is most closely associated with the type of phrase that follows a copula (linking verb), such as my father in He is my father or very unhappy in She looked very unhappy.

complementarity n. 1. the quality of a relationship between two people, objects, or situations such that the qualities of one supplement or enhance the different qualities of the others. 2. in any dyadic relationship, the existence of different personal qualities in each of the partners that contribute a sense of completeness to the other person and provide balance in the relationship. Certain behaviors or traits tend to elicit the complementary behaviors or traits from partners (e.g., dominance often is followed by submission, and vice versa). Complementarity is an important factor in building rapport and the therapeutic relationship in psychotherapy because it reduces anxiety, preserves self-concept, and reinforces the interaction pattern. —complementary adj.

complementary and alternative medicine (CAM) a group of therapies and health care systems that fall outside the realm of conventional Western medical practice. These include but are not limited to acupuncture, chiropractic, meditation, aromatherapy, homoeopathy, naturopathy, osteopathy, touch therapy, reflexology, reiki, and the use of certain dietary supplements. Complementary medicine is used as an adjunct to conventional treatment; alternative medicine stands alone and replaces conventional treatment. See also integrative medicine.

complementary class in set theory, the totality of elements that do not belong to a particular class. For example, if A is the class of all psychologists, then its complementary class is the class of all people who are not psychologists.

complementary classification in classification tasks, the grouping of items from conceptually different categories into a superordinate class based on an individual’s mental associations from past experience. For example, cow, tractor, and farmer may be grouped because they are all found on a farm. Also called functional classification; schematic classification; thematic classification. Compare conceptual classification; idiosyncratic classification; perceptual classification.

complementary colors see antagonistic colors.

complementary distribution the situation in which two or more allophones of a phoneme occur in mutually exclusive phonetic environments. Compare free variation.

complementary identification in psychoanalysis, a form of countertransference in which the analyst identifies with a significant object (person) in the patient’s life and experiences the affects that the object would have in relation to the patient. For instance, the patient might project feelings of parental neglect onto the analyst and imply that the analyst is ignoring him or her. This induces feelings of guilt in the analyst, who feels like the rejecting, neglectful parent. Also called complementary countertransference. Compare concordant identification. [introduced by Polish-born Argentinian psychoanalyst Heinrich Racker (1910–1961)]

complete block design a study in which participants are first divided into blocks (relatively homogeneous sub-groups) according to some characteristic (e.g., age) that is not a focus of interest and are then assigned to the different treatments or conditions in such a manner that each treatment appears once in each block. Thus, the number of par-
participants in each block must equal the number of experimental conditions. For example, the following arrangement of four treatments (A, B, C, D) and 16 individuals (from four age groups) is a complete block design:

<table>
<thead>
<tr>
<th>Block #</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (children)</td>
<td>A  B  C  D</td>
</tr>
<tr>
<td>2 (adolescents)</td>
<td>B  C  D  A</td>
</tr>
<tr>
<td>3 (young adults)</td>
<td>C  D  A  B</td>
</tr>
<tr>
<td>4 (older adults)</td>
<td>D  A  B  C</td>
</tr>
</tbody>
</table>

By ensuring that the “nuisance” characteristic (here, age) is equally represented across all conditions, complete block designs reduce or eliminate its contribution to experimental error. Compare incomplete block design. See also block design; randomized block design.

**complete-case analysis** see listwise deletion.

**complete counterbalancing** a process of arranging a series of experimental conditions or treatments in such a way that every possible sequence of conditions is given at least once during the study. For instance, the following arrangement of sequences of three treatments (A, B, C), each assigned to a different subgroup of participants, demonstrates complete counterbalancing: A-B-C, A-C-B, B-C-A, B-A-C, C-A-B, and C-B-A. Compare incomplete counterbalancing.

**complete factorial design** a research study involving two or more independent variables in which every possible combination of the levels of each variable is represented. For instance, in a study of two drug treatments, one (A) having two dosages and the other (B) having three dosages, a complete factorial design would pair the dosages administered to different individuals or groups of participants as follows: A₁ with B₁, A₁ with B₂, A₁ with B₃, A₂ with B₁, A₂ with B₂, and A₂ with B₃. Compare fractional factorial design.

**completion test** a type of test in which the participant is usually required to supply a missing phrase, word, or letter in a written text. In nonverbal completion tests, a missing number, symbol, or representation must be supplied. See also word-stem completion.

**complex** a group or system of related ideas or impulses that have a common emotional tone and exert a strong but usually unconscious influence on the individual’s attitudes and behavior. The term, introduced by Carl Jung to denote the contents of the personal unconscious, has taken on an almost purely pathological connotation in popular usage, which does not necessarily reflect usage in psychology. Primary examples from classical psychoanalysis and its offshoots are Jung’s power complex, Sigmund Freud’s castration complex and oedipus complex, and Alfred Adler’s inferiority complex.

**complex behavior** an activity that requires many decisions and actions in rapid order or simultaneously. Dancing in a ballet is an example of a complex behavior.

**complex cell** a neuron in the cerebral cortex that responds to visual stimulation of appropriate contrast, orientation, and direction anywhere in the receptive field. Compare simple cell.

**complex comparison** an evaluation that involves comparing some combination of two or more groups against one or more other groups. For example, a researcher investigating the influence of a new teaching style on test scores might examine whether the average score across two classrooms of students differs from that of a third classroom. Compare simple comparison.

**complex emotion** any emotion that is an aggregate of two or more others. For example, hate may be considered a fusion of anger, fear, and disgust, whereas love blends ten- derness, pleasure, devotion, and passion. Comprising the majority of one’s affective experiences, complex emotions include, among others, awe, disgust, embarrassment, envy, gratitude, guilt, jealousy, pride, remorse, shame, and worry. Research suggests that these emotional composites are seen more often in older adults than in children, who have only a partial conceptualization of such complexity: They understand the arousal associated with the emotion but have no knowledge of the kinds of situations that evoke it. Conversely, simple emotions are those that are irreducible by analysis to any other emotion. They are pure, unmixed states and include anger, fear, and joy, among others.

**Complex Figure Test** a nonverbal memory test for a complex design. The individual is first asked to copy a complex design without being forewarned about a later memory test. This is followed by immediate and delayed recall trials in which the individual is asked to reproduce the complex figure from memory. A comparison of performance on the copy and recall trials allows the examiner to estimate the contribution of visuospatial and visuomotor processes, task strategy, and memory abilities to the individual’s performance. The Children’s Complex Figure Test is a version of this test for children. Also called Rey Complex Figure Test (RCFT); Rey–Osterrieth Complex Figure Test (ROCFT). [originally developed by Swiss psychologists André Rey (1906–1965) and Paul-Alexandre Osterrieth]

**complex ideas** in associationism, those conceptions that are more abstract and involved than simple ideas. Associationists held that complex ideas, such as beauty, were derived from simple sensations by means of mental processes, such as comparing and generalizing. See association of ideas. [defined by John Locke]

**complexity factor** in psychological aesthetics, a dimension of artistic style involving high levels of complexity (multiplicity). High complexity may reflect the artist’s feelings of tension or anger and convey similar feelings. By contrast, a simple work of art may convey a feeling of tranquillity.

**complexity hypothesis** a hypothesis that conscious experiences arise from massive neuronal activity in the thalamocortical system of the brain, particularly when interactivity in a dynamic core of neurons reaches a high level. Complexity is a mathematically defined measure of neuronal integration and differentiation. [proposed by Italian–U.S. neuroscientist Giulio Tononi (1960–) and U.S. neuroscientist Gerald M. Edelman (1929–2014)]

**complexity of an attitude** the number of distinct dimensions underlying attitude-relevant knowledge. The greater the number of dimensions (i.e., distinct categories of attitude-relevant information), the greater the complexity of an attitude. Researchers have sometimes distinguished between two components of complex attitudes: differentiation (the number of distinct dimensions) and integration (the extent to which those dimensions are seen as
related to one another). All complex attitudes are high in differentiation but may vary in their level of integration.

**complexity theory** a field that studies nonlinear systems with very large numbers of interacting variables using mathematical modeling and computer simulation. In general, it proposes that such systems are too complex to be accurately predicted but are nevertheless organized and nonrandom. Complexity theory has important applications in such fields as ecology, epidemiology, finance, and information science. See also CHAOS THEORY; DYNAMIC SYSTEMS THEORY.

**complex motives** simultaneous, multiple desires to achieve one or more goals. For example, desires may be compatible and oriented toward the same goal (e.g., working hard due to a desire for success as well as a desire for money) or incompatible and oriented toward opposing goals (e.g., desiring to achieve success through work while simultaneously desiring to relax by not working).

**complex of ideas** a set of related ideas closely associated with emotions, memories, and other psychic factors so that when one of the ideas is recalled, other aspects of the complex are recalled with it. See also COGNITIVE SYSTEM.

**complex partial seizure** a PARTIAL SEIZURE that is characterized by complex psychological symptoms, repetitive motor activities, and specific sensory experiences. During the seizure the individual is in an impaired or altered, often trancelike, state of consciousness, typically accompanied by FALSE MEMORIES (e.g., déjà vu), and may experience such emotions as fear, anxiety, or (less commonly) sadness or pleasure. Stereotyped motor behavior includes grimacing, sucking, chewing, and swallowing, and there may also be visual or olfactory hallucinations. Complex partial seizures are most commonly associated with abnormal discharges from neurons in the temporal lobe. Also called psychomotor seizure.

**complex reaction time** see CHOICE REACTION TIME.

**complex schedule of reinforcement** a SCHEDULE OF REINFORCEMENT in which simple schedules are presented in combination. Examples include the CONJOINT SCHEDULE, CONJUNCTIVE REINFORCEMENT, and INTERLOCKING REINFORCEMENT SCHEDULE.

**complex sentence** in linguistics, a sentence consisting of a main clause and one or more subordinate clauses, as contrasted with a simple sentence consisting of a single main clause or a compound sentence consisting of several main clauses linked by coordinating conjunctions (see COORDINATION). See also EMBEDDED SENTENCE.

**complex tone** a sound that consists of two or more components of different frequencies. See SOUND SPECTRUM. Compare PURE TONE.

**complex trauma** see DEVELOPMENTAL TRAUMA DISORDER.

**compliance** n. 1. submission to the demands, wishes, or suggestions of others. See also CONFORMITY, 2. a change in a person’s behavior in response to a direct request. A variety of techniques have been developed to enhance compliance with requests. Although some techniques may enhance compliance by producing ATTITUDE CHANGE, behavioral change is the primary goal of these techniques. See DISRUPT-THEN-REFRAME TECHNIQUE; DOOR-IN-THE-FACE TECHNIQUE; FOOT-IN-THE-DOOR TECHNIQUE; LOW-BALL TECHNIQUE; THAT’S-NOT-ALL TECHNIQUE. 3. in pharmacotherapy, see ADHERENCE. 4. in SAFETY ENGINEERING, adherence to workplace codes or guidelines designed to enforce safe behaviors and exclude behaviors that increase the risk of injury or illness. Compliance is the end goal of workplace attempts to train or warn employees exposed to hazards. —compliant adj. —comply vb.

**compliant character** a submissive personality whose prime motive is to seek affection from others. Karen D. HORNBY defined the development of such a character as one of three basic NEUROTIC TRENDS used as a defense against BASIC ANXIETY. Compare AGGRESSIVE CHARACTER; DETACHED CHARACTER.

**complicated grief** a response to death (or, sometimes, to other significant loss or trauma) that deviates significantly from normal expectations. Three different types of complicated grief are posited: chronic grief, which is intense, prolonged, or both; delayed grief; and ABSENT GRIEF. The most often observed form of complicated grief is the pattern in which the immediate response to the loss is exceptionally devastating and in which the passage of time does not moderate the emotional pain or restore competent functioning. The concept of complicated grief was intended to replace the earlier terms ABNORMAL GRIEF and PATHOLOGICAL GRIEF.

**complication** n. an additional disease, disorder, or condition that occurs or develops during the course of another disease or disorder or during a medical procedure. See also COMORBIDITY.

**complication experiment** an experiment in which two or more events occur simultaneously, but only one is the focus of attention. Such experiments indicate that the events occurring outside the focus of attention are perceived as being displaced in time. See LAW OF PRIOR ENTRY.

**component evaluation** an approach in PROGRAM EVALUATION that examines the separate elements comprising a SERVICE DELIVERY SYSTEM or intervention program. The unit of analysis in the evaluation shifts from the program level to components or links between components and subsequent PROGRAM OUTCOMES.

**componential analysis** 1. any analysis in which a process or system is separated into a series of subprocesses or components. 2. a set of information-processing and mathematical techniques that enables an investigator to decompose an individual’s performance on a cognitive task into the underlying elementary COGNITIVE PROCESSES. For example, solving an analogy requires encoding of stimuli, inference of the relation between the first two terms of the analogy, and so forth. Componential analysis enables the investigator to ascertain, for each individual, (a) the identities of the components used, (b) the strategy by which the components are combined, (c) the amount of time spent on each component, (d) the susceptibility of the component to erroneous execution, and (e) information regarding the mental representation upon which the component acts. [devised by U.S. psychologist Robert J. Sternberg (1949–)]. 3. a formal semantic analysis in which words are broken down into their separate elements, for example, man = human + male. Componential analysis is often employed to aid understanding of the meaning of words used by members of a particular culture.

**componential subtheory** a subtheory in the TRIARCHIC THEORY OF INTELLIGENCE that specifies three kinds of information-processing components in human intelligence. The three components are (a) metacomponents, which are used to plan, monitor, and evaluate problem-solving.
component instinct

solving and decision making; (b) performance components, which are actually used to solve the problems or make the decisions; and (c) knowledge-acquisition components, which are used to learn how to solve the problems or make the decisions in the first place.

component instinct  in psychoanalytic theory, a fundamental element of the sexual instinct that has a specific source in one part of the body (e.g., the oral instinct) and a particular aim (e.g., instinct to master). The component instincts are posited to function independently during the early stages of psychosexual development and later to fuse during the genital stage, which begins at puberty. Also called partial instinct; part instinct.

components of an attitude see BASES OF AN ATTITUDE.

composite figure  in psychoanalytic theory, a person or object in a dream whose image is created from the features or qualities of two or more individuals or objects (actual or existing in fantasy or imagination) by the process of condensation.

composite hypothesis  a statistical hypothesis that is not specific about all relevant features of a population or that does not give a single value for a characteristic of a population but allows for a range of acceptable values. For example, a statement that the average age of employees in academia exceeds 50 is a composite hypothesis, as there are a variety of ages above that number that the average could assume to validate the statement. Alternatively, a composite hypothesis could give a specific value for one characteristic (e.g., the mean) but not others (e.g., the variance). Compare SIMPLE HYPOTHESIS.

composite reliability  1. the aggregate reliability of two or more similar items, such as judges’ ratings. 2. in STRUCTURAL EQUATION MODELING, the extent to which the set of constructs represented in the model relate to a given latent variable. CRONBACH’S ALPHA is an index of such reliability.

composition of movement  the sequence and pattern of neuromuscular activity involved in movement (e.g., walking), including the integration of signals in the premotor and cerebellar areas of the brain.

compos mentis  in law, mentally competent; that is, neither mentally deficient nor legally insane. See COMPETENCE. Compare NON COMPOS MENTIS.

compound n.  in linguistics, two or more words or other linguistic units combined into a single unit, as in a compound noun (e.g., bypass), a compound verb (e.g., shall go), or a compound sentence (e.g., John ate a sandwich, and Mary did too).

compound action potential  a recording of the ACTION POTENTIALS from several axons of a nerve when different axons are stimulated together. The different amplitudes and conduction velocities of the fibers account for the compound nature of the response. See also EVOKED POTENTIAL.

compound bilingual  see COORDINATE BILINGUAL.

compound eye  the type of eye found in certain lower forms of animals (e.g., insects), which is composed of a number of separate visual units (ommatidia). Compare SIMPLE EYE.

compound probability  the likelihood that two unrelated (independent) events will occur together, either simultaneously or in succession. For example, one could calculate the compound probability of rolling a 6 twice in a row on a die, of rolling a 6 on the first turn and a 2 on the second, and so forth.

compound reaction time  see CHOICE REACTION TIME.

compound reflex  a set of reflexes that are evoked together.

compound schedule of reinforcement  a procedure for studying a single response in which two or more schedules of reinforcement are arranged to alternate, to appear in succession, or to be in effect simultaneously (i.e., concurrently). See CONJOINT SCHEDULE; MIXED REINFORCEMENT SCHEDULE; MULTIPLE REINFORCEMENT SCHEDULE; TANDEM REINFORCEMENT.

compound sentence  see COMPLEX SENTENCE.

compound stimulus  a stimulus comprising two or more simple stimuli that occur at the same time.

comprehension  n. the act or capability of understanding something, especially the meaning of a communication. Compare APPREHENSION. See also VERBAL COMPREHENSION. —comprehend vb.

comprehension test  1. a reading-ability test in which understanding is assessed by asking questions about the passages read. 2. a test requiring individuals to state how they would deal with a given practical situation. For example, a testee might be asked what he or she would do upon finding a letter on the street that has an address written on it and that is stamped with the proper postage.

comprehensive functional assessment  an assessment that is broad in scope, often implemented by an interdisciplinary team, and most frequently focuses on a person with intellectual or developmental disabilities. It typically incorporates findings regarding specific developmental strengths and individual preferences, specific functional and adaptive social skills that the individual needs to learn, the nature of any presenting disabilities and their causes, and the need for a wide range of services.

comprehensive mental health center  see COMMUNITY MENTAL HEALTH CENTER.

compressed speech  recorded speech that has been transformed so that it can be replayed without unacceptable distortion at a higher rate (in words per minute) than that at which it was originally produced. Speech compression is usually accomplished by DIGITAL coding and modifying the coded representation to preserve the characteristics of speech that are essential to its intelligibility while speeding its flow.

compression n.  in neurology, pressure on the brain, spinal cord, or a nerve. Compression inside the skull raises intracranial pressure and may be caused by, for example, edema, hydrocephalus, or a tumor. Symptoms include motor disorders and disturbances of sensation, memory, or consciousness.

compression of morbidity  the hypothesis that the impact of chronic and disabling disease on an individual may be compressed into a shorter period of time before death if the first occurrence of the disease can be delayed to a later age of onset (e.g., by reducing lifetime health risks that cause morbidity and mortality). [proposed by U.S. physician James F. Fries (1938– )]

compromise formation  in psychoanalytic theory, the conscious form of a repressed wish or idea that has been
modified or disguised, as in a dream or symptom, so as to be unrecognizable. Thus, it represents a compromise between the demands of the ego's defenses and the unconscious wish. This serves to protect the person from the perceived feeling of anxiety, conscious or unconscious.

compulsion n. a type of behavior (e.g., hand washing, checking) or a mental act (e.g., counting, praying) engaged in to reduce anxiety or distress. Typically, the individual feels driven or compelled to perform the compulsion to reduce the distress associated with an obsession or to prevent a dreaded event or situation. For example, individuals with an obsession about contamination may wash their hands repetitively until their skin is cracked and bleeding. Such compulsions do not provide pleasure or gratification, although the individual may experience some temporary relief from engaging in them, and they are disproportionate or irrelevant to the feared situation that they are used to neutralize. See COUNTERCOMPULSION; OBSESSIVE-COMPULSIVE DISORDER. —compulsive adj.

compulsion to repeat see REPETITION COMPULSION.

compulsive character a personality pattern characterized by rigid, perfectionistic standards; an exaggerated sense of duty; and meticulous, obsessive attention to order and detail. Individuals of this type are sometimes humorless, parsimonious, stubborn, inhibited, rigid, and unable to relax. Also called compulsive personality. See also OBSESSIVE-COMPULSIVE PERSONALITY DISORDER.

compulsive disorder any disorder in which the individual feels forced to perform acts that are against his or her wishes or better judgment. The act may be associated with an experience of pleasure or gratification (e.g., compulsive gambling, drinking, or drug taking) or with the reduction of anxiety or distress (e.g., rituals in OBSESSIVE-COMPULSIVE DISORDER). See INTERMITTENT EXPLOSIVE DISORDER; KLEPTOMANIA; PARAPHILIA; PATHOLOGICAL GAMBLING; PYROMANIA; SUBSTANCE ABUSE; TRICHOTILLOMANIA. See also IMPULSIVE-CONTROL DISORDER.

compulsive drinker an individual who has an uncontrollable urge to drink excessively; an ALCOHOLIC. See ALCOHOL DEPENDENCE.

compulsive eating an irresistible drive to overeat, in some cases as a reaction to frustration or disappointment. See also BINGE-EATING DISORDER; BULIMIA NERVOSA; FOOD ADDICTION.

compulsive exerciser an individual who feels it is necessary to participate in moderate to high-level physical activity on a regular basis, often daily.

compulsive gambling see GAMBLING DISORDER; PATHOLOGICAL GAMBLING.

compulsive laughter persistent, inappropriate, and apparently uncontrollable laughter of which the individual may be unaware. See also INAPPROPRIATE AFFECT.

compulsiveness n. a behavior pattern associated with OBSESSIVE-COMPULSIVE DISORDER or OBSESSIVE-COMPULSIVE PERSONALITY DISORDER. See COMPLUSION.

compulsive orderliness overconcern with everyday arrangements, such as a clean desk or dust-free house, with unbearable anxiety if there is any variation. See OBSESSIVE-COMPULSIVE DISORDER; OBSESSIVE-COMPULSIVE PERSONALITY DISORDER.

compulsive personality see COMPULSIVE CHARACTER.

compulsive personality disorder see OBSESSIVE-COMPULSIVE PERSONALITY DISORDER.

compulsive repetition the irresistible drive to perform needless acts, such as checking and rechecking a door to see whether it has been locked. See COMPULSION; OBSESSIVE-COMPULSIVE DISORDER.

compulsive stealing see KLEPTOMANIA.

compunction n. distress or guilt associated with wrongdoing or with an anticipated action or result.

computational epistemology see CYBERNETIC EPistemology.

computational formula the equation used to calculate values for a statistical concept. This contrasts with the DEFINITIONAL FORMULA, which is the formal verbal definition of the concept.

computational linguistics an interdisciplinary field of study in which techniques from computer science and artificial intelligence are used to model theories based on linguistic analysis. Computers have been used experimentally to evaluate a range of hypotheses about phonetic perception and language processing. More practical applications have included the development of automatic translation systems and programs that can simulate or transcribe human speech.

computational metaphor a model of the mind as a device for performing operations on symbols that are analogous to those performed by a computer.

computational model any account of cognitive or psychobiological processes that assumes that the human mind functions like a digital computer, specifically in its ability to form representations of events and objects and to carry out complex sequences of operations on these representations.

computed tomography (CT) a radiographic technique for quickly producing detailed, three-dimensional images of the brain or other soft tissues. An X-ray beam is passed through the tissue from many different locations, and the different patterns of radiation absorption are analyzed and synthesized by a computer. Because a CT scan produces many slice-by-slice pictures of the head, chest, or abdomen, it is possible to locate abnormalities, such as lesions or tumors, without exploratory surgery. Also called COMPUTER-ASSISTED TOMOGRAPHY: COMPUTERIZED AXIAL TOMOGRAPHY (CAT); COMPUTERIZED TOMOGRAPHY. See also MAGNETIC RESONANCE IMAGING.

computer adaptive testing (CAT) a method of computer testing for particular skills or abilities in which the test items are automatically adjusted to match the level of proficiency demonstrated by the participant. The difficulty level of the items is reduced after an incorrect answer and increased after a correct answer. The testing stops once the participant’s ability has been estimated to a predetermined level of accuracy.

computer addiction see INTERNET ADDICTION.

computer anxiety strong apprehension about computers and computer use that is disproportionate to the actual threat posed by these machines. The anxiety may be related to fear of the unknown or fear of the possible outcome of trying to use a computer (e.g., failure, frustration, embarrassment, or disappointment). If the anxiety is sufficient to cause significant distress and impairment, it may
computer-assisted diagnosis

be classified as a specific phobia, situational type. Also called computer phobia.

computer-assisted diagnosis see computerized diagnosis.

computer-assisted instruction (CAI) a sophisticated offshoot of programmed learning, in which the memory-storage and retrieval capabilities of the computer are used to provide drill and practice, problem solving, simulation, and gaming forms of instruction. It is also useful for relatively individualized tutorial instruction. Also called computer-assisted learning (CAL). See also computer-managed instruction.

computer-assisted psychotherapy see computerized therapy.

computer-assisted testing 1. assessment of skills that is given on, or with the support of, a computer. It can assess the ability of an individual (usually a student or an employee) to access specific material using a computer or to interact directly with a computer in order to complete an assessment. 2. any testing that uses a computer. Such testing does not assess computer skills, and no previous computer experience or skills are required.

computerized assessment the process of using a computer to obtain and evaluate psychological information about a person. The computer presents questions or tasks and then makes diagnoses and prognoses based on a comparison of the participant’s responses or performance to databases of previously acquired information on many other individuals. Also called automated assessment.

computerized diagnosis the use of computer programs for cataloging, storing, comparing, and evaluating psychological and medical data as an aid to clinical diagnosis. In view of the possible variables involved in a particular type of disorder, computerized diagnosis makes use of information based on thousands of similar or related sets of signs and symptoms in previous patients, as well as information on diagnoses and effective treatments stored in databases. Also called computer-assisted diagnosis. See problem-oriented record.

computerized therapy the use of a specially programmed computer to provide therapy, under the auspices of a trained therapist. Also called computer-assisted psychotherapy.

computer literacy the ability to understand what computers and computer networks do, how they function, and how to use them effectively for such purposes as composing and editing text, sending and receiving e-mail, and finding information through the Internet.

computer-managed instruction a method of instruction in which a computer is used to assist the teacher in carrying out a plan of individualized instruction. The computer processes daily data regarding the performance of each student; such data can then be used in prescribing the next instructional step for each student. The learner does not interact directly with the computer.

computer model a computer simulation of an external entity, such as a psychological function, for the purpose of helping to understand its components. Such models may be designed, for example, to enable a scientist to approximate, manipulate, and revise a particular human decision-making process.

computer network a group of computers interconnected by communication lines. Computer networks vary in size and complexity from local area networks (LANs) to the global Internet. Connections between network nodes (i.e., computers) can be wireless (for short distances) or via copper wires (as in traditional telephone lines) or optical fibers.

computer of averaged transients an instrument that enables the computerized averaging of several successive responses to stimuli, as recorded by electroencephalography, in order to raise the ratio of signal to noise so that event-related potentials can be seen. This enables the responses to be distinguished above the noise of ongoing activity. See also average evoked potential.

computer phobia see computer anxiety.

computer programming the process of giving coded instructions to a computer that direct it to perform a specific set of operations. The instructions are given in a formal computer programming language that the computer can read and understand. There are hierarchies of programming languages from low-level machine code and assembly languages to high-level languages, such as fortran, lisp, logo, and prolog.

computer simulation 1. in cognitive psychology, a technique in which a model of cognitive processes is implemented as a computer program. This technique is generally used to investigate specific theories of cognitive processing rather than to explore the more general issues that are the province of artificial intelligence. 2. in linguistics, see computational linguistics.

computer slang slang or jargon used in computer contexts. Examples include flaming to denote the sending of intemperate Internet messages.

Comrey Personality Scales (CPS) an inventory of individual differences in eight personality traits constructed primarily through factor analysis and yielding scores on eight scales: trust versus defensiveness, orderliness versus lack of compulsion, social conformity versus rebelliousness, activity versus lack of energy, emotional stability versus neuroticism, extraversion versus introversion, masculinity versus femininity, and empathy versus egocentrism. Designed for individuals ages 16 years and over, it consists of 180 statements to which participants respond using a 7-point likert scale format, ranging from never to always or from definitely not to definitely. [developed in 1970 by Andrew Laurence Comrey (1923—), U.S. psychologist]

COMT abbreviation for catechol-O-methyltransferase.

Comte’s paradox an articulation, attributed by William James to Auguste Comte, of the difficulty associated with any science of human beings in which the mind becomes both the instrument of study and the object of study. That is, objective study of the rational mind by the rational mind seems paradoxical.

COMT gene the gene that codes for catechol-O-methyltransferase (COMT). Lack of one copy of the gene due to a condition affecting chromosome 22 (see 22q11.2 deletion syndrome) is associated with increased risk of schizophrenia, depression, anxiety, and bipolar disorder. Other variations in the COMT gene may also have roles in anxiety and bipolar disorder as well as in eating disorders, obsessive-compulsive disorder, and panic disorder.

CON abbreviation for certificate of need.
conarium n. in the theory of René Descartes, the point of contact between mind (RES COGNITANS) and body (RES EXTENSA), which he located in the pineal gland of the brain. According to some interpreters, Freud’s ID represents much the same concept. See CARTESIAN DUALISM.

conation n. the proactive (as opposed to habitual) part of motivation that connects knowledge, affect, drives, desires, and instincts to behavior. Along with affect and cognition, conation is one of the three traditionally identified components of mind. The behavioral basis of attitudes is sometimes referred to as the conative component. See also BASES OF AN ATTITUDE; TRIPARTITE MODEL OF ATTITUDES.

conative adj. characterized by volition or self-activation toward a goal.

concaveation n. in animal behavior, a form of sensitization whereby a virgin female, through repeated exposure to young animals, begins to display maternal behavior despite having no prior experience and undergoing none of the hormonal changes associated with pregnancy and nursing.

Concealed Figures Test see CLOSURE FLEXIBILITY TEST.

concealed measure see UNOBTRUSSIVE MEASURE.

concentration n. 1. the act of bringing together or focusing, as, for example, bringing one’s thought processes to bear on a central problem or subject (see ATTENTION). 2. the proportion of a dissolved substance in a solution or mixture. —concentrate vb.

concentration-camp syndrome a variant form of POSTTRAUMATIC STRESS DISORDER suffered by survivors of concentration camps. Persistent stress symptoms in survivors consist of severe anxiety, defenses against anxiety, an obsessive ruminative state, psychosomatic reactions, depression, and survivor guilt produced by remaining alive while so many others died.

concentrative meditation a type of MEDITATION that focuses on a specific image (e.g., a YANTRA; a specific sound, syllable, word, or phrase (see MANTRA); or a specific thought. It is the opposite of insight in that thoughts unrelated to the stimulus ideally do not enter the consciousness. See also TRANSCENDENTAL MEDITATION. Compare MINDFULNESS MEDITATION.

concept n. 1. an idea that represents a class of objects or events or their properties, such as cats, walking, honesty, blue, or fast. See CONCEPTUALIZATION; CONJUNCTIVE CONCEPT; DISJUNCTIVE CONCEPT. See also ABSTRACT IDEA. 2. in conditioning, a class of stimuli to which an organism responds in a similar or identical manner (see STIMULUS GENERALIZATION) and that the organism discriminates from other classes. —conceptual adj.

concept acquisition see CONCEPT FORMATION.

concept-discovery task a task in which the participant must try to discern the rule used to define members and nonmembers of a category. Also called concept-identification task. See also ABSTRACTION EXPERIMENT; CONCEPT-FORMATION TEST.

concept formation the process by which a person abstracts a common idea from one or more particular examples and learns the defining features or combination of features that are characteristic of a class (e.g., those describing a bird) or that are necessary and sufficient to identify members of a class of objects, relations, or actions (e.g., the concepts triangle, above, or more). Also called CONCEPT ACQUISITION: CONCEPT LEARNING. See also ABSTRACTION.

concept-formation test any test used in studying the process of concept formation and in assessing the level of formation achieved by a specific individual. See also ABSTRACTION EXPERIMENT; CONCEPT-DISCOVERY TASK.

concept hierarchy a collection of objects, events, or other items with common properties arranged in a multi-level structure. Concepts on the higher levels have broad meanings, whereas those at lower levels are more specific. For example, a concept hierarchy of ANXIETY DISORDERS would place that term on top, with PHOBIAS lower, and specific types of phobia (e.g., CLAUSTROPHOBIA) on the bottom.

concept-identification task see CONCEPT-DISCOVERY TASK.

conception ratio 1. in human demography, the proportion of males to females conceived, which is about 150:100. Male embryos are more vulnerable than female embryos, and the ratio of live births (the BIRTH RATIO) is about 105 boys to 100 girls in the United States. See SEX RATIO. 2. in animal husbandry, the ratio of the number of times a female becomes pregnant to the number of times she is mated.

concept learning see CONCEPT FORMATION.

conceptual apraxia a profound inability to use tools in an appropriate way. Conceptual apraxia is characterized by conceptual errors, in contrast to ideomotor APRAXIA, in which spatial errors are typically encountered.

conceptual classification in classification tasks, the grouping of items on the basis of their shared function or membership in a similar category, for example, cow, dog, horse; tractor, bus, motorcycle. Also called CATEGORICAL CLASSIFICATION: NOMINAL CLASSIFICATION: SIMILARITY CLASSIFICATION: TAXONOMIC CLASSIFICATION. Compare COMPLEMENTS AND CLASSES; SIMILARITY CLASSIFICATION; COMPARATIVE CLASSIFICATION.

conceptual complexity the degree to which an idea or an argument is difficult to understand, owing to the number of abstract concepts involved and the intricate ways in which they connect. See also COGNITIVE COMPLEXITY.

conceptual dependency a formalized SEMANTIC NETWORK designed for use in computer programs to capture and understand the conceptual relationships of sentences in natural (human) language. There are four primitive (or atomic) components of this network: actions, objects (picture producers), modifiers of actions, and modifiers of objects. See also COMPUTATIONAL SEMANTICS.

conceptual disorder a disturbance in the thinking process or in the ability to formulate abstract ideas from generalized concepts.

conceptual disorganization irrelevant, rambling, or incoherent verbalizations, frequently including NEOLOGISMS and stereotyped expressions. It is one of the major signs of disorganized thought processes. See also SCHIZOPHRENIC THINKING.

conceptual formula see DEFINITONAL FORMULA.

conceptual imagery the MENTAL REPRESENTATION of concepts or conceptual relationships. See IMAGERY.

conceptualization n. the process of forming concepts, particularly those of an abstract nature, out of experience
conceptually driven processing

or learned material. See also ABSTRACT CONCEPTUALIZATION; CONCEPT FORMATION. —conceptualize vb.

correctly driven processing see TOP-DOWN PROCESSING.

correctly guided control a stage or level of human INFORMATION PROCESSING that is controlled by higher order constructs, such as concepts or CONCEPTUAL SYSTEMS. Conceptually guided control functions primarily to direct thinking processes toward certain well-established goals.

correctual model 1. a diagram, such as a VENN DIAGRAM or a tree diagram, used to represent in visual form the relations between concepts or between concepts and their attributes. 2. in computing, an organizing principle that is used to structure the presentation of programs, files, and information to the end-user in ways that he or she will find conceptually familiar. Such a model is often based on a real-world analogy, as with the desktop and the spreadsheet.

correctal nervous system a hypothetical model of the neurological and physiological functions of the nervous system that can be manipulated to provide analogies of behavioral activities. Critics claim that research should be concentrated on the actual nervous system rather than on this type of model. However, Donald O. Hebb pointed out that, over time, conceptual models of the nervous system have acquired more of the properties of the actual nervous system and that modeling properties of the nervous system has been fruitful in encouraging research.

correctual replication see REPLIICATION.

correctal system the organization of a person’s cognitive abilities, emotional awareness, experience, and philosophical or religious orientation into a system for understanding events, data, or experience. See also COGNITIVE STRUCTURE FRAME.

correctal tempo the pace that is typical of a person’s approach to cognitive tasks, for example, a hasty rather than a deliberate approach to observing, thinking, and responding. Correctual tempo is an aspect of COGNITIVE STYLE. See also REFLECTION–IMPULSIVITY.

correctal test a memory test that involves processing the meaning of a stimulus. Conceptual tests can be used to measure both implicit memory, as in the CATEGORY PRODUCTION TEST, and explicit memory, as in FREE RECALL. Compare PERCEPTUAL TEST.

Concerta n. a trade name for METHYLPHENIDATE.

conclusion 1. in logic and philosophy, the proposition to which a line of argument or analysis leads. The conclusion is that which an argument is intended to establish as valid. See INFERENCE. 2. in science, a general law or principle derived from experimental evidence by a process of INDUCTION.

228
abstract. In some traditional societies, such thinking may be a type of thought or feeling that depends on immediate experience or events. It is characteristic of young children and may also be seen in people with schizophrenia and people who have suffered a brain injury, especially frontal lobe damage. Compare ABSTRACT THINKING.

concrete word in linguistics, a word denoting a physically real and perceptible entity, such as tree, airplane, or James. Compare ABSTRACT WORD.

concretism n, in the ANALYTIC PSYCHOLOGY of Carl Jung, a type of thought or feeling that depends on immediate physical sensation and displays little or no capacity for abstraction. In some traditional societies, such thinking may manifest itself in fetishism and belief in magic. In the modern world, it may display itself as an inability to think beyond the obvious material facts of a situation.

concretization n, 1. inability to think abstractly in which there is an overemphasis on details and immediate experience. It occurs in such conditions as dementia and schizophrenia. 2. the process of being specific or of giving an example of a concept or relationship.

concurrency seeking striving to avoid disagreements and debates within a group, particularly during discussions or decision making. Concurrency seeking is pronounced in groups experiencing GROUP THINKING.

 concurrent-chains procedure a procedure in which completion of either of two CONCURRENT SCHEDULES OF REINFORCEMENT, called the initial links, results in presentation of another schedule of reinforcement, called a terminal link, rather than primary reinforcement itself. Completion of the terminal-link schedule results in primary reinforcement. The initial links are concurrently available, in effect giving the organism an opportunity to choose between two terminal links. Once a terminal link is earned, however, it must be completed before the next period of choosing is made available.

concurrent medical audit see MEDICAL AUDIT.

concurrent operants two or more OPERANT responses that are available at the same time; they can be chosen simultaneously or alternately.

concurrent review an analysis of admissions to a psychiatric hospital or clinic carried out while care is being provided. It comprises certification of the necessity for admission (see ADMISSION CERTIFICATION) and assessment of the need for care to be continued (see CONTINUED-STAY REVIEW).

concurrent schedules of reinforcement a procedure in OPERANT CONDITIONING in which two or more separate reinforcement schedules, each associated with an independent OPERANT (response), are in effect simultaneously.

concurrent therapy 1. the use of two treatments at the same time. 2. in COUPLES THERAPY and FAMILY THERAPY, the simultaneous treatment of spouses or other family members in individual or group therapy, either by the same therapist or different therapists. See also COMBINED THERAPY.

concurrent validity the extent to which one measurement is backed up by a related measurement obtained at about the same point in time. In testing, the validity of results obtained from one test (e.g., self-report of job performance) can often be assessed by comparison with a separate but related measurement (e.g., supervisor rating of job performance) collected at the same point in time. See also CRITERION VALIDITY.

concussion n. mild injury to the brain, due to mechanical trauma or ACCELERATION–DECELERATION INJURY, that disrupts brain function but is typically followed by spontaneous recovery. Concussion usually involves at least brief unconsciousness, although it may be diagnosed in the absence of unconsciousness. The symptoms may include memory loss, headache, irritability, inappropriate emotional reactions, and changes in behavior. Concussions may be classified by severity based on the period of unconsciousness or the extent of memory loss for events before and after the trauma. See HEAD INJURY.

condensation n. the fusion of multiple meanings, concepts, or emotions into one image or symbol. Condensation is particularly common in dreams, in which, for example, one dream character may fuse the dreamer’s feelings toward several people, or one dream action may combine different emotional impulses.

condition 1. n. a logical antecedent on which a conclusion is dependent or an empirical antecedent on which an event or state is dependent. A necessary condition is one without which the idea would not logically follow or the event would not occur. A sufficient condition is one that directly entails a particular conclusion or that has the power to produce a particular event regardless of other conditions. 2. n. in statistics and experimental research, a category or level of a variable whose values are manipulated by a researcher. Study participants are then assigned to receive or be exposed to one or more of the different conditions. 3. vb. to inculcate a response or a behavior in an organism by means of CLASSICAL CONDITIONING, OPERANT CONDITIONING, or other behaviorist paradigms (see BEHAVIORISM). The term implies that the learning is largely automatic, based on processes more like reflexes than conscious mental activity. —conditioned adj.

conditional clause a subordinate CLAUSE that expresses a hypothesis or possibility, typically one introduced by if or unless. See also COUNTERFactual.

conditional discharge the release of a patient from a psychiatric facility with imposition of certain conditions and limitations (such as periodically reporting to a supervisor or taking medications).

conditional discrimination a DISCRIMINATION in which reinforcement of a response in the presence of a stimulus depends on the presence of other stimuli. For example, in a MATCHING-TO-SAMPLE procedure, responding to a comparison stimulus that matches the sample stimulus is reinforced; that is, determining the correctness of a response depends on the sample stimulus. See also SIMULTANEOUS DISCRIMINATION; SUCCESSIVE DISCRIMINATION.

conditional positive regard an attitude of acceptance and esteem that others express toward an individual on a conditional basis, that is, depending on the acceptability of the individual’s behavior in accordance with the others’ personal standards. In his theory of personality, Carl...
Rogers proposed that although the need for positive regard is universal, conditional regard works against sound psychological development and adjustment in the recipient. Compare unconditional positive regard.

Conditional probability the likelihood that an event will occur given that another event is known to have occurred. Conditional probability plays an important role in statistical theory. The probability of observing a particular outcome given that another outcome is known to have occurred can be derived from a contingency table. Also called conditional likelihood.

Conditional reasoning reasoning that takes the form “if X, then Y,” as in If Sam is male, then Sam is not a mother. In formal logic, the statement that follows if is called the antecedent and that following then is called the consequent.

Conditional strategy the ability of organisms to develop behavioral strategies appropriate for current conditions. An experienced adult male animal, for example, might actively defend a territory and guard females (see mate guarding), while a young male stays as a satellite male, not forming or defending the territory but attempting to copulate with available females (see sneak mating). If the resident male dies or disappears, the young male can rapidly change strategies to become a territory-defending male.

Conditional adj. relating to or describing behavior whose occurrence, form of display, or both is a result of experience. The two main classes of experience resulting in conditioned behavior are operant conditioning and classical conditioning.

Conditional aversion a tendency or desire to avoid one stimulus that results from its pairing with another stimulus that is experienced as unpleasant. Such an aversion may arise after a single pairing of the stimuli (see conditioned taste aversion) or as part of a process of deliberate repeated pairings (as in aversion conditioning). For example, a person who is trying to stop nail biting may paint her fingernails with a bitter substance, such that the foul taste experienced each time she chews a nail eventually leads to cessation of the behavior.

Conditional avoidance response (CAR) an acquired (learned) response that prevents, postpones, or reduces the frequency or intensity of an aversive stimulus. A conditioned response that stops an aversive stimulus is known as a conditioned escape response. For example, if a monkey learns to press a lever that turns off a loud noise, the lever press is a conditioned escape response. See avoidance conditioning.

Conditional emotional response (CER) any negative emotional response, typically fear or anxiety, that becomes associated with a neutral stimulus as a result of classical conditioning. It is the basis for conditioned suppression.

Conditional escape response see conditioned avoidance response.

Conditional inhibition the diminution of a conditioned response that occurs on presentation of a stimulus that has previously been experienced in different circumstances.

Conditional place preference (CPP) a process in which experience with certain stimuli renders as reinforcing the place where that experience occurred. For example, a rat might be injected with cocaine and then restricted to one side of a two-compartment chamber. After a number of trials, a test is conducted in which the rat can move freely between the two compartments. If the rat spends a majority of its time on the side in which it experienced cocaine, a CPP has been developed. Also called place conditioning.

Conditional reflex see conditioned response.

Conditional reinforcement see secondary reinforcement.

Conditional reinforcer see natural reinforcer.

Conditional response (CR) in classical conditioning, the learned or acquired response to a conditioned stimulus. Also called conditioned reflex.

Conditional stimulus (CS) a neutral stimulus that is repeatedly associated (see pairing) with an unconditioned stimulus until it acquires the ability to elicit a response that it previously did not. In many (but not all) cases, the response elicited by the conditioned stimulus is similar to that elicited by the unconditioned stimulus. A light, for example, by being repeatedly paired with food (the unconditioned stimulus), eventually comes to elicit the same response as food (i.e., salivation) when presented alone. Also called conditioned stimulus.

Conditional stimulus preexposure effect see latent inhibition.

Conditional stimulus–unconditioned stimulus interval (CS-US interval) the time period between a participant’s exposure to a stimulus for which there has been response training (i.e., conditioning) and the participant’s exposure to a stimulus for which there has been no training.

Conditional suppression a phenomenon that occurs during an operant performance test when a conditioned response to a positive stimulus is reduced by another stimulus that is associated with an aversive stimulus. For example, a rat may be trained to press a lever to receive food. During this procedure, the rat is occasionally exposed to a series of brief electric shocks that are preceded by a tone (the conditioned stimulus). As a result, when the rat subsequently hears the tone alone, its rate of lever pressing is reduced. Conditioned suppression is also used to study classical conditioning.

Conditional taste aversion the association of the taste of a food or fluid with an aversive stimulus (usually gastrointestinal discomfort or illness), leading to a very rapid and long-lasting aversion to, or at the least a decreased preference for, that particular taste. Conditioned taste aversion challenges traditional theories of associative learning, since very few pairings between the food and illness are needed to produce the effect (often one pairing will suffice), the delay between experiencing the taste and then feeling ill can be relatively long (i.e., a long delay of reinforcement), and the aversion is highly resistant to extinction. This brainstem-based aversion has been observed both in humans and in nonhuman animals such as raccoons and octopuses. Also called Garcia effect: learned taste aversion: taste-aversion learning: toxicosis. See also preparedness.

Conditioning n. the process by which certain kinds of experience make particular actions more or less likely. See
conditioning apparatus in nonhuman animal research, any apparatus used in conditioning procedures. The most common conditioning apparatus is the OPERANT CHAMBER. See also OPERANT CONDITIONING CHAMBER.

conditioning of attitudes the formation or change of an attitude as a result of the association of an ATTITUDE OBJECT with a pleasant or unpleasant stimulus in the environment. Attitudes may be conditioned via CLASSICAL CONDITIONING or OPERANT CONDITIONING processes.

conditioning therapy see BEHAVIOR THERAPY.

conditions of worth the state in which an individual considers love and respect to be conditional on meeting the approval of others. This belief derives from the child’s sense of being worthy of love on the basis of parental approval: As the individual matures, he or she may continue to feel worthy of affection and respect only when expressing desirable behaviors. See CONDITIONAL POSITIVE REGARD. [proposed by Carl Rogers]

condom n. a sheath, usually made of latex rubber, placed over the erect penis to prevent pregnancy and to avoid sexually transmitted diseases.

conduct disorder (CD) in DSM–IV–TR, a persistent pattern of behavior that involves violating the basic rights of others and ignoring age-appropriate social standards. Specific behaviors include lying, theft, arson, running away from home, aggression, truancy, burglary, cruelty to animals, and lighting. Specifications for the disorder from DSM–5 include callousness, lack of guilt, and a shallow affect. CD is distinguished from OPPOSITIONAL DEFIANT DISORDER by the increased severity of the oppositional and conduct behaviors and their occurrence independently of an event occasioning opposition. ATTENTION-DEFICIT/HYPERACTIVITY DISORDER frequently coexists with or is misdiagnosed as conduct disorder.

conduction n. in physiology, the transmission of excitation along a nerve, muscle, or other tissue. In a neuron, subthreshold stimulation results in DECREMENTAL CONDUCTION, whereas suprathreshold stimulation results in a propagated ACTION POTENTIAL or nerve impulse.

conduction aphasia a form of APHASIA characterized by difficulty in repeating words and phrases accurately, even though language comprehension may be intact. Spontaneous speech tends to be grammatically correct but with frequent errors in the sounds of words and in finding the correct words to convey meaning. It is classically associated with lesions in the ARCULATE FASCICULUS, the tract linking the areas of the brain involved in the interpretation and control of speech, but modern research indicates that a lesion centered around the SUPRAMARGINAL GYRUS and the PLANUM TEMPORALE is responsible.

conduction deafness loss of hearing due to a disorder in the structures that transmit sound to the cochlea. The cause may be an injury or disease that interferes with the normal functioning of the OSSICLES. Also called CONDUCTIVE DEAFNESS. Compare CENTRAL DEAFNESS; SENSORYNEURAL DEAFNESS. See AIR–BONE GAP.

conduction time (CT) the time required for transmission of activity, such as an ACTION POTENTIAL, between two points.

conduction velocity see VELOCITY OF CONDUCTION.

conductivity n. 1. the ability of a substance to transmit energy, as in electrical conduction, thermal conduction, or skin conduction. 2. the ability of a tissue to convey SIGNALS and respond to stimuli.

cone n. see RETINAL CONE.

cone opsin see IODOPSIN.

confabulation n. the falsification of memory in which gaps in recall are filled by fabrications that the individual accepts as fact. It is not typically considered to be a conscious attempt to deceive others. Confabulation occurs most frequently in KORSAKOFF’S SYNDROME and to a lesser extent in other conditions associated with neurologically based amnesia (e.g., Alzheimer’s disease). In forensic contexts, eyewitnesses may resort to confabulation if they feel pressured to recall more information than they can remember. —confabulate vb.

confederate n. 1. in an experimental situation, an aide of the experimenter who poses as a participant but whose behavior is rehearsed prior to the experiment. 2. in para-psychology, an individual who assists a supposed psychic by covertly providing him or her with information about a client’s concerns, preferences, background, or situation, thus creating or strengthening the illusion of the psychic’s paranormal abilities.

conference method a method of PERSONNEL TRAINING in which participants work together in an attempt to resolve typical work-related problems and issues. Participants develop their problem-solving and decision-making abilities, acquire new information, and modify their attitudes in the process of pooling ideas, testing assumptions, discussing new approaches, and drawing inferences and conclusions. See also BUSINESS GAME; CASE METHOD; MULTIPLE-ROLE PLAYING; SCENARIO ANALYSIS.

confidence interval (CI) a range of values for a population PARAMETER that is estimated from a sample with a preset, fixed probability (known as the CONFIDENCE LEVEL) that the range will contain the true value of the parameter. The width of the confidence interval provides information about the precision of the estimate, such that a wider interval indicates relatively low precision and a narrower interval indicates relatively high precision. For example, a confidence interval for the population mean could be calculated with data obtained from a sample and would provide an estimated range of values within which the actual population mean is believed to lie. A confidence interval often is reported in addition to the POINT ESTIMATE of a population parameter.

confidence level a value expressing the frequency with which a given CONFIDENCE INTERVAL contains the true value of the parameter being estimated. For example, a 95% confidence level associated with a confidence interval for estimating a population mean indicates that in 95% of all estimates based on a random sample of a given size the confidence interval will contain the true value of the population mean. The particular confidence level used is up to the researcher but generally is 95% or 99%.

confidence limit either of the values at the upper and lower ends of a CONFIDENCE INTERVAL, which provide an estimated range for the value of a population PARAMETER. Also called confidence bound.

confidentiality n. a principle of PROFESSIONAL ETHICS requiring providers of mental health care or medical care to limit the disclosure of a patient’s identity, his or her condi-
configural-cue approach

tion or treatment, and any data entrusted to professionals during assessment, diagnosis, and treatment. Similar protection is given to research participants and survey respondents against unauthorized access to information they reveal in confidence. See INFORMED CONSENT; TARASOFF DECISION. —confidential adj.

configural-cue approach an experimental approach based on the theory that the response to a compound stimulus is to its whole rather than to its individual parts; as such, it contrasts with the stimulus-element approach, which posits that each part of a compound stimulus is perceived the way it would be as an individual stimulus.

configural display see OBJECT DISPLAY.

configural learning learning to respond to two or more stimuli on the basis of their combination rather than on the individual experience of any of those stimuli alone. For example, if neither a tone nor a light presented separately is followed by food, but a tone–light combination is, configural learning has occurred when a conditioned response is elicited by the tone–light combination.

configural superiority effect in visual perception, a phenomenon in which a configuration of elements or features is easier to identify than a single feature alone. Two examples are the word-superiority effect and the object-superiority effect.

configuration n. 1. an arrangement of elements or components in a particular pattern or figure. See GOODNESS OF CONFIGURATION. 2. the usual English translation of GESTALT. —configurational adj.

configurational analysis an integrative psychodynamic model for case formulation, psychotherapy, and outcome evaluation. Maladaptive states of mind in the context of the client’s problems, topics of concern, defenses, identity, and relationships are the focus of assessment and therapy. [developed by 20th-century U.S. psychiatrist Mardi J. Horowitz]

confinement study a study in a controlled environment to determine at what point physiological and psychological impairment occurs as a result of spatial restrictions. Such studies are important in space or marine exploration, during which individuals live and work in an artificial environment. The variables studied include length of time in confinement, area available, and crew size. These variables may have effects on sleep loss and ability to perform operational tasks.

confirmed proposition a statement or conclusion that is capable of being confirmed or falsified by experimental procedures. In LOGICAL POSITIVISM, all other propositions (except those of logic and mathematics) are considered essentially meaningless.

confirmation n. in PURPOSEFUL BEHAVIORISM, the fulfillment of an expectancy that reinforces the behavior that led to the fulfillment.

confirmation bias the tendency to gather evidence that confirms preexisting expectations, typically by emphasizing or pursuing supporting evidence while dismissing or failing to seek contradictory evidence.

confirmatory data analysis a statistical analysis designed to address one or more specific research questions, generally with the aim of confirming preconceived hypotheses. Compare EXPLORATORY DATA ANALYSIS.

confirmatory factor analysis (CFA) any method of testing A PRIORI hypotheses to the effect that the relationships among a set of observed variables are due to a particular set of unobserved variables. Unlike EXPLORATORY FACTOR ANALYSIS, in which all measured (manifest) variables are examined in relation to all underlying (latent) variables, confirmatory factor analysis imposes explicit theoretical restrictions so that observed measures relate with some (often just one) latent factors but not others.

confirmatory research research conducted with the aim of testing one or more preexisting hypotheses. Compare EXPLORATORY RESEARCH.

conflict n. the occurrence of mutually antagonistic or opposing forces, including events, behaviors, desires, attitudes, and emotions. This general term has more specific meanings within different areas of psychology. For example, in psychoanalytic theory, it refers to the opposition between incompatible instinctual impulses or between incompatible aspects of the mental structure (i.e., the id, ego, and superego) that may be a source of NEUROSIS if it results in the use of defense mechanisms other than SUBLIMATION. In interpersonal relations, conflict denotes the disagreement, discord, and friction that occur when the actions or beliefs of one or more individuals are unacceptable to and resisted by others.

conflict behavior behavior that results from experiencing two incompatible motivational states at the same time. It commonly occurs as a result of an APPROACH–AVOIDANCE CONFLICT, as when a hungry animal must leave shelter to feed in the presence of a predator (feeding vs. fear) or when a territorial male is in the presence of a potential mate (agression vs. sex). Conflict behavior may be manifested in alternations of approach and retreat or in unrelated behavior (see DISPLACEMENT BEHAVIOR).

conflict-free sphere in EGO PSYCHOLOGY, an area of the ego that develops and functions without giving rise to internal conflict. Functions ordinarily controlled by the conflict-free sphere include speech, motility, planning, and other autonomous ego functions. Psychoanalysis is thought to increase the conflict-free sphere of the ego and therefore to free up an individual’s capacities in life, the result of reducing neurotic symptoms and releasing the energy bound up in them. Also called conflict-free area.

conflict of interest a state of incompatibility among an individual’s or group’s various interests and motivations, particularly when professional interests and responsibilities are inconsistent with personal motives and goals. For example, psychologists who are employed by a health agency may find that their obligation to help their clients is incompatible with the agency’s requirement to minimize treatment costs.

conflict resolution the reduction of discord and friction between individuals or groups, usually through the use of active strategies, such as CONCILIATION, NEGOTIATION, and BARGAINING. See also CONSTRUCTIVE CONFLICT RESOLUTION.

conflict spiral a pattern of escalating tension and discord between two or more parties. Parties in such conflicts counter one another’s responses with more negative and more extreme responses.

conflict theory 1. any conceptual analysis of the causes and consequences of interpersonal conflict. 2. more specifically, a sociological approach that stresses the inevitability of conflict in any setting in which resources are un-
confusion effect

evenly distributed among interactants. See REALISTIC GROUP CONFLICT THEORY.

confluence n. a fusion or merging of several elements, for example, motives or perceptual elements. —confluent adj.

confluence model a controversial theory that intelligence of siblings is correlated with family size. According to this model, average intelligence generally declines as the number of children in a family increases. Intelligence is also held to decline with BIRTH ORDER. The one exception is an only child, whose intelligence suffers because he or she does not have an older sibling to serve as a teacher. However, many variables (e.g., spacing of children) could affect and reverse such generalizations. [proposed in 1975 by Robert B. Zajonc and Greg Markus]

conformity n. the adjustment of one’s opinions, judgments, or actions so that they become more consistent with (a) the opinions, judgments, or actions of other people or (b) the normative standards of a social group or situation. Conformity includes temporary outward acquiescence (COMPLIANCE) as well as more enduring private acceptance (CONVERSION). Compare ANTCOMFORMITY; NONCONFORMITY. See also MAJORITY INFLUENCE; PEER PRESSURE.

confound n. in an experiment, an independent variable that is conceptually distinct but empirically inseparable from one or more other independent variables. Confounding makes it impossible to differentiate that variable’s effects in isolation from its effects in conjunction with other variables. For example, in a study of high-school student achievement, the type of school (e.g., private vs. public) that a student attended prior to high school and his or her prior academic achievements in that context are confounds. Also called confounding variable.

confounded comparison a comparison of values obtained by different experimental groups on an outcome or dependent variable when two or more predictor or independent variables vary simultaneously across the groups. In such cases it is impossible to differentiate the effects of the independent variables. For example, consider a researcher studying how material presentation format (lecture vs. computer) and teacher sex (male vs. female) affect student learning. If the investigator were to examine data for only two groups of students (those who had a male teacher and lecture presentation format vs. those who had a female teacher and computer presentation format), he or she would have created a confounded comparison.

confounded effects the indivisible effects of two or more predictor or independent variables on a single response or dependent variable. That is, the unique influence of one predictor cannot be separated out from that of the others. For example, assume a researcher is examining the effectiveness of a hunger-reduction pill for weight loss. If some of the participants receiving the pill discover they are part of the treatment group and concurrently adopt better eating habits and increase their exercise levels, this additional healthy activities will also affect weight loss. Since those in the control group (receiving a PLACEBO sugar pill) are not engaging in these same supplemental activities, effects of eating habits, exercise levels, and the actual treatment will have become confounded.

confounding variable see CONFOUND.

confrontation n. 1. an argument or hostile disagreement. 2. the act of directly facing, or being encouraged or required to face, a difficult situation, realization, discrepancy, or contradiction involving information, beliefs, attitudes, or behavior. Confrontational techniques may be used therapeutically, for example, to reveal and invite self-examination of inconsistencies in a client’s reported and actual behavior, but they have a potential for disruptive as well as constructive effects. 3. in INDIVIDUAL PSYCHOLOGY, a statement or question calculated to motivate the client to make a decision or face the reality of a situation. —confrontational adj.

confrontational method an approach that aims to change behavior in individuals by aggressively compelling them to acknowledge their failures and weaknesses. Such methods are used, for example, in residential drug programs staffed by ex-addicts. Similar but less aggressive methods are used in ENCOUNT GROUPS as a means of increasing awareness and modifying behavior. Research has not supported the efficacy of confrontational approaches, and many individuals subjected to them respond with increased resistance to change.

confrontation naming any procedure that requires the naming of an object presented visually or from its pictorial representation—that is, an individual is “confronted” with a stimulus and asked to name it.

confusability index in ergonomics, any quantity used to express the degree to which a symbol, graphic, display item, or other object is capable of being misunderstood by the user or assigned a meaning other than its intended meaning.

confusion n. a mental disturbance characterized by bewilderment, inability to think clearly or act decisively, and DISORIENTATION for time, place, and person. Also called mental confusion.

confusional arousal a PARASOMNIA in which an individual partially awakens during NREM SLEEP, appears fully awake but is unresponsive to or exhibits impaired orientation to environmental stimuli, and has no memory afterward for events occurring during an episode. Individuals experiencing a severe episode may become aggressive toward others or self-injurious. Confusional arousal is especially common in children but can occur in adults as well. Also called sleep disorientation; sleep drunkenness; somnolentia.

confusional psychosis a form of CYCLOID PSYCHOSIS in which disturbances of cognitive processes are prominent and accompanied by a labile (highly changeable) emotional state characterized alternately by manifest anxiety, with the individual often misidentifying other people, and by mutism and greatly decreased movement. The latter differs from CATATONIC STUPOR in that self-care and spontaneity are preserved and negativism is absent. [defined by German psychiatrist Karl Leonhard (1904–1988)]

confusional state a state of impaired mental functioning in which awareness is retained but with loss of cognitive coherence and orientation to time, place, and sometimes identity. It may be accompanied by rumbling or incoherent speech, visual hallucinations, and PSYCHOMOTOR disturbances. It can arise from a wide variety of causes, including brain lesions, trauma, toxicity, medications, neurotransmitter imbalances, sleep disturbances, sedation, or fever. See also DELIRIUM.

confusion effect an ANTIPREDATOR BEHAVIOR in which each of several animals moves or vocalizes in a highly random way, making it difficult for predators to locate and attack any one individual. See also DELUSION EFFECT.
congenital anomaly see CONGENITAL DEFECT.

congenital cataract opacity of the lens of the eye that is present at birth or occurs soon after birth. Its effect is to scatter light and blur the image on the retina, which prohibits the development of pattern vision because of visual deprivation. Central vision is always affected, and peripheral vision may also be reduced. Congenital cataract can occur in one or both eyes; it may be hereditary or caused by congenital infection or metabolic disorders.

congenital character a character or trait that is present at birth. It may be hereditary or result from the influence of factors experienced during fetal development or delivery.

congenital color blindness see COLOR BLINDNESS.

congenital deafness deafness that exists from birth, regardless of the cause. Compare ADVENTITIOUS DEAFNESS.

congenital defect any abnormality present at birth, regardless of the cause. It may be caused by faulty fetal development (e.g., spina bifida, cleft palate), hereditary factors (e.g., Huntington's disease), chromosomal aberration (e.g., Down syndrome), maternal conditions affecting the developing fetus (e.g., fetal alcohol syndrome), metabolic defects (e.g., phenylketonuria), or injury to the brain before or during birth (e.g., some cases of cerebral palsy). A congenital defect may not be apparent until several years after birth (e.g., an allergy or a metabolic disorder) or even until after the individual has reached adulthood (e.g., Huntington's disease). Also called birth defect: congenital anomaly.

congenital glaucoma an eye disease, present at birth, in which a sustained, abnormally high fluid pressure within the eyeball damages the optic nerve (see GLAUCOMA). This causes enlargement of the eye (buphthalmos). In 70% of cases, both eyes are affected; the condition is found more frequently in males than in females and carries a 5% increased risk of occurrence in siblings and offspring. Congenital glaucoma may occur in association with many developmental syndromes (e.g., ANIRIDIA, STURGE–WEBER SYNDROME). Decreased vision may result from optic atrophy, corneal clouding, astigmatism, visual deprivation, high myopia, and strabismus. In addition, children typically show PHOTOPHOBIA and BLEPHAROSPASM.

congenital hypothyroidism a condition occurring when the thyroid gland fails to develop or function properly in a newborn. If untreated, congenital hypothyroidism can lead to intellectual disability and abnormal growth. If treatment begins in the first month after birth, infants usually develop normally. See CREtinism.

congenital oculomotor apraxia a condition, present at birth, in which a child is unable to fixate objects normally (see OCULOMOTOR APRAXIA). It is characterized by the absence of SACCADES and SMOOTH-PURSUIT EYE MOVEMENTS in the horizontal plane, but vertical eye movements are preserved: Children with this condition are often mistakenly thought to be blind. Between the ages of 4 and 6 months, they develop thrusting, horizontal head movements, sometimes blinking prominently or rubbing their eyelids when they attempt to change fixation. The cause of congenital oculomotor apraxia is unknown, but there is usually an improvement with age.

congenital rubella syndrome a complex of congenital defects in infants whose mothers were infected by the rubella virus early in pregnancy. The defects may include deafness, cataracts, heart disease, and microcephaly (small head). Neurological abnormalities occur in about 80% of affected individuals, and brain weight is usually subnormal. Psychomotor retardation, marked by general lack of response to stimuli, and intellectual impairment are common. In developed nations, rubella vaccination has resulted in a massive decline in the occurrence of this syndrome. See also GERMAN MEASLES.

congenital sensory neuropathy with anhidrosis a disorder marked by the absence of pain perception. Severe injuries, such as multiple fractures, may go untreated because they cause no pain. Affected individuals tend to show delayed intellectual development, with IQs below 80. Skin biopsies show normal but nonfunctional sweat glands.

congenital trichomegaly see TRICHOMEgAL–REtINAL DEGENERATION SYNDROME.

congenital visual agnosia a form of VISUAL AGNOSIA that is present at birth, due to abnormal development of those parts of the brain responsible for the visual identification of objects, faces, or both. Congenital visual agnosia represents a specific visual cognitive disorder that cannot be explained by visual, cognitive, or language deficits. Also called developmental visual agnosia.

congenital visual impairment partial or total visual impairment already present at birth or occurring soon after birth. Major causes are infections, bilateral cataracts, and prematurity. Unless specially stimulated, children with this impairment are likely to show delay in sensory, motor, and social development. Compare ADVENTITIOUS VISUAL IMPAIRMENT.

congruence n. 1. in general, agreement, harmony, or conformity. 2. a match between psychological attributes and behavior. 3. in the phenomenological personality theory of Carl Rogers, (a) the need for a therapist to act in accordance with his or her true feelings rather than with a stylized image of a therapist or (b) the conscious inte-
mation of an experience into the self. 4. in environmental psychology, see PERSON–ENVIRONMENT INTERACTION.

—congruent adj.

congruity validity see CONVERGENT VALIDITY.

congruity theory a COGNITIVE CONSISTENCY THEORY that focuses on the role of persuasive communications in attitude change. Congruity theory is similar to BALANCE THEORY in that it postulates that people tend to prefer elements within a cognitive system to be internally consistent with one another. Accordingly, if the person receiving a persuasive communication has a negative attitude to the content of the message but a positive attitude to the source of the message, or vice versa, then he or she will be motivated to revise both of these attitudes in some degree in order to restore congruity. Congruity theory differs from balance theory in that it takes into account gradations of evaluation of elements and therefore makes more precise predictions regarding the magnitude of change required to restore congruity among elements. [first proposed by U.S. psychologists Charles Osgood and Percy Tannenbaum (1927–2009)]

CONJ abbreviation for CONJUNCTIVE REINFORCEMENT.

conjoined twins MONOZYGOTIC TWINS whose bodies join or fail to separate completely during embryonic life; the exact mechanism and cause are not understood. Many conjoined twins are stillborn or die shortly after birth. Conjoined twins may have two bodies that are attached at the rib cage, head, or other location; alternatively, they may share one torso, limbs, or some internal organs. In some cases, surgical separation is possible. The popular name, Siamese twins, derives from the brothers Eng and Chang (1811–1874), who were born in Thailand (Siam) and exhibited in sideshows.

conjoint analysis a method of assessing behavioral choices in which participants are compared on pairs of attributes that have been selected by the researcher as potential explanations or predictors of such choices. For example, an investigator looking at vacation preferences might choose to examine such attributes as warm versus cold climates, hotels versus bed-and-breakfast accommodations, destinations in the United States versus destinations in Europe, and so forth. Conjoint analysis is used particularly in studies of consumer decision making.

conjoint behavioral consultation see BEHAVIORAL CONSULTATION.

conjoint schedule a type of COMPOUND SCHEDULE OF REINFORCEMENT under which two or more schedules of reinforcement operate simultaneously for a single response.

conjoint therapy therapy in which the partners in a relationship or members of a family are treated together in joint sessions by one or more therapists, instead of being treated separately. Also called conjoint counseling. See also COUPLES THERAPY; FAMILY THERAPY.

conjugate movements coordinated movements of the two eyes.

conjugate reinforcement a REINFORCEMENT CONTINGENCY in which some aspect of the reinforcer (e.g., its magnitude) varies systematically with some property of behavior (e.g., rate or force).

conjunction n. in linguistics, a FUNCTION WORD that serves to conjoin two or more sentence constituents or sentences, the most common being and, as in John and Mary got married. Other common conjunctions include but, because, or, and if. See COORDINATION.

conjunction search a search task in which the target has two or more relevant features. According to FEATURE-INTEGRATION THEORY, conjunction search proceeds in a serial manner.

conjunctival reflex the automatic closing of the eyelid when the SCLERA is stimulated.

conjunctive concept a concept that is defined by a set of attributes, every member of which must be present for the concept to apply. For example, the concept brother requires the joint presence of the attributes (a) male and (b) sibling, neither of which may be omitted. Compare DISJUNCTIVE CONCEPT.

conjunctive motivation the drive to achieve true and lasting (rather than temporary or substitute) satisfaction. Compare DISJUNCTIVE MOTIVATION. [defined by Harry Stack Sullivan]

conjunctive reinforcement (CONJ) a type of INTERMITTENT REINFORCEMENT in which two or more SCHEDULES OF REINFORCEMENT must be completed before reinforcement can be given. The order in which the schedules are completed is irrelevant. Also called conjunctive reinforcement schedule; conjunctive schedule of reinforcement.

conjunctive task a group task or project that cannot be completed successfully until all members of the group have completed their portion of the job (e.g., a factory assembly line). This means that the speed and quality of the work are determined by the least skilled member. Compare ADDITIVE TASK; COMPENSATORY TASK; DISJUNCTIVE TASK.

conname adj. see CONGENITAL.

connected discourse a relatively long and integrated unit of language, such as a written argument or spoken conversation. See DISCOURSE ANALYSIS.

connectionism n. 1. an approach that views human cognitive processes in terms of massively parallel cooperative and competitive interactions among large numbers of simple neuronlike computational units. Although each unit exhibits nonlinear spatial and temporal summation, units and connections are not generally to be taken as corresponding directly to individual neurons and synapses. See also NEURAL NETWORK; PARALLEL DISTRIBUTED PROCESSING. 2. as used by Edward L. THORNDIKE, the concept that learning involves the acquisition of neural links, or connections, between stimulus and response. —connectionist adj.

connectionist model any of a class of theories hypothesizing that knowledge is encoded by the connections among representations stored in the brain rather than in the representations themselves. Connectionist models suggest that knowledge is distributed rather than being localized and that it is retrieved through SPREADING ACTIVATION among connections. The connectionist model concept has been extended to artificial intelligence, particularly to its NEURAL NETWORK models of problem solving. Compare INFORMATION-PROCESSING MODEL.

connector neuron see INTERNEURON.

Conners’ Comprehensive Behavior Rating Scales (Conners CBRS) a questionnaire that assesses a variety of emotional, behavioral, and academic problems in those 6 to 18 years of age and aids in the identification
Conners' Rating Scales

of certain disorders. It includes a 203-item parent form, a 204-item teacher form, and a 179-item self-report, and it provides evaluations in nine areas: emotional distress, aggressive behaviors, language and math difficulties, hyperactivity–impulsivity, social problems, separation fears, perfectionist and compulsive behaviors, violence potential, and physical symptoms. [originally developed in 2008 by C. Keith Conners, U.S. clinical psychologist]

Conners' Rating Scales (CRS) a questionnaire used to assess ATTENTION-DEFICIT/HYPERACTIVITY DISORDER and diagnose the most common comorbid disorders in those 6 to 18 years of age. It includes a 110-item parent form, a 115-item teacher form, and a 99-item self-report, and it provides evaluations in seven areas: inattention, hyperactivity–impulsivity, learning problems, executive functioning, aggression, peer relations, and family relations. Participants respond to items—such as “argues with adults” for parents, “talks excessively” for teachers, and “I break the rules” for self-report—using the four rating options of not at all, just a little, pretty much, or very much. This widely used instrument was originally published in 1989 and subsequently revised in 1997 (Conners’ Rating Scales–Revised; CRS-R) and in 2008 (Conners’ Third Edition: Conners 3). [developed by C. Keith Conners]

connotative meaning see DENOTATIVE MEANING.

Conn’s syndrome see ALDOSTERONE. [Jerome W. Conn (1907–1994), U.S. physician]

CONOPS acronym for CONTINUOUS OPERATIONS.

consanguineous family see EXTENDED FAMILY.

consanguinity n. a biological relationship between two or more individuals who are descended from a common ancestor. Compare AFFINITY.

conscience n. an individual’s sense of right and wrong or of transgression against moral values. In psychoanalysis, conscience is the SUPEREGO, or ethical component of personality, which acts as judge and critic of one’s actions and attitudes. More recent biological approaches suggest that the capacity of conscience may be neurologically based, whereas psychosocial approaches emphasize the role of learning in the development of conscience and its influence in the formation of groups and societies. See also KOHLBERG’S THEORY OF MORAL DEVELOPMENT; PIAGETIAN THEORY.

conscientiousness n. the tendency to be organized, responsible, and hardworking, construed as one end of a dimension of individual differences (conscientiousness vs. lack of direction) in the BIG FIVE PERSONALITY MODEL. It is also a dimension in the FIVE-FACTOR PERSONALITY MODEL. Also called industriousness. —conscientious adj.

conscientious objector an individual who is opposed to war and preparations for war and who refuses to serve in the armed forces for religious reasons or for other beliefs of conscience.

conscious (Cs) 1. adj. relating to or marked by awareness or consciousness. 2. n. in the classical psychoanalytic theory of Sigmund Freud, the region of the psyche that contains thoughts, feelings, perceptions, and other aspects of mental life currently present in awareness. The content of the conscious is thus inherently transitory and continuously changing as the person shifts the focus of his or her attention. Compare PRECONSCIOUS; SUBCONSCIOUS; UNCONSCIOUS.

conscious access hypothesis the notion that a primary function of consciousness is to mobilize and integrate brain functions that are otherwise separate and independent. This hypothesis is part of GLOBAL WORKSPACE THEORY.

conscious automatism see EPIPPHENOMENALISM.

conscious intention a purpose or goal that one has explicitly chosen to pursue. Compare UNCONSCIOUS INTENTION.

conscious memory see DEclarATIVE MEMORY; EXPLICIT MEMORY.

conscious mentalism any theory that posits the reality of purely mental phenomena, such as thinking, feeling, desiring, preferring, and (particularly) intention, holding that these mental phenomena are the chief causes of behavior and that they are available to the conscious mind. The rise of BEHAVIORISM was largely a reaction against MENTALISM as an explanation for behavior. Although most forms of conscious mentalism hold that mental phenomena have a nonmaterial existence, some recent mentalistic positions have been materialistic, accepting that mental states and processes have their origin in physical states and processes. Compare ELIMINATIVISM; EPIPPHENOMENALISM; REDUCTIONISM.

conscious moment the present moment of experience, often thought to be about 2 to 4 seconds in duration, the approximate decay period for conscious sensory perceptions that are not susceptible to longer term recall. WORKING MEMORY is believed to extend the available present to 10 to 30 seconds. See also SPECIOUS PRESENT.

consciousness n. 1. the state of being conscious. 2. an organism’s AWARENESS of something either internal or external to itself. 3. the waking state (see WAKEFULNESS). 4. in medicine and brain science, the distinctive electrical activity of the waking brain, as recorded via scalp electroencephalogram, that is commonly used to identify conscious states and their pathologies.

Beyond these succinct, in some cases everyday, senses of the term, there are intricate philosophical and research controversies over the concept of consciousness and multiple perspectives about its meaning. Broadly, these interpretations divide along two (although not always mutually exclusive) major lines: (a) those proposed by scholars on the basis of function or behavior (i.e., consciousness viewed “from the outside”—the observable organism); and (b) those proposed by scholars on the basis of experience or subjectivity (i.e., consciousness viewed “from the inside”—the mind). The former generally represents the reductionist or materialist perspective (see MATERIALISM), whereas the latter generally represents the immaterialist perspective (see IMMATERIALISM). For example, functional or behavioral interpretations tend to define consciousness in terms of physical, neurobiological, and cognitive processes, such as the ability to discriminate stimuli, to monitor internal states, to control behavior, and to respond to the environment. According particularly to this view, the contents of CONSCIOUSNESS are assessed through their ability to be reported accurately and verifiably (see REPORTABILITY), although recent brain imaging research suggests that brain indices of conscious contents may become available.

Experiential or subjective interpretations, however, tend to define consciousness in terms of mental imagery; intuition; subjective experience as related to sensations, perceptions, emotions, moods, and dreams; self-awareness;
awareness of awareness itself and of the unity between the self and others and the physical world: STREAM OF CONSCIOUSNESS; and other aspects of private experience. According to this view, the contents of consciousness can be assessed to some extent by their reportability but must also, given their phenomenological nature, rely on INTROSPECTION. See also ALTERED STATE OF CONSCIOUSNESS; EVOLUTION OF CONSCIOUSNESS.

**consciousness-altering substance** any PSYCHOACTIVE DRUG that affects conscious experience and perception.

**consciousness of freedom** the sense of choice people tend to experience in making decisions and controlling actions in the absence of overt coercion. It may be the intuitive basis for the widespread belief in FREE WILL.

**consciousness raising** a process, often used in group discussion, directed toward greater awareness of (a) one’s self, such as one’s condition, needs, values, and goals; or (b) a political or social issue, such as discrimination against self, such as one’s condition, needs, values, and goals; or

**consciousness studies** a multidisciplinary field that combines approaches from cognitive science, neurophysiology, and PHILOSOPHY OF MIND to investigate the nature of CONSCIOUSNESS. Major concerns include the relationship of the mind to the body (see MIND–BODY PROBLEM), the HARD PROBLEM of subjective experience, the significance of ALTERED STATES OF CONSCIOUSNESS, and the possibility of consciousness in computers or other manmade systems (see MACHINE CONSCIOUSNESS).

**conscious process** a mental operation of which a person is explicitly aware and often in control. Compare UNCONSCIOUS PROCESS. See also AUTOMATICITY.

**conscious resistance** in psychoanalysis, the patient’s deliberate withholding of unconscious material that has newly risen into consciousness. This withholding tends to occur because of shame, fear of rejection, or distrust of the analyst.

**consensual drift** the tendency for two or more observers who are working together to depart gradually from accuracy or an agreed standard, such that they are making errors in the same direction and to the same extent. See OBSERVER DRIFT.

**consensual eye reflex** a phenomenon in which the pupil of a shaded eye contracts when the other eye is stimulated by bright light. Also called consensual light reflex.

**consensual validation** the process by which a therapist helps a client check the accuracy of his or her perception or the results of his or her experience by comparing it with those of others, often in the context of GROUP THERAPY.

**consensus** n. general agreement among the members of a group, especially when making an appraisal or decision. In tests of PERSON PERCEPTION, a consensus that a target person has a certain trait can act as a standard against which to compare the self-related biases of those who disagree with the group view. See also FALSE-CONSENSUS EFFECT.

**consent** n. voluntary assent or approval given by an individual; specifically, permission granted by an individual for medical or psychological treatment, participation in research, or both. Individuals should be fully informed about the treatment or study and its risks and potential benefits (see INFORMED CONSENT).

**consentience** n. a lesser form of consciousness attributed to nonhuman animals.

**consequate** vb. to establish a consequence to a behavior. If the behavior becomes more probable, consequation is said to have resulted in REINFORCEMENT. If the behavior becomes less probable, consequation has resulted in PUNISHMENT. —consequation n.

**consequent** n. 1. an event, state, or circumstance that follows from some other event, state, or circumstance. 2. in a conditional proposition of the if . . . then form, the statement that follows the connective then. The consequent is what is expected to be the case given that the antecedent (the statement following if) is true. For example, in the conditional proposition, If Socrates is a man, then he is mortal, the statement he is mortal is the consequent.

**consequent variable** a variable that is correlated with a primary outcome or DEPENDENT VARIABLE and whose value is predicted by that outcome variable. For example, in studies examining the influence of teaching style on student academic achievement, student motivation may be a consequent variable of achievement. Compare ANTecedent VARIABLE.

**conservation** n. the awareness that physical quantities do not change in amount when they are altered in appearance, such as when water is poured from a wide, short beaker into a thin, tall one. According to PIAGETIAN THEORY, children become capable of this mental operation in the CONCRETE OPERATIONAL STAGE. See also REVERSIBILITY.

**conservation psychology** a subfield of psychology that seeks to understand the attitudes and behavior of individuals and groups toward the natural environment so as to promote their use of environmentally sustainable practices. Because of the highly diverse categories of behavior being studied, conservation psychologists generally focus on specific actions, such as paper recycling, rather than general tendencies. Although related to ENVIRONMENTAL PSYCHOLOGY, conservation psychology is distinct in its orientation toward protecting ecosystems and preserving resources while ensuring quality of life for humans and other species.

**conservation withdrawal** a response to emotional or physical stressors (or both) in which a person tends to withdraw from family and friends and to have less energy and strength for activities. A means of conserving energy and recouping psychological and physical strength, this response resembles symptoms experienced as part of a MAJOR DEPRESSIVE EPISODE.

**conservatism** n. an attitude characterized by a positive regard for the past or the status quo (e.g., established principles and procedures) and sometimes, but not necessarily or wholly, by dislike or distrust of change. —conservative adj.

**conservative** adj. describing statistical methods that have a reduced likelihood of error, particularly of incorrectly rejecting the NULL HYPOTHESIS, but that are less capable of detecting significant relationships among variables. In other words, conservative approaches have less POWER and thus tend to underestimate associations or effects.

**conservatorship** n. a legal arrangement by which an individual is appointed by a court to protect the interests and property of a person who is unable by reason of a physical or mental condition to take full responsibility for
consideration

managing his or her own affairs. See also LIMITED GUARDI-

consideration n. in leadership theory, a component of effective leadership that involves showing concern for the feelings of subordinates, thereby reducing conflict, maintain-

consilience n. the view that the laws of physics and the rules of biological evolution underlie all aspects of human existence. All human endeavor should reflect these influences and exhibit a unity on the basis of a few basic scientific principles arising from them. [proposed by U.S. biologist Edward O. Wilson (1929— ) in his book Consilience: The Unity of Knowledge (1998)]

consistency check a method often built into an experi-

consistency motive the desire to confirm one’s current beliefs about one’s self, including experimentally induced beliefs. Self-consistency strivings are thought to minimize discomfort associated with disjunctions between different aspects of self-knowledge. Compare SELF-ASSESSMENT MO-

consistency theory a class of social psychological the-

consistent estimator an ESTIMATOR calculated from sample data whose value becomes more and more representa-

consistent mapping a condition of a SEARCH task in which a given stimulus is either (a) always a target or (b) always one of the DISTRACTOR stimuli among which the target is embedded; it is never a target at one time and a distractor at another. Consistent mapping usually produces a much more efficient search performance. Compare VAR-

consistent missing in parapsychology experiments using ZENER CARDS or similar targets, the phenomenon in which a participant’s “calls,” or guesses, are consistently wrong or significantly below chance expectations. Some people attribute such systematic failure to processing error or a conscious or nonconscious reluctance to confirm psychic ability. See also PSI-FAILURE.

consolidation n. the neurobiological processes by which a permanent memory is formed following a learning experience. See PEERERELATION—CONSOLIDATION HYPOTHESIS.

consolidation hypothesis see PERSEVERATION—CON-

consolidation period the time following a learning ex-

consolidation theory see SPACING EFFECT.

consonance n. 1. the quality of harmony between ele-

consonant n. 1. a VOICED or UNVOICED speech sound that is produced when the vocal tract is partly or wholly con-

consonant trigram three consonants, which normally do not spell a word, used in verbal learning experiments (e.g., JCL). See NONSENSE SYLLABLE. 3. adj. characterized by or exhibiting consonance, or harmony.

Consonar n. a trade name for brofaromine.

conspecific 1. adj. belonging to the same species. 2. n. a member of the same species.

conspicuity n. the ability of an object to attract atten-

conspicuous consumption see CONSUMERISM.

constancy n. see PERCEPTUAL CONSTANCY.

constancy law see PRINCIPLE OF CONSTANCY.

constancy of the IQ a tendency for IQ results to re-

constancy principle the general principle that psychic forces and energies tend to remain in a steady or balanced
state or tend to seek a return to a state of balance or of decreased energy. The idea is related to other general conceptions of constancy found in many scientific fields. In the psychology of Sigmund Freud, constancy refers specifically to the tendency of psychic energy, or libido, to seek a homeostatic or balanced state. The same principle lies behind Freud’s notion of catharsis.

constancy scaling the mental readjustment of a stimulus attribute (most commonly size) so that the stimulus is perceived as unaffected by the viewing conditions. For example, the small retinal angle subtended by a person seen in the distance is mentally scaled to a larger size so that the person is perceived to be of normal size rather than tiny.

constant 1. n. in mathematics, a fixed quantity that remains unchanged during a specified operation or series of operations. For example, the element $a$ in the regression equation $y = a + bx + e$ is a constant. Compare variable. 2. adj. unvarying or continual.

constant comparative analysis a procedure for evaluating qualitative data in which the information is coded and compared across categories, patterns are identified, and these patterns are refined as new data are obtained. For example, a researcher might use constant comparative analysis to assess responses to interview questions, creating categories of answers according to the perspectives expressed, examining their different items, and integrating categories or revising their properties before formulating a theory. Also called constant-comparison method.

constant error a systematic error in some particular direction. Constant error is computed as the average positive or negative difference between the observed and actual values along a dimension of interest. For example, if a weight of 1 kg is judged on average to be 1.5 kg, and a weight of 2 kg is judged to be 2.5 kg, the constant error is 500 g. See also absolute error; random error.

constant stimulus method see method of constant stimulus.

constellation n. in cognitive psychology, a group of ideas with a common theme or association. —constellatory adj.

constipation n. difficult or infrequent excretion of feces. The normal frequency of human bowel movements varies from three times a day to one every 3 days. In addition to diseases and mechanical obstructions, constipation may be caused by psychogenic factors. Psychogenic constipation is observed in some individuals with obsessive-compulsive disorder who assign such importance to regularity that abnormal amounts of time and effort are devoted to daily bowel movements.

constituent n. a linguistic unit that is a component of a larger and more complex unit. Although the term is used in the more traditional forms of sentence parsing, it is now mainly associated with the type of constituent analysis practiced in phrase-structure grammar and other forms of generative grammar. In this form of analysis a canonical English sentence, such as The man opened a window, is usually said to have the immediate constituents “noun phrase” (NP) and “verb phrase” (VP); the verb phrase can be further subdivided into the constituents “verb” (V) and “noun phrase,” and both noun phrases into “determiner” (det) and “noun” (N).

constitution n. 1. the sum of an individual’s innate characteristics. 2. more broadly, the basic psychological and physical makeup of an individual, due partly to heredity and partly to life experience and environmental factors. —constitutional adj.

constitutional disorder a condition, disease, behavior, or constellation of behaviors arising from or inherent within some aspect of the individual’s physical makeup or physiological characteristics.

constitutional factor a basic physiological tendency that is believed to contribute to personality, temperament, and the etiology of specific mental and physical disorders. Examples of this factor include hereditary predispositions and physiological characteristics (circulatory, musculoskeletal, glandular, etc.).

constitutional psychopathic inferior a former name for an individual with antisocial personality disorder. The term psychopathic inferior was introduced in 1888 by German physician Robert Koch (1843–1910) and included by Emil Kraepelin in his classification of mental disorders (1893). Adolf Meyer added the word constitutional in the sense of deep-seated (but not congenital).

constitutional type a classification of individuals based on physique and other biological characteristics or on a hypothetical relationship between physical and psychological characteristics, such as temperament, personality, and a tendency to develop a specific type of mental disorder. See carus typology; kretschmer typology; sheldon’s constitutional theory of personality.

constrained association see controlled association.

constraint commitment see structural commitment.

construal n. a person’s perception and interpretation of attributes and behavior of the self or of others. See also independent self-construal; interdependent self-construal.

construct n. 1. a complex idea or concept formed from a synthesis of simpler ideas. See higher order construct. 2. an explanatory model based on empirically verifiable and measurable events or processes—an empirical construct—or on processes inferred from data of this kind but not themselves directly observable—a hypothetical construct. Many of the models used in psychology are hypothetical constructs. 3. in the study of social cognition, an element of knowledge (a cognitive construct).

constructural apraxia an impaired ability to re-create visual images as drawings or other forms of construction (e.g., blocks or puzzle pieces).

constructural praxis the ability to draw, copy, or manipulate spatial patterns or designs.

constructionism n. see constructivism.

constructive alternativism in the personality construct theory of George A. Kelly, the capacity to view the world from multiple perspectives, that is, to envision a variety of alternative constructs.

constructive conflict resolution the use of collaborative, salutary methods, such as bargaining, negotiation, accommodation, and cooperation, to resolve interpersonal or intergroup disagreements.

constructive confrontation an organizational development initiative in which employees gather to identify, analyze, and plan solutions to work-related problems. At
constructive coping

the heart of the method is a free and open discussion in which individuals can be frank without fear of punishment or blame.

**constructive coping** any instrumental approach to stress management that is generally considered to be adaptive or otherwise positive. Examples include planning and strategizing, seeking help and support from others, reframing the situation, and meditating. Constructive coping strategies are task relevant and action oriented and are divided into one of three categories: problem-focused coping, emotion-focused coping, and appraisal-focused coping. They rely on realistic assessments of stressors and available coping resources, and their use is associated with better physical and mental health outcomes than the use of other strategies (e.g., active coping, passive coping, defense mechanisms). Research suggests that constructive coping is likely to be used when stressors are of high intensity or when there is little negative emotional arousal generated in the context of the stressful experience or event.

**constructive memory** remembering conceived as involving the use of general knowledge stored in one’s memory to construct a more complete and detailed account of an event or experience by changing or filling in various features of the memory. See RECONSTRUCTIVE MEMORY; REPEATED REPRODUCTION.

**constructive obedience** compliance with the orders of a social authority that results in some benefit to the compliant individual or the larger society of which he or she is a part. Examples of constructive obedience include accident victims obeying the commands of emergency personnel and citizens adhering to laws within their communities, which reduces crime and makes neighborhoods safer, thus instilling a sense of security and well-being for individuals living within those neighborhoods. Compare Destructive Obedience.

**constructive play** a form of object play in which children manipulate materials in order to create or build objects, for example, making a sand castle or using blocks to build a house. Constructive play facilitates creativity, learning, and the development of motor and other skills.

**constructive theory of perception** any theory proposing that perceivers unconsciously combine information from a stimulus (such as a retinal image) with other information (such as apparent or expected distance and previous experience) to construct a perception.

**constructive thinking** the ability to solve problems in everyday life with minimal stress.

**Constructive Thinking Inventory (CTI)** a self-report measure of experiential intelligence, yielding scores on such dimensions as superstitious thinking, categorical thinking, naive optimism, and defensiveness. Designed for individuals ages 18 to 80 years, it consists of 108 self-statements about thoughts and behavior to which participants respond using a 5-point Likert scale format, ranging from definitely false to definitely true. [originally developed in 1989 by U.S. psychologist Seymour Epstein (1924–)]

**constructivism** n. the theoretical perspective, central to the work of Jean Piaget, that people actively build their perception of the world and interpret objects and events that surround them in terms of what they already know. Thus, their current state of knowledge guides processing, substantially influencing how (and what) new information is acquired. Also called **constructionism**. See also SOCIAL CONSTRUCTIVISM. Compare DIRECT PERCEPTION.—**constructivist adj.**

**Constructivist Learning Environment Survey (CLES)** a questionnaire consisting of 30 statements (e.g., “I help the teacher to assess my learning”) that students rate using a 5-point Likert scale format, ranging from almost never to almost always. It assesses the degree to which a particular classroom’s environment is consistent with a constructivist epistemology and helps teachers to reflect on their epistemological assumptions and reshape their teaching practice. [developed in the 1990s by Australian educators Peter Charles Taylor and Barry J. Fraser]

**constructivist psychotherapy** any psychotherapy approach that shares the theoretical perspective of CONSTRUCTIVISM and focuses on meaning-making to help clients reconceptualize their problems in a more life-enhancing way by using story, myth, poetry, and other linguistic and nonverbal forms. Constructivist psychotherapy began as an application of PERSONAL CONSTRUCT THEORY. See also NARRATIVE THERAPY; PERSONAL CONSTRUCT THERAPY.

**constructivist theory of emotion** any theory holding that emotions are not innate but constructed through social and cultural experience. See SOCIAL CONSTRUCTIVISM.

**construct validity** the degree to which a test or instrument is capable of measuring a concept, trait, or other theoretical entity. For example, if a researcher develops a new questionnaire to evaluate respondents’ levels of aggression, the construct validity of the instrument would be the extent to which it actually assesses aggression as opposed to assertiveness, social dominance, and so forth. A variety of factors can threaten the basic construct validity of an experiment, including (a) mismatch between the construct and its operational definition, (b) various forms of bias, and (c) various experimenter effects and other participant reactions to aspects of the experimental situation. There are two main forms of construct validity in the social sciences: CONVERGENT VALIDITY and DISCRIMINANT VALIDITY.

**consultant n.** 1. a mental health care or medical specialist called upon to provide professional advice or services in terms of diagnosis, treatment, or rehabilitation. 2. in the United Kingdom, a hospital doctor of the most senior rank in his or her field.

**consultee** n. **see** BEHAVIORAL CONSULTATION; MENTAL HEALTH CONSULTATION.

**consultee-centered consultation** see MENTAL HEALTH CONSULTATION.

**consulting** n. the use of the particular skill, experience, and expertise of an individual or group to advise individuals, groups, or organizations.

**consulting psychology** the branch of psychology that provides expert psychological guidance to business and industry, federal and state agencies, the armed forces, educational and scientific groups, religious groups, and volunteer and public service organizations. **Consulting psychologists** specialize in a variety of approaches—clinical, community, school, education, and industrial and organizational—and offer a wide variety of services, the most common of which are individual assessment, individual and group-process consultation, organizational development, education and training, employee selection and ap—
focuses on good decision making in personal money management and follow these acts. In obtaining, consuming, and disposing of economic goods and services, including the decision processes that precede the acts of individuals or groups. Also called consumer behavior and consumer psychology. Consumer research may include studies of consumer tastes and preferences, the influence of branding and package design, and the personality traits of a target audience. See also market research; motivation research.

corporate support for programs, services, and social activities offered in a nonclinical environment, with the ultimate goal of both empowering participants and reintegrating them into the greater community. It differs from a general drop-in center in that those who use the center also run its programs and assist the other people seeking help there. Such programs can include support groups, exercise classes, arts and crafts, excursions, guest speakers, access to and training on computers, employment services, personal and political advocacy, assistance with basic needs (e.g., laundry), and outreach programs.

corporate survey a survey of consumer likes and dislikes in certain product categories (e.g., beverages) that may yield information about designing and packaging a product in ways the consumer will find attractive. Consumer surveys may be conducted by questionnaires, in-depth interviews, group interviews, visualization, and similar techniques.

corporateism n. 1. the purchase and consumption of goods and services in amounts that exceed basic needs. Consumerism is often tied to the socioeconomic behavior of conspicuous consumption, whereby individuals acquire and display expensive goods as a means of obtaining or maintaining social status. See also ethical consumerism. 2. a movement to protect the rights of the consumer with regard to the quality and safety of available products and services (including psychotherapeutic and medical care). Consumers of mental health care have a number of clearly defined rights, including the right to know, confidentiality, to choice, to determination of treatment, to non-discrimination, to treatment review, and to accountability of treating professionals. Also called consumer activism.

—consumerist adj.

corporate jury technique a method of testing advertising appeals before an actual product promotion campaign is started in a test market. “Jury” members usually consist of typical consumers of the product category. They are shown a selection of proposed advertisements and asked to evaluate them in terms of which advertisement would be most likely to induce them to purchase the product. The consumer-jury technique has been found to be an accurate predictor of advertising effectiveness. See also continuous panel.

corporate neuroscience see neuromarketing.

corporate psychology the branch of psychology that studies the behavior of individuals as consumers and the marketing and communication techniques used to influence consumer decisions. Consumer psychologists investigate the psychological processes underlying consumer behavior and responses to both for-profit and not-for-profit marketing.

contact comfort the positive effects experienced by in-
contact desensitization

A variation of systematic desensitization involving participant modeling instead of relaxation training, used especially in the treatment of anxiety. The therapist demonstrates appropriate behaviors, beginning with those in the weakest anxiety-provoking situation for the client, and then assists the client in performing such behaviors. For example, in working with a client who is afraid of spiders, the therapist might first sit near a spider, then touch the spider, and then pick it up while the client observes. The client, with the guidance and assistance of the therapist, would then perform the same activities in the same order.

contact hypothesis

The proposition that interaction among people belonging to different groups will reduce intergroup prejudice. Research indicates that the prejudice-alleviating effects of contact are robust across many situations, but that they are strengthened when the people from the different groups are of equal status, are not in competition with each other, and do not readily categorize the others as very different from themselves. Also called intergroup-contact hypothesis.

contact language

An improvised system of communication, such as a pidgin, that emerges in situations of contact between speakers of different languages. Contact languages are usually characterized by a restricted lexicon, simplified sentence structures, and the absence of complex grammatical inflections.

contagion

See Social Contagion.

containment

In object relations theory, the notion that either the mother or the analyst aids growth and alleviates anxieties by acting as a “container,” or “holding environment,” for projected aspects of the child’s or patient’s psyche (see projection). For instance, the infant, overwhelmed by distress and having no context to understand the experience, is held and soothed by the parent, who thus creates a safe context for the child and endows the experience with meaning. The psychoanalyst does this metaphorically by helping the patient reduce the anxiety to tolerable levels.

contamination

1. In testing and experimentation, the situation in which prior knowledge, expectations, or other factors relating to the variable under study are permitted to influence the collection and interpretation of data about that variable. 2. The mixing together of two or more discrete percepts, such as might occur on the rogerschach inrblot test or the mackovec draw-a-person test. 3. The creation of a neologism by combining a part of one word with a part of another, usually resulting in a word that is unintelligible.

contamination obsession

An intense preoccupation with disease, dirt, germs, mud, excrement, sputum, and so forth, based on a feeling that the world is disgusting, decaying, and dying. It is a frequent symptom of obsessive-compulsive disorder, and, in extreme cases, it is regarded as a symptom of schizophrenia.

contemporaneity

In psychotherapy, the principle of focusing on immediate experience. See also Here and Now.

contempt

An emotion characterized by negative regard for anything or anybody considered to be inferior, vile, or worthless. —contemptuous adj.

content

In psychology and psychotherapy, the actual thoughts, images, and emotions that occur in conscious experience. Thus, content may be contrasted with the mental processes or the neural structures that underlie them.

content-addressable store

A model of memory, borrowed from computer science, in which a memory is stored and retrieved based on representation of its contents rather than by an arbitrary tag. Knowledge or memory is represented by values along certain dimensions, such as temporal (e.g., last summer) or semantic (a vacation); an effective retrieval cue using the same values along those dimensions will access the information stored.

content analysis

1. A systematic, quantitative procedure for coding the themes in qualitative material, such as projective-test responses, propaganda, or fiction. 2. A systematic, quantitative study of verbally communicated material (e.g., articles, speeches, films) by determining the frequency of specific ideas, concepts, or terms. Also called quantitative semantics.

Contention Scheduling System

(CSS) In the control of action model, a cognitive mechanism that is held to be active in routine situations where decision making and other executive functions are not required. Perceptual triggers are held to activate previously learned schemas that correspond to habitual tasks and actions, which are thus selected for performance. Compare supervisory attentional system. [described in 1980 by U.S. cognitive scientist Donald A. Norman (1935–) and British neuropsychologist Timothy Shallice (1940–)].

contentiousness

A tendency toward disputes and strife; quarrelsomeness. Contentiousness may be observed in mania and in the early stages of predominantly persecutory delusional disorders when individuals perceive that they are being treated unfairly.

content psychology

An approach to psychology that is concerned with the role of conscious experience and the content of that experience. The term is mainly applied to early structuralism. Compare act psychology.

content-referenced test

See criterion-referenced test.

contents of consciousness

See consciousness.

content-thought disorder

A type of thought disturbance, typically found in schizophrenia and some other mental disorders (e.g., obsessive-compulsive disorder, mania), characterized by multiple fragmented delusions.

contentual objectivism versus contextual subjectivism

The question of whether the proper subject matter (content) of psychology is objective behavior or the subjective realm of the mind or consciousness. This question is often seen as the principal issue at stake in the conceptual confrontation between structuralism and behaviorism in the early history of psychology. See also methodological objectivism versus methodological subjectivism.

content validity

The extent to which a test measures a representative sample of the subject matter or behavior under investigation. For example, if a test is designed to
items or material that an organism is exposed to and the context or circumstance in which that exposure occurs. For instance, a lecture may be associated with the classroom in which it occurs: That contextual association facilitates retrieval, so recall of the lecture should be better in the classroom than outside it.

**contextual interference effect** an effect on learning that may occur when training occurs in different contexts or when trials on one task are alternated with those on a different task. Learning is slowed by changing contexts or by intervening tasks, but the knowledge is more enduring and more readily transferable to different tasks or domains.

**contextualism** n. 1. the theory that memory and learning are not the result only of linkages between events, as in the associationist doctrine, but are also due to the meaning given to events by the context surrounding the experiences. 2. a worldview asserting that the environment in which an event occurs intrinsically informs the event and its interpretation.

**contextualize** vb. to interpret an event within a preexisting mental framework. —**contextualization** n.

**contextual subtheory** a part of the **triarchic theory of intelligence** according to which factors in the environment affect both an individual’s intelligence and what constitutes an intelligent response to a given situation. The subtheory postulates that people are intelligent in context to the extent that they effectively adapt to, shape, and select environments.

**contiguity** n. the co-occurrence of stimuli in time or space. Learning an association between two stimuli is generally thought to depend at least partly on the contiguity of those stimuli. See **association by contiguity**, **law of contiguity**. —**contiguous** adj.

**contiguity learning theory** a theory stating that if a pattern of stimulation and a response occur together in time and space, learning occurs by the formation of associations between them, so that the same stimulus pattern will elicit the same response on subsequent occasions. See also S–R PSYCHOLOGY. [proposed by Edwin R. Guthrie]

**contiguity of association** see **association by contiguity**.

**contiguity principle** see **law of contiguity**.

**continence** n. the ability to control sexual urges or the urge to defecate or urinate. —**continent** adj.

**continental philosophy** a loose designation for philosophical developments originating in continental Europe from the middle of the 20th century, encompassing such movements as **phenomenology**, **existentialism**, **structuralism**, and **deconstruction**. Continental philosophy is often contrasted with the Anglo-American tradition of **analytic philosophy**.

**contingencies of self-worth** particular areas of life in which people invest their **self-esteem**, such that feedback regarding their standing or abilities in these domains has a strong effect on their self-concept. Research indicates that people choose to stake their self-esteem in different domains, so that for some people material or professional success is vital to their sense of self-worth, whereas for others this is much less important than being well liked or sexually attractive. Also called **contingencies of self-esteem**. [first described in 2001 by U.S. psychologist Jennifer Crocker (1952–)]
contingency

contingency n. a conditional, probabilistic relation between two events. When the probability of Event B given Event A is 1.0, a perfect positive contingency is said to exist. When Event A predicts with certainty the absence of Event B, a perfect negative contingency is said to exist. Probabilities between −1.0 and 1.0 define a continuum from negative to positive contingencies, with a probability of 0 indicating no contingency. Contingencies may be arranged via dependencies or they may emerge by accident (see accidental reinforcement). See also LAW OF CONTINGENCY; REINFORCEMENT CONTINGENCY.

contingency awareness 1. awareness of a relationship or connection between two occurrences. See CO-OCCURRENCE. 2. awareness of the dependence of one variable on another. See CORRELATION.

contingency contract a mutually agreed-upon statement between a teacher and student, a parent and child, or a client and therapist regarding the change or changes desired, typically specifying behaviors and their positive and negative consequences.

contingency-governed behavior behavior that is directly and solely the result of reinforcement contingencies. It occurs without deliberation. Compare rule-governed behavior.

contingency management in behavior therapy, a technique in which a reinforcement, or reward, is given each time the desired behavior is performed. This technique is particularly common in substance abuse treatment.

contingency model any theory or model based on the generalization that there is no universal, ideal approach to structuring organizations and managing people. Rather, the most effective approach will depend on factors such as the nature of the task, the culture and environment of the organization, and the characteristics of the people involved. Also called situational approach. See also CONTINGENCY THEORY OF LEADERSHIP.

contingency table a two-dimensional table in which frequency values for categories of one variable are presented in the rows and values for categories of a second variable are presented in the columns. Values that appear in the various cells then represent the number or percentage of cases that fall into the two categories that intersect at this point. For example, the sex and geographical locations of a sample of individuals applying for a particular job may be displayed in a contingency table. Thus, the number of women from Los Angeles would be given, the number of men from Los Angeles would be given, the number of women from New York City would be given, and so on. Also called cross-classification table.

contingency theory of leadership any of various models predicting that leadership performance depends on the interaction of the personal characteristics of the leader and the nature of the group situation. The prototypical contingency theory emerged from the conceptual analysis of leadership effectiveness developed by Fred Fiedler in the 1960s. Fiedler’s model differentiates between task-motivated and relationship-motivated leaders, as indicated by scores on the LEAST PREFFERED COWORKER SCALE, and predicts that task-motivated leaders will be most effective in extremely favorable or unfavorable group settings, whereas relationship-motivated leaders will be more effective in moderately favorable settings. Other models of this kind include the SITUATIONAL LEADERSHIP THEORY, the SUBSTITUTES FOR LEADERSHIP THEORY, and the VROOM–YETTON–JAGO DECISION MODEL. See also COGNITIVE RESOURCE THEORY.

contingent adj. dependent on circumstances, events, or conditions. See also CONTINGENCY.

contingent aftereffect an altered visual perception in which one stimulus dimension (e.g., color) depends on a separate stimulus dimension (e.g., orientation). The McCollough effect is an example in which repeated serial exposure to horizontal red bars followed by vertical green bars induces an aftereffect of horizontal white bars appearing green and vertical white bars appearing red. The color of the aftereffect is contingent on the orientation of the test stimulus.

contingent negative variation (CNV) a slow EVENT-RELATED POTENTIAL that is recorded from the scalp. A CNV arises in the interval between a warning signal and a signal that directs action and is indicative of readiness or expectancy. Also called expectancy wave. See also EVOKED POTENTIAL.

contingent probability the probability, expressed as a number between 0 and 1, that one event or category of outcome will occur if another one does. An example is the probability that the child of a drug user will become a drug user himself or herself. Unusually high or low contingent probabilities (compared to the general population) may, but do not necessarily, imply a causal relationship between the two events.

contingent reinforcement the process or circumstances in which the delivery of positive stimulus events (e.g., material goods, verbal praise) and, more rarely, the elimination of negative stimulus events (e.g., penalties) depend on the performance of desired behavior. In leadership and management, the term is applied to any approach in which a leader relies on rewards and penalties to motivate his or her followers. Also called contingent reward.

continuance commitment that element of an employee’s ORGANIZATIONAL COMMITMENT that can be attributed to the cost, inconvenience, or difficulty of changing employers. Compare AFFECTIVE COMMITMENT.

continued-stay review (CSR) a UTILIZATION REVIEW in which an internal or external auditor determines if continued inpatient care is medically necessary or if the current health care facility is still the most appropriate to provide the level of care required by the patient. See also CONCURRENT REVIEW; EXTENDED-STAY REVIEW.

continuing bond the emotional attachment that a bereaved person continues to maintain with the deceased long after the death. The increasingly influential continuing-bond approach to the bereavement process focuses on ways in which the emotional and symbolic relationship with the deceased can be reconstructed and integrated into the bereaved’s life. This approach is in contrast to the view, particularly prevalent following Sigmund Freud’s 1917 essay “Mourning and Melancholia,” that successful mourning must necessarily involve the bereaved’s complete emotional detachment from the deceased. See also GRIEF WORK; MOURNING; OBJECT LOSS. [introduced by Dennis Klass, Phyllis R. Silverman, and Steven L. Nickman in their 1996 edited volume, Continuing Bonds: New Understandings of Grief].

continuing care retirement community (CCRC) a facility that offers a range of services and living arrange-
ments that older adult residents can use as the need arises. A full spectrum of such services and arrangements might include independent living arrangements for the healthy and comparatively healthy; access to on-site nursing care and other medical services for those temporarily ill, recovering from surgery, or returning from an extended stay in a hospital or rehabilitation facility; and terminal care for the dying.

**continuing care unit (CCU)** a hospital unit to which a patient with a catastrophic or chronic illness is transferred for additional care after the acute hospitalization period. Compare INTENSIVE CARE UNIT. See also SKILLED NURSING FACILITY.

**continuing education** 1. a subset of ADULT EDUCATION in which an adult updates or augments a previously acquired skill set, knowledge base, or area of expertise. 2. a requirement imposed by PROFESSIONAL LICENSING bodies for the purpose of ensuring that professionals stay current with new developments in their field and maintain competence to practice.

**continuing medical education (CME)** postdoctoral educational activities that serve to develop or extend the knowledge, skills, and professional qualities that a physician uses to provide health care services.

**continuity n.** the quality or state of being unending or connected into a continuous whole. For example, the traditional concept of continuity of care implies the provision of a full range of uninterrupted medical and mental health care services to a person throughout his or her lifespan, from birth to death, as needed.

**continuity hypothesis** 1. the assumption that successful DISCRIMINATION LEARNING or problem solving results from a progressive, incremental, continuous process of trial and error. Responses that prove unproductive are extinguished, whereas every reinforced response results in an increase in ASSOCIATIVE STRENGTH, thus producing the gradual rise of the LEARNING CURVE. Problem solving is conceived as a step-by-step learning process in which the correct response is discovered, practiced, and reinforced. Compare DISCONTINUITY HYPOTHESIS. 2. the contention that psychological processes of various kinds (e.g., learning, childhood development) take place either in small steps or continuously, rather than in jumps or discontinuously from one identifiable stage to another. Also called continuity theory.

**continuity of germ plasm** see GERM PLASM.

**continuity theory** 1. a theory proposing that people generally maintain the same personality style, activity level, interests, and social roles as they age. Compare ACTIVITY THEORY; DISENGAGEMENT THEORY. 2. see CONTINUITY HYPOTHESIS.

**continuity versus discontinuity** the scientific debate over whether developmental change is gradual (continuous) or relatively abrupt (discontinuous).

**continuous adj.** describing a variable, score, or distribution that can take on any numerical values within its range. Compare DISCONTINUOUS; DISCRETE. See also CONTINUOUS VARIABLE.

**continuous avoidance** see SIDMAN AVOIDANCE SCHEDULE.

**continuous control** in ergonomics, a control device operated by continuous movements, such as a computer mouse used to move a cursor on a screen, as opposed to a discrete control device, such as an on-off switch or the like. See also ISOMETRIC CONTROL; ISOTONIC CONTROL.

**continuous distractor task** a test of memory retention in which a continuous string of items to be remembered is presented: Every few items, the participant is presented with one of the items previously presented and must remember the item following it, while also retaining the other items in sequence. A continuous distractor task contrasts with a study-trial/test-trial procedure.

**continuous distribution** a DISTRIBUTION in which values can occur anywhere along an unbroken continuum. An example would be any distribution showing variation in human height or weight. A continuous distribution can be plotted as a single smooth line, and it may be used to display the likelihood of specific values occurring (a continuous probability distribution) or the actual number of times they have been observed to occur, such as in a research sample (a continuous frequency distribution). Compare DISCRETE DISTRIBUTION. See also CONTINUOUS VARIABLE.

**continuous group** see OPEN GROUP.

**continuous improvement** see TOTAL QUALITY MANAGEMENT.

**continuous movement task** a purposeful movement that has no recognizable beginning or end—the behavior continues until it is arbitrarily stopped. Examples include cross-country running and steering a car. Compare DISCRETE MOVEMENT TASK.

**continuous operations (CONOPS)** military operations conducted without interruption, which require strict discipline, planning, time management, and coordination. They may cause sleep loss and affect ability to perform operational tasks.

**continuous panel** a form of consumer jury in which members serve on a more or less permanent basis so that consumer psychologists can detect shifts in attitudes, values, or behavior (see CONSUMER-JURY TECHNIQUE). The panel members are carefully selected to represent the demographic or psychographic characteristics of a population, and they are tested periodically for signs of psychic mobility that may also represent attitude changes in the general population.

**continuous performance test (CPT)** any test that measures sustained attention and concentration, usually by requiring responses to an auditory or verbal target stimulus while ignoring nontarget stimuli.

**continuous rating scale** a scale on which ratings are assigned along a continuum (e.g., a line) rather than according to categories. Such ratings are made by making a mark on the scale to indicate the exact “placement” of the rating or by assigning a precise numerical value. Also called continuous scale.

**continuous recognition task** a memory task in which a series of items is presented, with some items presented on multiple occasions in the series. The participant responds to each item by indicating whether it is old (seen previously in the series) or new (not seen earlier in the series).

**continuous reinforcement** (CRF) in operant and instrumental conditioning, the REINFORCEMENT of every correct (desired) response. It is identical to a fixed-ratio 1...
continuous spectrum

schedule of reinforcement (see **fixed-ratio schedule**). Also called **continuous reinforcement schedule**: **continuous schedule of reinforcement**.

**continuous spectrum** see **sound spectrum**.

**continuous variable** a variable that may in theory have an infinite number of possible values. For example, time is a continuous variable because accurate instruments will enable it to be measured to any subdivision of a unit (e.g., 1.76 seconds). By contrast, number of children is not a continuous variable as it is not possible to have 1.76 children. In practice, a continuous variable may be restricted to an artificial range by instrumentation constraints, practical limitations, or other reasons. For example, a researcher assessing the influence of a new technique on student study time may only be able to observe a group of individuals for 1 hour per day, such that the range of time in the data he or she collects may span 0 minutes to 60 minutes, even though some people will in actuality have exceeded that upper figure. Compare **discontinuous variable**.

**continuum approach** an approach based on the view that behavior ranges over a continuum from effective functioning to severe abnormality. It assumes that differences between people’s behavior are a matter of degree rather than kind.

**continuum of care** provision over a period of time of continuous, comprehensive, and integrated care that involves health, mental health, and social services—in the home, a health care setting, or the community—at the appropriate level of intensity. The wide range and levels of available services in a continuum of care allow for adjustments to be made in treatment when the patient or client improves (e.g., during successful drug addiction treatment) or worsens (e.g., as the health of a terminally ill patient declines).

**contra-** prefix against or opposing.

**contraception** n. any method intended to prevent conception, that is, the natural fertilization of the female ovum by the male spermatozoa. See **birth control**. —**contraceptive** n., adj.

**contract** n. an explicit written agreement between parties or individuals. A contract between a client and therapist may detail (a) both the client’s and the therapist’s obligations, (b) the provisions for benefits or privileges to be gained through achievements, and (c) the specified consequences of failures (e.g., missing sessions). See also **behavior contract**; **contingency contract**.

**contractility** n. the capacity of living tissue, particularly muscle, to contract in response to a stimulus. Also called **contractibility**.

**contraction** n. 1. a shortening or tensing of a group of muscle fibers. See **muscle contraction**. 2. in linguistics, a word formed by combining two or more words and eliminating some of the letters or sounds. For example, **don’t** is a contraction of the words **do** and **not**.

**contract plan** a plan used in some schools in which a student signs a contract agreeing to change a certain behavior, such as raising a grade in a class. The contract enhances accountability for behavior; it often carries with it a reward for completion and sometimes a **response cost** for failure to perform.

**contracture** n. an abnormal shortening or tightening of a muscle, which can result in permanent disability due to difficulty in stretching the muscle. A contracture often follows a disorder or injury that makes movement painful or is a consequence of prolonged, enforced inactivity (e.g., a coma).

**contradictory representation** a condition in which one mental image prevents another from occurring owing to conflict between the two images. For example, it is impossible to hold an image of the same object as both round and square. The effect of contradictory representation is to inhibit further mental activity of which the image in question is an essential part.

**contralateral** adj. situated on or affecting the opposite side of the body. For example, motor paralysis occurs on the side of the body contralateral to the side on which a brain lesion is found. Compare **ipsilateral**. —**contralaterally** adv.

**contralateral control** the arrangement whereby the **motor cortex** of each cerebral hemisphere is mainly responsible for control of movements of the contralateral (opposite) side of the body.

**contralateral deficit** see **ipsilateral deficit**.

**contralateral eye** the eye located on the opposite side of the body to another structure or object. For example, Layer 6 of the left **lateral geniculate nucleus** receives input from the **retinal ganglion cell** axons that originate in the right (i.e., contralateral) eye. Compare **ipsilateral eye**.

**contralateral hemisphere** the **cerebral hemisphere** on the opposite side of the body from any organ or part that is being considered as the reference point. See also **contralateral control**.

**contraprepared learning** see **preparedness**.

**contrast** n. 1. that state in which the differences between one percept, thing, event, or idea and another are emphasized by a comparison of their qualities. This may occur when the stimuli are juxtaposed (**simultaneous contrast**) or when one stimulus immediately follows the other (**successive contrast**). For example, meeting a person in a social context that includes physically attractive people could lead to a more negative evaluation of the attractiveness of that person than would have been the case otherwise. The evaluation of the person’s attractiveness has been contrasted away from the social context. Compare **assimilation**. 2. in statistics, see **comparison**.

**contrast analysis** 1. comparisons between two or more groups that address specific questions about the patterning of the **means** of these groups. 2. a focused analysis of data that is designed to determine the specific degree to which obtained data agree with predicted data (i.e., to which they support a hypothesis or theory). Contrast analysis yields an estimate of **effect size** and an associated level of significance for each contrast computed.

**contrast coding** in **analysis of variance** and **multiple regression**, a method of assigning weights to values so that specific comparisons of interest can be made. To ensure the statistical independence of the particular quantities being evaluated, the process requires that the weights in each comparison sum to 0. For example, consider a researcher investigating four different methods for teaching course content. If he or she wanted to compare the average performance of the first group to the average performance of the remaining three groups, the investigator would
apply contrast weights of +3, −1, −1, and −1 to the respective group means. If, however, he or she wanted to compare the average performance of the first group to the average performance of the fourth group, the investigator instead would apply contrast weights of +1, 0, 0, and −1 to the respective group means. Also called orthogonal coding. Compare dummy variable coding; effect coding.

contrast detector 1. any of the RETINAL GANGLION CELLS that are sensitive to contrast (i.e., light–dark borders). See also feature detector. 2. any structure, neural or theoretical, that is sensitive to contrast.

contrast effect 1. the perception of an intensified or heightened difference between two stimuli or sensations when they are juxtaposed or when one immediately follows the other. Examples include the effect produced when a trombone follows a violin or when bright yellow and red are viewed simultaneously. 2. in psychology experiments, an effect in which participants’ judgments shift away from an anchor after it is introduced. Compare assimilation effect.

contrast error a type of rating error in which the evaluation of a target person in a group is affected by the level of performance of others in the group. When the others are high in performance, there may be a tendency to rate the target lower than is correct. When the others are low in performance, there may be a tendency to rate the target higher than is correct.

contrast illusion a class of visual illusions in which the degree of a stimulus attribute, such as perceived size, color, brightness, or angle, is affected by the presence of additional stimuli that differ in the same attribute. For example, a small circle at the center of many large circles will appear to be smaller than the same circle at the center of many smaller circles.

contrastive analysis in linguistics, a comparison of the structures of two languages, usually with the goal of providing insight into effective second- or foreign-language instruction. See also language transfer.

contrastive rhetoric in linguistics, the theory that different languages have different rhetorical characteristics, as seen, for example, in the different ways they structure and present an argument. The idea of contrastive rhetoric has been much discussed in the field of second-language teaching, especially at the more advanced levels. It is said to explain, for example, why native speakers will often feel that there is something odd or “wrong” about essays, business letters, and so on produced by nonnative speakers, even when the grammar and vocabulary are flawless. Contrastive rhetoric has sometimes been linked to the wider hypothesis that languages embody culture-bound thought patterns (see linguistic determinism). [Introduced in 1966 by U.S. applied linguist Robert B. Kaplan]

contrast polarity the degree of contrast between two visual elements, particularly figure and background. Contrast can be positive (light objects against dark backgrounds, e.g., a white letter printed upon black paper) or negative (dark objects against light backgrounds, e.g., a black letter printed upon white paper).

contrast sensitivity a measure of spatial resolution based on an individual’s ability to detect subtle differences in light and dark coloring or shading in an object of a fixed size. Detection is affected by the size of contrasting elements and is usually tested using a grating of alternating light and dark bars, being defined by the minimum contrast required to distinguish that there is a bar pattern rather than a uniform screen. Contrast sensitivity is less for both coarse and fine gratings than it is for gratings of intermediate frequency. Humans have peak contrast sensitivity for gratings with 4 to 8 cpd (cycles per degree) and can detect contrast over a range from about 0.5 cpd to 50 to 60 cpd. Contrast sensitivity can be reduced after injury to the peripheral or central visual system: Patients complain of visual blurring, although visual acuity may be only moderately affected. Also called spatial contrast sensitivity. See also spatial frequency.

contrast-sensitivity function (CSF) a graphical representation of contrast sensitivity as a function of spatial frequency. The CSF for normal humans peaks at about 4 to 8 cpd (cycles per degree).

contravolitional adj. against the wishes of an individual or beyond his or her control.

contrecoup n. brain injury on one side of the head resulting from a blow to the opposite side.

contributing cause a cause that is not sufficient to bring about an end or event but that helps in some way to bring about that end or event. A contributing cause may be a necessary condition or it may influence events more indirectly by affecting other conditions that make the event more likely.

control n. 1. authority, power, or influence over events, behaviors, situations, or people. Researchers have hypothesized a need for control, and they also distinguish between primary control and secondary control. 2. the regulation of all extraneous conditions and variables in an experiment so that any change in the independent variable can be attributed solely to manipulation of the independent variable and not to any other factors. 3. see statistical control.

control adoptees see cross-fostering.

control analysis psychoanalytic treatment conducted by a trainee under the guidance of a qualified psychoanalyst, who helps the trainee decide the direction of the treatment and become aware of his or her countertransference. Also called supervised analysis; supervisory analysis.

control condition in an experiment or research design, a condition that does not involve exposure to the treatment or intervention under study. For example, in an investigation of a new drug, participants in a control condition may receive a pill containing some inert substance, whereas those in the experimental condition receive the actual drug of interest.

control device the mechanism that allows the operator of an environmental control device to transmit instructions to a target device to perform a function. See also feedback device; switch device.

control discriminability in ergonomics, the ease with which a control can be distinguished from other controls or objects on the interface and matched correctly to the effect that its activation or use will have on the system. The discriminability of a control will be a function of size, shape, color, and other design features.

control–display ratio in ergonomics, the ratio between the distance that a control or input device (e.g., a computer mouse) is moved by the operator and the conse-
control experiment

A follow-up experiment designed to check that the findings of an initial study were in fact caused by the factor under investigation and not by some other variable. For example, consider a case in which initial research appeared to demonstrate the beneficial effect of a new treatment for depression. To confirm these results a control experiment might be devised in which a similar group of individuals was tracked to find the number of individuals whose depression was alleviated without use of the treatment.

Control function logic in ergonomics, a logical or typical and expected relationship between the operation of a control or input device and the resulting action or effect on a display. For example, if a person moves a computer mouse to the left, the on-screen cursor should also move to the left to preserve control function logic. See also display-control compatibility.

Control group a comparison group in a study whose members receive either no intervention at all or some standard and systematic conditions rather than casual or potential consumer responses.

Controlled experiment A method of choosing cases for research in which certain characteristics are considered undesirable and the probability of their being selected is therefore minimized. For example, an educational researcher may need to adjust his or her sampling technique if certain subsets of students are costly to find or if their obtained data may exert undue influence upon study results or otherwise present logistical difficulties.

Controlled Substances Act (CSA) the section of the Comprehensive Drug Abuse Prevention and Control Act of 1970 regulating the manufacture and use of certain drugs specified in five schedules as having abuse and dependence potential. See scheduled drug.

Controlled trial A study in which patients with a particular condition, disease, or illness are assigned either to a treatment group, which receives the new intervention under investigation, or to a control group, which receives either no intervention or some standard intervention already in use. If individuals are allocated to the different groups at random, then the design is a randomized clinical trial. Also called comparative trial.

Controlling goal A goal, usually set by others, that must be achieved in order to receive an extrinsic reward.

Control-mastery theory 1. A perspective, underlying an integrative form of psychotherapy, that focuses on changing a client’s unconscious and maladaptive beliefs developed in childhood due to thwarted attempts to achieve attachment and safety in the client's family. The client is seen to have an inherent motivation toward health that results in testing these beliefs through transference and through passive-into-active behaviors; when such testing is productive, the client is then free to pursue adaptive goals. [Developed by U.S. psychiatrist Joseph Weiss] 2. An integrative approach to child development that focuses on thoughts, feelings, and behaviors resulting from children’s needs for attachment and safety in the family.

Control of action model A cognitive model in which action selection is held to be controlled by two distinct processes: the contention scheduling system, which makes choices between routine functions that are performed automatically, and the supervisory attentional system, which is required in nonroutine situations involving decision making and other executive functions. Also called attentional control of action model: Norman and Shallice model. [Proposed in 1980 by U.S. cognitive scientist Donald A. Norman (1935— ) and British neuropsychologist Timothy Shallice (1940— )]

Control order in ergonomics, the specific type of relationship between the operation of a control or input device and the resulting action or effect on a display. For example, a joystick may have either position or velocity control over cursor movements on a monitor.

Control procedure A procedure applied before commencing a study in order to equate participants with regard to some variable that is not of research interest but nonetheless may influence the outcome. Matching is an example of a control procedure.

Control processes Those processes that organize the flow of information in an information-processing system. See also cognitive control; executive.

Control question test (CQT) A technique used in pol-
conversational maxims

YGRAPH testing, typically for criminal investigations. In addition to questions relevant to the crime and general questions to get a baseline pattern of physiological responses (i.e., irrelevant questions), the CQT also includes questions about past behavior (e.g., “Have you ever cheated on your taxes?”) with the aim of eliciting strong physiological reactions on the part of examinees. See ZONE OF COMPARISON TEST; RELEVANT–IRRELEVANT TEST.

control theory 1. the idea that people regulate their behavior through repeated cycles of comparing their current state to a standard and acting to reduce discrepancies. [first proposed in 1982 by U.S. social psychologists Charles S. Carver (1947– ) and Michael Scheier] 2. a field of mathematics and engineering dealing with monitoring and controlling the behavior of certain physical processes and systems to produce the desired or best outcome.

control variable a variable that is considered to have an effect on the response measure in a study but that itself is not of particular interest to the researcher. To remove its effects a control variable may be held at a constant level during the study or managed by statistical means (e.g., a PARTIAL CORRELATION). Also called controlled variable.

controversial child see SOCIOMETRIC STATUS.

contusion n. a bruise. For example, various kinds of head injury can result in CEREBRAL CONTUSION.

convalescent center see SKILLED NURSING FACILITY.

convenience sampling any process for selecting a sample of individuals or cases that is neither random nor systematic but rather is governed by chance or ready availability. Interviewing the first 50 people to exit a store is an example of convenience sampling. Data obtained from convenience sampling do not generalize to the larger population; there may be significant SAMPLING BIAS, and SAMPLING ERROR cannot be estimated. Also called accidental sampling; opportunity sampling.

conventional antipsychotic see ANTIPSYCHOTIC.

conventionalism n. a personality trait marked by excessive concern with and inflexible adherence to social customs and traditional or accepted values and standards of behavior. The term is also used to refer specifically to one of the traits associated with the AUTHORITARIAN PERSONALITY.

conventional level in KOLBERG’S THEORY OF MORAL DEVELOPMENT, the intermediate level of moral reasoning, characterized by an individual’s identification with and conformity to the expectations and rules of family and society; the individual evaluates actions and determines right and wrong in terms of other people’s opinions. This level is divided into two stages: the earlier interpersonal concordance (or good-boy-nice-girl orientation; Stage 1 in Kohlberg’s overall theory), in which moral behavior is that which obtains approval and pleases others; and the later law-and-order (or authority and social order maintaining) orientation (Stage 4), in which moral behavior is that which respects authority, allows the person to do his or her duty, and maintains the existing social order. Also called conventional morality. See also PRECONVENTIONAL LEVEL; POSTCONVENTIONAL LEVEL.

convergence n. the rotation of the two eyes inward toward a light source so that the image falls on corresponding points on the foveas. Convergence enables the slightly different images of an object seen by each eye to come together and form a single image. The muscular tension exerted is also a cue to the distance of the object from the eyes.

convergence theory a conceptual analysis of COLLECTIVE BEHAVIOR that assumes that MORE; SOCIAL MOVEMENTS, and other forms of mass action occur when individuals with similar needs, values, goals, or personalities come together.

convergent evolution the tendency of unrelated organisms in a particular environment to evolve superficially similar body structures that enable them to adapt effectively to their habitat. Thus, many aquatic animals acquire a streamlined form and smooth surfaces for rapid movement through water. See also HOMOPLASY. Compare DIVERGENT EVOLUTION.

convergent production the capacity to produce the right answer to a question or to choose the best solution to a problem. It is one of the abilities recognized in the STRUCTURE OF INTELLECT MODEL. Compare DIVERGENT PRODUCTION.

convergent strabismus see CROSS-EYE; STRABISMUS.

convergent thinking critical thinking in which an individual uses linear, logical steps to analyze a number of already formulated solutions to a problem to determine the correct one or the one that is most likely to be successful. Compare DIVERGENT THINKING. [defined in 1967 by Joy Paul GUILFORD]

convergent validity the extent to which responses on a test or instrument exhibit a strong relationship with responses on conceptually similar tests or instruments. This is one of two aspects of CONSTRUCT VALIDITY, the other being DISCRIMINANT VALIDITY. Also called congruent validity.

conversation n. the use of speech to communicate ideas and information between or among people. Conversations arise flexibly in response to such elements as topic, private and public goals, rhetorical devices, temporal constraints, and individual speaking styles. Conversations proceed only through the mutual belief that the addressee has understood the speaker well enough for immediate purposes. Forms of this type of verbal exchange include small talk, gossip, repartee, debate, and negotiation, among others.

—conversational adj.

conversational inference the process by which people engaged in a conversation can frequently infer the meanings intended by the other speakers, even when these are unstated or implicit. Such inferences will be based partly on a knowledge of the personal background and general context but more importantly on an awareness of conversational norms within a particular culture and the expectations that these create. Conversational inference does not depend on logical inference. For example, if a speaker says My boss has been sober all week, most listeners will understand that this person is frequently drunk, even though such an inference is not valid in logic. The listeners will assume, probably correctly, that such a statement would not be made in such a form unless it reflected an exceptional, rather than the usual, state of affairs. See also IMPICATURE; INDIRECT SPEECH ACT.

conversational maxims the four basic rules governing interpersonal communications. The rules state that such communications should be (a) truthful; (b) as informative as is required; (c) relevant to the matter under discussion; and (d) clear, orderly, and brief. Violations of these
conversational repair

maxims are usually presumed to be deliberate or indicative of a cognitive disturbance. [introduced by British-born U.S. philosopher H. Paul Grice (1913–1988)]

conversational repair see REPAIR.

conversation analysis 1. a specialty within DISCOURSE ANALYSIS that focuses upon casual discussions as well as other more formal, extended verbal exchanges between two or more speakers. 2. in ergonomics, a method of evaluating a system or product that involves the examination of conversations occurring between two or more users interacting with it. Conversation analysis can be either qualitative or quantitative. It is a form of KNOWLEDGE ELICITATION.

converse accident a type of informal FALLACY or a persuasive technique that involves arguing from a qualified position or particular case to an unqualified and general rule. For example, because patients with certain illnesses are permitted to use marijuana, marijuana use should be legal for everyone. In empirical research, the same fallacy can result from drawing conclusions from data based on small or nonrepresentative samples. Also called hasty generalization.

conversion n. 1. in psychoanalytic theory, an unconscious process in which anxiety generated by psychological conflicts is transformed into physical symptoms. Traditionally, this process was presumed to be involved in CONVERSION DISORDER, but current diagnostic criteria for the disorder do not include such an implication. 2. actual change in an individual’s beliefs, attitudes, or behaviors that occurs as a result of SOCIAL INFLUENCE. Unlike COMPLIANCE, which is outward and temporary, conversion occurs when the targeted individual is personally convinced by a persuasive message or internalizes and accepts as his or her own the beliefs expressed by other group members. Also called private acceptance. See also CONFORMITY. 3. the movement of all members of a group to a single, mutually shared position, as when individuals who initially offer diverse opinions on a subject eventually come to share the same position. See GROUP POLARIZATION. 4. the process by which a person comes to embrace a new religious faith (or, sometimes, a more intense version of his or her existing belief). For example, a nonbeliever who becomes Catholic has experienced a conversion, as has a member of a minority religion who adopts the beliefs of a more mainstream faith. In Protestant traditions, conversion is often seen as a sudden transformation in which a person apparently undergoes a dramatic change in his or her personality, values, and lifestyle. Compare DECONVERSION. —convert vb.

conversion anesthesia a SENSORY CONVERSION SYMPTOM marked by the absence of sensation in certain areas of the body that cannot be accounted for by any identifiable biological pathology or defect. See GLOVE ANESTHESIA: STOCKING ANESTHESIA.

conversion disorder in DSM–IV–TR, a SOMATOFORM DISORDER in which patients present with one or more symptoms or deficits affecting voluntary motor and sensory functioning that suggest a physical disorder but for which there is instead evidence of psychological involvement. These conversion symptoms are not intentionally produced or feigned and are not under voluntary control. Symptoms can include paralysis, loss of voice, blindness, seizures, GLOBUS PHARYNGEUS, disturbance in coordination and balance, and loss of pain and touch sensations (see MOTOR CONVERSION SYMPTOMS; SENSORY CONVERSION SYMPTOMS). The formal criteria for the disorder in DSM–5, which refers to it also as functional neurological symptom disorder, primarily emphasize that there must be clear clinical evidence of symptom incompatibility with recognized neurological pathology before a diagnosis can be made. That there may also be psychological involvement in the onset of symptoms, or that stress or trauma of any sort, either psychological or physical, may have etiological relevance, is recognized in DSM–5 as among “associated features” that, if found, support diagnosis. The absence of feigning, however, is no longer a required criterion for diagnosis due to the clinical challenge of reliably discerning its absence.

conversion hysteria a former name for CONVERSION DISORDER.

conversion nonepileptic seizure a form of PSYCHOGENIC NONEPILEPTIC SEIZURE (PNES) that is a result of a diagnosed CONVERSION DISORDER. It is not associated with abnormal electrical activity on an electroencephalogram. Most PNESs are conversion nonepileptic seizures. Also called conversion seizure.

conversion paralysis a PSYCHOGENIC DISORDER in which there is an apparent loss of function of the muscles of a limb or a portion of the body for which no neurological cause can be identified. Unlike ORGANIC PARALYSIS, reflexes may be intact, muscle tone may be normal, and the paralyzed limb may be moved inadvertently when the patient’s attention is elsewhere. This is one of the possible symptoms of CONVERSION DISORDER.

conversion seizure see CONVERSION NONEPILEPTIC SEIZURE.

conversion symptom see CONVERSION DISORDER.

conversion therapy a highly controversial, ethically questionable, and generally discredited process intended to change individuals of same-sex or bisexual orientation to heterosexual orientation. Associated with religious proscriptions against homosexuality and outdated psychoanalytic theories about dysfunctional family dynamics and childhood trauma, conversion therapy has been denounced by the professional organizations of the major fields of psychiatry, psychology, and social work. There is a lack of empirical evidence to support its effectiveness, and studies suggest that the practice actually may be harmful; clients have reported such negative side effects as poor self-esteem, depression, suicidality, anxiety, social withdrawal, and sexual difficulties. Nonetheless, practitioners do exist often citing client distress and personal choice as reasons for offering the intervention; they claim that most individuals benefit by experiencing their changed sexual orientation and improved psychological functioning (e.g., through stress reduction, feeling a sense of community or belonging).

Opponents of the practice argue that the research does not support this claim and cite numerous reasons not to acquiesce to a client’s desire to change his or her sexual orientation, particularly the fact that such requests stem from a climate of social intolerance. Critics also argue that conversion therapy continues to stigmatize homosexuality as a pathological condition to be cured rather than a natural variation of human sexuality. Many suggest that a better approach to addressing client dissatisfaction with sexual orientation is to offer affirmative, evidence-based, multicultural interventions that help clients explore their sexuality, evaluate their conflicts, and come to individual resolution about managing them, and that do not impose
an outcome with regard to a specific sexual orientation identity. Also called change therapy; reorientation therapy; reparative therapy; sexual orientation change efforts (SOCE).

conviction n. in social psychology, the subjective sense that an attitude is a valued possession or an important aspect of self-concept. Conviction is related to attitude strength.

convolution n. a folding or twisting, especially of the surface of the brain.

covey model of social relations a theory that conceptualizes relationships as an evolving social network hierarchy of three concentric circles surrounding an individual, with each circle representing a relationship that has a different level of perceived intimacy or closeness to the individual at a given point in time. The theory attempts to account for how relationships of importance to the individual (i.e., that provide a secure base for individual functioning) change as she or he ages. [originally proposed by U.S. social psychologist Robert L. Kahn and U.S. developmental psychologist Toni C. Antonucci (1948– )]

covulant n. any substance that causes or otherwise results in convulsions, usually by blocking inhibitory neurotransmission.

covulsion n. an involuntary, generalized, and violent muscular contraction, in some cases tonic (contractions without relaxation) and in others clonic (alternating contractions and relaxations of skeletal muscles).

covulsive disorder any form of epilepsy that involves recurrent generalized seizures or partial seizures with convulsions.

covulsive therapy any treatment that is based on the induction of a generalized seizure by electrical or chemical means. See electroconvulsive therapy; metrazol shock treatment; shock therapy.

co-occurrence n. a relation between two or more phenomena (objects or events) such that they tend to occur together. For example, thunder co-occurs with lightning, and in English the letter Q typically co-occurs with the letter U. By itself, co-occurrence does not imply a causal link; for co-occurrence to become covariation, there must be a systematic correlation between both the occurrence of the phenomena and their nonoccurrence. —co-occur vb.

cooing n. vowel-like sounds produced by young infants when they are seemingly happy and contented.

cookies pl. n. small files automatically saved on a computer that provide records of websites that the user has viewed. They enable Web servers to identify and track an individual user’s online activities and preferences, thereby making it possible, for example, for Web-based marketers to pitch a different advertisement to the user each time he or she returns to a website. Cookies are considered by some users to be an invasion of privacy and may be disabled.

Cook’s distance (Cook’s D) in an analysis of the relationship between a response variable and one or more predictor variables, a measure of the difference that is made to the result when a single observation is dropped from the analysis. Cook’s D thus indicates the degree of influence of a particular data value. An observation typically is considered influential if it has a Cook’s D larger than 4/(n − k − 1), where n is the sample size and k is the number of terms in the model. [R. Denis Cook (1944—), U.S. statistician]

Coolidge Assessment Battery (CAB) a self-administered rating-scale instrument used to measure DSM-IV-TR personality (Axis II) disorders, as well as five major clinical (Axis I) disorders and executive function. Developed in 1999, it comprises 225 items to which participants respond using a 4-point Likert scale ranging from strongly false (1) to strongly true (4). The CAB is a more comprehensive successor to the Coolidge Axis II Inventory. [Frederick L. Coolidge (1948– ), U.S. neuropsychologist]

Coolidge effect increased sexual vigor when a human or nonhuman animal mates with multiple partners. The phenomenon is named for U.S. President Calvin Coolidge, alluding to a visit that he and his wife made to a farm where Mrs. Coolidge observed a rooster mating frequently. She allegedly asked the farmer to point this out to her husband, who is said to have replied “Same hen each time?”

cooperating teacher an experienced teacher assigned to supervise student teacher trainees who are learning to teach in classrooms. Student teachers are thus provided with an opportunity to put into practice the principles of teaching that they have learned in their teacher education training programs. Cooperating teachers introduce the teacher trainees to the practical component of teaching in such a manner as to minimize the mistakes that they are likely to make.

cooperation n. a process whereby two or more individuals work together toward the attainment of a mutual goal or complementary goals. This contrasts with competition, in which an individual’s actions in working toward a goal lessen the likelihood of others achieving the same goal. In game theory, cooperation is regarded as the strategy that maximizes the rewards and minimizes the costs for all participants in the game; this is sometimes posited as an explanation for cooperation. —cooperative adj.

cooperative breeding a type of mating system in which typically only one male and one female breed while other group members help in taking care of the offspring (see alloparenting). Subordinate animals are reproducively inhibited, either physiologically or behaviorally; they have few options other than to assist the breeding pair and wait for a breeding vacancy to occur.

cooperative education a school-administered program that combines study with employment. In higher education, the program especially seeks to enrich academic studies by supplementing them with practical field experience, ideally in responsible jobs in the student’s field of interest. Periods of full- or part-time study alternate at intervals of 3 or 6 months.

cooperative goal structure a performance setting structured in such a way that individuals can reach their goals more easily if they work with others rather than against them. When goal structures are purely cooperative, individuals can succeed only when others succeed as well. Compare competitive goal structure.

cooperative learning 1. learning in small groups, to
cooperative motive

which each student in the group is expected to contribute using interpersonal skills and face-to-face interaction. Students also participate in regular assessment of the group process. 2. a formal method of acquiring information that combines knowledge obtained in a classroom setting with that obtained in a work or applied setting. Typically, the formal classroom aspect of instruction is focused specifically on the actual work experience. See also COOPERATIVE TRAINING.

cooperative motive the drive or dispositional tendency to respond cooperatively in interpersonal and performance settings by helping others achieve their goals. Compare COMPETITIVE MOTIVE.

cooperativeness n. see CLONINGER’S PSYCHOBIOLOGICAL MODEL OF PERSONALITY: TEMPERAMENT AND CHARACTER INVENTORY.

cooperative play see SOCIAL PLAY.

cooperative reward structure a performance setting in which rewards are assigned on the basis of group rather than individual achievement, and the success of each member promotes the success of the group as a whole. In most cases, such structures improve group trust and communication and possibly foster greater achievement. Compare COMPETITIVE REWARD STRUCTURE: INDIVIDUALISTIC REWARD STRUCTURE.

cooperative training a vocational program for high school students who are placed in jobs related to the occupational fields of their choice. A program coordinator provides classroom instruction that supplements the job experience while monitoring the students’ progress on the job by consulting with employers.

cooperativity n. the affinity of a series of binding sites to an enzyme or receptor following its binding to the first of those sites. Cooperativity may be positive (i.e., increased) or negative (i.e., decreased).

Cooper–Harper Handling Qualities Rating Scale a standardized measure of COGNITIVE LOAD devised for use by NASA. After a test flight, pilots were asked to evaluate, using a simple decision tree, the handling qualities of the aircraft and the demands placed on themselves as a result of any deficiencies. It has since been adapted to many other settings. Also called Cooper–Harper rating scale: Cooper–Harper scale. [introduced in 1969 by George E. Cooper and Robert P. Harper Jr., U.S. pilots]

cordinate bilingual a person who regularly uses two languages, the second language having been learned independently from the first and within a different contextual environment. The mental representation of knowledge about the two languages is thought to be relatively independent. In contrast, a compound bilingual is a person who regularly uses two languages but who learned the languages as a result of equal and simultaneous exposure to them. See CODE SWITCHING; DUAL CODING THEORY.

coordination n. 1. the capacity of various parts to function together. This can be applied to body parts (e.g., the two legs while walking or the eyes and hands while drawing), to joints (e.g., the motion at the elbow and shoulder as the arm is swung back and forth), and to the muscles producing force at a joint (see ANTAGONISTIC MUSCLES). 2. in linguistics, the linking of two or more CLAUSES of equal status by means of a coordinating CONJUNCTION (e.g., and or but), as in The boy ate the cake, and the girl drank the milk. This contrasts with subordination, in which one of the clauses is dependent on the other for its meaning, as in The boy ate the cake that the girl liked. See COMPLEX SENTENCE. —coordinate vb.

coordination loss in groups, a reduction in productivity caused by the imperfect integration of the efforts, activities, and contributions of each member of the group. See also PROCESS LOSS.

coordination of secondary circular reactions see SECONDARY CIRCULAR REACTION.

coordinative structure see SYNERGY.

coparenting n. the practice by which parents coordinate their child-rearing practices. It can be supportive in nature, with partners reinforcing one another in child-rearing activities, but it may also be antagonistic, whereby partners are either inconsistent in parenting (e.g., show discrepant levels of parent–child engagement) or undermine each other’s child-rearing efforts (e.g., compete for their children’s attention or are in conflict about their children). Also called PARENTAL ALLIANCE.

COPD abbreviation for CHRONIC OBSTRUCTIVE PULMONARY DISEASE.

Copernican theory see HELIOCENTRIC THEORY.

copicide n. see SUICIDE BY COP.

coping n. the use of cognitive and behavioral strategies to manage the demands of a situation when these are appraised as taxing or exceeding one’s resources or to reduce the negative emotions and conflict caused by stress. See also COPING STRATEGY. —cope vb.

coping behavior a characteristic and often automatic action or set of actions taken in dealing with stressful or threatening situations. Coping behaviors can be both positive (i.e., adaptive), for example, taking time to meditate or exercise in the middle of a hectic day; or negative (i.e., maladaptive, avoidant), for example, not consulting a doctor when symptoms of serious illness appear or persist. See also COPING MECHANISM; COPING STRATEGY.

coping imagery a DESENSITIZATION technique in which relaxation is accompanied by images that have proved successful in controlling anxiety in situations that had previously aroused fear. See also COPING-SKILLS TRAINING. [developed by U.S. psychologist Joseph R. Cautela (1927–1999)]

coping mechanism any conscious or unconscious adjustment or adaptation that decreases tension and anxiety in a stressful experience or situation. Modifying maladaptive coping mechanisms is often the focus of psychological interventions. See also COPING BEHAVIOR; COPING STRATEGY.

coping potential an individual’s evaluation of the prospects of successfully managing environmental demands or personal commitments. Coping potential differs from COPING in that it deals with prospects of successful management (rather than with actual deployment of resources).

coping-skills training therapy or educational interventions to increase an individual’s ability to manage a variety of often uncomfortable or anxiety-provoking situations, ranging from relatively normal or situational problems (e.g., test taking, divorce) to diagnosed disorders (e.g., phobias). The types of skills taught are tailored to the situation and can involve increasing cognitive, behavioral, and affective proficiencies.

coping strategy an action, a series of actions, or a
thought process used in meeting a stressful or unpleasant situation or in modifying one’s reaction to such a situation. Coping strategies typically involve a conscious and direct approach to problems, in contrast to defense mechanisms. See also coping behavior; coping mechanism; emotion-focused coping; problem-focused coping.

coping style the characteristic manner in which an individual confronts and deals with stress, anxiety-provoking situations, or emergencies.

copro- (copro-, kopro-, kopr-) combining form 1. feces or filth (e.g., coprophilia). 2. obscenity (e.g., coprophemia).

coprolalia n. spontaneous, unprovoked, and uncontrollable use of obscene or profane words and expressions, particularly those related to feces. It is a symptom that may be observed in individuals with a variety of neurological disorders, particularly Tourette’s disorder. See also Latah. Also called coprophagia.

coprophagia n. the eating of feces. Also called coprophagy.

coprophilia (coprophemia) n. the use of obscene words or phrases to stimulate sexual excitement. See scatophilia.

coprophilia n. literally, the love of feces, which is manifested in behavior as an excessive or pathological preoccupation with the bodily product itself or with objects and words that represent it. In classical psychoanalytic theory, these tendencies are held to represent a fixation during the anal stage of development.

coprophagia n. see coprolalia.

copula n. in linguistics, a verb used so that it has little meaning other than to express equivalence between the subject and the complement in a sentence. In English, the most important copula is the verb be, as in He is my uncle or She is angry. Other verbs that can function as copulas include become, feel, get, seem, and look. Also called linking verb.

copulation n. sexual intercourse: coitus. Copulation usually includes mounting, intromission (insertion of the penis into the vagina), and ejaculation. In some species (e.g., rats), several intromissions are necessary prior to ejaculation, and a female must receive several intromissions in order for ova to be implanted in the uterus. In other species, copulation is necessary to induce ovulation. In many socially monogamous species, such as human beings, copulation can occur irrespective of the stage of the female’s ovulatory cycle.

copulatory lock see mate guarding.

cordocentesis n. see percutaneous umbilical cord blood sampling.

core area the central part of a group’s home range that is used most extensively, often where the major locations of food or shelter are found. Home ranges of groups may overlap considerably, but it is rare to find overlap in core areas.

core conflictual relationship theme (CCRT) a method of research, case formulation, and psychoanalytic psychotherapy that emphasizes central relationship patterns in clients’ stories. Three components are analyzed: the wishes, needs, or intentions of the client with regard to another person; the other person’s expected or actual reaction to these; and the client’s emotion, behavior, or symptoms as they relate to the other person’s reaction. [developed by Lester Luborsky]

core emotion see primary emotion.

core gender identity in psychoanalytic theory, an infant’s sense of himself or herself as male or female, typically solidifying in the second year of life. See also gender identity.

core hours see flextime.

core knowledge the psychological and neural mechanisms underlying human cognition. Typically, each mechanism is characterized as having four properties. First, it is domain specific and functions to represent a particular kind of entity (e.g., individual objects, object kinds, places in the environment). Second, it is task specific and uses its representations to track and recognize objects and locations. Third, it uses only a subset of the information delivered by the organism’s input systems (e.g., visual perception) and sends information only to a subset of its output systems. Fourth, it is relatively automatic and impervious to explicitly held beliefs. In neotraditional theory, infants and young children are thought to possess core knowledge in areas (relating, e.g., to people and social relations, objects, numbers, and quantities) that have been important throughout human evolutionary history. Its mechanisms are considered to be shared with many non-human species.

coremeter n. see pupillometry.

core relational themes 1. in the cognitive appraisal theory of emotions, a person’s judgments of the specific significance of particular events to himself or herself, resulting in the generation of specific emotional states (e.g., anger, joy, envy, or shame) in that person. Any core relational theme has three components: goal relevance, ego involvement, and coping potential. See appraisal dimension; primary appraisal; secondary appraisal. 2. repetitive patterns of relating to others that are presumed to be determined by relationships with parents and other influential individuals in early life. These relational themes can include dependent patterns and distrustful patterns, among others.

core temperature see deep body temperature.

CORFing acronym for cutting off reflected failure. See basking in reflected glory.

Coricidin n. a trade name for dextromethorphan.

Corino de Andrade’s paramyloidosis see andrade’s syndrome.

cornea n. the transparent part of the outer covering of the eye, through which light first passes. It is continuous laterally with the sclera. The cornea provides the primary refractive power of the eye. —corneal adj.

corneal reflection technique a method of studying eye movements using light reflected from the cornea.

corneal reflex the reflexive closing of the eyelids when the cornea is touched.

Cornelia de Lange syndrome a genetic disorder characterized by slow growth before and after birth, intellectual disability, skeletal abnormalities involving the arms and hands, microcephaly, short stature, and distinctive fa-
C

copy of an intended motor command, which is sent to a
Lange syndrome; often leads to fatal myocardial
Also called half of the body or brain from the back (posterior) half.
usually called third of cases of the disorder, the cause is unknown. Also
those seen in NIPBL mutations but are less common. In a third
of cases of the disorder, the cause is unknown. Also
called Amsterdam dwarf disease: Brachmann–Lange syndrome: de Lange syndrome. [Cornelia de Lange (1871–1950), Dutch pediatrician]
Cornell Medical Index (CMI) a psychological test originally designed for screening military personnel in World War II and later adapted for other purposes, such as diagnosing psychosomatic disorders on the basis of pathological mood and anxiety. The test is now rarely used. Also called Cornell Selective Index.
cornu ammonis see HIPPOCAMPUS.
corollary discharge a neuronal signal that encodes a copy of an intended motor command, which is sent to a structure in the brain (a BRAIN COMPARATOR) that can compare the intended movement with the sensory feedback (REAFFERENCE) that results from the actual movement. For example, when the eyes move, the world does not appear to move, even though the image of the world moves across the retina. The corollary discharge of the intended movement in effect cancels out the movement of the world over the retina. When the eye is moved passively by gently pushing on the eyelid, there is no corollary discharge, and the world appears to jump. Also called efference copy.
corona glandis the prominent posterior border of the head of the penis. See GLANS PENIS.
coronal plane the plane that divides the front (anterior) half of the body or brain from the back (posterior) half. Also called frontonal plane.
coronal section the cross section made by the CORONAL PLANE. Also called frontonal section.
coronary artery bypass graft (CABG) surgery designed to improve blood flow to the heart when coronary arteries are blocked by hardened plaque. A healthy artery or vein from the body is connected, or grafted, to the blocked coronary artery; creating a new path for oxygen-rich blood to flow to the heart muscle. It is the most common type of open heart surgery in the United States.
coronary heart disease (CHD) a cardiovascular disorder characterized by restricted flow of blood through the coronary arteries supplying the heart muscle. The cause is usually ATHEROSCLEROSIS of the coronary arteries and often leads to fatal myocardial INFACTION. Behavioral and psychosocial factors are frequently involved in the development and prognosis of the disease. Also called coronary artery disease. See CARDIAC PSYCHOLOGY.
coronary-prone behavior actions or patterns of actions believed to be associated with an increased risk of coronary heart disease. See TYPE A PERSONALITY.
coronary thrombosis see THROMBOSIS.
corp.- combining form body or structure.
corpora pl. n. see CORPUS.
corporal adj. of or relating to the body.
corporal punishment physical punishment; that is, punishment that uses physical force that causes pain but not injury to correct or control an individual’s behavior (e.g., spanking a child). Compare ABUSIVE PUNISHMENT.
corposereal adj. of a material, tangible nature, as opposed to spiritual.
corps phobia see NECROPHOBIA.
corpus n. (pl. corpora) 1. a body or distinct anatomical structure, such as the CORPUS CALLOSUM or CORPUS LUTEUM. 2. a body of linguistic data, such as recorded conversation or written text, that is subjected to linguistic or psycholinguistic analysis.
corpus callosum a large tract of nerve fibers running across the LONGITUDINAL FISSURE of the brain and connecting the cerebral hemispheres. It is the principal connection between the two sides of the brain. The largest of the inter-hemispheric commissures, it is known as the great commissure. See also COMMISSURAL FIBER.
corpus callosum agenesis see AGENESIS.
corpus cavernosum (pl. corpora cavernosa) either of the columns of erectile tissue that form the superior (upper) portion of the body of the penis. A third column of tissue, the CORPUS SPONGIOSUM, lies inferior to the corpora cavernosa.
corpus luteum a yellowish glandular mass in the ovary that remains after a GRAAFIAN FOLLICLE has ruptured and released an ovum. Its development is stimulated by LUTEINIZING HORMONE secreted by the anterior pituitary gland, and it functions as a transient endocrine gland, secreting PROGESTERONE.
corpus mammillare see MAMILLARY BODY.
corpus planning see LANGUAGE PLANNING.
corpus spongiosum a column of tissue on the inferior (lower) side of the body of the penis that surrounds the urethra and extends into the GLANS PENIS. Above it lie the two columns of the corpora cavernosa (see CORPUS CAVERNOUS). The three columns, which are bound together by connective tissue, make up the erectile tissue of the penis. However, the corpus spongiosum does not become as erect as the corpora cavernosa during an erection. Also called corpus cavernosum urethrae.
corpus striatum see BASAL GANGLIA.
correct detection in SIGNAL DETECTION TASKS, an accurate report of a target stimulus (signal) by the participant in trials in which the signal is present, often expressed as a percentage accuracy rate (see HIT RATE). See also CORRECT REJECTION; FALSE DETECTION; FALSE REJECTION.
correction n. 1. a quantity that is added, subtracted, or otherwise introduced to remove inaccuracy from a measurement, calculation, or analysis. Corrections are made, for example, when the ASSUMPTIONS about data that accompany a statistical procedure do not correspond to the actual data being analyzed. 2. in optometry, the rectification of visual defects that are due to refractive errors through the use of CORRECTIVE LENSES.
correctional facility any facility that houses or detains individuals who have been formally processed by the criminal or juvenile justice system, for the purpose of reform or rehabilitation. Examples include prisons, juvenile halls, and jails. Also called correctional institution.
correctional psychology a branch of FORENSIC PSYCHOLOGY concerned with the application of counseling and

clinical techniques to criminal and juvenile offenders in penal and correctional facilities (e.g., reformatories, penitentiaries). Correctional psychologists also participate professionally in court activities, probation departments, parole boards, prison administration, supervision of inmate behavior, and programs for the rehabilitation of offenders.

correction for attenuation in analyses estimating the relationship between two variables, an adjustment for error introduced during the process of obtaining the measures, where such error serves to underestimate the measured effect.

correction for continuity a procedure that is applied to adjust for the fact that a statistical method is based on an assumption that the data have a continuous distribution when, in fact, they have a discrete distribution. Yate’s correction for continuity is an example.

correction for guessing a scoring rule for multiple-choice tests such that the expected value of getting an item correct under the assumption of no knowledge is 0 rather than 1/n, where n is the number of alternatives. Thus, if a test taker incorrectly answered four questions, a further 4/n would be deleted from his or her score. By thereby penalizing inaccurate responses, the correction discourages a test taker from guessing and provides a better estimate of that person’s true ability.

correction procedure the repetition or continuation of particular stimulus conditions (usually in discrimination training) after certain responses (usually errors) or in the absence of certain responses.

corrective advertising advertising required of companies found guilty of deceptive advertising by the Federal Trade Commission. Such advertising is designed to counter the incorrect inferences deduced from the deceptive advertisement.

corrective emotional experience 1. an experience through which one comes to understand an event or relationship in a different or unexpected way that results in an emotional coming to terms with it. 2. originally, a concept from psychoanalysis positing that clients achieve meaningful and lasting change through new interpersonal affective experiences with the therapist, particularly with regard to situations that clients were unable to master as children. [originally described in 1946 by Hungarian psychoanalyst Franz Alexander (1891–1964) and U.S. physician Thomas Morton French (b. 1892)].

corrective lens a lens worn on or in front of the eye to correct or improve vision. In eyeglasses, a pair of corrective lenses is mounted in a frame worn on the face; in contact lenses, the corrective lens is applied directly to the eye.

corrective therapy see kinesiotherapy.

correct rejection in signal detection tasks, an accurate decision by the participant that a target stimulus (signal) is not present. See also correct detection; false detection; false rejection.

correct n. a variable that is related to another variable. See correlation. 2. vb. to calculate a correlation coefficient.

correlated samples see dependent samples.

correlation n. the degree of a relationship (usually linear) between two variables, which may be quantified as a correlation coefficient.

correspondence n. in attribution theory, the extent to which an observed behavior, such as pushing past others to go to the front of a line, is believed to correlate to a general personality trait in the actor, such as rudeness or aggressiveness. Observers have a strong tendency to overestimate the correspondence of behaviors with traits (the
correspondence bias

FUNDAMENTAL ATTRACTION ERROR). See ACTOR-OBSERVER EFFECT; CORRESPONDENT INFERENCE THEORY. —correspondent adj.

correspondence bias see FUNDAMENTAL ATTRACTION ERROR.

correspondence problem the requirement that elements in one image must be matched by the visual system with the same elements in another image when the two images differ from one another in some respect. In APPARENT MOVEMENT, the elements in one stationary image must be matched with the same elements in the next stationary image if the elements are to be perceived as moving. Theories of object recognition must take into account the ability to recognize objects as the same, even though they may appear from different perspectives in two different scenes. The correspondence problem is solved effortlessly by the visual system but has proven to be extremely difficult to solve in artificial vision.

correspondence training a BEHAVIOR THERAPY intervention for children and adolescents in which the clients are tangibly or socially reinforced either for verbally promising to do something and then following through or for doing a desired behavior and then verbally reporting on the activity. Promises and reports can be made to either an adult or a peer.

correspondent inference theory a model describing how people form inferences about other people’s stable personality characteristics from observing their behaviors. Correspondence between behaviors and traits is more likely to be inferred if the actor is judged to have acted (a) freely, (b) intentionally, (c) in a way that is unusual for someone in the situation, and (d) in a way that does not usually bring rewards or social approval. See also ATTRACTION THEORY. [proposed in 1965 by U.S. social psychologists Edward E. Jones (1926–1993) and Keith E. Davis (1936–)].

corridor illusion an illustration of SIZE CONSTANCY in which two identical figures appear to be radically different in size. If the figures are placed in a picture of a corridor, the one placed in the distance appears larger than the one placed in the foreground. This is because DEPTH CUES affect expectations about true size.

corroboration n. evidence to support a theory, fact, opinion, or the like. Austrian-born British philosopher Karl Popper (1902–1994) regarded mere corroboration as insufficient grounds for acceptance of a theory. He held instead that the proper test of a theory was one that had a high probability of refuting the theory if it was wrong, and that a theory lacking FALSIFIABILITY was not scientific. —corroborate vb.

cortex n. (pl. cortices) the outer or superficial layer or layers of a structure, as distinguished from the central core. In mammals, the cortex of a structure is identified with the name of the gland or organ, for example, the adrenal cortex (see ADRENAL GLAND), CEREBELLAR CORTEX, or CEREBRAL CORTEX. Compare MEDULLA. —cortical adj.

cortical activation activation of regions of the cerebral cortex or cerebellar cortex. It can be achieved by sensory stimulation or engagement in cognitive tasks or by such techniques as TRANSCRANIAL MAGNETIC STIMULATION. The activation can be recorded by noninvasive techniques, such as ELECTROENCEPHALOGRAPHY, FUNCTIONAL MAGNETIC RESONANCE IMAGING, or POSITRON EMISSION TOMOGRAPHY.

cortical amnesia see AMNESIS.

cortical amnesia a form of amnesia due to neurological causes, such as a stroke or brain injury.

cortical area see BRODMANN’S AREA; CEREBRAL CORTEX.

cortical-arousal factor in psychological aesthetics, a response to a work of art that is associated with ratings that are high on the drowsy–alert and weak–powerful scales. Compare UNCERTAINTY-AROUSAL FACTOR. [proposed by Daniel E. BERLYNE]

cortical barrel in nonhuman animals with facial whiskers, a column of neurons in the SOMATOSENSORY AREA that receives sensory information from those whiskers. The cortical barrels correspond to the whiskers in a somatotopic fashion (see SOMATOTOPIC ORGANIZATION).

cortical blindness blindness, with normal pupillary responses, that is due to complete destruction of the OPTIC RADICATIONS or the STRIATE CORTEX. Because the subcortical structures (white matter) of the visual system are involved, it is also called CEREBRAL BLINDNESS. Typically caused by a stroke affecting the occipital lobe of the brain, cortical blindness can also result from traumatic injury or HYPOXIA. In children, it is often a consequence of hydrocephalus, meningitis, toxic or hypertensive encephalopathy, trauma, or diffuse demyelinating degenerative disease. Complete loss of vision in a portion of the visual field is called PARTIAL CEREBRAL BLINDNESS.

cortical center 1. an area of the CEREBRAL CORTEX where sensory fibers terminate or motor fibers originate. 2. an area of the cerebral cortex specialized for a certain function, such as the speech center or the vision center.

cortical column one of the vertical groups of interconnected neurons that span several CORTICAL LAYERS and constitute the basic functional organization of the NEOCORTEX. Columnar organization is most evident in visual cortex (see OCULAR DOMINANCE COLUMN; ORIENTATION COLUMN).

cortical control 1. the normal regulation of an activity, such as movement of a limb, by the CEREBRAL CORTEX. 2. control of a PROSTHESIS by signals recorded from the cerebral cortex, which are computer-processed and amplified.

cortical deafness deafness that is caused by damage to auditory centers in the cerebral cortex of the brain. The peripheral auditory system (which includes the retrocochlear neural pathways terminating in the brainstem) can be intact in this condition.

cortical dementia dementia arising from degeneration of the cortical areas of the brain, rather than the subcortical (deeper) areas. The most common dementia of this type is ALZHEIMER’S DISEASE. Compare SUBCORTICAL DEMENTIA.

cortical dysplasia abnormality in the development (e.g., size, shape) of the cerebral cortex.

cortical evoked potential an EVOKED POTENTIAL observed in the cerebral cortex. Also called CORTICAL EVOKED RESPONSE.

cortical hearing loss hearing loss associated with auditory disorders due to damage to the higher neurological centers of the brain.
cortical inhibition n. Inhibition of activity originating in the cerebral cortex or cerebellar cortex.

corticalization n. See ENCEPHALIZATION.

cortical lamina Any of the layers of cells in the cerebral cortex. See BRODMANN’S AREA.

cortical layers The layers of neurons that constitute the structure of the cerebral cortex and cerebellar cortex. In the cerebral cortex the number of layers varies, reaching a maximum of six in the neocortex. These six layers, identified by Roman numerals and starting from the outer surface, are I, the plexiform molecular layer, a narrow band of myelinated fibers; II, the external granular layer, containing granule cells and pyramidal cells; III, the external pyramidal layer, with medium-sized pyramidal cells in the outer zone and larger pyramidal cells in the inner zone; IV, the internal granular layer, which contains synapses of layer-III cells along with stellate cells categorized as granule cells; V, the ganglionic (or internal pyramidal) layer, which includes large pyramidal cells and the giant Betz cells; and VI, the polymorphic fusiform (or multiform) layer, which contains cells of many shapes but mainly spindle-shaped and pyramidal cells.

cortical lesion A pathological change in the cerebral cortex of the brain, which may be congenital or acquired and due to any cause.

cortical magnification factor The population density of the neurons in a cortical map with respect to degrees of visual angle. Visual topographic maps in the brain contain topographical representations of the visual field. Earlier maps of this kind preserved point-to-point correspondence with the retina and are therefore called retinotopic maps. In such maps the cortical magnification factor can be expressed in terms of the number of square millimeters of cortical surface needed to represent each degree of visual angle. At the center of gaze, the retinal fovea centralis (2°–4° of visual angle) has a high cortical magnification factor compared to the periphery. Also called magnification factor.

cortical map A topographical representation of arrays of sensory receptors or motor effectors (muscle units) in the cerebral cortex. Examples are the topographical maps of visual point features such as light, contrast, spatial frequency (size), color, movement, and so forth in the visual cortex (see Retinotopic Map) and the sound frequency maps of the auditory cortex (see TONOTOPIC ORGANIZATION). See also LOCALIZATION OF FUNCTION; TOPOGRAPHIC ORGANIZATION.

cortical neuron A nerve cell that has its cell body in the cerebral cortex.

cortical potential An electric potential that originates in neurons of the cerebral cortex. See BRAIN WAVES; ELECTROENCEPHALOGRAPHY.

Cortical process any of the mechanisms of the cerebral cortex that are involved in cognition. The early stages of cognitive input analysis are called early cortical processes; the later, more complex mechanisms are called higher cortical processes. See also EXECUTIVE FUNCTIONS.

cortical sensory aphasia See WERNICKE’S APHASIA.

cortical–subcortical motor loop A loop, made up of projections between the motor cortex and structures in the basal ganglia and the thalamus, that monitors and sequences ongoing motor behaviors.

cortico- combining form cortex.

cortico basal ganglionic degeneration (CBGD) A degenerative condition of the basal ganglia resulting in apraxia, rigidity, dystonia, and cognitive deficits. Also called corticostriatonginal degeneration.

corticobulbar fiber See CORTICONUCLEAR FIBER.

corticofugal adj. Describing nerve fibers or tracts that exit from the cerebral or cerebellar cortex. Corticofugal nerve fibers from the cerebral cortex include corticospinal, corticoonuclear, and corticopontine fibers. Compare corticopetal.

corticomedial group One of the two main groups of nuclei in the amygdala within the brain. It includes the central nucleus and receives mainly olfactory and pheromonal information; its output, via the stria terminalis, is to the hypothalamus and the basomedial forebrain. See also BASOLATERAL GROUP.

corticonuclear fiber Any of a group of fibers forming part of the pyramidal tract that extend from the cerebral cortex to nuclei in the midbrain, pons, and medulla oblongata. Also called corticobulbar fiber.

corticopetal adj. Describing nerve fibers or tracts that are directed toward the cerebral or cerebellar cortex. Compare corticofugal.

corticopontine adj. Relating to or connecting the cerebral cortex and the pons in the brain.

corticospinal fiber A nerve fiber of the corticospinal tract.

corticospinal tract A major motor pathway that originates in the cerebral cortex (see motor cortex), passes through the pyramid of the medulla oblongata, and descends to terminate in the spinal cord. At the pyramid, most of its fibers cross over to form the lateral corticospinal tract; the remaining fibers, forming the smaller anterior corticospinal tract, descend anteriorly in the white matter of the spinal cord to terminate in the anterior horns. See also PYRAMIDAL TRACT.

corticosteroid n. Any of the steroid hormones produced by the adrenal cortex, the outer layer of the adrenal gland. They include glucocorticoids (e.g., cortisol), which are involved in carbohydrate metabolism; and the mineralocorticoids (e.g., aldosterone), which have a role in electrolyte balance and sodium retention. Also called adrenocorticoid.

corticosteroid therapy Medical treatment that involves the use of corticosteroid drugs. Both MINERALOCORTICOIDS and glucocorticoids may be used as replacement therapy in patients whose secretion of the natural hormones is deficient, either through disease or surgical removal of one or both adrenal glands. However, glucocorticoids are most widely used as anti-inflammatory agents; they are also used in the treatment of asthma, dermatologic conditions, and seasonal rhinitis.

corticosterone n. A corticosteroid hormone with glucocorticoid functions that include regulating the metabolism of proteins, fats, and carbohydrates into energy sources for body cells. The concentration of corticosterone in the plasma is used as an index of stress.
corticostriatonigral degeneration see CORTICOSTRIATIONAL GANGLIONIC DEGENERATION.

corticotropin n. a hormone secreted by the anterior pituitary gland, particularly when a person experiences stress. It stimulates the release of various other hormones (primarily CORTICOSTEROIDS) from the adrenal cortex, the outer layer of the adrenal gland. Also called adrenocorticotropic hormone (ACTH); adenocorticotropic.

corticotropic releasing factor (CRF) a neuropeptide produced by the hypothalamus that is important in the control of the hypothalamic–pituitary–adrenal response to stress (see HYPOTHALAMIC–PITUITARY–ADRENAL AXIS). It controls the daily rhythm of corticotropin (ACTH) release by the pituitary gland and is also involved in a number of behaviors, such as anxiety, food intake, learning, and memory. Also called ACTH-releasing factor: corticotropin-releasing hormone (CRH).

cortisol n. a CORTICOSTEROID hormone whose GLUCOCORTICOID activity increases BLOOD SUGAR levels. Blood levels of cortisol in humans vary according to sleep–wake cycles (generally being highest around 9:00 a.m. and lowest around midnight) and other factors; for example, they increase with lack of sleep and during pregnancy but decrease with diseases of the liver and kidneys. Cortisol is considered the primary STRESS HORMONE. In response to stress or injury; blood cortisol levels, and therefore glucose levels, increase, as does blood pressure, whereas activity of the immune system decreases and release of inflammatory substances in the body is contained. Cortisol thus improves the body’s ability to manage stress and to repair itself, and, since 1963, it and its synthetic analogs have been administered in the treatment of chronic inflammatory and autoimmune disorders. Exposure to prolonged stress, however, can lead to excessive levels of cortisol, which can have deleterious effects on the body (e.g., hyperglycemia). Cortisol has also been implicated in intrauterine growth retardation of the fetuses of pregnant women exposed to profound environmental stress (e.g., trauma, industrial or natural disasters). Also called hydrocortisone.

cortisone n. a CORTICOSTEROID that is produced naturally by the adrenal cortex or synthetically. Cortisone is biologically inactive but is converted to the active hormone cortisol in the liver and other organs. It is used therapeutically in the management of disorders caused by corticosteroid deficiency.

correlation n. in conversations between friends or other individuals in a dyadic relationship, an excessive focus on personal problems and negative affect to the exclusion of any other topic of conversation. [proposed in 2002 by U.S. psychologist Amanda J. Rose]

coryza n. the common cold, usually with nasal discharge (runny nose).

COSC abbreviation for COMBAT AND OPERATIONAL STRESS CONTROL.

cosleeping n. a practice in which one or both parents sleep in the same room with their infant, near enough for them to touch. Cosleeping arrangements may include three-sided bassinets that attach to the adult bed or cribs placed next to the bed. These arrangements are thought to promote BONDING, encourage breastfeeding, and improve infant sleep. See also BED-SHARING.

cosmetic surgery a general category of multiple specific surgical procedures designed to improve or enhance some aspect of physical appearance. See PLASTIC SURGERY.

cosmic consciousness as originally conceived by Canadian psychiatrist Richard M. Bucke (1837–1902), the highest level of consciousness that can be attained by humans, experienced as a sense of the order, totality, and “living presence” of the universe and accompanied by intellectual enlightenment, moral exaltation, and a “consciousness of eternal life” or immortality. Bucke arrived at his coinage and understanding of the term initially through a mystical experience that he had at the age of 36. His best known book on the subject, Cosmic Consciousness: A Study in the Evolution of the Human Mind, was published in 1901. The term has since become more restrictively described as a sense of the totality of the universe and more broadly associated not only with mystical ecstasy but also with PEAK EXPERIENCES, with the use of hallucinogenic drugs, and with such techniques as meditation, yoga, breathing exercises, fasting, and dwelling on certain paradoxic sayings (see ZEN BUDDHISM). See also ALTERED STATE OF CONSCIOUSNESS; MYSTICISM.

COSR abbreviation for combat and operational stress reaction. See COMBAT STRESS REACTION.

cost analysis a systematic determination of the costs associated with the implementation of a program’s services. These include direct personnel, material, and administrative costs, calculated from the perspective of a given purchaser (e.g., government agency, client), budgetary category, and time period. Once determined, these costs are utilized further in COST–BENEFIT ANALYSIS or COST-EFFECTIVENESS ANALYSIS.

cost–benefit analysis 1. an analytic procedure that attempts to determine and compare the economic efficiency of different programs. Costs and benefits are reduced to their monetary value and expressed in a cost-benefit (or benefit–cost) ratio. Compare COST-EFFECTIVENESS ANALYSIS. See also COST-OFFSET ANALYSIS. 2. in BEHAVIORAL ECOLOGY, a method of predicting which behavioral strategies are likely to be adaptive by comparing the potential costs and potential benefits of each possible behavior. Those behaviors that will lead to greater benefits relative to costs will be those that survive through NATURAL SELECTION. 3. see COST–REWARD ANALYSIS.

cost containment a program goal that seeks to control the costs involved in managing and delivering the PROGRAM OUTCOME. In health administration, a range of fiscal strategies is used to prevent health care costs from increasing. See also COST ANALYSIS.

cost-effectiveness analysis a measure of PROGRAM EFFICACY or economic efficiency expressed in terms of the cost of achieving a unit of PROGRAM OUTCOME. Cost-effectiveness analysis measures the monetary value of resources used with clinical health effects (e.g., death rate, test performance), whereas in a COST–BENEFIT ANALYSIS the economic return (e.g., reduced future use of health services) is expected to exceed the treatment cost (e.g., providing vaccinations). Cost-effectiveness analysis is most appropriate when programs have one main identifiable evaluation outcome, when future costs are not confounded with changes in outcome, or when outcomes are not directly reducible to monetary payoffs. See also COST-OFFSET ANALYSIS.

cost of concurrence the decrease that occurs in performance of a task that is placed in a dual-task context.
even when the instructions are to emphasize that task. This cost is measured in terms of changes in reaction time or accuracy and is estimated from an analysis of a PERFORMANCE-OPERATING CHARACTERISTIC.

**cost-offset analysis** a measure of economic efficiency expressed in terms of interventions that save money independent of their health benefits. This saving is related to reduced health care utilization and costs (e.g., the use of generic vs. nongeneric pharmaceuticals) and may be a component included in COST–BENEFIT ANALYSIS or COST-EFFECTIVENESS ANALYSIS.

**cost–reward analysis** in social psychology, a model that attempts to explain helping behavior in terms of the reinforcements and costs associated with specific helping actions. A helping act that possesses either high reinforcement value or very low cost value is more likely to be performed than a low-reinforcement, high-cost act. Also called cost–benefit analysis.

**Cotard’s syndrome** a psychotic condition characterized by severe depression and intense nihilistic delusions (see Nihilism) in which individuals insist that their bodies or parts thereof, and in some cases the whole of reality, have disintegrated or ceased to exist. [First reported in 1830 by Jules Cotard (1840–1887), French neurologist, who called it délire de négation (“delirium of negation”)].

**cot death** see SUDDEN INFANT DEATH SYNDROME.

**cottage therapy** n. therapy by two therapists working with a client, pair of clients (e.g., a couple), family, or group to enhance understanding and to change behavior and relationships during treatment.

**cotwin control** see TWIN CONTROL.

**couch** n. in psychoanalysis, the article of furniture on which the patient reclines. The use of the couch is based on the theory that this posture will facilitate free association, encourage the patient to direct attention inward to his or her world of feeling and fantasy, and enable the patient to access his or her unconscious mind. The expression “on the couch” is sometimes used popularly to indicate psychoanalytic treatment. Also called analytic couch.

**cough suppressant** see ANTITussive.

**counfellor** n. an excessive, persistent, and irrational fear of clowns. Situations in which clowns may be encountered (e.g., at birthday parties, circuses) are often avoided or else endured with intense anxiety or distress.

**counseling** n. professional assistance in coping with personal problems, including emotional, behavioral, vocational, marital, educational, rehabilitation, and life-stage (e.g., retirement) problems. The COUNSELOR makes use of such techniques as ACTIVE LISTENING, guidance, advice, discussion, CLARIFICATION, and the administration of tests.

**counseling process** the interpersonal process engaged in by COUNSELOR and client as they attempt to define, address, and resolve specific problems of the client in face-to-face interviews. See also COUNSELING.

**counseling psychology** the branch of psychology that specializes in facilitating personal and interpersonal functioning across the lifespan. Counseling psychology focuses on emotional, social, vocational, educational, health-related, developmental, and organizational concerns—such as improving well-being, alleviating distress and maladjustment, and resolving crises—and addresses issues from individual, family, group, systems, and organizational perspectives. The COUNSELING PSYCHOLOGIST has received professional education and training in one or more COUNSELING areas, such as educational, vocational, employee, aging, personal, marriage, or rehabilitation counseling. In contrast to a clinical psychologist (see CLINICAL PSYCHOLOGY), who usually emphasizes origins of maladaptations, a counseling psychologist emphasizes adaptation, adjustment, and more efficient use of the individual’s available resources.

**counseling relationship** the interaction between counselor and client in which the relationship is professional yet also characterized by empathic warmth and AUTHENTICITY, with the counselor bringing professional training, experience, and personal insight to bear on the problems revealed by the client. The relationship is considered to be of central importance in bringing about desired change.

**counseling services** professional help provided by a government, social service, or mental health agency to individuals, families, and groups. Services are typically provided by licensed counselors, psychologists, social workers, and nurses. See also COUNSELING.

**counselor** n. an individual professionally trained in counseling, psychology, social work, or nursing who specializes in one or more counseling areas, such as vocational, rehabilitation, educational, substance abuse, marriage, relationship, or family counseling. A counselor provides professional evaluations, information, and suggestions designed to enhance the client’s ability to solve problems, make decisions, and effect desired changes in attitude and behavior.

**counterargument** n. the contradiction of specific points in a formal ARGUMENT, of information in a persuasive message, or of content in an internal thought.

**counterattitudinal advocacy** a persuasive message that contradicts a person’s current attitude.

**counterattitudinal behavior** behavior that is inconsistent with an attitude. Having a negative attitude toward a political candidate but agreeing to donate money to that candidate’s political campaign is an example of counterattitudinal behavior. See also ATTITUDE–BEHAVIOR CONSISTENCY. Compare PROATTITUdINAL BEHAVIOR.

**counterattitudinal role play** a technique used in PSYCHodrama or ROLE PLAY in which the individuals taking part are directed to express opinions contrary to those in which they believe.

**counterbalancing** n. arranging a series of experimental conditions or treatments in such a way as to minimize the influence of extraneous factors, such as practice or fatigue, on experimental results. In other words, counterbalancing is an attempt to reduce or avoid CARRIER EFFECTS and ORDER EFFECTS. A simple form of counterbalancing would be to administer experimental conditions in the order A-B to half of the participants and in the order B-A to the other half; a LATIN SQUARE would be a more complex form.

**countercathexis** n. see ANTICATHEXIS.

**countercompulsion** n. a COMPULSION that is secondarily developed to resist the original compulsion when the latter cannot be continued. The new compulsion then replaces the original so that the compulsive behavior can continue.
counterconditioning

**counterconditioning** n. an experimental procedure in which a nonhuman animal, already conditioned to respond to a stimulus in a particular way, is trained to produce a different response to the same stimulus that is incompatible with the original response. This same principle underlies many of the techniques used in behavior therapy to eliminate unwanted behavior in people.

counterculture

**counterculture** n. a social movement that maintains its own alternative mores and values in opposition to prevailing cultural norms. The term is historically associated with the hippie movement and attendant drug culture of the late 1960s and early 1970s, which rejected such societal norms as the work ethic and the traditional family unit. See also subculture, youth culture. —countercultural adj.

counterfactual

**counterfactual** n. in linguistics, a conditional statement that is contrary to fact, as in If the Japanese had not bombed Pearl Harbor, the United States would not have become engaged in World War II. See conditional clause.

counterfactual thinking

1. imagining ways in which events in one's life might have turned out differently. This often involves feelings of regret or disappointment (e.g., If only I hadn't been so hasty) but may also involve a sense of relief, as at a narrow escape (e.g., If I had been standing 3 feet to the left . . .). 2. any process of reasoning based on a conditional statement of the type "If X, then Y" where X is known to be contrary to fact, impossible, or incapable of empirical verification. Counterfactual thinking of the first sort is common in such historical speculations as If Hitler had been killed in July 1944, then . . . . Counterfactual thinking of the second and third types can play a useful role in evaluating the implications of a theory or heuristic and in thought experiments. See also as-if hypothesis; conditional reasoning.

counteridentification

**counteridentification** n. see concordant identification.

countermeasure

**countermeasure** n. in polygraph testing, any effort on the part of an individual to avoid being classified as deceitful or dishonest. Typically, individuals may use either drugs to reduce their level of physiological arousal or physical means (e.g., biting their tongue) to increase arousal to questions unrelated to the issue of interest.

countermeasure-intervention program see social reform program.

counterphobic character

**counterphobic character** a personality that takes pleasure in pursuing risky or dangerous activities that other people would normally find anxiety provoking. In psychoanalytic theory, this is explained as a manic defense that achieves satisfaction from the feeling of mastering anxiety.

counterproductive work behavior (CWB)

**counterproductive work behavior** (CWB) undesirable employee behavior that can undermine the goals of an organization or its members and can negatively affect the organization’s financial well-being. CWBs cover a wide range of behavior, such as sabotage, theft, absenteeism, bullying, sexual harassment, discrimination, workplace violence, drug and alcohol abuse, and violation of confidentiality agreements. These behaviors, as well as their testing and assessment, are the subject of considerable research in industrial and organizational psychology. See also integrity testing.

countershading

**countershading** n. a form of camouflage that involves using differential light and dark areas on the body to minimize the ability of predators to detect the organism. For example, fish often have dark-colored backs and light-colored bellies. A predator from below has difficulty discriminating the fish from the sky above, and a predator from above has difficulty discriminating the fish from the dark substrate below.

countershock

**countershock** n. a mild electric shock administered to a patient undergoing electroconvulsive therapy (ECT) for 1 minute after the convulsive shock. The countershock is intended to relieve some of the common aftereffects of ECT, such as postconvulsion confusion or amnesia.

countershock phase see general adaptation syndrome.

countersuggestion

**countersuggestion** n. in psychotherapy, a suggestion by the therapist that contradicts or opposes a previous suggestion or a particular fixed idea. This strategy is used to decrease the influence of the previous suggestion or idea, provide an alternative, or both.

countertransference

**countertransference** n. the therapist’s unconscious (and often conscious) reactions to the patient and to the patient’s transference. These thoughts and feelings are based on the therapist’s own psychological needs and conflicts and may be unexpressed or revealed through conscious responses to patient behavior. The term was originally used to describe this process in psychoanalysis but has since become part of the common lexicon in other forms of psychodynamic psychotherapy and in other therapies. In classical psychoanalysis, countertransference was viewed as a hindrance to the analyst’s understanding of the patient, but to modern analysts and therapists, it may serve as a source of insight into the patient’s effect on other people. In either case, the analyst or therapist must be aware of, and analyze, countertransference so that it can be used productively within the therapeutic process. See also control, analysis.

coupled oscillators

**coupled oscillators** a dynamic system model used to represent many aspects of rhythmic movements, such as those of the lower limbs during locomotion. See also central pattern generator.

couples counseling

**couples counseling** counseling in which guidance and advice focus on issues confronting relationships between partners. Couples counseling is short-term and problem oriented; it may include a variety of approaches to such difficult areas as shared responsibilities, expectations for the future, and loyalties.

couples therapy

**couples therapy** therapy in which both partners in a committed relationship are treated at the same time by the same therapist or therapists. Couples therapy is concerned with problems within and between the individuals that affect the relationship. For example, one partner may have undiagnosed depression that is affecting the relationship, or both partners may have trouble communicating effectively with one another. Individual sessions may be provided separately to each partner, particularly at the beginning of therapy; most of the course of therapy, however, is provided to both partners together. Couples therapy for married couples is known as marital therapy.

coupon-return technique

**coupon-return technique** a method of testing advertising effectiveness in a printed medium, such as a magazine or newspaper, by inducing the reader to return a coupon by mail. The technique is sometimes used on a
SPLIT-RUN basis in which the coupon is offered only to one part of the publication’s readership; alternatively, variations of an advertisement may be tested in different demographic areas in which the publication is sold. Some publications cooperate with advertisers using the coupon-return technique by charging for advertising space on a per-inquiry (p.i.) basis. Each coupon returned counting as an inquiry.

courage *n.* the ability to meet a difficult challenge despite the physical, psychological, or moral risks involved in doing so. Examples of acts of courage include saving another’s or one’s own life against a meaningful threat; coping with a painful, debilitating, or terminal illness; overcoming a destructive habit; and voicing an unpopular opinion. Also called *bravery; valor. —courageous adj.*

course *n.* the length of time a disorder, illness, or treatment typically lasts; its natural progression; and (if applicable) its recurrence over time.

course modifier a pattern that develops in a disorder (e.g., recurrence, seasonal variation) that helps to predict its future course or may serve to alter its usual course.

courtesan fantasy see *HETAERIAL FANTASY.*

court-ordered treatment any assessment, treatment, consultation, or other service for defendants, plaintiffs, or criminal offenders that is mandated by a judge or magistrate.

courtship *n.* the process of attracting a partner as part of sexual behavior, a period critical to reproductive success in many species. Animal courtship involves such activities as identifying and evaluating a potential mate, locating and defending appropriate sites for nests or dens, synchronizing the hormones involved in reproduction and engaging in other physiological preparations, and at times forming or strengthening pair bonds. Human courtship enables couples to develop mutual commitment, which has marriage as its goal, although it may take widely different forms in different cultures. For example, in some societies bodily contact between courting couples may be forbidden, whereas in others it may be accepted and even encouraged; or a man may be required in certain societies to obtain parents’ permission before asking a woman to marry him yet in others such a practice may be considered unnecessary or even impolite. See also *MATE SELECTION.*

couvade *n.* 1. a custom in some cultures in which the father takes to bed before or after his child is born, as if he himself suffered the pain of childbirth. 2. abdominal pain or other somatic symptoms appearing in male partners of pregnant women, usually presumed to be psychogenic in origin. Also called *couvade syndrome.*

covariance *n.* a scale-dependent measure of the relationship between two variables such that corresponding pairs of values of the variables are studied with regard to their relative distance from their respective means. A positive covariance results when values of one variable that lie above the mean of that variable tend to be paired with values of the second variable that also lie above the mean of that variable. A negative covariance results when values of one variable that lie above the mean tend to be paired with values of the second variable that lie below the mean.

covariance matrix a square matrix that represents how variance in each variable in a set is related to variance in all other variables in the set. The covariances between pairs of variables are located at the intersection of the row and column that correspond to the two variables. The quantities along the diagonal of the matrix are variances rather than covariances. Also called dispersion matrix: variance–covariance matrix.

covariate *n.* a variable that exhibits covariation with a measured outcome or dependent variable. It is often included in an analysis so that its effect may be taken into account when interpreting the effects of the independent variables of interest. For example, covariates are used in analyses of covariation to statistically adjust groups so that they are equivalent with regard to these variables; they may also be used in multiple regression to minimize error that may arise from omitting any noncentral but potentially influential variables. Also called concomitant variable.

covariation *n.* a relationship between two quantitative variables such that as one variable tends to increase (or decrease) in value, the corresponding values of the other variable tend to also increase (or decrease). For example, if a person’s weight consistently rises as he or she grows older, then the two variables would be exhibiting covariation. See also *ILLUSORY COVARIATION.* —covary vb.

covariation principle see *ATTRIBUTION THEORY.*

covenant marriage a legal innovation in American marriage, first enacted in Louisiana in 1997 but not available in all states, in which heterosexual couples agree to participate in premarital counseling and to accept significantly more restricted grounds for divorce. Covenant marriage laws were designed to reduce the likelihood of divorce by strengthening marriages while making divorces more difficult to obtain. More symbolically, covenant marriage laws allow spouses to signal to each other and to their families and social networks that they view their marital vows as especially meaningful and permanent. Covenant marriage laws are usually written without regard to religion, but in practice, couples who choose a covenant marriage tend to be religious. Thus, although covenant marriage is associated with a lower risk of divorce, this may be attributable to the spouses’ religious beliefs and practices rather than to the covenant marriage per se.

coverage *n.* health care benefits and services provided within a given health plan.

covering-law model a model for scientific explanation positing that a phenomenon is explained only if it can be deduced from a set of statements among which is at least one general scientific law. Thus, a phenomenon can be explained only if it can be predicted. See also *DEDUCTIVE-NOMOLOGICAL MODEL.* [proposed by German philosopher of science Carl Gustav Hempel (1905–1997)]

cover memory see *SCREEN MEMORY.*

cover story a plausible but false statement about the purpose of a research study given to research participants to avoid disclosing to them the true hypothesis being investigated. Such deception may be practiced when the participants’ behavior in the study is apt to be affected by knowledge of the experiment’s true purpose. For ethical reasons, the deception should not flagrantly violate the participants’ right to know what they will be getting into by taking part in the investigation; that is, the deception should not lead participants into harmful, embarrassing, risky, or otherwise compromising behavior. Participants should be debriefed about the cover story as soon as is feasible. See *DECEPTION RESEARCH.*
covert adj. denoting anything that is hidden or that is not directly observable, open to view, or publicly known, whether by happenstance or by deliberate design. Compare overt.

covert attention attention directed to a location that is different from that on which the eyes are fixated. See covert orienting.

covert behavior behavior that is not directly observable and can only be inferred by the observer or reported by the subject. For example, imagining something is covert behavior. See also private event.

covert conditioning a technique of behavior therapy that relies on the use of imagination and assumes that overt and covert behaviors are associated, that each affects the other, and that both forms of behavior depend on the laws of learning. The individual imagines performing a desired behavior in a problematic real-life situation, rewards himself or herself for mentally engaging in the behavior, and finally chooses an actual change in behavior. Also called covert behavioral reinforcement. [developed in 1966 by U.S. psychologist Joseph R. Cautela (1927–1999)]

covet desensitization a form of desensitization therapy in which an individual is helped to overcome a fear or anxiety by learning to relax while imagining an anxiety-producing stimulus. A hierarchy is devised with a sequence of items that range from the least to the most anxiety-producing aspects of the stimulus. The individual then uses relaxation techniques while progressively imagining items on the hierarchy until able to imagine the stimulus without feeling anxious. Compare in vivo desensitization. See also systematic desensitization.

covert extinction a covert conditioning procedure in which the client first imagines performing an unwanted behavior and then imagines failing to be rewarded or to receive reinforcement for the behavior. See also covert positive reinforcement.

covert incest 1. a form of emotional abuse in which a parent turns to his or her child as a surrogate partner, seeking from the child the emotional support that would more appropriately be provided by the person’s spouse or another adult. 2. see emotional incest. [concept developed by U.S. psychologist Kenneth M. Adams]

covet modeling a covert conditioning procedure in which the client pictures a role model, imagines behaving as this person might, and then visualizes specific favorable consequences of the behavior. See also covert positive reinforcement.

covert negative reinforcement in behavior therapy, a technique in which the client first imagines an aversive event and then switches to imagining engaging in a behavior that reverses the adversiveness of the event. For example, a client might imagine that he or she is alone at a restaurant, feeling insecure and unhappy, and then switches the imaginary scene to one in which he or she is asking another person for a date and that person says yes. Compare covert positive reinforcement.

covert orienting the shifting of attentional focus independently of the direction of gaze. Covert orienting can be shown by improved detection or identification of target stimuli at a cued location in the absence of eye movements. See covert attention.

covert positive reinforcement in behavior therapy, a technique in which a person imagines performing a desired behavior that is followed by a pleasant consequence and subsequently rehearsing the behavior in the hope that it will eventually be adopted. Also called covert reinforcement. Compare covert negative reinforcement.

covet rehearsal a technique in which rote repetition in one’s mind of words or behaviors is used to improve memory or to prepare for overt speech or behavior. See also behavior rehearsal.

covert reinforcement see covert positive reinforcement.

covert response any generally unobservable response, such as a thought, image, emotion, or internal physiological reaction, the existence of which is typically inferred or measured indirectly. For example, covert preparation for physical responses can be observed in an electric brain potential called the lateralized readiness potential and in electromyographic measures of muscle activity. Also called implicit response. Compare overt response.

covet sensitization a behavior therapy technique for reducing an undesired behavior in which the client imagines performing the undesired behavior (e.g., overeating) and then imagines an unpleasant consequence (e.g., vomiting).

covert speech talking to oneself. Covert speech is usually seen as the externalization of a person’s inner voice: Some explanations have equated it with thought itself. See also subvocal speech.

COWAT abbreviation for controlled oral word association test.

Cowper’s glands see bulbourethral glands. [William Cowper (1660–1709), English surgeon]

Cox regression analysis a statistical technique used to build multivariate models that relate one or more continuous or categorical variables to survival times, without requiring researchers to specify in advance the form or nature of such relationships. For example, one might use Cox regression to determine how likely it is that alcoholics who are abstinent at 3 months and at 6 months will relapse. A key methodological concept in Cox regression analysis is the hazard, that is, the immediate potential or risk, of event occurrence. There are two types of Cox regression: the simpler standard Cox regression model (or proportional hazards model) and a more complex generalization known as the extended Cox regression model. The standard model is used when the risk of event occurrence for the reference and comparison groups remains constant relative to one another over all time points, whereas the extended model is used when the effect of particular variables upon the occurrence of the event of interest changes over time. [David R. Cox (1924—), British statistician]

CP abbreviation for cerebral palsy.

CPA abbreviation for Canadian Psychological Association.

CPI abbreviation for California Psychological Inventory.

CPP abbreviation for conditioned place preference.

CPQ abbreviation for children’s personality questionnaire.

CPR fees abbreviation for customary, prevailing, and reasonable fees.
crack n. a dried mixture of cocaine and baking soda that can be smoked. It produces a rapid, short-lived high. It is less pure than freebase cocaine and therefore less expensive and more accessible.

crack baby slang for an infant whose mother used crack cocaine during pregnancy. In utero exposure to cocaine has associated negative effects on learning and functioning, although such effects are now believed to be less drastic than feared during the height of the crack epidemic in the 1980s.

cracking facades the process of encouraging people to reveal their true selves. It is associated with Carl Rogers’s encounter-group work.

Cramér’s V (symbol: V: ɸ) a measure of the degree of association between two variables that have two or more unordered response categories. More specifically, it is an omnibus effect size that quantifies the overall association among the rows and columns in a contingency table. Also called Cramér’s phi. [Harald Cramér (1893–1985), Swedish mathematician]

cramp n. a painful muscle spasm (contraction). See also dystonia.

cranial adj. referring or relating to the cranium.

cranial anomaly an abnormal head due to a congenital defect. The head may be abnormally large (as in hydrocephalus), abnormally small (as in microcephaly), or square shaped (as in some cases of osteopetrosis), or it may have sutures that fail to close. The defect is often related to a chromosome abnormality. Chromosomes 17 and 18 are associated with premature fusion of cranial bones, resulting in a skull deformation, usually congenital, that involves the face and cranium. Disorders characterized by such anomalies include Treacher Collins syndrome, Crouzon’s syndrome, and Hurler’s syndrome (see gargoylism).

craniofacial dysostosis see Crouzon syndrome.

cranigraphy n. the study of the skull using graphs and drawings made from measurements of the configuration of the skull and the relations of its angles and craniometric points. The technique is not widely used now.

craniology n. 1. the scientific study of the size, shape, and other characteristics of the human skull. 2. see phrenology.

cranimetry n. the scientific measurement of the skull. —cranimetric adj.

craniosacral system a less common name for the parasympathetic nervous system.

craniosenosis n. a skull deformity caused by premature closing of the cranial sutures. The condition restricts normal development of brain structures and usually results in intellectual disability.

craniosynostosis syndrome a condition caused by premature closure of the cranial sutures. The condition is characterized by such anomalies include anencephaly or encephalocoele. Also called cranium bifidum.

cranial capacity the volume of the skull.

cranial diameter the maximal width of the skull.

cranial division the part of the parasympathetic nervous system whose fibers extend from cranial nerves. Compare sacral division.

cranial electrical stimulation see electrosleep therapy.

cranial index see cephalic index.

cranial nerve any of the 12 pairs of nerves that arise directly from the brain and are distributed mainly to structures in the head and neck. Some of the cranial nerves are sensory, some are motor, and some are mixed (i.e., both sensory and motor). Cranial nerves are designated by Roman numerals, as follows: I, olfactory nerve; II, optic nerve; III, oculomotor nerve; IV, trochlear nerve; V, trigeminal nerve; VI, abducens nerve; VII, facial nerve; VIII, vestibulocochlear nerve; IX, glossopharyngeal nerve; X, vagus nerve; XI, accessory nerve; and XII, hypoglossal nerve.

cranial pia mater see pia mater.

cranial reflex a reflex mediated by one of the cranial nerves, such as the blink reflex in response to a bright light or to a touch to the cornea.

craniofacial anomaly a structural deformity, usually congenital, that involves the face and cranium. Disorders characterized by such anomalies include Treacher Collins syndrome, Crouzon’s syndrome, and Hurler’s syndrome (see gargoylism).

CPS abbreviation for COMBINE PERSONALITY SCALES.

CPT 1. abbreviation for COGNITIVE PROCESSING THERAPY. 2. abbreviation for CONTINUOUS PERFORMANCE TEST.

CR10 scale see BORG SCALE.

CR crash n. 1. the withdrawal symptoms, usually dominated by feelings of severe depression, that occur following a lengthy period of amphetamine intoxication. The user may sleep for several days more or less continuously, displaying signs of exhaustion and irritation during waking periods. See AMPHETAMINE WITHDRAWAL. 2. the period following the “rush” or “high” produced by intravenous cocaine administration. As feelings of euphoria wear off, they are re-
craving

**n.** an unrelenting desire, urge, or yearning. It is often a criterion for the diagnosis of drug addiction or alcoholism.

**creative thinking** the mental processes leading to a new invention, solution, or synthesis in any area. A creative solution may use preexisting elements (e.g., objects, ideas) but creates a new relationship between them. Products of creative thinking include, for example, new machines, social ideas, scientific theories, and artistic works. Compare **CRITICAL THINKING.** See also **DIVERGENT THINKING.**

craziness n., pl. crazinesses. See **DREAD.**

craze n. See **FAD.**

CRB abbreviation for clinically relevant behavior. See **FUNCTIONAL ANALYTIC PSYCHOTHERAPY.**

creatine kinase (CK) an enzyme present in heart muscle, skeletal muscle, and brain tissues. High levels in the blood may be a sign of disease or tissue damage, such as muscular dystrophy or myocardial infarction. The enzyme consists of two subunits, of which there are two possible alternatives: M and B. The combination of subunits is characteristic of certain tissues and can be identified via electrophoresis techniques as myocardial (MB), skeletal muscle (MM), and brain (BB). The MB form is usually specific for myocardial infarction.

creationism n. 1. in its most general sense, the view that the universe was created out of nothing by a higher intelligence, in contrast to the view that it came into being without any such intervention, or that it has existed forever. Although most varieties of this view are religious, all need not be. 2. in a more restricted sense, a family of views that reject evolutionary theories in favor of a literal acceptance of the biblical creation story, holding (among other things) that the world was created by God in 6 days (or fairly short time periods) and that each species of animal (including humans) was created by a separate act of God. See also **INTELLIGENT DESIGN.** —creationist adj., n.

creative arts therapy therapeutic interventions that use artistic endeavors or mediums, such as music, poetry, dance, and drama, to facilitate communication and emotional expression, enhance self-awareness, and foster health and change. See also **ART THERAPY; DANCE THERAPY; DRAMA THERAPY; MUSIC THERAPY; POETRY THERAPY.**

creative dramatics the use, especially with children, of spontaneous drama-oriented play ("pretending") as a therapeutic technique designed to enhance creativity and imagination, improve communication and social skills, and foster health. The emphasis in creative dramatics is not on the end product (e.g., performance) but rather on the creative process itself.

creative genius See **EXCEPTIONAL CREATIVITY.**

creative imagination the faculty by which new, uncommon ideas emerge, especially when emergence does not seem explicable by the mere combination of existing ideas. The operations of the creative imagination are sometimes explained by the interaction of dormant or nonconscious elements with active, conscious thoughts. See also **CREATIVE THINKING; CREATIVITY; DIVERGENT THINKING; IMAGINATION.**

creative intelligence in the **TRIARCHIC THEORY OF INTELLIGENCE,** the set of skills used to create, invent, discover, explore, imagine, and suppose. This set of skills is alleged to be relatively (although not wholly) distinctive with respect to analytical and practical skills. Compare **ANALYTICAL INTELLIGENCE; PRACTICA L INTELLIGENCE.**

creative synthesis the combination of several ideas, images, or associations into a new whole that differs fundamentally from any of its components. See also **MENTAL SYNTHESIS.** [coined by Wilhelm Wundt]

credible interval in **BAYESIAN** methods, a range within which a particular value of a population characteristic has a specified probability of falling. It is the Bayesian equivalent of the **CONFIDENCE INTERVAL** used in **FREQUENTIST** approaches. Also called **credible region.**

creep test in **ECOLOGICAL** studies, a test for monitoring the movement of a chemical that is applied to a soil sample. The chemical moves through the soil and is detected at different depths, allowing the investigator to determine the rate of movement and potential environmental impact.

creeping cracked a condition of the skin and subcutaneous tissues that is similar to eczema but characterized by the formation of thin, scaly, red patches. See also **ECZEMA.**

crepu scular animals animals that are most active in a dimly lighted environment. For example, at dawn or dusk.**

crespi effect in conditioning, an increase (or decrease) in a response that is disproportionate to the reinforcement. This occurs when there is a sudden shift in the amount of reinforcement, for example, if the amount of food given as reinforcement is suddenly increased from 1 g to 6 g, the level of performance is higher than if 6 g of food had been the only reinforcement given. Compare **BEHAVIORAL CONTRAST.** [Leo P. Crespi (1916–2008), U.S. psychologist]

cretinism n. a condition associated with thyroid deficiency that, if untreated, results in delayed physical growth
and intellectual disability. The term is derived from the French word chrétien (Christian) because many early victims were children of an Alpine Christian sect whose diet was deficient in iodine, a necessary element for the synthesis of thyroid hormone. See ATHEROSCLEROSIS; CONGENITAL HYPOTHYROIDISM. [first described in 1657 by Austrian physician Wolfgang Hoeyer]

Creutzfeld–Jakob disease (CJD) a rapidly progressive neurological disease caused by abnormal PRION proteins and characterized by DEMENTIA, involuntary muscle movements (especially MYOCLONUS), ATAXIA, visual disturbances, and seizures. Vacuoles form in the gray matter of the brain and spinal cord, giving it a spongy appearance; the prion is thought to cause misfolding of other proteins, leading to cellular pathology. Classical CJD occurs sporadically worldwide and typically affects individuals who are middle-aged or older. A small proportion (about 10%) of cases are inherited. Early symptoms are muscular incoordination (ataxia), with abnormalities of gait and speech, followed by worsening dementia and myoclonus. Death occurs usually within 1 year of the onset of symptoms. Variant CJD (vCJD) was first reported in Great Britain in the 1990s. It causes similar symptoms but typically affects younger people, who are believed to have acquired the disease by eating meat or meat products from cattle infected with bovine spongiform encephalopathy (BSE). Also called Jakob–Creutzfeldt disease: subacute spongiform encephalopathy (SSE). See also PRION DISEASE.

Crib death see SUDDEN INFANT DEATH SYNDROME.

Cribriform plate a sievelike layer in the skull that supports the Olfactory bulb and permits olfactory receptor fibers to extend through its holes to the OLFACTORY EPITHELIUM.

Cri du chat syndrome a chromosomal disorder involving deletion of the short arm of chromosome 5 and characterized by intellectual disability and developmental delays, walking and talking difficulty or inability, and an anomaly of the epiglottis and larynx that causes infants a high-pitched wailing cry like that of a cat. Almost all affected individuals have very small heads (see Microcephaly). The disorder is hereditary in only 10% of cases and more often results from a random event during early fetal development. Also called cat-cry syndrome: chromsome 5 deletion of short arm: crying-cat syndrome: Lejeune syndrome: monosomy 5p.

Crime control model a view of legal process that places a premium on upholding law and order, the protection and safety of the public, and the apprehension and efficient processing of criminals. Compare DUE PROCESS MODEL.

Criminal anthropology an early positivist approach to criminology (see POSITIVIST CRIMINOLOGY) associated with the theories of Italian criminologist and psychiatrist Cesare Lombroso (1835–1909). It embraced the notion of the “born criminal” or criminal type, based on the belief that criminals had certain physical characteristics (e.g., sloping forehead, large ears) that distinguished them from non-criminals. Lombroso identified these characteristics as “atavistic anomalies . . . that bring man closer to the inferior animals,” then developed a hypothesis that linked delinquency to constitutional anomalies and attributed the primary cause of crime to hereditary flaws.

Criminal commitment the confinement of people in mental institutions either because they have been found NOT GUILTY BY REASON OF INSANITY or to establish their COMPETENCY TO STAND TRIAL as responsible defendants.

Criminal conviction a court declaration finding a person guilty and responsible for a criminal offense.

Criminal intent see MENS REA.

Criminally insane describing defendants who are judged to have a mental illness or defect that absolves them of legal responsibility for the criminal acts they are alleged to have committed. The term is now seldom used.

Criminal profiling techniques used to narrow a criminal investigation to suspects with certain personality and behavioral traits that might be inferred from the way a crime was committed, where it occurred, and other information such as the background of the victim or victims (i.e., victimology). Psychologists have played a central role in studying and developing these techniques. Although some research validates profiling as a tool that helps police concentrate their investigations, there is also controversy regarding such issues as hasty identifications that ignore or foreclose other leads, methodological flaws, and the like.

Criminal psychopath a person with ANTISOCIAL PERSONALITY DISORDER who repeatedly violates the law.

Criminal responsibility a defendant’s ability to formulate criminal intent (see MENS REA) at the time of the crime with which he or she is charged: it must be proved in court before the person can be convicted. Criminal responsibility may be excluded for reason of INSANITY (see DURHAM RULE: IRRESISTIBLE IMPULSE RULE: M’NAUGHTEN RULE) or mitigated for a number of other reasons (see DIMINISHED CAPACITY; DIMINISHED RESPONSIBILITY).

Criminal type a classification of individuals who repeatedly engage in criminal or illegal acts, supposedly because of a genetic predisposition to do so.

Criminology n. the scientific study of crime and criminal behavior, which includes its causes, prevention, and punishment. See also POSITIVIST CRIMINOLOGY. —criminologist n.

Crisis n. (pl. crises) 1. a situation (e.g., a traumatic change) that produces significant cognitive or emotional stress in those involved in it. 2. a turning point for better or worse in the course of an illness. 3. a state of affairs marked by instability and the possibility of impending change for the worse, for example, in a political or social situation. 4. in the analysis of SCIENTIFIC REVOLUTIONS by U.S. philosopher of science Thomas Kuhn (1922–1996), the situation that occurs when a particular theoretical system is overcome by so many anomalies that it is perceived to be failing and a search for a better theoretical system is under way.

Crisis center a facility established for emergency therapy or referral, sometimes staffed by medical and mental health professionals and paraprofessionals. See DROP-IN CENTER.

Crisis counseling immediate drop-in, phone-in, or on-site professional counseling provided following a trauma or sudden stressful event, often for emergency situations or in crisis counseling
the aftermath of a disaster. See DISASTER COUNSELING; HOT- 
LINE.

**crisis intervention** 1. the brief ameliorative, rather than specifically curative, use of psychotherapy or counsel-
ing to aid individuals, families, and groups who have un-
dergone a highly disruptive experience, such as an un-
expected bereavement or a disaster. Crisis intervention may 
prevent more serious consequences of the experience, 
such as posttraumatic stress disorder. See also EMERGENCY 
INTERVENTION. 2. psychological intervention provided on a 
short-term, emergency basis for individuals experiencing 
mental health crises, such as anACUTE PSYCHOTIC EPISODE 
or ATTEMPTED SUICIDE.

**crisis intervention service** any of the services pro-
vided (usually by governmental or social agencies) during 
energies, disasters, and personal crises. Such services 
include hotlines, drop-in services, and on-site intervention 
at the scene of a disaster.

**crisis management** the organization and mobilization 
of resources to overcome the difficulties presented by a 
sudden and unexpected threat, such as widespread food con-
tamination or a financial catastrophe. The psychological 
stress produced by a crisis can reduce the information-pro-
cessing capacities of those affected, which should be taken 
into account by crisis managers when considering possible 
solutions.

**crisis team** a group of professionals and paraprofession-
als trained to help individuals cope with psychological re-
actions during and following emergencies or mental health 
 crises, such as natural disasters or suicide threats or at-
tempts.

**crisis theory** the body of concepts that deals with the 
nature, precipitants, prevention, and resolution of, as well 
as the behavior associated with, a crisis.

crista (crysta) n. the structure within the ampulla at the 
end of each SEMICIRCULAR CANAL that contains hair cells 
sensitive to the direction and rate of movements of the head.

**criteria of evaluation** the criteria used to specify or 
measure PROGRAM IMPACT or, often, PROGRAM OUTCOME as 
stated in the EVALUATION OBJECTIVES of a study.

**criteria of the psychic** a proposed set of signs or indica-
tors that would allow one to be confident in concluding that 
an organism possesses consciousness, or that a behav-ior arises from consciousness as opposed to purely physio-
logical sources. The idea that such criteria could be 
formulated was proposed by Robert M. YERKES. Yerkes's 
structural criteria were general morphology, neural organi-
zation, and neural specialization; his proposed functional 
criteria were discrimination, modifiability of reaction, and 
variability of reaction.

criterion n. (pl. criteria) a standard against which a 
judgment, evaluation, or comparison can be made. For ex-
ample, a well-validated test of creativity might be used as 
the criterion to develop new tests of creativity.

**criterion-based content analysis** (CBCA) a form of 
STATEMENT VALIDITY ANALYSIS in which children’s state-
ments in instances of alleged abuse are analyzed in terms of 
key content criteria to evaluate their truth.

**criterion contamination** a situation in which a re-
spose measure (the criterion) is influenced by factors that 
are not related to the concept being measured. Evidence of 
this may be observed through correlations of the response 
measure with variables that are conceptually distinct from 
that measure. For example, performance discrepancies (in 
dollars sold) among insurance agents may arise not from 
any actual differences in ability but rather from socioeco-
nomic differences in territories assigned to the salespeople.

**criterion cutoff** see CUTOFF SCORE.

**criterion data** information obtained from supervisors 
or other sources, such as absence records, that may be used 
in measuring the performance of employees in a job. See 
JOB CRITERION; JOB PERFORMANCE.

**criterion dimensions** in industrial and organizational 
psychology, multiple standards or variables used to evalu-
ate the overall JOB PERFORMANCE of an employee. These 
may include such aspects of performance as productivity, 
effectiveness, absences, errors, and accidents. Multiple cri-
teria are often preferred over the use of a single criterion 
because an individual may be outstanding in one aspect of 
job performance but below average in another.

**criterion group** a group tested for traits its members 
among already known to possess, usually for the purpose of 
demonstrating that responses to a test represent the traits 
they were intended to represent. For example, a group of 
children with diagnosed visual disabilities may be given a 
visual test to assess its validity as a means of evaluating the 
presence of visual disabilities.

**criterion problem** see PARTICULARISM.

**criterion-referenced test** an exam from which deci-
sions are made about an individual’s absolute level of ac-
shallishment (i.e., mastery or nonmastery) of the 
material covered in that exam according to some standard 
reference point. For example, if a student obtains a score of 
70% on a reading exam and a passing score is 65%, then he 
or she has done acceptably well. Also called CONTENT-
referenced test. See also DOMAIN-REFERENCED TEST; 
NORM-REFERENCED TEST.

**criterion score** 1. a score on a variable that serves as a 
standard against which other scores may be judged in a 
CRITERION-REFERENCED TEST. 2. in REGRESSION ANALYSIS, 
a predicted score on an attribute or variable.

**criterion validity** an index of how well a test correlates 
with an established standard of comparison (i.e., a CRITE-
RION). Criterion validity is divided into three types: PREDIC-
TIVE VALIDITY, CONCURRENT VALIDITY, and RETROSPECTIVE 
VALIDITY. For example, if a measure of criminal behavior is 
valid, then it should be possible to use it to predict whether 
an individual (a) will be arrested in the future for a crimi-
nal violation, (b) is currently breaking the law, and (c) has 
a previous criminal record. Also called criterion-refer-
ced validity; criterion-related validity.

**criterion variable** see DEPENDENT VARIABLE.

**critical** adj. 1. essential or necessary as an attribute or as 
a part of some process. A CRITICAL PERIOD, for example, is 
an essential stage in the developmental process. 2. empha-
sizing real or imagined faults. 3. characterized by or denot-
ing thorough, impartial evaluation or review.

**critical band** the band of frequencies in a masking noise 
that are effective in masking a tone of a given frequency 
(see AUDITORY MASKING). The width of this band, in hertz (Hz), is the critical bandwidth. For example, in detecting a 1 
kHz tone in white NOISE, only frequency components in the 
noise between 920 Hz and 1080 Hz contribute signifi-
critical period for language acquisition in human infants.

critical care unit (CCU) see INTENSIVE CARE UNIT.

critical flicker frequency (CFF) the rate at which a periodic change, or flicker, in an intense visual stimulus fuses into a smooth, continuous stimulus. A similar phenomenon can occur with rapidly changing auditory stimuli. Also called flicker fusion frequency.

critical-incident stress debriefing (CISD) a structured and programmed process of PSYCHOLOGICAL DEBRIEFING designed predominantly as a group-based intervention to help individuals who witness or work at the scene of a critical incident or disaster (e.g., firefighters). The process relies heavily on reconstruction of the traumatic event, VENTILATION, and normalization of distress. There is contradictory published data on the outcomes of CISD, with some studies showing no measurable effect or a paradoxical effect, whereby those who are debriefed are more likely to develop posttraumatic stress disorder than are nondebriefed individuals. [developed by U.S. psychologist Jeffrey T. Mitchell (1948—) ]

critical-incident technique (CIT) a method designed to investigate factors associated with unusually good or unusually poor job performance. Observers record unusual outcomes and specific incidents, behaviors, or system features that may have triggered these outcomes. Data collected in this way are then classified and analyzed to identify key themes. The critical-incident technique is widely used in such areas as ACCIDENT PREVENTION and the creation of BEHAVIORALLY ANCHORED RATING SCALES for use in employee evaluation. See also BEHAVIORAL OBSERVATION SCALE, MIXED-STANDARD SCALE.

critical life event an event in life that requires major adjustment and adaptive behavior. Such events may be regarded in retrospect as unusually formative or pivotal in shaping attitudes and beliefs. Common critical life events include the death of a loved one, divorce, and unemployment. See also LIFE EVENTS.

critical period 1. an early stage in life when an organism is especially open to specific learning, emotional, or socializing experiences that occur as part of normal development and will not recur at a later stage. For example, the first 3 days of life are thought to constitute a critical period for IMPRINTING in ducks, and there may be a critical period for language acquisition in humans. See also SENSITIVE PERIOD. 2. in vision, the period of time after birth, varying from weeks (in cats) to months (in humans), in which full, binocular visual stimulation is necessary for the structural and functional maturation of the VISUAL SYSTEM. See also MONOCULAR REARING.

critical point a point in the course of psychotherapy at which the client sees his or her problem clearly and decides on an appropriate course of action to handle or resolve it.

critical range a range of values that may be obtained from a statistical procedure that would lead to rejecting a specific claim about a population. More specifically, it is the portion of a PROBABILITY DISTRIBUTION containing the values for a test statistic that would result in rejection of a NULL HYPOTHESIS in favor of its corresponding ALTERNATIVE HYPOTHESIS. Also called rejection region. Compare acceptance region.

critical thinking a form of directed, problem-focused thinking in which the individual tests ideas or possible solutions for errors or drawbacks. It is essential to such activities as examining the validity of a hypothesis or interpreting the meaning of research results. Compare CREATIVE THINKING, SEE CONVERGENT THINKING.

critical value a value used to make decisions about whether a test result is statistically meaningful. For example, to evaluate the result of a T TEST to determine whether a sample mean is significantly different from the hypothesized population mean, a researcher would compare the obtained test statistic to the values from a T DISTRIBUTION at a given PROBABILITY LEVEL. If the statistic exceeds the critical value within that distribution, the NULL HYPOTHESIS is rejected and the result is considered significant. Also called rejection value. See also CRITICAL REGION.

CRM abbreviation for CUSTOMER RELATIONSHIP MANAGEMENT.

Crocker–Henderson odor system a theory that posits four primary odor qualities: acid, burnt, caprylic, and fragrant. The presence of each primary in an odor is assessed via a 9-point scale (0–8) indicating the relative intensity of each quality. See also HENNING’S ODOR PRISM. [Ernest C. Crocker (1888–1964) and Lloyd E. Henderson, U.S. chemists]

Cro-Magnon n. an early form of modern human (Homo sapiens) inhabiting Europe in the late Paleolithic period, so named because the first skeletal remains were found in the Cro-Magnon cave in southern France.

Cronbach’s alpha a measure of the average strength of association between all possible pairs of items contained within a set of items. It is a commonly used index of the internal consistency of a test and ranges in value from 0, indicating no internal consistency, to 1, indicating perfect internal consistency. Also called alpha coefficient; coefficient alpha. [Lee J. CRONBACH]

cross-correlation theory see SYNESThesIA.

cross-adaptation n. the change in sensitivity to one stimulus caused by adaptation to another. See CROSS-NASAL ADAPTATION.

cross-addiction n. see CROSS-DEPENDENCE.

crossbreeding n. see OUTBREEDING.

cross-classification n. the placing of observations or individuals into classes based on the features of two or more variables. More specifically, it is a system of classification used in experimentation in which each person or other sampling unit is assigned to the intersection of a row category and a column category. This is usually carried out by means of a CONTINGENCY TABLE.

cross-classification table see CONTINGENCY TABLE.

cross-conditioning n. conditioning to a NEUTRAL STIMULUS when this stimulus by coincidence occurs simultaneously with an UNCONDITIONED STIMULUS.

cross-correlation n. a measure of the degree of associ-
cross-correlation mechanism

The cross-correlation mechanism is the auditory mechanism thought to underlie sound localization based on interaural time differences (see binaural cue).

cross-correspondence

In spiritualism and parapsychology, the situation in which two or more mediums, who claim to be in touch with the same spirit source but not with each other, produce similar or complementary messages. To the believer, cross-correspondence provides firm evidence for the objective reality of spirit messages (or, at the very least, for some form of telepathy between the mediums). A more mundane explanation might stress (a) the mediums’ access to the same biographical facts about the dead person and the same information regarding his or her interests, tastes, and opinions and (b) the mediums’ knowledge of the same spiritualist texts concerning the nature of the afterlife and the spirit world.

cross-cuing

The use of one sense modality to identify an object when another, more direct sense modality is not available. For example, commissurotomy (the split-brain technique) has revealed that auditory information may be used to name a visual object when visual information is not available to the cerebral hemisphere mainly responsible for speech.

cross-cultural approach

A research method in which specific social practices, such as courtship behavior, child-rearing practices, or therapeutic attitudes and techniques, are studied and compared across a number of different cultures. Also called cross-cultural method.

cross-cultural psychology

A branch of psychology that studies similarities and variances in human behavior across different cultures and identifies the different psychological constructs and explanatory models used by these cultures. It has been influenced by anthropology and emphasizes social psychological analyses of international differences. See also ethnic psychology; multicultural psychology.

cross-cultural research

The systematic study of human psychological processes and behavior across multiple cultures, involving the observation of similarities and differences in values, practices, and so forth between different societies. Cross-cultural research offers many potential advantages, informing theories that accommodate both individual and social sources of variation, but also involves numerous risks, notable among them the production of cultural knowledge that is incorrect because of flawed methodology. Indeed, there are a host of methodological concerns that go beyond monocultural studies, including issues concerning translation, measurement, equivalence, sampling, data analytic techniques, and data reporting. Also called cross-cultural method: cross-cultural study.

cross-cultural testing

The assessment of individuals from different cultural backgrounds. The use of instruments that are free of bias is essential to valid cross-cultural testing, as it provides for the measurement equivalency necessary to ensure that outcomes have the same meaning across diverse populations of interest. For example, scores on a coping questionnaire that possesses bias may be a legitimate measure of coping if they are compared within a single cultural group, whereas cross-cultural differences identified on the basis of this questionnaire may be influenced by other factors, such as translation issues, item inappropriateness, or differential response styles. See also culture-fair test.

cross-cultural treatment

Treatment in situations in which therapist and client differ in terms of race, ethnicity, language, or lifestyle. Mental health providers should be atten- tive to cultural differences with clients for the following (among other) reasons: (a) Social and cultural beliefs influence diagnosis and treatment; (b) diagnosis differs across cultures; (c) symptoms are expressed differently across cultures; (d) formal diagnostic categories reflect majority cultural values; and (e) most providers are from the majority culture.

cross-dependence

1. The ability of one substance to prevent withdrawal symptoms from a different substance of the same class or with a similar effect. This is the pharmacological mechanism behind substitution pharmacotherapy. Cross-dependence allows the substitution of a less dangerous drug as treatment for substance dependence, as in the substitution of methadone for heroin. 2. the condition of becoming rapidly dependent on a substance that is related to one for which there is already dependence. 3. The condition of being simultaneously dependent on more than one substance. Also called cross-addiction. Compare cross-tolerance.

cross-dimensional attitude consistency

The extent to which the dimensions (i.e., distinct categories of information) underlying attitude-relevant knowledge are evaluatively consistent with one another. For example, if the information related to one dimension is extremely positive and the information related to a second dimension is extremely negative, cross-dimensional attitude consistency is low. Also called between-dimension consistency. See also ambiguity of an attitude; complexity of an attitude; within-dimension attitude consistency.

cross-dressing

The process or habit of putting on the clothes of the opposite sex. It is done for a variety of reasons, such as, for example, as part of a performance, as social commentary, or for sexual pleasure. See transvestism.

crossed aphasia

Aphasia resulting from damage to the right hemisphere of the brain rather than the left hemisphere, which is more common.

crossed disparity

See uncrossed disparity.

crossed dominance

The tendency for some right-handed people to have a stronger or dominant left eye, and vice versa for the left-handed.

crossed-extension reflex

A reflexive action by a contralateral limb to compensate for loss of support when the ipsilateral limb withdraws from a painful stimulus. The reflex, which helps shift the burden of body weight, is also associated with the coordination of legs in walking by flexing muscles on the left side when those on the right are extending, and vice versa.

crossed-factor design

A study that involves two or more conditions or treatments in which each level of one condition or treatment is combined with each level of every other condition or treatment. For instance, a pharmacutical treatment (Drug A vs. Drug B) may be combined with a biofeedback treatment (biofeedback vs. no biofeedback) so that each drug is combined with each type of biofeedback to form four possible interventions or treatment plans. The individual conditions being manipulated
are known as \textit{crossed factors} or \textit{crossed treatments}. Also called \textit{crossed design}.

\textbf{crossed reflex} a reflex that occurs on the opposite side of the body from the part stimulated, such as the \textit{crossed-extension reflex}.

\textbf{cross-education} n. see \textit{CROSS-TRAINING}.

\textbf{cross-eye} n. a type of \textit{strabismus} (squint) in which there is a deviation of one or both eyes toward the other. The condition usually begins in infancy and is caused by deficient activity of one or more \textit{extrinsic eye muscles}. Uncorrected cross-eye results in double visual images or \textit{functional amblyopia}. Cross-eye can be treated surgically in most cases. Also called \textit{convergent strabismus; esotropia}.

\textbf{cross-fostering} n. 1. in \textit{Animal Behavior} studies, the exchange of offspring between litters as a means of separating the effects of genetics from early experience. Wild rats reared by laboratory rats display less aggressive behavior, and mice from a polygenic species with low levels of territorial aggression that are cross-fostered to monogamous territorial mice display increased aggression and have patterns of brain neuuropeptides more similar to their foster parents than to their natural parents. See also \textit{Sexual imprinting}. 2. a similar technique used for investigating the effect of genetic factors in the development of a disorder. It involves either (a) having the offspring of biological parents who do not show the disorder reared by adoptive parents who do or (b) having offspring of parents who show the disorder reared by parents who do not. Children cross-fostered in this manner are called \textit{index adoptees}, whereas \textit{control adoptees} are children whose biological parents and adoptive parents do not show the disorder.

\textbf{cross-functional team} in business, a work group composed of members of diverse departments across the organization and different levels of authority. Each member of the team brings specific functional expertise necessary to handle a specific product, issue, or customer. Also called \textit{project team}. See also \textit{Subject-Matter Expert}.

\textbf{cross-gender behavior} the process or habit of assuming the role of the opposite gender by adopting the clothes, hair style, and manner of speaking and gesturing that society considers characteristic of that gender. See \textit{Cross-dressing}.

\textbf{crossing over} in genetics, see \textit{Recombination}.

\textbf{cross-lagged panel design} a study of the relationships between two or more variables across time in which one variable measured at an earlier point in time is examined with regard to a second variable measured at a later point in time, and vice versa. For example, suppose an organizational researcher measures job satisfaction and job performance at the beginning of a fiscal year and at the beginning of a second fiscal year. Examining the correlations between satisfaction and performance at the different times provides information about their possible causal association: If the correlation between high performance at Time 1 and satisfaction at Time 2 is significantly stronger than the correlation between satisfaction at Time 1 and performance at Time 2, it is potentially the case that those who perform better are the ones who subsequently are more satisfied with their jobs.

\textbf{cross-linkage theory} the concept that biological aging results from functional deterioration of body tissues due to the molecular cross-linkages of and subsequent structural changes in collagen and other proteins. [proposed in 1942 by Finnish-born U.S. chemist Johan Bjorksten (1907–1995)]

\textbf{cross-modal association} 1. the coordination of sensory inputs involving different brain regions. It is usually required in tasks that involve matching auditory and visual inputs, tactile and visual inputs, or a similar combination of cognitive functions. Lesions in the temporal, parietal, or occipital lobes may be diagnosed by cross-modal association testing. See \textit{Perceptual synthesis; Sensory interaction}. 2. a phenomenon in which the input to one sense reliably generates an additional sensory output that is usually generated by the input to a separate sense.

\textbf{cross-modality matching} a \textit{direct scaling} method of matching the magnitude of a stimulus (e.g., the brightness of a light) to the magnitude of another stimulus to which a different sense responds (e.g., the loudness of a sound).

\textbf{cross-modal matching} the ability to recognize an object initially inspected with one modality (e.g., touch) via another modality (e.g., vision). Also called \textit{intermodal matching}.

\textbf{cross-modal perception} see \textit{Intersensory perception}.

\textbf{cross-modal transfer} recognition of an object through a sense other than the sense through which the object was originally encountered.

\textbf{cross-nasal adaptation} \textit{Olfactory adaptation} in one side of the nose after presenting a stimulus to the other side of the nose. Typically, cross-nasal adaptation is less pronounced than the adaptation in the side of the nose that receives the stimulus.

\textbf{crossover design} a study in which different treatments are applied to the same individuals but in different sequences. In the most basic crossover design, a group of participants receives Treatment A followed by Treatment B whereas a second group receives Treatment B followed by Treatment A. For example, a researcher could use such a design to assess the effect of attending a day service on stroke survivors, randomly assigning participants to one of two groups, the first of which would attend the service for 6 months and then not attend for 6 months, and the second of which would not attend the service for 6 months and then would attend for 6 months. As with \textit{Within-Subjects Designs}, the benefit of this design is the reduction in \textit{error variance}. Also called \textit{Crossover study; Crossover trial}. Compare \textit{Parallel-Groups Design}. See also \textit{Graeco-Latin square; Latin square}.

\textbf{cross-product} n. the set of values obtained by multiplying each value of one variable \((x)\) by each value of a second variable \((y)\).

\textbf{cross section} a slice cut through any plane of an object or organ for examination. See \textit{Coronal section; Horizontal section}. —\textit{cross-sectional} adj.

\textbf{cross-sectional analysis} the examination of data that have been collected at a single point in time. For example, a researcher might conduct a cross-sectional analysis after measuring the income of people in different professions at the end of a particular year. Compare \textit{Time-series analysis}.

\textbf{cross-sectional design} a research design in which in-
cross-sectional sampling a sampling method in which scores are obtained at a single point in time. For example, cross-sectional sampling may involve collecting data from individuals of various ages or developmental levels so as to study behavioral or other differences among them.

cross-sectional design a study in which two or more groups of individuals of different ages are directly compared over a period of time. It is thus a combination of a cross-sectional design and a longitudinal design. For example, an investigator using a cross-sectional design to evaluate children’s mathematical skills might measure a group of 5-year-olds and a group of 10-year-olds at the beginning of the research and then subsequently reassess the same children every 6 months for the next 5 years. Also called cross-sectional study.

cross-situational consistency the degree to which a psychological attribute, such as a personal disposition or a cognitive style, is displayed in the same, or a functionally equivalent, manner in different social environments.

cross-tabulation n. the number, proportion, or percentage of cases that have specific combinations of values on two variables that each have multiple categories. Such information may be presented visually in a cross-tabulation table. For example, a cross-tabulation table could be used to show the number of study participants according to both their sex and marital status.

cross-talk n. a pattern of errors that occurs during the concurrent performance of tasks when the components of one task impinge on those of the other task, for example, when performing a different task with each hand. See dual-task performance.

cross-tolerance n. a condition in which TOLERANCE to one drug results in a lessened response (i.e., increased tolerance) to a related drug. Cross-tolerance may be seen with amphetamines, benzodiazepines, hallucinogens, and opiates, among other drugs. Compare cross-dependence.

cross-training n. 1. training employees in a variety of tasks or jobs that are outside their specialty areas so that they can substitute for one another when unforeseen absences occur. Cross-training is used to develop employee skills and to increase the flexibility with which a group or organization can deal with work demands. 2. improvement in skill performance of one part of the body (e.g., the left hand) as a result of practice with another part of the body (e.g., the right hand). Also called cross-education. 3. in sport, combining different sport or fitness activities to improve such areas as performance, endurance, flexibility, or weight loss. Combinations such as running (track), swimming, and weightlifting are typical. —cross-train vb.

cross-validation n. a procedure used to assess the utility or stability of a statistical model. A data set is randomly divided into two subsets, the first of which (the derivation sample) is used to develop the model and the second of which (the cross-validation sample) is used to test it. In regression analysis, for example, the first subset would be analyzed in order to develop a regression equation, which would then be applied to the remaining subset to see how well it predicts the scores that were actually observed.

Crouzon syndrome a condition in which a wide skull with a protrusion near the anterior fontanel (on top of the head, at the front) is associated with a beaked nose and ocular abnormalities (see CRANIOSYNOSTOSIS SYNDROME). The latter may include atrophy, divergent strabismus, and blindness. Neurological disorders may result from intracranial pressure, and intellectual disability may occur in some cases. Also called craniofacial dysostosis. See also Apert syndrome. [described in 1912 by Octave Crouzon (1874–1938), French neurologist]

crowd n. a sizable gathering of people who temporarily share a common focus and a single location. Crowds vary in shape, size, and type; some common types include casual crowds and milling crowds that form in the street, audiences, queues, and mobs.

crowd behavior the activities or conduct of a group of people who congregate temporarily while their attention is focused on the same object or event. Such behavior may differ depending on the nature of the crowd. For example, an audience tends to be relatively passive (smiling, laughing, applauding), whereas a street or milling crowd typically moves without apparent aim and a mob may act violently. See also collective behavior.

crowding n. 1. psychological tension produced in environments of high population density, especially when individuals feel that the amount of space available to them is insufficient for their needs. Crowding may have a damaging effect on mental health and may result in poor performance of complex tasks, stressor aftereffects, and increased physiological stress. In nonhuman animals, crowding can lead to impaired reproduction, decreased life expectancy, and a variety of pathological behaviors. Two key mechanisms underlying crowding are lack of control over social interaction (i.e., privacy) and the deterioration of socially supportive relationships. See also behavioral sink; density. 2. a phenomenon in which the perception of a suprathreshold target is impaired by nearby distractors, reflecting a fundamental limitation on visual spatial resolution. In reading, for example, letter recognition is reduced by crowding from adjacent letters. Also called crowding effect.

crowd psychology 1. the mental and emotional states and processes unique to individuals when they are members of street crowds, mobs, and other such collectives. 2. the scientific study of these phenomena. See also collective psychology.

cRS abbreviation for Conners’ Rating Scales.

crus n. (pl. crura) 1. the portion of the leg between the knee and the ankle. 2. a leglike part of the body, such as the ventral portion of a cerebral peduncle. —crural adj.

crus cerebri see cerebral peduncle.

crutch n. 1. a device, usually made of metal or wood, designed to provide ambulatory support to people with disabilities or other problems affecting the lower limbs. 2. colloquially, a nonspecific coping or support mechanism, which may be of a psychological, medicinal, or other nature. 3. a learning aid.

crying-cat syndrome see cri du chat syndrome.
cryogenics n. the branch of physics concerned with the study of extremely low temperatures and resulting phenomena. It has diagnostic and therapeutic application, as when certain immunoglobulins associated with a variety of diseases are detected in the blood by reducing the temperature of a blood sample to the point at which the substances separate from the blood serum. Cryogenic methods are also used to freeze tissue samples to be sliced for microscopic examination or to be destroyed, as in cryogenic surgery, which selectively destroys diseased tissue by freezing it.

cryogenic suspension the attempt to preserve a corpse with the intention of subsequent revival and restoration to healthy life. Dr. James H. Bedford, a retired professor of psychology who died on January 12, 1967, is thought to have been the first person to be placed in cryonic suspension (in a stainless steel chamber filled with liquid nitrogen). An estimated 250 people have since undergone the procedure upon their death. No human resuscitations from cryonic suspension have yet been reported or, as far as is known, even attempted.

cryptostat n. a device for cutting thin, frozen sections (slices) of tissue, used, for example, in preparing brain and other tissue sections for microscopic examination. Compare MICROTOME.

crypsis n. the ability to remain inconspicuous through immobility and other behavior or through the use of CAMOUFLAGE. —cryptic adj.

cryptarithmetic n. in studies of problem solving, an arithmetic problem in which the digits are replaced with letters. The participant must determine which digit is represented by each letter. See also CODE TEST; CRYPTOGRAM.

cryptesthesia (cryaesthesia) n. an experience of CLAIRVOYANCE, CLAIRAUDIENCE, TELEPATHY, or some other form of Extrasensory Perception that cannot be explained with reference to any known sensory stimulus. Also called TELESTHESIA. —cryptesthetic adj.

cryptic female choice a practice in which females mate with several males but “choose” which one’s sperm will fertilize their eggs, concealing these decisions from the males. This practice allows females more choice in MATE SELECTION. In studies demonstrating cryptic female choice, it is the sperm that is genetically most compatible that fertilizes the female’s eggs, rather than sperm from the most attractive males.

crypto- (crypt-) combining form concealed.

crypto- (cryo-) combining form cold or freezing.

cryptophobia n. secret or incomprehensible language, especially the peculiar communication patterns that are sometimes developed between twins and are understandable only to them.

cryptophoric symbolism a type of REPRESENTATION expressed indirectly in the form of a metaphor. For example, a person may describe a difficult relationship in terms of an illegible map or a stuck door. In METAPHOR THERAPY, patients are encouraged to alter their attitudes or perceptions by finding new metaphors. Also called METAPHORIC SYMBOLISM. [described by U.S. psychotherapist Richard R. Kopp (1942–2012)]

cryptophthalmos syndrome a familial or hereditary disorder in which a child is born with skin covering the eyes. The anomaly may occur on one side or both. The eyes are usually present under the facial skin but abnormal: eyelids, eyelashes, and, usually, tear ducts are lacking. The individual may be able to discern light and colors. Hearing loss is common, as are ear anomalies. Intellectual disability, malformations in the genitals, and syndactyly (fused fingers or toes) can also occur. Also called FRAISER–FRANÇOIS SYNDROME: FRASER SYNDROME.

cryptorchidism n. the failure of one or both testes to descend into the scrotum. It is not unusual and does not interfere with male hormonal function, but spermatogenesis is unlikely if the individual with this condition is not treated in childhood. The untreated condition is also associated with an increased incidence of testicular cancer in later life. Also called ARRESTED TESTIS; HYPERMOBILE TESTIS; MONORCHIDISM. —cryptorchid adj., n.

cryta n. see CRISTA.

crystal gazing 1. in certain alternative therapies, a technique in which an individual is instructed to visualize significant experiences or produce associations while staring into a glass ball, light bulb, mirror, or other shiny or transparent object. 2. the occult practice in which a fortune teller or clairvoyant looks into a crystal ball to “see” visions of future or hidden events, usually in the life of a particular client. It is a form of SCRrying.

Crystal healing a pseudoscientific medical practice in which the alleged power of certain crystals to affect the human energy field is used to treat physical or mental ailments. See REICHENBACH PHENOMENON. See also FAITH HEALING; PSYCHIC HEALING.

crystalization n. in social psychology, ATTITUDE STRENGTH or, more specifically, the level of persistence of an ATTITUDE over time and the level of resistance to active attempts to change it.

crystallized intelligence (crystallized ability) see CATTELL–HORN THEORY OF INTELLIGENCE.

CS abbreviation for CONSCIOUS.

CS abbreviation for CONDITIONED STIMULUS.

CSA abbreviation for CONTROLLED SUBSTANCES ACT.

CSAI abbreviation for COMPETITIVE STATE ANXIETY INVENTORY.

C-section n. abbreviation for CESAREAN SECTION.

CSERP abbreviation for CHEMOSENSORY EVENT-RELATED POTENTIAL.

CSES abbreviation for COLLECTIVE SELF-ESTEEM Scale.
**CSF** 1. abbreviation for CEREBROSPINAL FLUID. 2. abbreviation for CONTRAST-SENSITIVITY FUNCTION.

**CSI effect** a presumed phenomenon in which popular television crime shows are thought to raise jurors’ expectations about forensic science and influence their verdicts if the evidence they hear at trial does not meet those expectations. This effect, according to observations from attorneys, judges, and journalists, is manifested as jurors tending to believe they understand the manner in which investigators collect, analyze, and interpret crime scene evidence; to insist on large amounts of often highly technical evidence in determining defendant guilt; and to overvalue the conclusiveness of DNA testing—that is, to have forensic presumptions of the sort that are the stock and trade of popular crime dramas on television. Despite the amount of media attention devoted to the CSI effect, preliminary research on its existence has produced mixed results. [coined from CSI: Crime Scene Investigation, the name of a popular U.S. forensics-based television program that began in 2000, as well as its spin-offs]

**CSR** 1. abbreviation for COMBAT STRESS REACTION. 2. abbreviation for CONTINUED-STAY REVIEW.

**CSS** abbreviation for CONTENTION SCHEDULING SYSTEM.

**C-suite** the highest ranking executives in a corporation, collectively. The term is derived from the tendency to give the most important senior-level executives titles beginning with chief, as in chief executive officer, chief operating officer, and so forth. Also called C-level executives.

**CS–US interval** abbreviation for CONDITIONED STIMULUS–UNCONDITIONED STIMULUS INTERVAL.

**CT** 1. abbreviation for COGNITIVE THERAPY. 2. abbreviation for COMPUTED TOMOGRAPHY. 3. abbreviation for CONDUCTION TIME.

**CTD** abbreviation for cumulative trauma disorder (see REPETITIVE STRAIN INJURY).

**CTI** abbreviation for CONSTRUCTIVE THINKING INVENTORY.

**CTS** abbreviation for CARPAL TUNNEL SYNDROME.

**CT scan** abbreviation for COMPUTED TOMOGRAPHY scan.

**CTT** abbreviation for CLASSICAL TEST THEORY.

**CTZ** abbreviation for CHEMORECEPTOR TRIGGER ZONE.

**cube model** a three-dimensional model of the information cues that determine causal attributions. The cues are consistency (the extent to which observed behavior agrees with previous behavior), distinctiveness (the contextual, or situational, variability surrounding the behavior), and consensus (the extent to which others act similarly in the same situations). See ATtribution THEORY.

**cubic difference tone** see COMBINATION TONE.

**cubicle etiquette** a set of workplace SOCIAL NORMS for the behavior of employees in partitioned cubicles, governing such issues as privacy, noise, odors, and WORKSPACE cleanliness.

**cuckoldry** n. sexual behavior in which a pair-bonded female mates with a male other than her partner. Only about 10% of bird species that are socially monogamous are genetically monogamous as well (see MONOGAMY). Males whose mates engage in EXTRAPARITAL MATING assist in the rearing of the unrelated offspring. Females practicing cuckoldry may benefit from having progeny from genetically higher quality males; for example, female blackbirds that do this have more surviving offspring than monogamous blackbirds.

**cuddling** n. holding close; a form of ATTACHMENT BEHAVIOR between individuals that is intended to convey affection or give comfort. In developmental psychology, it typically refers to such behavior between a parent or caregiver and a child.

**cue** n. a stimulus, event, or object that serves to guide behavior, such as a RETRIEVAL CUE, or that signals the presentation of another stimulus, event, or object, such as an unconditioned stimulus or reinforcement.

**cue-controlled relaxation** a technique in which a client is taught to associate a cue word with the practice of relaxing. See also APPLIED RELAXATION.

**cue-dependent forgetting** forgetting caused by the absence at testing of a stimulus (or cue) that was present when the learning occurred. See also CONTEXT-SPECIFIC LEARNING; MOOD-DEPENDENT MEMORY; STATE-DEPENDENT LEARNING.

**cued panic attack** a PANIC ATTACK that occurs almost invariably upon exposure to, or in anticipation of, a specific situational trigger. For example, an individual with social phobia may have a panic attack as a result of just thinking about an upcoming presentation. Also called SITUATIONALLY BOUND PANIC ATTACK. See also SITUATIONALLY PREPARED PANIC ATTACK. Compare UNCUED PANIC ATTACK.

**cued recall** a type of memory task in which an item to be remembered is presented for study along with a CUE and the participant subsequently attempts to recall the item when given the cue.

**cued speech** speech that is supplemented with manual gestures for the benefit of people with hearing impairment. Hand positions are used to indicate certain phonemic distinctions that are not visible. For example, the distinction between /p/ and /t/ when spoken is visible, whereas the distinction between /l/ and /d/ is not. Unlike SIGN LANGUAGE and FINGERSPELLING, the hand positions are not adequate to convey communication without the accompanying speech.

**cue exposure** a BEHAVIOR THERAPY technique in which a client is exposed to stimuli that induce cravings for substances (e.g., alcohol, tobacco) while the therapist uses other techniques to reduce or eliminate the craving. This technique is most frequently used in substance abuse and smoking cessation programs. See also EXPOSURE THERAPY.

**cue-overload principle** the principle that a RETRIEVAL CUE starts to lose its effectiveness in aiding recall as items associated with that particular cue increase in number.

**cure reversal** changing the outcome of a stimulus so that it signals the opposite of that with which it was first associated. For example, after learning that Stimulus A signals food and Stimulus B does not, during cue reversal the outcomes are exchanged, and the individual must now learn that Stimulus B signals food and Stimulus A does not.

**cul-de-sac** n. see BLIND ALLEY.

**culpability** n. in law, the state of being found criminally responsible for one’s actions and subject to legal sanctions. See CRIMINAL RESPONSIBILITY. —culpable adj.

**cult** n. 1. a religious or quasi-religious group characterized by unusual or atypical beliefs, seclusion from the outside world, and an authoritarian structure. Cults tend to be
highly cohesive, well organized, secretive, and hostile to nonmembers. 2. the system of beliefs and rituals specific to a particular religious group.

**cult of personality** exaggerated devotion to a charismatic political, religious, or other leader, often fomented by authoritarian figures or regimes as a means of maintaining their power. Also called personality cult.

**cultural absolutism** see CULTURAL UNIVERSALISM.

**cultural adaptability** the ability of individuals or groups to adjust and become accustomed to the values, traditions, and other characteristics of a different society, such as those of a new community to which they have migrated. See ACCULTURATION.

**cultural anthropology** see ANTHROPOLOGY.

**cultural assimilation** see ACCULTURATION STRATEGIES.

**cultural bias** the tendency to interpret and judge phenomena in terms of the distinctive values, beliefs, and other characteristics of the society or community to which one belongs. This sometimes leads people to form opinions and make decisions about others in advance of any actual experience with them (see PREJUDICE). Cultural bias has become a significant concern in many areas, including PSYCHOMETRICS, ERGONOMICS, and CLINICAL PSYCHOLOGY. See also CULTURE-FAIR TEST; CULTURE-FREE TEST; ETHNOCENTRISM.

**cultural blindness** the inability to understand how particular matters might be viewed by people of a different culture because of a rigid adherence to the views, attitudes, and values of one’s own culture or because the perspective of one’s own culture is sufficiently limiting to make it difficult to see alternatives.

**cultural competence** 1. possession of the skills and knowledge that are appropriate for and specific to a given culture. 2. the capacity to function effectively in cultural settings other than one’s own. This usually involves a recognition of the diversity both between and within cultures, a capacity for cultural self-assessment, and a willingness to adapt personal behaviors and practices. Cultural competence has become a central concept in health care, with educators and practitioners focused on recognizing the cultural variation in clients’ health-related beliefs and activities in order to improve cross-cultural communication and health outcomes. See also CULTURAL SENSITIVITY.

**cultural conserve** anything (e.g., a legend, tradition, or artifact) that has the effect of preserving valuable cultural memories, such as skills, discoveries, concepts, or moral values. See also CULTURAL HERITAGE. [introduced by Jacob L. Moreno]

**cultural deprivation** 1. lack of opportunity to participate in the cultural offerings of the larger society due to such factors as economic deprivation, substandard living conditions, or discrimination. See PSEUDORETARATION. 2. loss of identification with one’s cultural heritage as a result of assimilation into a larger or dominant culture. See DE- CULTURATION. 3. lack of culturally stimulating phenomena in one’s environment.

**cultural determinism** the theory or premise that individual and group characteristics and behavior patterns are produced largely by a given society’s economic, social, political, and religious organization. See NATIONAL CHARACTER. See also SOCIAL DETERMINISM.

**cultural diversity** the existence of societies, communities, or subcultures that differ substantially from one another. 2. communities or subcultures that function within a larger society while maintaining their distinct CULTURE TRAITS. See also MULTICULTURALISM.

**cultural drift** the gradual, uncontrolled changing of a culture, with its distinctive norms, values, and patterns of behavior, over time. Also called culture drift. See also CULTURE CHANGE; SOCIAL CHANGE; SOCIAL EVOLUTION.

**cultural epoch theory** the theory, formerly influential but now largely discredited, that all human cultures pass through the same stages of social and economic organization in the same order. In most versions of the theory, this involves progress from a hunting-based society through pastoral, agricultural, and early industrial epochs to the modern developed world, with each stage being seen as more complex, organized, and secular than previous stages. See MODERNIZATION; PRIMITIVE; RECAPITULATION THEORY; SOCIAL DARWINISM.

**cultural ergonomics** a specialty area of ERGONOMICS that focuses on cultural factors relevant to human performance and the design and evaluation of work systems. Such factors as national culture, ethnicity, gender, and class are assessed as part of the task of creating systems that can be used efficiently and safely by a particular culture or subculture. See also INDIGENOUS RESEARCHER; POPULATION STEREOTYPE.

**cultural genocide** destruction of a culture’s heritage, values, and practices, usually by another, dominant cultural group.

**cultural heritage** the customs, language, values, and skills that are handed down from each generation to the next in a particular cultural group and that help to maintain its sense of identity. The cultural heritage also includes specific technological or artistic achievements. See SOCIAL HERITAGE; SOCIAL TRANSMISSION.

**cultural learning** the transmission, with a high degree of fidelity, of acquired information and behavior both within and across generations. Cultural learning theory proposes three stagelike levels of cultural learning: IMITATIVE LEARNING, INSTRUCTED LEARNING, and COLLABORATIVE LEARNING. [proposed by U.S. psychologist Michael Tomasello (1950–) and colleagues]

**culturally loaded item** in testing and assessment, a question that is more relevant to the background and experience of the individual who wrote the question than to the individual who is trying to answer the question, such that the response may not be a fair indication of the responder’s knowledge. For example, if a question included content about a particular religious tradition it might be perceived as being a culturally loaded item if the test taker were an atheist or of a completely different religion. See CULTURE-FAIR TEST.

**cultural memory** see COLLECTIVE MEMORY.

**cultural monism** a view or perspective holding that MULTICULTURALISM operates against social cohesion and that ethnic and other minorities should therefore be encouraged to assimilate with the dominant culture.

**cultural neuroscience** an emerging discipline that uses brain-imaging technology to show how environment and beliefs can shape mental function. One study found, for example, that reward circuitry fired in the limbic system of American participants when they viewed silhouettes of humans in dominant poses but did not fire when they
viewed silhouettes in submissive poses, whereas the brains of Japanese participants responded in the opposite manner: Their reward circuitry fired in response to submissive, but not dominant, silhouettes. The study suggests that even as people perceive the same stimulus, their brains may activate differently, showing neural responses that reflect their cultural values. See also SOCIAL NEUROSCIENCE.

cultural norm a societal rule, value, or standard that delineates an accepted and appropriate behavior within a culture. See also NORMATIVE INFLUENCE; SOCIAL NORM.

cultural parallelism in anthropology, the development of analogous cultural patterns, such as sun worship, in geographically separate groups assumed to have had no communication with each other.

cultural pluralism see MULTICULTURALISM.

cultural process the manner in which ethnic and social values are transmitted across generations and modified by the influences prevailing over each.

cultural psychology an interdisciplinary extension of general psychology concerned with those psychological processes that are inherently organized by culture. It is a heterogeneous class of perspectives that focus on explaining how human psychological functions are culturally constituted through various forms of relations between people and their social contexts. As a discipline, cultural psychology relates to cultural anthropology, sociology, semiotics, language philosophy, and culture studies. Within psychology, it relates most closely to cultural, social, developmental, and cognitive issues. See also CROSS-CULTURAL PSYCHOLOGY; ETHNIC PSYCHOLOGY.

cultural relativism the view that attitudes, behaviors, values, concepts, and achievements must be understood in the light of their own cultural milieu and not judged according to the standards of a different culture. In psychology, the relativist position questions the universal application of psychological theory, research, therapeutic techniques, and clinical approaches, because those used or developed in one culture may not be appropriate or applicable to another. Compare CULTURAL UNIVERSALISM.

cultural residue see CULTURE LAG.

cultural sensitivity awareness and appreciation of the values, norms, and beliefs characteristic of a cultural, ethnic, racial, or other group that is not one’s own, accompanied by a willingness to adapt one’s behavior accordingly. See CULTURAL COMPETENCE.

cultural specificity of emotions the finding that the elicitors and the expressions of emotions differ dramatically in members of different cultures and societies. Compare UNIVERSALITY OF EMOTIONS.

cultural tailoring adapting a questionnaire, intervention, or the like for the particular cultural population in which it will be used, with an awareness of the population’s values, attitudes, history, and other influences on behavior. Cultural tailoring is intended to maximize rates of participant recruitment for studies, increase rates of completion for surveys and other instruments, enhance accuracy in language and understanding in communications, and increase positive outcomes from treatment.

cultural test bias partiality of a test in favor of individuals from certain backgrounds at the expense of individuals from other backgrounds. The partiality may be in the content of the items, in the format of the items, or in the very act of taking a test itself. For example, suppose a verbal comprehension exam was delivered on a computer and incorporated passages, pictures, and questions drawn from American literature. The exam is likely to favor individuals who grew up in American families that could afford to have computers and a variety of books at home. In contrast, poorer individuals who emigrated to America and were without computers or many books in the home might find that the exam had some degree of cultural test bias. See also CULTURALLY LOADED ITEM; TEST BIAS.

cultural transmission the processes by which customs, beliefs, rites, and knowledge are imparted to successive generations within a society.

cultural turn 1. a general trend toward considering culture when analyzing and framing psychological, educational, sociological, political, and other issues. 2. a movement within POSTMODERNISM that gained traction among social science scholars and historians in the 1970s, in which culture was considered when analyzing behavior and events.

cultural universalism the view that the values, concepts, and behaviors characteristic of diverse cultures can be viewed, understood, and judged according to universal standards. Such a view involves the rejection, at least in part, of CULTURAL RELATIVISM. Also called CULTURAL ABSOLUTISM.

culture n. 1. the distinctive customs, values, beliefs, knowledge, art, and language of a society or a community. These values and concepts are passed on from generation to generation, and they are the basis for everyday behaviors and practices. 2. the characteristic attitudes and behaviors of a particular group within society, such as a profession, social class, or age group. See also COUNTERCULTURE; SUBCULTURE; YOUTH CULTURE. —cultural adj.

culture-bias theory the theory that measurements of intelligence may be biased in favor of members of certain cultural groups and against members of other cultural groups.

culture bound describing attitudes, practices, or behaviors that are the products of a particular culture and that are not widely found in other cultures.

culture-bound syndrome a pattern of mental illness and abnormal behavior that is unique to a specific ethnic or cultural population and does not conform to standard classifications of psychiatric disorders. Culture-bound syndromes include, among others, AMOK, AMURAKH, BANGUN-GUT, HSIEH-PING, IMU, JUMPING FRENCHMEN OF MAINE SYNDROME, KORO, LATAH, MAL DE PELLA, MYRIACHT, PI-BLOKTO, SUSTO, VOODOO DEATH, and WINDIGO PSYCHOSIS. Also called CULTURE-SPECIFIC SYNDROME.

culture change modification of a community’s culture, whether gradually over time (see CULTURAL DRIFT) or more rapidly as the result of contact with other cultures (see ACCLIMATION; DECLIMATION). Also called CULTURAL CHANGE. See also SOCIAL CHANGE.

culture clash a situation in which the diverging attitudes, morals, opinions, or customs of two dissimilar cultures or subcultures are revealed. This may occur, for example, when people in different professions, such as academics and business people, collaborate on a project. See also CULTURE CONFLICT; CULTURE SHOCK.

culture complex a distinctive pattern of activities, beliefs, rites, and traditions associated with one central fea-
ture of life in a particular culture. An example is the cluster of activities, ceremonies, folklore, songs, and stories associated with the hunting and use of the buffalo by Native American peoples. Also called culture pattern. Compare CULTURE TRAIT.

culture conflict 1. tension or competition between different cultures. It often results in the weakening of a minority group’s adherence to cultural practices and beliefs as these are superseded by those of a dominant or adjoining culture. 2. the conflicting loyalties experienced by individuals who endorse the cultural beliefs of their subgroup but are also drawn to the practices and beliefs of the dominant culture. Also called internal culture conflict. See CULTURE SHOCK.

culture-fair test a test based on common human experience and considered to be relatively unbiased with respect to special background influences. Unlike some standardized intelligence assessments, which may reflect predominantly middle-class experience, a culture-fair test is designed to apply across social lines and to permit equitable comparisons among people from different backgrounds. Nonverbal, nonacademic items are used, such as matching identical forms, selecting a design that completes a given series, or drawing human figures. Studies have shown, however, that any assessment reflects certain socioethnic norms to some degree and hence may tend to favor people with certain backgrounds rather than others. For example, an item that included the phrase “bad rap” could be unclear, as the phrase could refer to unjust criticism or to rap music that was either not very good or rather good, depending on an individual’s common use of the word “bad.” See also CROSS-CULTURAL TESTING.

culture-free test an intelligence test designed to eliminate cultural bias completely by constructing questions that contain either no environmental influences or no environmental influences that reflect any specific culture. However, the creation of such a test is probably impossible, and psychometricians instead generally seek to develop culture-fair tests.

culture lag 1. the tendency for some aspects of a culture to change at a slower rate than others, resulting in the retention of beliefs, customs, and values that no longer seem appropriate to altered economic or technological conditions. 2. a specific cultural survival of this kind. Compare CULTURE LEAD. Also called cultural lag: cultural residue.

culture lead a particular aspect of a culture that appears to be changing faster than the culture as a whole. Technological and economic changes are often of this kind. Compare CULTURE LAG.

culture of children the customs, values, beliefs, and rituals of children that distinguish them from adults. Rules and norms of behavior are initially passed down from older children to younger children, but in later childhood and adolescence, norms are maintained by means of peer pressure.

culture of honor a CULTURAL NORM in a region, nation, or ethnic group prescribing immediate, definitive retribution as the preferred reaction to an insult or other transgression, particularly one that threatens a person’s reputation. Ethnographic studies suggest that cultures that subsist by herding typically attach more importance to honor and reputation than do people from agrarian societies, since a person in a herding culture who vociferously defends against threats is less likely to have his or her livelihood taken away by rustlers. This phenomenon seems to apply to the translocated descendants of such cultures as well. For example, Whites in the southern United States, who derive historically from Scotch-Irish herding societies, have been found to be more likely to hold values about honor and reputation and to respond to insults with swift action than are northern Whites descended from agrarian societies. A related concept is the subculture of violence, used by U.S. criminologist Marvin Wolfgang (1924–1998) and Italian criminologist Franco Ferracuti to explain the relatively high rates of violent crime among certain minority populations in impoverished urban areas.

culture pattern see CULTURE COMPLEX.

culture-relevant tests tests that are designed specifically to be relevant to a given cultural context. These tests typically differ at least somewhat from one culture to another beyond mere differences in language, and they have been carefully screened for appropriateness.

culture shock loneliness, anxiety, and confusion experienced by an individual or group that has been suddenly thrust into an alien culture or otherwise encounters radical cultural change. For example, a Filipino student studying at an American university may experience culture shock, as may a businessperson traveling abroad.

culture-specific syndrome see CULTURE-BOUND SYNDROME.

culture trait any basic belief, practice, technique, or object that can be said to identify a given culture in some aspect of its economic, political, social, or religious organization, such as a specific agricultural practice, law, ritual, belief about child-rearing, or architectural design. Compare CULTURE COMPLEX.

cumulant n. one of a set of values that describes the basic nature of a DISTRIBUTION. A cumulant is similar to a logarithmic function of a moment of a distribution, especially for the first few values. The first cumulant (like the first moment) is concerned with the mean or average of a set of numbers, the second cumulant (like the second moment) refers to the variance or degree of spread in a set of numbers, and the third cumulant (like the third moment) indicates the skewness or degree of lopsidedness in a set of numbers. Cumulants and moments may differ beyond these initial values, and statistical methods generally are concerned only with the first three cumulants or moments of a distribution, as well as the fourth moment, KURTOSIS.

cumulative continuity the process by which an individual’s actions produce results that accumulate over time and move him or her along specific life trajectories.

cumulative distribution function (CDF) a formula that gives the PROBABILITY, from 0 to 1, that a variable will have a score less than or equal to a specific value. When this is plotted on a graph, the vertical y-axis will indicate the probability value from 0 to 1 for each possible score of the variable listed along the horizontal x-axis. This type of graph usually shows a pattern with a curve that rises from the lower left up to a peak at the upper right, where for the last score the probability that a variable will have a value equal to or less than the highest possible score is 1. Also called distribution function.

cumulative educational advantage an advantageous position that is achieved as the result of knowledge acquired over a period of time.
cumulative frequency

**cumulative frequency** (CF) a running total of how often specific values occur. Cumulative frequencies are used in DESCRIPTIVE STATISTICS when listing the number of participants who fall into each of several categories of a variable that can be ordered from low to high. For example, if test scores in a particular classroom are 1 F, 2 Ds, 4 Cs, 3 Bs, and 2 As, the cumulative frequency is obtained by successively adding the number of students at each score from an F to an A. Thus, the cumulative frequency values from the lowest to the highest would be 1, 3, 7, 10, and 12 for F, D, C, B, and A, respectively. See also **cumulative relative frequency**.

**cumulative frequency distribution** a table with three columns where the first column (labeled X) lists the possible values for a variable, the second column (labeled f, for frequency) lists the number of scores that occur at each of the possible values given in the first column, and the third column (labeled CF, for **cumulative frequency**) gives the running total of each of the values in the second column. This type of table is useful in DESCRIPTIVE STATISTICS to depict the number of scores at or below each score level, and to provide an organized display of data that could also be graphed in a **cumulative frequency polygon** or **cumulative frequency curve**. Also called **cumulative distribution**: **cumulative frequency table**.

**cumulative percentage** a running total of the percentage values occurring across a set of responses. The total will either remain the same or increase, reaching the highest value of 100% after totaling all of the previous percentages. For example, if the percentage of freshmen, sophomores, juniors, and seniors among all of the students at a college were 40%, 25%, 20%, and 15%, respectively, the cumulative percentage values would be 40%, 65%, 85%, and 100% when summing from the percentage of freshman up to the percentage of seniors.

**cumulative probability** a running total of the chance of a score occurring at or below a certain point, where the largest running total is a value of 1.0. For example, a college teacher may want to know the cumulative probability values showing the chance that a grade selected from the entire set of grades on a recently given test would be an F, D, C, B, or A. If there were 8.3% Fs, 16.7% Ds, 33.3% Cs, 25% Bs, and 16.7% As, the cumulative probability values would be .083, .250, .583, .833, and 1.000, respectively, when totaling from the F to the A values.

**cumulative probability distribution** a graphical representation of a set of data that displays along the vertical y-axis the chance that a case picked at random from that set will have a value less than or equal to the corresponding value on the horizontal x-axis. When the variable of interest has discrete or categorical whole-integer values, as with the number of students in a class, the cumulative probability distribution also may be called a **cumulative probability function**.

**cumulative record** a continuous tally or graph to which new data are added. In conditioning, for example, a cumulative record is a graph showing the cumulative number of responses over a continuous period of time. It is often used in such contexts to display performance of *free-operant* behavior under a SCHEDULE OF REINFORCEMENT and provides a direct and continuous indicator of the rate of response.

**cumulative rehearsal** a strategy for retaining information in short-term memory in which a person repeats the most recently presented item (e.g., a word) and then hears it (see **rehearsal**) with all the items that have been presented before it, thus reviewing earlier items upon each presentation of a new item. Cumulative rehearsal is associated with higher levels of free-recall performance than is passive rehearsal. Also called **active rehearsal**.

**cumulative relative frequency** a running sum of the proportion of times specific scores occur compared to the total number of individual score occurrences in a set of data. For example, a teacher may find that there was just one score of F out of a total of 12 scores, such that the first cumulative relative frequency distribution value was .083 (i.e., 1/12). If there were two scores of D added to the one score of F, the second value would be .250 (i.e., 1/12 + 2/12 = 3/12); and so on up through the values to a score of A, which would equal 1.0 as all of the scores would be taken into account at that point (i.e., 12/12 = 1.0). A collection or table of cumulative relative frequencies is called a **cumulative relative frequency distribution**, and a plot of the values is called a **cumulative relative frequency curve**, **cumulative relative frequency diagram**, or cumulative relative frequency graph. Also called **cumulative proportion**.

**cumulative response curve** a cumulative record, in the form of a graph, of the responses in a conditioning experiment. Lack of response is indicated by a flat horizontal line, whereas faster responses are indicated by steeper slopes away from the horizontal. Also called **cumulative response record**.

**cumulative scale** see **GUTTMAN SCALE**.

**cumulative trauma disorder (CTD)** see **repetitive strain injury**.

**cuneate** adj. wedge-shaped. See **cuneus**.

**cuneate fasciculus** the lateral portion of either of the dorsal columns of the spinal cord, which is wedge-shaped in transverse section. It is composed of ascending fibers that terminate in the NUCLEUS CUNEATUS of the medulla oblongata. Also called **fasciculus cuneatus**. See also **gracile fasciculus**.

**cuneate nucleus** see **nucleus cuneatus**.

**cuneate tubercle** a swelling at the upper end of the CUNEATE FASCICULUS that contains the NUCLEUS CUNEATUS, which receives fibers from sensory nerves of the upper part of the body. The cuneate tubercle is the largest of the three nuclear swellings on the dorsal surface of the MEDULLA OB- LONGATA; together with the GRACILE TUBERCLE, it forms the origin of the MEDIAL LEMNISCUS.

**cuneus** n. (pl. cunei) the wedge-shaped portion of the OCCIPITAL LOBE on the medial surface of each cerebral hemisphere above the posterior CALCARINE FISSURE.

**cunnilingus** n. Stimulation of the external female genital organs (i.e., the clitoris and vulva) with the mouth or tongue. Also called **cunnilinctus**: **cunnilinction**: **cunnilinclus**: cunnilingam. See also **OROGENITAL ACTIVITY**.

**cypripedium** n. a gelatinous cup that forms part of the crista within the ampulla at the end of a SEMICIRCULAR CANAL.

**curare** n. any of various toxic plant extracts, especially extracts from plants of the genus *Strychnos*. Curare and related compounds exert their effects by blocking the activity of *acetylcholine* at neuromuscular junctions, resulting in paralysis. Curare has a long ethnopharmacological history among indigenous peoples of the Amazon and Orinoco.
river basins, where it was applied to the tips of arrows to paralyze prey. It was brought to Europe in the 16th century by explorers of South America, but it was not introduced into clinical use until the 1930s, when it was used to treat patients with tetanus and other spas tic disorders. It has also been used in experiments showing that stimulus-response associations can be formed in paralyzed animals. The development of neuromuscular blocking agents with more predictable pharmacological profiles led to the abandonment of curare as a clinical agent.

curative damages a sum of money awarded to a charity on behalf of the plaintiff in a civil lawsuit. Conceptually similar to SPLIT RECOVERY, curative damages were first invoked in the United States in a 1995 Ohio case in which the parents of a son who died when his car collided with a train sued the railroad and then donated their monetary award to an organization promoting railroad crossing safety. The intent is thus to “cure” a problem by achieving a social good that offsets the harm done by the defendant, rather than to punish the defendant (as in PUNITIVE DAMAGES) or to make amends to the plaintiff (as in COMPENSATORY DAMAGES).

curative factors see THERAPEUTIC FACTORS.

curiosity n. the impulse or desire to investigate, observe, or gather information, particularly when the material is novel or interesting. This drive appears spontaneously in nonhuman animals and in young children, who use sensory exploration and motor manipulation to inspect, bite, handle, taste, or smell practically everything in the immediate environment. See EXPLORATORY DRIVE. —curious adj.
current material information about a client’s present feelings, interpersonal relationships, and life events that is used in understanding that person’s PSYCHO DYNAMICS.

curricular field experience knowledge gained from on-the-job activity or observation in a specific area of professional interest or academic pursuit. It often fulfills partial requirements for a course of study or an academic course. See also COOPERATIVE TRAINING.

curriculum n. 1. a set of required or prescribed courses of study, across many subjects or within a specific subject area, that a student must fulfill in order to meet the requirements of a particular degree or educational program. 2. all of the coursework available at an educational institution or within a department of that institution. 3. the total combined unit of coursework constituting a specialized major or minor area of emphasis, most often in a college setting.

curriculum-based assessment 1. a complete, broad evaluation profile that reveals the degree of student mastery of a given defined body of content. The evaluation includes teacher-based testing (see CURRICULUM-BASED MEASUREMENT), classroom observation and interactions, standardized tests when relevant, and any other method of evaluation that yields data that can contribute to the overall assessment profile. 2. data that help determine specific standards, such as those involved in individualized educational planning, direct performance referrals, and other forms of systematic planning relative to student progress.

curriculum-based measurement a narrow evaluation of student performance based on the material that has actually been taught, as opposed to CURRICULUM-BASED ASSESSMENTS, which are much broader and compare students to state, national, or other standard norms.

customary, prevailing, and reasonable fees

curriculum development the process of designing materials for instruction that will be used within a particular school district, school, or classroom. This process takes account of several important factors: The curriculum must not conflict with the standard practice adopted by similar programs of study; it must identify and articulate core concepts; and it must include an empirical base as a foundation for the actual content, thus facilitating teaching strategies, assessment, and accountability.

curve fitting any of various statistical techniques for obtaining a function that graphically represents a given set of data as closely as possible, with minimal error. A simple example of curve fitting occurs in LINEAR REGRESSION, where a straight line function is said to provide the closest approximation to the expected values of the outcome with a specific predictor and have the fewest discrepancies between the predicted values and the actual, observed values.

curvilinear adj. describing an association between variables that does not consistently follow an increasing or decreasing pattern but rather changes direction after a certain point (i.e., it involves a curve in the set of data points). For example, the relationship between anxiety and achievement often has a curvilinear pattern of increasing achievement with increasing anxiety (i.e., motivation to study) up to a certain point when there is so much anxiety that achievement tends to decrease. Thus, individuals who are not at all anxious and those who are extremely anxious would both be expected to have poor performance, whereas moderately anxious individuals would be expected to have reasonably high performance. See also NONLINEAR.

curvilinear regression see NONLINEAR REGRESSION.

Cushing's syndrome a group of signs and symptoms related to a chronic overproduction of corticosteroid hormones, mainly CORTISOL, by the adrenal cortex. The condition occurs most commonly in women and is usually associated with a tumor of the adrenal or pituitary gland. Cushing's syndrome is characterized by a "moon face" due to fat deposits, "buffalo hump" fat pads on the trunk, hypertension, glucose intolerance, and psychiatric disturbances. [Harvey W. Cushing (1869–1939), U.S. surgeon]

-cusis suffix see -ACUSIA.

cusp catastrophe model see CATASTROPHE THEORY.

custodial care 1. care rendered to a patient with prolonged mental or physical disability that includes assisted daily living (e.g., the regular feeding and washing of bedridden patients) but typically not mental health services themselves. 2. confinement in such institutions as prisons and military correctional facilities that place restrictions on individuals' liberty under the rules of law and that protect and monitor the individual or protect others from the individual's violent and harmful tendencies or potential.

custodial case a court case concerning who should maintain legal custody of a child. See CHILD CUSTODY.

custom n. a traditional behavior, ritual, or action that is transmitted through the generations and is defined by a culture as appropriate or desirable for a particular situation. An example is the Chinese practice of maternal “confinement” or “doing-the-month” after childbirth, which involves formalized social support and recognition of the status of motherhood and has been presumed in anthropological literature to protect mothers of newborns from postpartum depression.
customer relationship management

(CPR fees) a criterion invoked in reimbursing health care providers. It is determined by profiling the prevailing fees in a geographic area. Also called usual, customary, and reasonable (UCR) fees.

customer relationship management (CRM) the use by companies of integrated computer databases to anticipate the future needs of their customers on the basis of information about their past purchasing behaviors.

cutaneous adj. relating to or affecting the skin. For example, a cutaneous receptor, such as a PACINIAN CORPUSCLE, is a specialized cell in the skin that detects and responds to specific external stimuli.

cutaneous experience a sensation resulting from the stimulation of receptors in the skin. Such sensations include warmth, coldness, tickle, itch, pinch (see PRICK EXPERIENCE), sharp pain, and dull pain. Also called cutaneous sensation: dermal sensation.

cutaneous perception perception of stimuli via activation of receptors in the skin. See CUTANEOUS SENSE.

cutaneous perception of color see DERO-MOPTICAL PERCEPTION.

cutaneous-pupillary reflex dilation of the pupil caused by scratching the skin of the cheek or chin. Also called pupillary-skin reflex.

cutaneous rabbit illusion the false perception that one has been tapped in the middle of the forearm after being tapped rapidly at the wrist and then the elbow: The taps seem to move along the forearm’s length much like a hopping rabbit. This illusion is consistently evoked as long as the tapping span does not cross the midline of the body. Slight variations in the timing of taps on the skin can produce wide fluctuations in the taps’ perceived locations, and evidence from FUNCTIONAL MAGNETIC RESONANCE IMAGING has revealed that the phantom sensations are associated with activity in the PRIMARY SOMATOSENSORY AREA, the same brain region initially activated by real tactile sensations. See also SALTATION. [first described in 1972 by U.S. psychologists Frank Arthur Geldard (1904–1984) and Carl Edwin Sherrick (1924–2005)]

cutaneous receptive field the area of skin being supplied by specific peripheral nerves and localized synaptic distribution in the central nervous system. See also RECEPTIVE FIELD.

cutaneous receptor a receptor organ in the skin that is responsible for CUTANEOUS EXPERIENCE. Cutaneous receptors include PACINIAN CORPUSCLES, BASKET ENDINGS, MEISSNER’S CORPUSCLES, and MERKEL’S TACTILE DISKS.

cutaneous sense any of the senses that are dependent on receptors in the skin sensitive to contact, pressure, vibration, temperature, or pain. Also called skin sense. See PRESSURE SENSE; TEMPERATURE SENSE; TOUCH SENSE.

cutoff score a value or criterion that is held to mark the lowest point at which a certain status or category is attained. For example, the cutoff score for passing a course is often 60%. Similarly, the cutoff score for being considered overweight is a body mass index of 25 to 29. Also called cutoff point; criterion cutoff.

cutting n. the act of cutting oneself, usually on the wrist or inside of the forearm. Often accompanied by a sense of heightened arousal and little sensation of pain, it occurs most frequently in the context of BORDERLINE PERSONALITY DISORDER and MAJOR DEPRESSIVE EPISODES. See also DELIBERATE SELF-HARM.

cutting off reflected failure (CORFing) see BASKING IN REFLECTED GLORY.

CV 1. abbreviation for CARDIOVASCULAR. 2. abbreviation for curriculum vitae.

CVA abbreviation for CEREBROVASCULAR ACCIDENT.

CVLT abbreviation for CALIFORNIA VERBAL LEARNING TEST.

CVS abbreviation for CHORIONIC VILLUS SAMPLING.

CWB abbreviation for COUNTERPRODUCTIVE WORK BEHAVIOR.

cyanopsia n. see CHROMATOPSIS.

cyberbullying n. see BULLYING.

cybernetic epistemology a study that addresses the philosophical issues of EPISTEMOLOGY in terms of cybernetics, often by making use of computational KNOWLEDGE REPRESENTATION and other techniques of ARTIFICIAL INTELLIGENCE. Grounding (how a system incorporates meaning into its problem solving), SCAFFOLDING (how a system uses its world as an essential component of its problem solving), and embodiment (how a system is defined as part of, and integrated into, an environment) are essential components of this study.

cybernetics n. the scientific study of communication and control as applied to machines and living organisms. It includes the study of self-regulation mechanisms, as in thermostats or feedback circuits in the nervous system, as well as transmission and self-correction of information in both computers and human communications. Cybernetics was formerly used to denote research in ARTIFICIAL INTELLIGENCE. [first defined in 1948 by U.S. mathematician Norbert Wiener (1894–1964)] —cybernetic adj.

cybernetic theory the study of how machines or other artificial systems can be made to regulate and guide themselves in the manner of living organisms. Its main application is the design of computer-controlled automated systems in manufacturing, transport, telecommunications, and other fields. The most widely used aspect of cybernetic theory is the self-regulatory model known as the FEEDBACK LOOP. [developed by U.S. mathematician Norbert Wiener (1894–1964)]

cycle n. a distinct pattern within a TIME SERIES of data for a specific variable. The pattern can be evenly spaced (e.g., as with seven-day weekly sales figures) or irregular (e.g., as with shifts in sales due to weather changes or economic factors).

cycle of violence a conceptual framework for understanding the persistence of battering relationships. The cycle has three phases: (a) a honeymoon phase, in which the batterer treats the partner lovingly; (b) a tension build-up phase, in which the batterer begins to display irritability and anger toward the partner; and (c) the violence phase, in which battering occurs. The phases are then proposed to recycle. As a battering relationship persists over time, the honeymoon phases shorten, and the tension-building and violence phases lengthen. Also called cycle of abuse. [proposed in 1979 by U.S. clinical and forensic psychologist Lenore E. Walker (1942– )]

cyclical adj. characterized by alternating phases. For example, an individual with BIPOLAR DISORDER involving alter-
nating depressive and manic episodes may be said to have a cyclic illness. Also called cyclical.

cyclic adenosine monophosphate see CYCLIC AMP.

cyclical vomiting syndrome recurrent, severe episodes of vomiting that may last for hours or days but are separated by intervals of completely normal health. Stress may be an important precipitant of cyclical vomiting, which occurs frequently in children.

cyclic AMP (cAMP; cyclic adenosine monophosphate) a SECOND MESSENGER that is involved in the activities of DOPAMINE, NOREPINEPHRINE, and SEROTONIN in transmitting signals at nerve synapses. Also called adenosine 3',5'-monophosphate.

cyclic data a set of information, especially a TIME SERIES, in which a recurring distinct pattern is identifiable. For example, a psychologist may note that patients tend to require more visits during regular time periods around holidays or the anniversary of the death of a loved one.

cyclic GMP (cGMP; cyclic guanosine monophosphate) a SECOND MESSENGER that is common in POSTSYNAPTIC neurons.

cyclic nucleotide a substance, such as CYCLIC AMP or CYCLIC GMP, that functions as a SECOND MESSENGER in cells to transduce an incoming signal, such as a hormone or neurotransmitter, into specific activity within the cell.

cyclobenzaprine n. a drug used for the treatment of acute skeletal muscle spasm (see MUSCLE RELAXANT). Structurally related to the tricyclic antidepressants, it has many features in common with them, including sedation and significant ANTICHOLINERGIC EFFECTS. Low doses are moderately effective in treating fibromyalgia. Because of its resemblance to the tricyclic drugs, cyclobenzaprine should not be taken concurrently with MONOAMINE OXIDASE INHIBITORS. U.S. trade name: Flexeril.

cycloid psychosis an atypical and controversial psychiatric disorder with several forms (e.g., CONFUSIONAL PSYCHOSIS). Symptoms, which resemble those of a SCHIZO-AFFECTIVE DISORDER, follow a phasically recurring course and may change rapidly. [as modified in 1957 by German psychiatrist Karl Leonhard (1904–1988) from the original 1924 conceptualization of German neuropsychiatrist Karl Kleist (1879–1960)]

cyclopean eye a theoretical eye, located on the midline between the real eyes, that has access to the functions of both eyes and is used in descriptions of space perception and eye movements.

cyclothymic disorder a mood disorder characterized by periods of hypomanic symptoms and periods of depressive symptoms that occur over the course of at least 2 years. The number, duration, and severity of these symptoms do not meet the full criteria for a MAJOR DEPRESSIVE EPISODE OR A HYPOMANIC EPISODE. It often is considered to be a mild BIPOLAR DISORDER. Also called cyclothymia.

cyclopropadine n. a drug that acts as an HISTAMINE and SEROTONIN ANTAGONIST and is used for the treatment of allergic symptoms (e.g., runny nose and watery eyes), loss of appetite, migraine headaches, and SEROTONIN SYNDROME. U.S. trade name (among others): Periactin.

cystathionine synthetase deficiency see HOMOCYSTINURIA.

cystathioninuria n. an inherited disorder of amino acid metabolism marked by deficiency of the enzyme cystathionase. The effects include vascular, skeletal, and ocular abnormalities. Intellectual disability occurs in less than 50% of cases, but is often accompanied by behavioral disorders. Also called gamma-cystathionase deficiency.

cyto- combining form cells.

cytoclinic n. the arrangement of cells in organs and tissues, particularly those in the NEOCortex. The different types of cortical cells are organized in CORtical LAYERS and zones. The number of layers varies in different brain areas, but a typical section of neocortex shows six distinct layers. Differences in cytoarchitecture have been used to divide the neocortex into 50 or more regions, many of which differ in function. The scientific study of the cytoarchitecture of an organ is called cytoarchitectonics. Also called ARCHITECTONIC structure. See also BRODMANN'S AREA.

cytoarchitecture adj.

cytoclinic characterized by predominance of liver and other drug metabolizing enzymes.

CYP abbreviation for CYTOCHROME P450.

cyproheptadine n. a drug that acts as an ANTICHOLINERGIC and SEROTONIN ANTAGONIST and is used for the treatment of allergic symptoms (e.g., runny nose and watery eyes), loss of appetite, migraine headaches, and SEROTONIN SYNDROME. U.S. trade name (among others): Periactin.

cytochrome oxidase an enzyme that occurs in the STRIA TE Cortex with greater than background levels of CYTOCHROME OXIDASE activity. Neurons in the CO blobs are sensitive to the wavelength of a visual stimulus. Also called blob.

CYP abbreviation for CYTOCHROME P450.

cytochrome P450 (CYP) a group of proteins located in the smooth ENDOPLASMIC RETICULUM of liver and other cells that, in combination with other oxidative enzymes, is responsible for the metabolism of various chemicals, including many psychotropic drugs. Approximately 50 cytochrome P450 enzymes (so named because their reduced forms show a spectroscopic absorption peak at 450 nm) are currently identified as being active in humans, of which cytochromes belonging to the CYP2D6 subclass, CYP2C variants, and CYP3A4/5 subclass predominate. Cytochromes are mainly active in Phase I DRUG METABOLISM; by donating an atom of oxygen, they tend to make parent drugs more water soluble and therefore more easily excreted. Because numerous drugs are metabolized via the same cytochrome, these enzymes are important in DRUG INTERACTIONS. Numerous functional genetic polymorphisms of cytochrome P450 can now be genotyped clinically.
cytogenetic map

cytogenetic map a type of chromosome map that depicts and enumerates the pattern of differentially staining bands produced when the chromosomes are treated with certain cytological stains. These bands are correlated with the physical location of particular genes.

cytokine n. any of a variety of small proteins or peptides that are released by cells as signals to those or other cells. Each type stimulates a target cell that has a specific receptor for that cytokine. Cytokines mediate many immune responses, including proliferation and differentiation of lymphocytes, inflammation, allergies, and fever.

cytology n. the branch of biology that deals with the development, structure, and function of cells. —cytological adj. —cytologist n.

cytomegalovirus n. a virus of the herpes group. Infection usually causes no symptoms and no long-term health implications, but if acquired during pregnancy it may have serious consequences for the fetus, such as microcephaly, jaundice, liver and spleen infection, pneumonia, deafness, psychomotor retardation, and intellectual disability.

Cytomel n. a trade name for liothyronine.

cytoplasm n. the contents of a cell excluding the nucleus. —cytoplasmic adj.

cytosine (symbol: C) n. a pyrimidine compound present in the nucleotides of living organisms. It is one of the four bases in DNA and RNA constituting the genetic code, the others being adenine, guanine, and thymine or uracil.

cytoskeleton n. an internal framework or “scaffolding” present in all cells. Composed of a network of filaments and microtubules, it maintains the cell shape and plays an important role in cell movement, growth, division, and differentiation, as well as in intracellular transport (e.g., the movement of vesicles).
d1. see COHEN’S D. 2. see GLASS’S D.

D 1. symbol for DIFFERENCE SCORE. 2. see COOK’S D.

d’ symbol for D PRIME.

DA 1. abbreviation for DEVELOPMENTAL AGE. 2. abbreviation for DOPAMINE.

DABS abbreviation for DIAGNOSTIC ADAPTIVE BEHAVIOR SCALE.

dACC abbreviation for dorsal ANTERIOR CINGULATE CORTEX.

Da Costa’s syndrome an anxiety state identified in soldiers during the American Civil War (1861–1865) in which heart palpitations were the most prominent symptom. It is now recognized as a form of COMBAT STRESS REACTION; EFFORT SYNDROME. [Jacob Méndez Da Costa (1833–1900), U.S. surgeon]

D’Acosta’s syndrome see ALTITUDE SICKNESS. [José de Acosta (1539–1600), Spanish geographer]

dactylography the communication of ideas by means of signs formed with the fingers. See FINGERSPELLING; SIGN LANGUAGE.

DAF abbreviation for DELAYED AUDITORY FEEDBACK.

DAH Test abbreviation for Machover Draw-a-House Test. See MACHOVER DRAW-A-Person TEST.

DAI abbreviation for DIFFUSE AXONAL INJURY.

daily stressor any normative, day-to-day event (e.g., demanding work, financial pressure, family conflict) that can influence physical and mental health and pose a risk to well-being.

DAISY acronym for Digital Accessible Information System. See TALKING BOOK.

Dale’s law the concept, now known to be incorrect for many neurons, that each terminal button (see AXON) of a neuron contains only one kind of neurotransmitter. Also called Dale’s principle. [Henry Hallet Dale (1875–1968), British neurophysiologist]

Dallenbach stimulator a device for providing controlled thermal stimulation to the skin. [Karl M. Dallenbach]

Dalmatian a trade name for FLURAZEPAM.

DALYS acronym for DISABILITY ADJUSTED LIFE YEARS.

damage-risk criteria (DRC) the levels and durations of sound exposures that are likely to cause permanent hearing loss. For example, according to the Occupational Safety and Health Administration (OSHA) standards, a continuous 8-hour noise exposure of less than 85 dB is acceptable, as is a continuous half-hour exposure of less than 110 dB. See SOUND-LEVEL METER.

damped regression see RIDGE REGRESSION.

damping n. a diminution of the amplitude of vibrations, often as a result of absorption of energy (e.g., electricity, sound) by the surrounding medium. In speech and singing, it refers to the tension and elongation of the vocal cords beyond the normal maximal level in an attempt to reach still higher tones on the ascending scale.

dance therapy the use of various forms of rhythmic movement—classical, modern, folk, or ballroom dancing; exercises to music; and the like—as a therapeutic technique to help individuals achieve greater body awareness and social interaction and enhance their psychological and physical functioning. See also MOVEMENT THERAPY. [pioneered in 1942 by U.S. dance professional Marian Chace (1896–1970)]

dancing language see BEE COMMUNICATION.

dancing mania see CHOREOMANIA.

dancing mania see CHOREOMANIA.

dancing mouse a strain of mice displaying behavior that resembles dancing. Mice of this strain have a genetic defect that causes degeneration of the HAIR CELLS of the inner ear. This degeneration produces deafness and impaired functioning of the Vestibular system of the ear, which is thought to cause the dancelike behavior.

Dandy–Walker syndrome a congenital anomaly involving a large cyst in the posterior region of the fetal brain. The syndrome is characterized by (a) blockage of the fourth ventricle, resulting in increased volume of brain fluid (see HYDROCEPHALUS), and (b) complete or partial agenesis (failure to develop) of the middle portion of the cerebellum (the vermis) because of its displacement by the cyst. [Walter Dandy (1886–1946), U.S. neurosurgeon; Arthur Earl Walker (1907–1995), U.S. neurologist]

dangerousness n. the state in which individuals become likely to do harm either to themselves or to others, representing a threat to their own or other people’s safety. —dangerous adj.

dantrolene n. a MUSCLE RELAXANT whose primary action is directly on skeletal muscles; it also indirectly affects the central nervous system as a secondary action. Dantrolene is used in the treatment of muscular spasm associated with spinal cord injury, stroke, cerebral palsy, and multiple sclerosis, as well as with NEUROLEPTIC MALIGNANT SYNDROME. U.S. trade name: Dantrium.

Daoism see TAOISM.

DAP Test abbreviation for MACHOVER DRAW-A-Person TEST.

D.A.R.E. acronym for Drug Abuse Resistance Education: a program through which police officers teach kindergarten through 12th grade students how to say no to drugs, including how to defend against peer pressure to use drugs.

dark adaptation the ability of the eye to adjust to conditions of low illumination by means of an increased sensitivity to light. The bulk of the process takes 30 minutes and
dark-adaptation curve

involves expansion of the pupils and retinal alterations, specifically the regeneration of rhodopsin and iodopsin. See also rod–cone break. Compare light adaptation.

dark-adaptation curve a graph of light sensitivity over time for an individual asked to detect dim flashes in total darkness. See also rod–cone break.

dark cell see type I cell.

dark light see retinal light.

darkness fear see fear of darkness.

Darvocet n. a former trade name for the analgesic combination propoxyphene and acetaminophen.

Darvon n. a former trade name for propoxyphene.

Darwinian algorithm in evolutionary psychology, an innate domain-specific cognitive program that evolved to accomplish specific adaptive functions. An example is the cognitive mechanism for face recognition. [Charles Darwin]

Darwinian fitness the relative success of a particular organism or genotype in producing viable offspring, which is determined by natural selection. [Charles Darwin]

Darwinian reflex a grasping response shown by newborn infants. See grasp reflex. [Charles Darwin]

Darwinism n. the theory of evolution by natural selection, as originally proposed by British naturalists Charles Darwin and Alfred Russel Wallace (1823–1913). In the 20th century, it was modified, as neo-Darwinism, to account for genetic mechanisms of heredity, particularly the sources of genetic variation upon which natural selection works. See also survival of the fittest.

DAS 1. abbreviation for developmental apraxia of speech. 2. abbreviation for differential ability scales.

Dasein n. in the thought of German philosopher Martin Heidegger (1889–1976), the particular kind of being manifest in humans. It is their being as Dasein that allows humans access to the larger question of being in general, since access to the world is always through what their own being makes possible. The term is commonly used in existential psychology and related therapeutic approaches. See being-in-the-world. [German, literally: “being there”]

Dasein analysis a method of existential psychotherapy emphasizing the need to recognize not only one’s being-in-the-world but also what one can become (see Dasein). Through examination of such concepts as intentionality and intuition, Dasein analysis attempts to help clients to accept themselves and realize their potential rather than adapt themselves to others’ expectations. [developed by Swiss psychiatrist Medard Boss (1903–1990)]

DAST abbreviation for drug abuse screening test.

DAT 1. abbreviation for dementia of the Alzheimer’s type. 2. abbreviation for differential aptitude tests.

data pl. n. (sing. datum) observations or measurements, usually quantified and obtained in the course of research. For example, a researcher may be interested in collecting data on health-related behaviors such as frequency and amount of exercise, number of calories consumed per day, number of cigarettes smoked per day, number of alcoholic drinks per day, and so forth.

data analysis the process of applying graphical, statistical, or quantitative techniques to a set of observations or measurements in order to summarize it or to find general patterns. For example, a very basic data analysis would involve calculating descriptive statistics (e.g., mean, median, mode, standard deviation) and possibly graphing the observations with a histogram or bar graph.

database n. a large, structured collection of information stored in retrievable form, usually electronically. For example, the information that researchers collect from their studies is usually kept in a computer database to allow for easy access, manipulation, and analysis in testing relevant hypotheses. In addition to their use as a research tool, databases are used in various sectors (e.g., health care) for record-keeping purposes (see problem-oriented record).

data collection a systematic gathering of information for research or practical purposes. Examples include mail surveys, interviews, laboratory experiments, and psychological testing.

data dredging the inappropriate practice of searching through large files of information to try to confirm a preconceived hypothesis or belief without an adequate design that controls for possible confounds or alternate hypotheses. Data dredging may involve selecting which parts of a large data set to retain to get specific, desired results. An extreme example would be if a marketing researcher found that 91 out of 100 people surveyed were opposed to a certain product and then chose to focus only on the last 10 people in order to state that 9 out of 10 people prefer this product, when in fact only 9 out of 100 preferred it. See data snooping.

data-driven processing see bottom-up processing.

data mining the automated (computerized) examination of a large set of observations or measurements, particularly as collected in a complex database, in order to discover patterns, correlations, and other regularities that can be used for predictive purposes. Although a relatively new discipline, data mining has become a widely utilized technique within commercial and scientific research. For example, retailers often use data mining to predict the future buying trends of customers or to design targeted marketing strategies, whereas clinicians may use it to determine variables predicting hospitalization for psychological disorders. Data mining incorporates methods from statistics, logic, and artificial intelligence.

data point a specific piece of information derived from a larger set of data. A data point is often formed by the intersection of two other pieces of information, as in the intersection of a person’s score on one variable with his or her score on a second variable in a scatterplot. For example, 10 people could be asked their average number of hours of sleep per night and the number of colds they tend to have in a year. Then, the number of sleep hours could be recorded along the horizontal x-axis and the number of colds per year recorded along the vertical y-axis, resulting in 10 separate data points.

data pooling combining the information from two or more studies or sub-studies, for example, by averaging standard deviations or variances across groups to form a single value for use in a t-test or analysis of variance. Although it can be helpful to synthesize information in this way, data pooling can sometimes lead to misleading conclusions, as in Simpson’s paradox.

data reduction the process of reducing a set of measurements or variables into a smaller, more manageable, more reliable, or better theoretically justified set or form.
For example, a researcher may conduct a factor analysis on a set of 50 items on well-being and satisfaction to determine whether the information could be summarized more efficiently on underlying dimensions of relationship satisfaction, degree of meaning in life, job satisfaction, and general health.

data screening a procedure in which one subjects a large set of information to preliminary review for any of a variety of reasons: to check for accuracy, to identify unusual patterns (e.g., outliers that are very different from the information from most participants) or any missing information, to determine whether the information would meet a statistical assumption (e.g., of normality), to reduce the data to more manageable dimensions, and so forth.

data set a collection of individual but related observations or measurements considered as a single entity. For example, the entire range of scores obtained from a class of students taking a particular test would constitute a data set.

data snooping 1. looking for unpredicted, post hoc effects in a body of data. 2. examining data before an experiment has been completed, which can sometimes result in erroneous or misleading conclusions. See also data dredging.

data types in the application of factor analysis to personality, various types of information collected on individuals and classified according to the information source. For example, Q data are collected on individuals from self-report questionnaires and inventories, and T data are acquired about individuals from the results of a formal scientific measurement or objective test. Other types include I data, or information gathered from individual life histories, and O data, or information gathered about individuals from other people (e.g., family members). [first specified by Raymond B. Cattell]

date rape sexual assault by an acquaintance, date, or other person known to the victim, often involving alcohol or date-rape drugs that may hinder the victim's ability to withhold consent. Also called acquaintance rape.

date-rape drug a common colloquial term for a drug that is surreptitiously administered to impair consciousness or memory for the purpose of sexual exploitation of the victim. Such drugs are typically introduced into alcoholic beverages in social settings. Date-rape drugs include barbiturates, high-potency benzodiazepines (flunitrazepam, triazolam), ketamine, and the illicit substance GHB (gamma-hydroxybutyrate). The most common slang for these drugs is roofies, from Rohypnol, the trade name for flunitrazepam. The U.S. Congress passed the Drug-Induced Rape Prevention and Punishment Act in 1996, making it a federal crime to give an unaware person a controlled substance (e.g., barbiturates). Date-rape (German, "perpetual sleep") has been used in the treatment of substance dependence, status epilepticus, and acute psychotic episodes. Its efficacy and use have been the subject of extreme controversy, and it is now rarely encountered clinically.

date rape see day blindness.

day camp a facility that provides recreational, educational, or therapeutic services to children on a short-term, day-by-day basis as opposed to long-term camps that require overnight accommodation.

day care center 1. See child care facilities. 2. a nonresidential facility that provides health and social services in a community setting for adults who are unable to perform many ordinary tasks without supervision or assistance. See adult day care.

daydream n. a waking fantasy, or reverie, in which wishes, expectations, and other potentialities are played out in imagination. Part of the stream of thoughts and images that occupy most of a person’s waking hours, daydreams may be unbidden and apparently purposeless or simply fanciful thoughts, whether spontaneous or intentional. Researchers have identified at least three ways in which individuals’ daydreaming styles differ: positive-constructive daydreaming, guilty and fearful daydreaming, and poor attentional control. These styles are posited to reflect the daydreamer’s overall emotion and personality tendencies. Among the important positive functions that daydreams may serve are the release of strong affect, the gaining of self-insight when reviewing past experiences or rehearsing for future situations, the generation of creative solutions, and the production of greater empathy for others.

day habilitation a home and community-based service provided for a person with an intellectual or development disability. This service provides productive daily schedules of activity based on individualized support planning, including clinical services, companion services, socialization, recreation, vocational development, and lifestyle enrichment. In practice, these services may be delivered on a person-by-person basis or in small groups in any location during daytime hours.

day hospital a nonresidential facility where individuals with mental disorders receive treatment and support services during the day and return to their homes at night. Specific service offerings vary across facilities but generally include psychological evaluation, individual and group psychotherapy, social and occupational rehabilitation, and somatic therapy. Staff members are multidisciplinary, comprising psychiatrists, psychologists, social workers, vocational counselors, and others.

daylight vision see photopic vision.

daymare n. an attack of acute anxiety, distress, or terror that is similar to a nightmare but occurs in a period of wakefulness and is precipitated by waking-state fantasies.

day treatment a program of coordinated interdiscipli-
nary assessment, treatment, and rehabilitation services provided by professionals and paraprofessionals for people with disabilities, mental or physical disorders, or substance abuse problems, usually at a single location for 6 or more hours during the day. Services also address skill and vocational development and may include adjustment programs or SHELTERED WORKSHOPS.

dB symbol for DECIBEL.

DBI abbreviation for DIAZEPAM-BINDING INHIBITOR.

DBS abbreviation for DEEP BRAIN STIMULATION.

DBT abbreviation for DIALECTICAL BEHAVIOR THERAPY.

dc (d/c) in pharmacology, abbreviation for double effect.

DC amplifier a direct-current device used to amplify the POTENTIAL difference across a neural membrane so that the cortical current can be recorded and studied.

D-cognition n. see BEING COGNITION.

DDAVP n. a trade name for DESMOPRIN.

DDE abbreviation for doctrine of double effect. See PRINCIPLE OF DOUBLE EFFECT.

DEA abbreviation for U.S. DRUG ENFORCEMENT ADMINISTRATION.

deadly catatonia see LETHAL CATATONIA.

deadly nightshade see BELLADONNA ALKALOID.

defaf-blind adj. lacking or having severely compromised vision and hearing concomitantly. People with deaf-blind impairment encounter significant—sometimes lifelong—challenges in communication, development, and education. Solutions involving tactile devices are often appropriate (e.g., BRAILLE). There are numerous known causes, including meningitis, congenital rubella syndrome, and Usher syndrome. —deaf-blindness n.

defafferentation n. the cutting or removal of sensory neurons or axons that convey information toward a particular nervous system structure (e.g., the olfactory bulb).

defaf hearing the capacity of some people with total deafness to detect and localize sounds without any conscious awareness of doing so. Studies suggest that this capacity is involuntary and is not accompanied by any ability to identify or interpret sounds. It has been proposed that such individuals may have a heightened sense of feeling that enables them to respond to the vibrations in sound waves. See also BLINDSIGHT; NUMB SENSE.

defaf-mute n. an obsolescent and pejorative name for an individual who cannot speak, or chooses not to speak, because of congenital or early-acquired profound deafness.

defaf mutism-retinal degeneration syndrome see DIALLINAS–AMALRIC SYNDROME.

defafness n. the partial or complete absence or loss of the sense of hearing. The condition may be hereditary or acquired by injury or disease at any stage of life, including in utero. The major kinds are CONDUCTION DEAFNESS, due to a disruption in sound vibrations before they reach the nerve endings of the inner ear, and SENSORYNURAL DEAFNESS, caused by a failure of the nerves or brain centers associated with the sense of hearing to transmit or interpret properly the impulses from the inner ear. Some individuals experience both conduction and sensorineural deafness, a form called mixed deafness. See also ADVENTI-

TIOUS DEAFNESS: CENTRAL DEAFNESS; CONGENITAL DEAFNESS; CORTICAL DEAFNESS; EXPOSURE DEAFNESS; PERCEPTION DEAFNESS. —deaf adj.

defaf n. 1. the permanent cessation of physical and mental processes in an organism. In the United States in the early 1980s, the American Medical Association and the American Bar Association drafted and approved the Uniform Determination of Death Act, in which death is defined as either the irreversible cessation of core physiological functioning (i.e., spontaneous circulatory and respiratory functions) or the irreversible loss of cerebral functioning (i.e., BRAIN DEATH). Given the emergence of sophisticated technologies for cardiopulmonary support, brain death is more often considered the essential determining factor, particularly within the legal profession. See also ASSISTED DEATH; DYING PROCESS; THANATOLOGY. 2. the degeneration or disintegration of a biological cell. See NECROSIS; NEO-

RINAL CELL DEATH; PROGRAMMED CELL DEATH.

defaf-anxiety emotional distress and insecurity aroused by reminders of mortality, including one’s own memories and thoughts of death (see also ONTOLOGICAL CONFRONTA-

TION). Classical psychoanalytic theory asserted that the unconscious cannot believe in its own death, therefore THANATOPHOBIA was a disguise for some deeper fear. Existentialists later proposed that death anxiety is at the root of all fears, though often disguised. A mass of research using self-report scales (see DEATH-ANXIETY SCALES) suggests that most people have a low to moderate level of death anxiety. See also EDGE THEORY; TERROR MANAGEMENT THEORY.

defaf-anxiety scales questionnaires that yield scores for the level of self-reported concern about death. Some scales distinguish between several types of concern, such as fear of pain or fear of nonbeing. See also THANATOPH-

BIA.

defafbed ents and visions auditory or visual hallucinations (or both) experienced near the end of life in which the “visitors” make themselves known only to the dying person. Sometimes the person describes the interaction or can be heard speaking with the apparitions; sometimes the event can only be inferred from observing the person’s nonverbal behavior. The visitors, when known, are usually deceased family members or spiritual beings in the ancient tradition of psychopomps (deathbed escorts to accompany the soul on its journey). See also NEAR-DEATH EXPERIENCE.

defaf concepts cognitive constructions of linear time, finality, certainty, irreversibility, universality, and personal vulnerability, which cohere with other elements to form a general understanding of mortality. The infant’s fear of separation is seen as an early precursor of these abstract and differentiated ideas, which usually do not develop until early adolescence. Even then, fantasy often continues to contend with reality in the acceptance of the finality and inevitability of death.

defaf education learning activities or programs designed to educate people about death, dying, coping with grief, and bereavement. Death education is typically pro-

vided by certified thanatologists from a wide array of mental and medical health personnel, educators, clergy, and volunteers. Individual or group sessions provide informa-

tion, discussion, guided experiences, and exploration of attitudes and feelings.

defaf feigning the act of becoming immobile, or “playing dead,” when threatened. Also called playing possum.

284
tonic immobility. See ANIMAL DEFENSIVE BEHAVIOR; IMMObILITY.

dead gene a gene that is expressed only when a cell becomes committed to PROGRAMMED CELL DEATH.

dead instinct in psychoanalytic theory, a drive whose aim is the reduction of psychic tension to the lowest possible point, that is, death. It is first directed inward as a self-destructive tendency and is later turned outward in the form of the AGGRESSIVE INSTINCT. In the DUAL INSTINCT THEORY of Sigmund Freud, the death instinct, or THANATOS, stands opposed to the LIFE INSTINCT, or EROS, and is believed to be the drive underlying such behaviors as aggressiveness, sadism, and masochism. See also NIBANA PRINCIPLE.

dead phobia see THANATOPHOBIA.

dead-qualified jury a jury in a criminal case whose members have been questioned under oath by either judges or attorneys and deemed to be capable of imposing the death penalty. See also MAINWRIGHT V. WITT; WITHERSPOON EXCLUDABLES.

dead rite a culture-bound ceremony, ritual, or other religious or customary practice associated with dying and the dead, such as a funeral rite. See RITE OF PASSAGE.

dead system the dynamic patterns through which a society mediates its relationship with mortality in order to remain viable as a culture and meet the needs of the individual. All cultures have a death system whose primary functions are warning and prediction, prevention, care for the dying, disposing of the dead, social consolidation after death, killing, and making sense of death. How these functions are performed is significantly influenced by a number of factors, including economic priorities, religious values, traditions of discrimination and enmity, and level of technological development. [first described in 1977 by Robert J. KASTENBAUM]

death taboo (death tabu) the belief that death is so dangerous and disturbing a subject that one should not only avoid contact with the dead, the dying, and the recently bereaved but also refrain from talking or even thinking about it. In 1959, U.S. psychologist Herman Feifel (1915–2003) proposed that the United States had such a denying and avoiding attitude toward death that it could be compared with the rigid and extreme patterns observed by anthropologists in many band-and-village societies.

death wish 1. an unconscious desire for one’s own death, as manifested in self-destructive or dangerous behaviors. 2. in psychoanalytic theory, a conscious or unconscious wish that another person, particularly a parent, will die. According to Sigmund Freud, such wishes are a major source of guilt, desire for self-punishment, and depression. See also DEATH INSTINCT.

decertification hypothesis the idea that mystical experience results from focused attention, as through meditation and similar techniques, that brings about the conscious, voluntary undoing of automatic or habitual processes associated with organizing, limiting, selecting, and interpreting perceptual stimuli. See AUTOMATICITY. [proposed in 1966 by U.S. psychiatrist Arthur J. Delkman (1929–2013)]

debilitative anxiety a level of anxiety that an individual (e.g., an actor, an athlete) perceives as interfering with performance. Examples include being psyched out (see PSYCHING OUT) or “out of the zone.”

debriefing n. the process of giving participants in a completed research project a fuller explanation of the study in which they participated than was possible before or during the research.

debt counseling counseling specifically aimed at helping individuals with financial problems, providing assistance with or advice about budgeting, credit-card usage, debt consolidation, and money management. Debt counseling may be provided by counselors or therapists as part of a larger process of addressing various problems in an individual’s life, or it may be carried out by financial planners and accountants as a discrete effort.

decadence n. 1. a presumed deterioration of a culture, society, or civilization because of a general collapse of moral character and traditional values. 2. generally, a loss or diminution of excellence or some other quality. 3. (typically capitalized) loosely, an artistic movement of the mid- and late 19th century, particularly in literature and the visual arts, that valued extreme aesthetic refinement, the superiority of artifice (i.e., human invention) over nature, and innovative and atypical experiential perspectives and modes of being. Also called Decadent movement.

Decadron n. a trade name for DEXAMETHASONE.

décage n. in PIAGETIAN THEORY, the invariant order in which cognitive accomplishments develop. See HORIZONTAL DÉCALAGE; VERTICAL DÉCALAGE. [French, “interval,” “shift”]

decarboxylase n. an enzyme that catalyzes the removal of a carboxyl group (–COOH) from a compound.

decarceration n. the process of removing offenders from correctional facilities, often to community facilities. 2. see DEINSTITUTIONALIZATION.

decatastrophizing n. a technique, used in treating people with irrational or exaggerated fears, that explores the reality of a feared stimulus as a way of diminishing its imagined or anticipated danger.

decathexis n. in psychoanalytic theory, the withdrawal of LIBIDO from objects (i.e., other people) in the external world. Compare CATHEXIS.

decay theory the theory that learned material leaves in the brain a trace or impression that autonomously recedes and disappears unless the material is practiced and used. Decay theory is a theory of forgetting. Also called trace-decay theory.

deceiver’s distrust the tendency of people who engage in acts of deception to perceive the recipients of those lies as untrustworthy and dishonest. Deceiver’s distrust presumably reflects the assumption that interaction partners are similar to oneself; thus, one’s own deceitfulness leads to the inference that the other is has been, or will be similarly deceitful. By assuming that others are also untruthful, deceivers can feel less guilt about having lied to them.

deceleration n. a decrease in speed of movement or rate of change. For example, a medical researcher may be interested in the deceleration of an illness or symptom as evidence that a treatment is working effectively. Compare ACCELERATION.

decentering n. 1. any of a variety of techniques aimed at changing one’s centered thinking (i.e., focus on only one salient feature at a time, to the total exclusion of other im-
D

decentralization

important characteristics) to openminded thinking. 2. dissolution of unity between self and identity. 3. see DECENTRATION. —decenter vb.

decentralization n. the trend to relocate patients with chronic mental illness from long-term institutionalization, usually at government hospitals, to outpatient care in community-based residential facilities. —decentralize vb.

decentralized organization an organizational structure in which decision-making authority is spread throughout the organization rather than being reserved for those at the top of the hierarchy. Compare CENTRALIZED ORGANIZATION.

decentration n. in PIAGETIAN THEORY, the gradual progression of a child away from egocentrism toward a reality shared with others. Occurring during the CONCRETE OPERATIONAL STAGE, decentration includes understanding how others perceive the world, knowing in what ways one's own perceptions differ, and recognizing that people have motives and feelings different from one's own. It can also be extended to the ability to consider many aspects of a situation, problem, or object, as reflected, for example, in the child's grasp of the concept of CONSERVATION. Also called decentering. Compare CENTRATION. —decenter vb.

decession n. 1. any distortion of or withholding of fact with the purpose of misleading others. For example, a researcher who has not disclosed the true purpose of an experiment to a participant has engaged in deception. 2. in nonhuman animal behavior, the provision of false information that results in the individual obtaining increased resources at the expense of others. Some animals give false alarm calls that disperse competitors and thus gain more food (see DISHONEST SIGNAL). Another form of deception is exhibited when certain animals engage in aggressive displays that make them appear larger than they really are. —deceive vb. —deceptive adj.

decession clue a behavioral indication that an individual is not telling the truth. Deception clues include inconsistencies between voluntary and involuntary behavior and unusual or exaggerated physiological or expressive responses to knowledge that only a guilty person possesses.

decession research any study in which participants are deliberately misled or not informed about the purpose of the investigation in order to avoid the possibility that their responses may be given to meet the perceived expectations of researchers. For example, a social psychologist may use a DECEPTION EXPERIMENT in which participants are randomly assigned to either of two scenarios that each describe job applicants in identical terms except that one is misleadingly said to be a male and the other a female. The researcher may then assess any gender bias in the participants by asking how likely the applicant is to be hired, instead of directly asking participants about their attitudes toward gender. See ACTIVE DECEPTION; DOUBLE DECEPTION; PASSIVE DECEPTION.

defective advertising advertising that leads to incorrect inferences on the part of consumers, for example, that taking a particular food supplement will help individuals lose weight.

decerebrate rigidity rigidity of the body that occurs when the brainstem is functionally separated from the cerebral cortex, typically as a result of a brain lesion or vascular disorder. It is marked by bilateral rigid extension, adduction, and hyperpronation of the legs and arms. Also called DECREASEbrate POSTURING; EXTENSOR POSTURING.

decerebration n. loss of the ability to discriminate, learn, and control movements as a result of transection of the brainstem, surgical removal of the cerebrum, or cutting off of the cerebral blood supply. DECREASEbrate (adj.) describes a human or nonhuman animal that has experienced decerebration; such an individual is also known as a decerebrate (n.).

debacle (symbol: db) n. a logarithmic unit used to express the ratio of acoustic or electric power (intensity). An increase of 1 bel is a 10-fold increase in intensity; a decibel is one tenth of a bel and is the more commonly used unit, partly because a 1 dB change in intensity is just detectable (approximately and under laboratory conditions). The SOUND INTENSITY (the numerator of the intensity ratio) or SOUND LEVEL is usually specified in decibels sound-pressure level (db SPL). The reference intensity (the denominator of the intensity ratio) for db SPL is 10^-12W/m2 and corresponds to a SOUND PRESSURE of 20 mPa (micropascal). A sound presented at the reference level has a level of 0 dB SPL and is close to the absolute threshold for a 1 kHz tone. Often SPL is omitted but is implied from the context: A “60 dB sound” usually means 60 dB SPL. The decibel, because it is a logarithmic measure, has caused much confusion. For example, decibels do not add: Two unrelated 60 dB SPL sounds when sounded simultaneously produce a 63 dB SPL sound, not a 120 dB SPL sound.

decime n. one of a series of values that divide a statistical distribution into 10 equal-sized parts. Thus, the first decile is the value below which lie 10% of cases, the second decile is the value below which lie 20% of cases, and so forth.

decisional balance a method of assessing the positive and negative consequences, for oneself and others, of selecting a new behavior. Decisional balance is frequently used in weighing the consequences of exercise behavior. For example, by beginning a regular early-morning exercise program, an individual would lose weight (a positive consequence), would not be available for early-morning meetings at work (a negative consequence), would gain greater respect from others (e.g., family, friends) for getting in shape (a positive consequence), and would incur costs in terms of gym fees and workout clothes (a negative consequence).

decisional competence the ability of a defendant to make the decisions normally faced in a criminal defense (e.g., deciding among various plea agreements). See also COMPETENCY EVALUATION; COMPETENCY TO STAND TRIAL: DUSKY STANDARD.

decision making the cognitive process of choosing between two or more alternatives, ranging from the relatively clear cut (e.g., ordering a meal at a restaurant) to the complex (e.g., selecting a mate). Psychologists have adopted two converging strategies to understand decision making: (a) statistical analysis of multiple decisions involving complex tasks and (b) experimental manipulation of simple decisions, looking at the elements that recur within these decisions.

decision-making model of counseling an approach that envisages counseling as a process with three stages: the problem definition phase, the work phase, and the action phase. The problem definition phase considers alternative definitions of the client’s presenting problem and encourages him or her to commit to one of these. Dur-
ing the work phase, the counselor helps the client to look at the problem from different perspectives and to consider solutions to it. In the action phase, the client chooses a solution and tests it in the home environment.

decision–redcision method a technique used in TRANSACTIONAL ANALYSIS that allows clients to reexperience “decision moments” from their childhood (e.g., internalized parental injunctions such as “Don’t be you,” “Don’t feel”) and to reconsider them with the goal of developing more positive self-assessments.

decision rule in HYPOTHESIS TESTING, a formal statement of the set of values of the test statistic that will lead to rejection of the NULL HYPOTHESIS that there is no significant effect in the study being examined. For example, a common decision rule is to reject the null hypothesis when the value of a Z TEST statistic exceeds 1.96.

decision theory a broad class of presumptions in the quantitative, social, and behavioral sciences that aim to explain chance levels and identify optimal ways of arriving at conclusions so that prespecified criteria are met.

decisive moment in psychotherapy, that moment at which a client makes a significant decision, such as revealing a secret or deciding to make a major life change. See also AHA EXPERIENCE.

declarative adj. denoting a sentence or clause that takes the form of a straightforward statement rather than a question, request, or command. See INDICATIVE.

declarative memory the ability to retain information about facts or events over a significant period of time and to consciously recall such declarative knowledge, typically in response to a specific request to remember. It is one of two major divisions in memory proposed in 1980 by U.S. neuroscientist and biological psychologist Larry R. Squire (1941–), and it generally is divided into two subtypes defined by Endel Tulving: EPISODIC MEMORY and SEMANTIC MEMORY. Declarative memory depends on the integrity of a set of highly interconnected structures in the medial temporal lobe and adjacent cortical areas—specifically, the HIPPOCAMPUS, DENTATE GYRUS, SUBICULUM, PERIRHINAL CORTEX, ENTORHINAL CORTEX, and the PARAHIPPOCAMPAL GYRUS. Both emotion and sleep are known to facilitate declarative memory, and abundant evidence indicates that exposure to acute stress enhances declarative memory consolidation. This form of memory is selectively impaired in AMNESIA and is known as EXPLICIT MEMORY in other theoretical classifications. Compare NONDECLARATIVE MEMORY. See also deClérambault’s syndrome.

deClérambault’s syndrome see de Clérambault’s syndrome.

decline effect in parapsychology experiments using ZENER CARDS or similar targets, the situation in which the accuracy of the participant’s “calls,” or guesses, begins at above-chance levels but progressively drops to chance levels as further trials are carried out. See REGRESSION TOWARD THE MEAN. See also DIFFERENTIAL EFFECT; FOCUSING EFFECT; PREFERENTIAL EFFECT; SHEEP–GOAT EFFECT.

decoding n. the process of translating coded information back into its source terms or symbols. Decoding is used in information processing, communication, and computer science. —decode vb.

decompensation n. a breakdown in an individual’s DEFENSE MECHANISMS, resulting in progressive loss of normal functioning or worsening of psychiatric symptoms.

decomposition n. 1. a process in which a complex item is separated into its simpler constituent elements. For example, in problem solving, it is a strategy in which a problem is transformed into two or more simpler problems. 2. in statistics, the breaking down of total effects or parameters into their different aspects. For example, in an ANALYSIS OF VARIANCE, one may break down the total variance into the portion that concerns how the means vary between groups and the portion that concerns how much random variance there is within each group. If the between-group variance is significantly larger than the within-group variance, there is some evidence for a difference in means across groups.

decomposition of movement difficulty of movement in which gestures are broken up into individual segments instead of being executed smoothly. It is a symptom of cerebellar lesions.

decompression sickness an adverse effect of rapid movement of a body from an environment of high pressure to one of lower pressure, resulting in the formation of nitrogen bubbles in the body tissues. The circulatory system is particularly sensitive to the effect. Neurological consequences may include loss of consciousness, convulsions, paresthesias, and damage to the brain and spinal cord. A form of decompression sickness that affects the cardiopulmonary system and may lead to circulatory collapse is called the chokes: it is characterized by discomfort underneath the sternum and coughing on deep inspiration. When decompression sickness affects mainly the bones and joints, it is called the bends.

deconditioning n. a technique in BEHAVIOR THERAPY in which learned responses, such as phobias, are “unlearned” (deconditioned). For example, a person with a phobic reaction to flying might be deconditioned initially by practicing going to the airport and using breathing techniques to control anxiety. See also DESENSITIZATION.

deconstruction n. a form of critical analysis of literary texts and philosophical positions that is based on the twin assumptions that there can be no firm REFERENCES for language and no adequate grounding for truth claims. Although deconstruction challenges the fundamental grounds of the Western philosophical tradition, it recognizes that both the tools and the motivation for doing so arise from that very tradition. A deconstructive reading of a text will generally use traditional analytical methods to expose the innumerable ways in which the text subverts its own claims to meaning and coherence. In much general usage, the term is now taken to be synonymous with the destruction of an idea or a truth claim. See also POSTSTRUCTURALISM. [introduced by French philosopher Jacques Derrida (1930–2004)] —deconstruct vb. —deconstructive adj.

decontextualization n. 1. the process of isolating a constituent from its normal or expected context. It may occur deliberately, as when visual artists isolate a familiar object from its everyday context by turning it upside down or vastly expanding its size to reveal a new perspective about it, or nonconsciously, as when one’s memory of a traumatic event becomes dissociated from the context in which the trauma occurred and acquires a quality of unreality. 2. in the study of perception, the process of making implicit stimulus features explicit and testable, as in the AMES ROOM and many other perceptual demonstrations. —decontextualize vb.
deconversion n. 1. loss of one’s faith in a religion, as in a Catholic of many years who becomes an atheist or agnostic. Research has shown that the bond between religious leaders and their followers is particularly significant in determining the strength of religious affiliation; thus, the severing of that bond is the most common cause of deconversion. Compare CONVERSION. 2. less commonly, regression from a more complex belief system to a simpler one.

decortication n. surgical removal of the outer layer (cortex) of an anatomical structure, especially the outer layer of the cerebrum of the brain (i.e., the CEREBRAL CORTEX).

decremental conduction the exponential decay in the size of a membrane potential with distance from the site of stimulation when a subthreshold stimulus is applied to an axon. Compare NONDECREMENTAL CONDUCTION. See also CABLE PROPERTIES.

decreolization n. a stage of linguistic evolution that sometimes follows the formation of a CREOLE, in which its structure is further elaborated through the influence of the standard language and other languages in contact. The complex linguistic situation that arises in such cases is often referred to as a POSTCREOLIZATION CONTINUUM.

decriminalization n. the reduction of legal ramifications for acts that were previously subject to criminal prosecution. It typically involves milder penalties for possession of small amounts of certain drugs, ranging, for example, from reduced or no jail time to paying a small fine.

decubitus ulcer see PRESSURE ULCER.

deculturation n. the processes, intentional or unintentional, by which traditional cultural beliefs or practices are suppressed or otherwise eliminated as a result of contact with a different, dominant culture. Compare ACCULTURATION. —deculturate vb.

decussation n. a crossing or intersection in the form of a letter X, as in the decussation of the PYRAMIDS of the medulla oblongata and of the fibers of the left and right optic nerves in the OPTIC CHIASM.

dedifferentiation n. loss of specialization or of advanced organizational and functional abilities. This may occur, for example, when mature cells within an organism regress to a more general, simplified state, as is sometimes seen in the progression of certain cancers, or as a form of thought disorganization seen in schizophrenia.

deduction n. 1. a conclusion derived from formal premises by a valid process of DEDUCTIVE REASONING. 2. the process of inferential reasoning itself. Compare INDUCTION. —deductive adj.

deductive-nomological model an influential model of SCIENTIFIC EXPLANATION in which laws describing regularities in nature (see NATURAL LAW) are used as initial premises or axioms to deduce working explanations of phenomena, which are then used to deduce specific testable predictions. See HYPOTHETICO-DEDUCTIVE METHOD; NOMOLOGY. See also COVERING-LAW MODEL. [identified by German philosopher of science Carl Gustav Hempel (1905–1997)]

deductive reasoning the form of logical reasoning in which a conclusion is shown to follow necessarily from a sequence of premises, the first of which stands for a self-evident truth (see AXIOM) or agreed-upon data. In the empirical sciences, deductive reasoning underlies the process of deriving predictions from general laws or theories. Compare INDUCTIVE REASONING. See also LOGIC.

deep body temperature the temperature of the body’s internal organs. Also called CORE TEMPERATURE.

deep brain stimulation (DBS) a neurosurgical procedure used most commonly to treat the disabling neurological symptoms of Parkinson’s disease (e.g., tremor, rigidity, stiffness, DYNSKINESIA), particularly when such symptoms cannot be adequately controlled with medications. An electrode is inserted through a small opening in the patient’s skull and implanted in the brain, and an insulated wire passed under the skin of the head, neck, and shoulder connects the electrode to a neurostimulator, which (similar to a heart pacemaker) is usually implanted under the skin near the collarbone. Electrical signals from the neurostimulator trigger the electrode to begin emitting small impulses of electricity to areas in the brain that control movement, blocking abnormal nerve signals that cause tremor and other neurological symptoms. DBS is also used for people with highly treatment-resistant major depression if multiple medications, psychotherapy, and electroconvulsive therapy have failed. The procedure does not damage healthy brain tissue by destroying nerve cells, and it is reversible. Potential side effects of DBS include a slight decline in memory and executive functioning. DEEP CEREBELLAR NUCLEUS any of the nuclei at the base of the CEREBELLM, such as the interpositus nucleus.

depression n. a severe MAJOR DEPRESSIVE EPISODE characterized by PSYCHOMOTOR RETARDATION, guilt, SUICIDAL IDEATION, and psychotic features. RUMINATION is frequent, and risk of suicide is high.

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by British neuropsychologists John C. Marshall (1939–2007) and Freda Newcombe (1925–2001)]

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by British neuropsychologists John C. Marshall (1939–2007) and Freda Newcombe (1925–2001)]

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by Canadian psychologists Fergus I. Craik (1935–) and Robert S. Lockhart]

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by Canadian psychologists Fergus I. Craik (1935–) and Robert S. Lockhart]

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by Canadian psychologists Fergus I. Craik (1935–) and Robert S. Lockhart]

depression a form of acquired DYSLEXIA characterized by semantic errors (e.g., reading parrot as canary), difficulties in reading abstract words (e.g., idea, usual) and function words (e.g., the, and), and an inability to read pronounceable nonwords. See also PHONOLOGICAL DYSLEXIA: SURFACE DYSLEXIA; [first described in 1973 by Canadian psychologists Fergus I. Craik (1935–) and Robert S. Lockhart]
the heart, liver, or kidney. 2. in TRANSFORMATIONAL GENERATIVE GRAMMAR, an abstract base form of a sentence in which the logical and grammatical relations between the constituents are made explicit. The deep structure generates the surface structure of a sentence through transformations, such as changes in word order or the addition or deletion of elements. Also called base structure.

deep trance in hypnosis and shamanistic practices, a state in which participants are minimally responsive to environmental cues.

deep vein thrombosis (DVT) the presence of a thrombus (clot) in a vein, most often in the leg or thigh, which may result from prolonged immobility and can lead to a pulmonary embolism.

Deese–Roediger–McDermott paradigm a laboratory memory task used to study false recall. It is based on a report in 1959 that, after presentation of a list of related words (e.g., snore, rest, dream, awake), participants mistakenly recalled an unpresented but strongly associated item (e.g., sleep). Called the Deese paradigm after its original investigator, U.S. psychologist James Deese (1921–1999), it has since been renamed to reflect renewed research into the technique by U.S. cognitive psychologists Henry L. Roediger III (1947–) and Kathleen B. McDermott (1968–).

default-mode network (DMN) a specific, anatomically defined brain system preferentially active when individuals are not focused on the external environment. It comprises the medial prefrontal cortex, posterior cingulate cortex, angular gyrus, precuneus, and middle frontal gyrus, among other regions. The DMN activates when individuals are engaged in internally focused tasks (i.e., those of a self-referential introspective nature), including autobiographical memory retrieval, envisioning the future, and conceiving the perspectives of others (see SOCIAL PERCEPTION). However, the network also maintains high levels of metabolic activity at rest, in the absence of any task demands. Some researchers thus have suggested that ongoing unconstrained self-reflective thought might be the natural (default) state of the mind when individuals are not otherwise engaged.

defecation reflex emptying of the rectum and lower portion of the colon in response to movement or pressure of fecal material. As the rectum fills, receptors send impulses to the spinal cord. Motor nerve impulses are transmitted through sacral fibers of the parasympathetic nervous system, causing relaxation of the inner anal sphincter and contraction of muscles of the abdominal wall. In order for the act to be completed, the outer sphincter muscle, which is controlled by voluntary, skeletal muscle nerves, must also be relaxed. The voluntary nervous system can override the reflex and, under normal conditions, prevent automatic defecation. Also called rectal reflex. See also ANAL STAGE; TOILET TRAINING.

defectology n. in Russian psychology, the field concerned with the education of children with sensory, physical, cognitive, or neurological impairment. It is roughly equivalent to special education and school psychology in the United States. It is based on the view that the primary problem of a disability is not the organic impairment itself but its social implications. [originally defined by Lev Vygotsky] 

defect orientation 1. in service-planning processes, an emphasis that focuses on the impairments, limitations, defects, or defects in functioning of individuals with disabilities but that excludes a corresponding assessment of and emphasis on their skills, abilities, and strengths. 2. see DEFECT THEORY. Compare DEVELOPMENTAL ORIENTATION.

defect theory the proposition that the cognitive processes and behavioral development of people with intellectual disabilities are qualitatively different from those of their peers without intellectual disabilities. Also called defect orientation; difference hypothesis. Compare DEVELOPMENTAL THEORY.

defender strategy a business strategy in which an organization attempts to compete in the marketplace by focusing on a narrow range of products and services and then protecting this niche by offering higher quality, superior service, and lower prices.

defense n. physical features or behavior that reduce the likelihood of an individual being harmed by another. In nonhuman animals, for example, defensive physical features include hard body parts (e.g., a turtle’s shell) and toxic or noxious substances (e.g., odor from a skunk; poison from snakes and spiders); DEFENSIVE BEHAVIOR includes SUBMISSIVE SIGNALS, defensive aggression, immobility, and flight. —defensive adj.

defense interpretation in psychoanalysis, an interpretation of the ways in which the patient protects himself or herself from anxiety. Such an interpretation aims to make the patient aware of his or her defenses and to uncover the source of the anxiety in intrapsychic conflict.

defense mechanism in classical psychoanalytic theory, an unconscious reaction pattern employed by the ego to protect itself from the anxiety that arises from psychic conflict. Such mechanisms range from mature to immature, depending on how much they distort reality: DENIAL is very immature because it negates reality, whereas SUBLIMATION is one of the most mature forms of defense because it allows indirect satisfaction of a true wish. In more recent psychological theories, defense mechanisms are seen as normal means of coping with everyday problems and external threats, but excessive use of any one, or the use of immature defenses (e.g., DISPLACEMENT OR REPRESSIO, IS still considered pathological. Also called escape mechanism. See also AVOIDANCE; PROJECTION; RATIONALIZATION; REPRESSION; SUBSTITUTION. [proposed in 1894 by Sigmund Freud]

defense reflex a sudden response elicited by a painful or unexpected stimulus. The term is applied to a variety of responses, ranging from an acceleration in heart rate in reaction to a startling auditory stimulus; through flight, fight, or freezing elicited by perceived threat; to complex psychological responses. Also called defense response.

defensible space a set of principles and guidelines for the design and planning of settings to reduce crime. Among the critical elements of defensible space are the creation of shared territories in which people have collective control, good surveillance, and markers and other symbols of ownership and primary territory. See TERRITORIALITY.

defensive aggression see ANIMAL DEFENSIVE BEHAVIOR.

defensive attribution a bias or error in attributing cause for some event such that a perceived threat to oneself is minimized. For example, people might blame an automobile accident on the other driver’s mistake because
defensive behavior

this attribution lessens their perception that they themselves are responsible for the accident.

**defensive behavior** 1. aggressive or submissive behavior in response to real or imagined threats of harm. A cat, for example, may exhibit defensive aggression by spitting and hissing, arching its back, and raising the hair along the back of the neck in anticipation of a physical threat (see ANIMAL DEFENSIVE BEHAVIOR). A human might fend off criticism by putting forth self-justifying excuses or by expressing an emotional reaction (e.g., crying) to limit another’s disapproval or anger. 2. in psychoanalytic theory, behavior characterized by the use or overuse of DEFENSE MECHANISMS operating at an unconscious level.

**defensive conditioning** a form of CLASSICAL CONDITIONING in which the UNCONDITIONED STIMULUS is noxious.

**defensive identification** 1. the process by which a victim of abuse psychologically identifies with the perpetrator of abuse, or with the group with which the perpetrator is identified, as a defensive strategy against continuing feelings of vulnerability to further victimization. 2. in the classical psychoanalytic theory of Sigmund Freud, part of the IDENTIFICATION process in which a child identifies with a parent (particularly the father) who is perceived to be powerful, threatening, and punitive. Freud proposed that this form of identification develops as the child’s defense against punishment by the parent. Compare ANACLITIC IDENTIFICATION. See also IDENTIFICATION WITH THE AGGRESSOR.

**defensiveness** n. a tendency to be sensitive to criticism or comment about one’s deficiencies and to counter or deny such criticisms. —defensive adj.

**defensive processing** the seeking out, attending to, encoding, interpreting, or elaborating of attitude-relevant information to support or confirm one’s initial attitude. For example, defensive processing can involve avoiding attitude-inconsistent information and seeking out attitude-consistent information. Similarly, it can involve elaborating attitude-inconsistent information in a highly critical fashion in order to refute it. See also BIASED ELABORATION; COUNTERARGUMENT; SELECTIVE INFORMATION PROCESSING.

**deferred imitation** imitation of an act minutes, hours, or days after viewing the behavior. Research indicates that deferred imitation of simple tasks can be initially observed or days after viewing the behavior. Research indicates that deferred imitation of simple tasks can be initially observed in infants late in their 1st year. See also SYMBOLIC FUNCTION.

**deferred prosecution** see DIVERSION PROGRAM.

**deficiency** n. a lack or shortage of something. A deficiency may, for example, be a relative or absolute lack of a skill, of a biological substrate or process, or of resources that enable specific functions or actions to be performed.

**deficiency cognition (D-cognition)** see BEING COGNITION.

**deficiency love** (D-love) in Abraham Maslow’s humanistic psychology, a type of love that is fulfillment oriented (e.g., based on a need for belonging, self-esteem, security, or power) and characterized by dependency, possessiveness, lack of mutuality, and little concern for the other’s true welfare. Compare BEING LOVE.

**deficiency motivation** in Abraham Maslow’s humanistic psychology, the type of motivation operating on the lower four levels of his hierarchy of needs (see MASLOW’S MOTIVATIONAL HIERARCHY). Deficiency motivation is characterized by the striving to correct a deficit that may be physiological or psychological in nature. Compare METAMOTIVATION.

**deficiency motive** any motive driven by the need to counter a deficiency, for example, eating simply to alleviate hunger.

**deficiency need** any need created by lack of a substance required for survival (e.g., food, water) or of a state required for well-being (e.g., security, love).

**deficient processing theory** see SPACING EFFECT.

**definite article** in linguistics, an ARTICLE (e.g., the in English) used with a noun phrase to indicate reference to a specific entity that has been or is about to be defined, as in The patient died last night or The patient who died last night. Compare INDEFINITE ARTICLE.

**definition** n. in optics, the clarity of an image reproduced by photography or an optical system. Compare RESOLUTION.

**definitional formula** the formal verbal definition of a statistical concept. For example, the definitional formula of VARIANCE states that it is the mean squared difference between a score and the mean of all of the scores. This contrasts with the COMPUTATIONAL FORMULA, which is the equation used to calculate values for the concept. Also called conceptual formula: definition formula.

**definitional validity** the extent to which the methods or approaches used by a researcher are consistent with the significance claimed (explicitly or implicitly) for the research. See also EXTERNAL VALIDITY; INTERNAL VALIDITY; EMPIRICAL VALIDITY; FACE VALIDITY.

**deformity** n. distortion or malformation of any part of the body. See DISFIGUREMENT.

**degeneracy** n. 1. a state in which a person has declined or reverted to an earlier or simpler state of development in physical, mental, or moral qualities. 2. the state of possessing few if any of the moral standards considered normal in one’s society. Degeneracy is often popularly used with special reference to sexual offenses. —degenerate adj.

**degenerating axon** the remnant of an injured or dead AXON. Degenerating axons leave a residue that absorbs particular dyes. Thus, a degenerating myelinated nerve fiber releases MYELIN, which absorbs osmium, producing a black trail where the healthy fiber had been.

**degeneration** n. 1. deterioration or decline of organs or tissues, especially of neural tissues, to a less functional form. 2. deterioration or decline of moral values. —degenerate vb.

**degenerative status** a constitutional body type marked by an accumulation of deviations from that considered normal, although a single deviant feature would have no particular pathological significance.

**deglutition** n. see SWALLOWING.

**degradation** n. 1. in neurophysiology, the process by which NEUROTRANSMITTER molecules are broken down into inactive metabolites. 2. more generally, the process or result of declining or reducing in value, quality, level, or status.

**degraded stimulus** a stimulus to which NOISE (visual or auditory) has been added to make it more difficult to perceive.
degrees of freedom 1. (symbol: \( df \)) the number of elements that are allowed to vary in a statistical calculation, or the number of scores minus the number of mathematical restrictions. If the mean of a set of scores is fixed, then the number of degrees of freedom is one less than the number of scores. For example, if four individuals have a mean IQ of 100, then there are three degrees of freedom, because knowing three of the IQs determines the fourth IQ.

2. in motor control, the various joints that can move or the various muscles that can contract to produce a movement.

degrees of freedom problem the fact that, in most movement situations, the brain has access to many more degrees of freedom than are necessary to accomplish the task and thus selects which posture or movement trajectory to use from the large set of those that are possible.

dehoaxing n. Debriefing participants who have been involved in deception research to inform them that they were misled as part of the study. This may involve desensitizing participants, so that their self-image is not harmed by having participated in a deceptive study.

dehumanization n. any process or practice that is thought to reduce human beings to the level of mechanisms or nonhuman animals, especially by denying them autonomy, individuality, and a sense of dignity. —dehumanize vb.

dehydration n. lack of water in the body tissues. Dehydration may be absolute, as measured in terms of the difference from normal body water content, or relative, as considered in terms of fluid needed to maintain effective osmotic pressure. The delay before drinking sufficient liquids for complete hydration following water loss through sweating and urination is called voluntary dehydration. Compare HYDRATION.

dehydration reactions metabolic and psychological disturbances occurring when the body's water supply falls far below its needs. Early symptoms are apathy, irritability, drowsiness, inability to concentrate, and anxiety. Dehydration reactions may progress to delirium, spasticity, blindness, deafness, stupor, and death if more than 10% of body weight is lost.

dehydrogenase n. an enzyme that catalyzes the removal of hydrogen atoms in biological reactions. See LACTATE DEHYDROGENASE.

decisive adj. See DEICTIC.

defamation n. 1. the elevation of a living or dead person to the position of a god, as in the case of certain Roman emperors and other rulers of the ancient world. 2. extreme adulation, or the endowment of a person or thing with godlike status. —defame vb.

defindividuation n. an experiential state characterized by loss of self-awareness, altered perceptions, and a reduction of inner restraints that results in the performance of unusual and sometimes antisocial behavior. It can be caused by a number of factors, such as a sense of anonymity or submission in a group.

definitionalization n. the joint process of moving people with developmental or psychiatric disabilities from structured institutional facilities to their home communities and developing comprehensive community-based residential, day, vocational, clinical, and supportive services to address their needs. See COMMUNITY CARE. —definitionalize vb.

definition n. a type of natural religion associated chiefly with the 18th-century Enlightenment. It is based on the premise that a benevolent God will make sure that the knowledge necessary for human happiness is (a) universally available and (b) accessible to the intellectual powers natural to human beings. It follows that divine truth will conform to human reason and the evidence provided by the natural creation. Deism thus contrasts with revealed religion, which requires a divine revelation of truth beyond what is available by the light of nature. Most forms of deism hold that God created the universe and the natural laws that govern it but has since dispassionately and detachedly allowed it to run its course. Compare PANTEISM; THEISM.

deficient adj. n.

Deiters cells cells that support the outer hair cells in the organ of corti. [Otto Deiters (1834–1863), German anatomist]

deficit n. in linguistics, the use of a word or phrase whose meaning is dependent on the situation in which it is used. For example, the meaning of The tree on my side of the fence depends on who says it and where that person is standing. Some words, including the personal and demonstrative pronouns and such adverbs as here, there, and now, are always deictic. The psychological interest in deixis stems from the recognition of the different possible perspectives that it entails. —deictic adj.

defi vécu a recurring feeling that one has lived previously (French, "already lived"); novel situations are experienced as strangely familiar, leading to a conviction that they are being recollected from a previous life. See FALSE MEMORY.

defi vu the feeling that a new event has already been experienced or that the same scene has been witnessed before (French, "already seen"). The feeling of familiarity may be due to a neurological anomaly, to resemblance between the present and the past scenes, or to a similar scene having been pictured in a daydream or night dream. The feeling may occur even though the person experiencing it cannot consciously recollect the earlier event or scene. See FALSE MEMORY.

de Lange syndrome see CORNELIA DE LANGE SYNDROME.

delay conditioning in CLASSICAL CONDITIONING, a procedure in which the conditioned stimulus is presented, and remains present, for a fixed period (the delay) before the unconditioned stimulus is introduced. After repeated exposure to such pairings, a conditioned response develops. If the delay is long enough, inhibition of delay may be observed. Also called delayed conditioning. Compare simultaneous conditioning.

delayed alternation task a delayed response task in which a nonhuman animal must alternate responses between trials. The most common version of this task is one in which a food reward is alternated from side to side with a delay between trials. The animal must learn that a well (cup) containing food is always on the opposite side from the previous trial. Also called delayed response alternation.

delayed auditory feedback (DAF) a technique of auditory feedback in which speakers listen through headphones to their own speech, which is heard a short time after it is spoken. It is one of several techniques that may be used to induce greater fluency and clearer articulation in those with various speech and language disorders, particu-
delayed conditioning

larly in those who stutter. Paradoxically, however, the delay in DAF has also been found to cause dysfluency in normally fluent speakers.

delayed conditioning see DELAY CONDITIONING.

delayed development slower than expected developmental increases in physical, emotional, social, or cognitive abilities or capacities. A child with delayed development may hold attitudes, exhibit habits, or engage in behaviors consistent with an earlier developmental level.

delayed effect an effect that is not observed for some period of time after the event or factor that is held to have caused it. Usually the precipitating event exerts an indirect influence by starting a process or chain of events that ultimately has a demonstrable effect. See CAUSAL LATENCY; REMOTE CAUSE.

delayed ejaculation see MALE ORGASMIC DISORDER.

delayed feedback the delay of feedback from the senses that is used to guide or monitor specific motor movements. Delayed feedback interferes with decision making and behavior; for example, DELAYED AUDITORY FEEDBACK when speaking can substantially interfere with the speed and processing of speech.

delayed matching to sample (DMTS) a procedure in which the participant is shown a sample stimulus and then, after a variable time, a pair of test stimuli and is asked to select the test stimulus that matches the earlier sample stimulus. Correct selection of the matching stimulus is reinforced. In zero-delay matching to sample, the test stimuli are presented as soon as the sample stimulus is removed. The task becomes more difficult as the time between the two presentations increases. In delayed non-matching to sample, the participant must choose the stimulus that was not presented in the sample phase. See also CONDITIONAL DISCRIMINATION; MATCHING TO SAMPLE.

delayed parenthood the state of people who have their first child relatively late in life, usually after their 30th birthday.

delayed posttraumatic stress disorder a form of POSTTRAUMATIC STRESS DISORDER that is diagnosed when the symptoms first appear more than 6 months after exposure to the traumatic stressor.

delayed recall the ability to recollect information acquired earlier. Frequently used in laboratory studies of memory, delayed recall is also used in neuropsychological examinations to determine the rate of loss of information presented earlier, in comparison to established norms.

delayed reflex a reflexive response that has an abnormally long latency after stimulation.

delayed reinforcement reinforcement that does not occur immediately after a response has been made. The delay may be signaled or unsignaled. If it is signaled, a stimulus change occurs immediately after the response, and this stimulus remains present until the reinforcer is delivered. If the delay is unsignaled, there is no change of stimulus.

delayed response a response that occurs some time after its discriminative stimulus has been removed. The most common delayed response task for nonhuman animals is one in which the animal is required to recall the location of a reward after a delay period has elapsed.

delayed response alternation see DELAYED ALTERNATION TASK.

delayed speech the failure of speech to develop at the expected age. It may be due to DEVELOPMENTAL DELAY, hearing loss, brain injury, intellectual disability, psychological disorder, or emotional disturbance.

delay of gratification forgoing immediate reward in order to obtain a larger, more desired, or more pleasurable reward in the future. Compare IMMEDIATE GRATIFICATION.

delay of reinforcement the time between a response and its reinforcer.

delay-of-reward gradient the relationship between DELAY OF REINFORCEMENT and the effectiveness of reinforcement. The effectiveness decreases as the delay increases. Also called delay-of-reinforcement gradient.

delboeuf illusion a size CONTRAST ILLUSION in which a larger enclosing circle influences the perceived size of a smaller enclosed circle. If the two circles are of similar sizes, the perceived size of the inner circle will be increased. If the size of the enclosing circle is significantly larger, then the perceived size of the inner circle will be decreased. [Joseph-Rémi-Léopold DELBOEUF]

delegation of authority an approach whereby a manager or supervisor assigns tasks to subordinates, along with commensurate responsibility for completion of the tasks, but without relinquishing the ultimate responsibility for any success or failure.

deletion n. 1. in genetics, a particular kind of MUTATION characterized by the loss of genetic material from a chromosome. Deletion of a gene or part of a gene may result in the development of a disease or abnormality. The deletion may involve the loss of one or several base pairs (point mutation) or a much larger segment of a chromosome (chromosomal mutation). 2. in GENERATIVE GRAMMAR, the process in which a constituent of the deep structure of a sentence is deleted from the surface structure (i.e., the sentence as used). For example, the sentence I am happy, my mother is too is derived from the deep structure I am happy, my mother is happy too, with the second happy deleted. The question of whether deletion can serve as a psychological model of sentence processing has been a subject of much psycholinguistic investigation. See also ELISION.

deliberate psychological education (DPE) a curriculum that is designed to affect personal, ethical, aesthetic, and philosophical development in adolescents and young adults, through a balance of real and role-taking experiences and reflective inquiry. Counselors act as psychological educators or developmental instructors.

deliberate sampling any method of selecting individuals to participate in research on the basis of a specific plan, rather than randomly. This includes simple nonrandom techniques, such as JUDGMENT SAMPLING and CONVENIENCE SAMPLING. In more sophisticated methods, such as QUOTA SAMPLING and STRATIFIED SAMPLING, various steps are taken with the aim of creating a sample that is representative of the larger population.

deliberate self-harm (DSH) the intentional, direct destruction of body tissue (most commonly by cutting, burning, scratching, self-hitting, self-biting, and head banging) without conscious suicidal intent but resulting in injury severe enough for tissue damage to occur. Although, by definition, DSH is distinguished from suicidal behaviors involving an intent to die, it is nonetheless potentially life-
threatening. Typically associated with borderline personality disorder, it has also been found to occur at high rates among nonclinical populations of adolescents. It is seen as well in individuals with intellectual and developmental disabilities, in whom it is usually known by its older synonym self-injurious behavior. Also called self-injury.

deliberative mind-set see Mind-set.

delinquency n. behavior violating social rules or conventions. The term is often used to denote the misbehavior of children or adolescents. See juvenile delinquency. —delinquent adj., n.

dédiré de négation see Cotard’s syndrome.

dédiré du toucher the compulsion to touch objects, which may be associated with obsessive-compulsive disorder or may be a complex tic in Tourette’s disorder.

delirant n. a substance capable of inducing acute delirium, commonly associated with restlessness or agitation. An acute delirium may result from excess ingestion of anticholinergic drugs (see anticholinergic syndrome) or withdrawal from alcohol and certain other substances.

delirium n. a disturbed mental state in which attention cannot be sustained, the environment is misperceived, and the stream of thought is disordered. The individual may experience changes in cognition (which can include disorientation, memory impairment, or disturbance in language), perceptual disturbances, hallucinations, illusions, and misinterpretation of sounds or sights. The episode develops quickly and can fluctuate over a short period. Delirium may be caused by a variety of conditions, such as infections, cerebral tumors, substance intoxication and withdrawal, head trauma, and seizures.

delirium of persecution delirium in which the predominant symptoms include intense mistrust and hallucinations that one is being threatened.

delirium tremens (DTs) a potentially fatal alcohol withdrawal syndrome involving extreme agitation and anxiety, paranoia, visual and tactile hallucinations, disorientation, tremors, sweating, and increased heart rate, body temperature, and blood pressure. Onset is usually within 72 hours of cessation of heavy alcohol use, but symptoms may occur up to 10 days after the last drink. The DTs are considered a medical emergency.

Delis–Kaplan Executive Function System (D-KEFS) a battery of nine measures used in the evaluation of higher cognitive functions (e.g., planning, problem solving, abstract thinking) in both children and adults. The battery consists of modifications of traditional measures (e.g., Trail Making Test, Verbal Fluency Test, Design Fluency Test) as well as newer measures (a sorting test, a word-context test). Each measure has multiple component scores, allowing for a process approach to the assessment of executive functioning. [First published in 2001 by U.S. neuropsychologists Dean C. Delis (1951–) and Joel H. Kramer]

delivery n. the second stage of childbirth, during which the infant travels through the birth canal and into the external world. See also afterbirth, labor.

Delphi technique a method of developing and improving group consensus by eliminating the effects of personal relationships and dominating personalities. Conflict is managed by circulating a questionnaire, which is edited and summarized on the basis of the last round of comments and then reissued for further response by those participating in the survey. The Delphi technique is used in many situations where convergence of opinion is desirable (e.g., for defining goals, setting standards, or identifying and ranking needs and priorities).

delta (symbol: ∆) n. 1. a measure of the change in a parameter. For example, AR2 indicates how much of the change in R2 (the coefficient of multiple determination) was caused or explained by a given step (e.g., adding a specific variable to an analysis). 2. see glass’s δ.

delta alcoholism see Jellinek’s alcoholism species.

delta movement a form of apparent movement in which a brighter stimulus appears to move toward a darker stimulus, provided that certain conditions of stimulus size, distance, and time between stimuli are met. Also called delta motion.

delta opioid receptor see opioid receptor.

delta rule the principle that the change in strength of an association during learning is a function of the difference between the maximal strength possible and the current strength of the association. The delta rule is used in associationist learning theory (see associative learning).

delta-9-tetrahydrocannabinol n. see tetrahydrocannabinol.

delta wave the lowest frequency brain wave recorded in electroencephalography. Delta waves are large, regular-shaped waves that have a frequency of 1 to 3 Hz. They are associated with deep sleep (delta-wave sleep) and indicate a synchronization of cells of the cerebral cortex. Also called delta rhythm, slow wave. See NREM sleep, stage 3 sleep, stage 4 sleep.

deltoid 1. n. a muscle that covers the shoulder and is used to raise the arm to the side. 2. adj. pertaining to the deltoid muscle.

delusion n. an often highly personal idea or belief system, not endorsed by one’s culture or subculture, that is maintained with conviction in spite of irrationality or evidence to the contrary. Delusions may be transient and fragmentary, as in delirium, or highly systematized and elaborate, as in delusional disorders, though most of them fall between these two extremes. Common types include delusional jealousy, delusions of being controlled, delusions of grandeur, delusions of persecution, delusions of reference, nihilistic delusions (see nihilism), and somatic delusions. Data suggest that delusions are not primarily logical errors but are derived from emotional material. They have come to represent one of the most important factors in systems for diagnostic classification. Some researchers believe that delusions may be the most important symptom of schizophrenia. See also bizarre delusion, fragmentary delusion, systematized delusion.

delusional disorder in DSM-IV-TR, any one of a group of psychotic disorders with the essential feature of one or more nonbizarre delusions that persist for at least 1 month but are not due to schizophrenia. The delusions are nonbizarre in that they feature situations that could conceivably occur in real life (e.g., being followed, poisoned, infected, deceived by one’s government). Diagnosis also requires that the effects of substances (e.g., cocaine) and a medical condition be ruled out as causes of the delusions. Seven types of delusional disorder are specified, according to the theme of the delusion: erotomanic, grandiose, jealous, persecutory, somatic, mixed, and unspecified. Criteria
changes for delusional disorder in DSM–5 include the following: The delusions may be either nonbizarre or bizarre (i.e., implausible), and their potential presence as a result of an ingested substance, a medical condition, or another mental disorder sometimes associated with firmly held delusional beliefs (e.g., obsessive-compulsive disorder, body dysmorphic disorder) must be ruled out. Formerly called paranoid disorder.

delusional jealousy a false belief that a spouse or partner is unfaithful. The individual is constantly on the watch for indications that this belief is justified; manufactures evidence if it is not to be found, and completely disregards facts that contravene the conviction. Also called morbid jealousy; Othello syndrome or delusion: pathological jealousy.

delusional mania a less common name for a MANIC EPISODE with PSYCHOTIC FEATURES.

delusional misidentification syndrome see MIS-IDENTIFICATION SYNDROME.

delusional parasitosis a rare psychiatric disorder (previously called ACAROPHOBIA) in which a person has the false and persistent belief of being infested by parasites (mites and lice), worms, insects, bacteria, or other small living organisms. It may occur in isolation or be secondary to dementia, psychosis, or various medical conditions. See also FORMICATION.

delusional system a more or less logically interconnected group of delusions held by the same person. Delusions that are tightly logical, but based on a false premise, are characteristic of persecutory type DELUSIONAL DISORDER. Also called delusion system.

delusion of being controlled the false belief that external forces, such as machines or other people, are controlling one’s thoughts, feelings, or actions.

delusion of grandeur the false attribution to the self of great ability, knowledge, importance or worth, identity; prestige, power, accomplishment, or the like. Also called grandiose delusion. See also MEGALOMANIA.

delusion of influence 1. the false supposition that other people or external agents are covertly exerting powers over oneself. IDEA OF INFLUENCE is used synonymously but with the implication that the condition is less definite, of shorter duration, or less severe. 2. the false belief that one’s intentions or actions directly control external events or the thoughts and behavior of other people.

delusion of negation see NIHILISM.

delusion of observation the false belief that one is being watched by others. Also called observation delusion.

delusion of persecution the false conviction that others are threatening or conspiring against one. Also called persecutory delusion.

delusion of poverty a false belief in which the individual insists that he or she is, or will soon be, entirely destitute.

delusion of reference the false conviction that the actions of others and events occurring in the external world have some special meaning or significance (typically negative) in relation to oneself. See also IDEA OF REFERENCE.

delusion of sin a delusion in which the individual is convinced of having committed unpardonable sins, for example, being to blame for wars, droughts, and other catastrophes. Such a delusion is frequently accompanied by intense fear of punishment.

delusion system see DELUSIONAL SYSTEM.

demand n. a requirement or urgent need, particularly any internal or external condition that arouses a DRIVE in an organism.

demand characteristics in an experiment or research project, cues that may influence or bias participants’ behavior, for example, by suggesting the outcome or response that the experimenter expects or desires. Such cues can distort the findings of a study. See also EXPERIMENTER EFFECT; SENSORY LEAKAGE.

demand feeding see SELF–DEMAND SCHEDULE.

demandingness n. insistence upon attention, help, or advice from others. It is commonly associated with depression. See also DEPENDENCE. —demanding adj.

demandment n. any self-constructed and often self-deceiving and nonconscious interpretation that converts personal desires and goals into absolute demands: “Because I am not performing well, as I absolutely must, I am a terrible person.” See RATIONAL EMOTIVE BEHAVIOR THERAPY. [defined by Albert Ellis]

demand reduction an approach to fighting addiction (including smoking and alcoholism) that attempts to reduce user demand for abused drugs through such tactics as antidrug education in schools, antidrug advertising (e.g., on television and billboards), and legislation requiring that health warnings be prominently placed on product packaging (e.g., cigarette packs, liquor bottles). In contrast, supply reduction attempts to lessen the supply of abused substances through, for example, DRUG INTERDICT, drug-seller arrests, and the requirement that retailers limit access to substances such as INHALANTS.

demand–withdraw pattern a pattern of interaction in which a person criticizes or requests changes in the behavior of a relationship partner, who responds by avoiding the demand, becoming defensive, or withdrawing from the conversation. This pattern of communication is considered dysfunctional and predicts marital deterioration and divorce. The pattern occurs more often with female demands and male withdrawal than vice versa. [first identified in the 1980s by U.S. psychologist Andrew Christensen and colleagues]

demasculinization n. 1. removal of the testes. 2. inhibition of masculine development in the fetus by insufficiency of androgens.

démence précoce see DEMENTIA PRAECOX.

dementia n. 1. a generalized, pervasive deterioration of memory and at least one other cognitive function, such as language and an EXECUTIVE FUNCTION, due to a variety of causes. The loss of intellectual abilities is severe enough to interfere with an individual’s daily functioning and social and occupational activity. In DSM–IV–TR, dementias are categorized according to the cause, which may be Alzheimer’s disease, cerebrovascular disease (see VASCULAR DEMENTIA), Lewy body dementia, Pick’s disease, Parkinson’s disease, Huntington’s disease, HIV infection (see AIDS DEMENTIA COMPLEX), Creutzfeldt–Jakob disease, head injury, alcoholism (see ALCOHOL–INDUCED PERSISTING DEMENTIA), or substance abuse (see SUBSTANCE–INDUCED PERSISTING DEMENTIA). Brain tumor, HYPOTHYROIDISM, HEMATOMA, or
other conditions, which may be treatable, can also cause dementia. The age of onset varies with the cause but is usually late in life. When occurring after the age of 65, it is termed senile dementia, and when appearing before 65, it is called presenile dementia, although these distinctions are becoming obsolete because its manifestations are the same no matter the age of onset. Dementia should not be confused with age-associated memory impairment or mild cognitive impairment, which have a much less deleterious effect on day-to-day functioning. DSM–5 has subsumed dementia and amnestic disorder into the diagnostic category major neurocognitive disorder, although it still accepts the term dementia where commonly used. 2. Historically, loss of ability to reason due to mental illness; diseases such as neurosyphilis (see general paresis), or advanced age (senility). [Latin, “out of mind”]

dementia of the Alzheimer's type (DAT)  another name for Alzheimer’s disease.

dementia paralytica see general paresis.

dementia praecox a progressively deteriorating psychotic disorder marked by severe, incurable cognitive disinhibition beginning in early adulthood (Latin, “premature dementia”). The term, now obsolete, was first used in 1891 by Czech psychiatrist and neuroanatomist Arnold Pick (1851–1924) and then formalized by German psychiatrist Emil Kraepelin as a taxonomic concept, defining it as one of two major classes of mental illness (the other being manic-depressive illness; see bipolar disorder) and distinguishing it from the “senile dementia” of advanced age. It is said to have originated as a translation of démence précoce, coined in 1852 by Austrian-born French psychiatrist Bénédict A. Morel (1809–1873), but some dispute that connection, arguing that Morel’s term was only a passing description of a group of young patients who suffered from “stupor,” a condition unrelated to the psychotic disorder that Kraepelin described more than 40 years later. Whatever its exact origins, the more prevalent Latin term was eventually replaced after Swiss psychiatrist Eugen Bleuler reframed the Kraepeliniand concept, deemphasizing its characterization as an early dementia with an irreversible disease course, and renamed it schizophrenia in 1908.

dementia pugilistica a chronic, slowly progressive dementia produced by repeated blows to the head, as may affect participants of contact sports such as boxing, football, and wrestling. Affected individuals are often described as “punch-drunk.” Common symptoms include poorly articulated speech (see dysarthria), poor balance, impaired memory and concentration, and involuntary movements. The term is often applied to the more advanced cases, whereas chronic traumatic encephalopathy refers to all types of cases. Also called boxer’s dementia.

Dementia Rating Scale (DRS) a neuropsychological assessment instrument used to measure cognitive status in adults with cognitive impairments due to brain pathologies. It comprises 36 tasks of varying difficulty (e.g., repeating a series of numbers, naming objects present in the immediate environment, copying designs from stimulus cards onto blank pieces of paper) that are presented to participants in a fixed order. The scale evaluates performance on five subscales: attention, initiation–perseveration, construction, conceptualization, and memory. Originally developed in 1973 by U.S. neuropsychologist Steven Mattis and published commercially in 1988, the DRS subsequently was revised in 2001 (DRS–2).

dementia syndrome of depression see pseudodementia.

demerol n. a trade name for meperidine.

deming management method an approach to management that uses a prescriptive set of 14 points as guidelines for appropriate organizational practice and that emphasizes the strategic role of senior management in meeting customer needs. The method was important in the development of total quality management. See also theory Z. [W. Edwards Deming (1900–1993). U.S. management expert]

demo- (dem-) combining form people or population.

democracy n. 1. a form of government in which the people either participate in the political process themselves or elect others to do so on their behalf (representative democracy) and in which decisions are made by majority vote. 2. more loosely, any society in which all citizens purportedly have equal rights and in which certain basic freedoms, such as freedom of speech, are upheld. See also open society. —democrat n. —democratic adj.

democratic atmosphere a climate of social and political equality in which group members resolve issues and make choices through the use of procedures that ensure that the final decision accurately reflects the predominant desires and intentions of the group.

democratic leader the type of leader who establishes and maintains an egalitarian group climate in which members themselves participate in planning activities, resolving issues, and making choices important to the group. Groups with democratic leaders tend to show greater originality, higher morale, and less anxiety, aggression, and apathy than do groups with authoritarian leaders or with laissez-faire leaders. Also called group-centered leader.

democratic parenting a parenting style, derived from the ideas of Alfred Adler, in which the parent guides the child’s development in an accepting but steady manner and fosters a climate in which cooperation, fairness, equality, and mutual respect between parent and child are assumed.

demographic research see population research.

demography n. the statistical study of human populations in regard to various factors and characteristics, including geographical distribution, sex and age distribution, size, structure, and growth trends. Such analyses are used in many types of investigation, including epidemiological studies. See also biostatistics; social statistics. —demographer n. —demographic adj.

demonic possession the supposed invasion of the body by an evil spirit or devil that gains control of the mind or soul, producing mental disorder, physical illness, or criminal behavior. Many forms of physical and psychological illness were formerly attributed to such possession, notably epilepsy, schizophrenia, and Tourette’s disorder. The traditional remedy for possession was ritual exorcism.

demonolatry n. the worship of devils or demons. See also Satanism; witchcraft. —demonolator n.

demonology n. the systematic study of belief in demons and evil spirits, frequently depicted in folklore and mythology as invading the mind, gaining possession of the soul, and producing disordered behavior. See also exorcism; Familiar: incubus; succubus; witchcraft. —demonological adj. —demonologist n.
demonomania n. a morbid preoccupation with demons and demonic possession, including the belief that one is possessed by or under the control of an evil spirit or demon.
demonstration experiment a demonstration, often by a teacher in a classroom, of a well-established fact. Demonstration experiments are usually not experiments in the technical sense of comparing experimental to control conditions after randomization.
demoralization n. a sense of threat to or a breakdown of values, standards, and mores in an individual or group, such as may occur in periods of rapid social change, extended crises (e.g., war, economic depression), or personal traumas. A demoralized person may be disheartened and feel helpless, bewildered, and insecure.—demoralize vb.
demoralization hypothesis the idea that effective psychotherapy depends on the therapist overcoming the client’s state of demoralization, which can be achieved by encouraging the client to confide, explaining his or her symptoms, and providing a therapeutic ritual through which these may be resolved. Such an approach is held to be a common factor underlying the success of various therapies. [proposed by Jerome D. Frank]
demotivation n. negative imagery or negative self-talk that emphasizes why one cannot do well in a task and thus discourages any attempt to perform it.
demyelinating disease any of various pathological conditions, such as multiple sclerosis, resulting from destruction of the myelin sheath covering nerve fibers in the central and peripheral nervous systems.
demyelination n. the loss of the myelin sheath that covers nerve fibers.
demyelination plaque see PLAQUE.
denasality n. see HYPONASALITY.
dendrite n. see HYPONASALITY.

demonstration experiment a demonstration, often by a teacher in a classroom, of a well-established fact. Demonstration experiments are usually not experiments in the technical sense of comparing experimental to control conditions after randomization.
demoralization n. a sense of threat to or a breakdown of values, standards, and mores in an individual or group, such as may occur in periods of rapid social change, extended crises (e.g., war, economic depression), or personal traumas. A demoralized person may be disheartened and feel helpless, bewildered, and insecure.—demoralize vb.
demoralization hypothesis the idea that effective psychotherapy depends on the therapist overcoming the client’s state of demoralization, which can be achieved by encouraging the client to confide, explaining his or her symptoms, and providing a therapeutic ritual through which these may be resolved. Such an approach is held to be a common factor underlying the success of various therapies. [proposed by Jerome D. Frank]
demotivation n. negative imagery or negative self-talk that emphasizes why one cannot do well in a task and thus discourages any attempt to perform it.
demyelinating disease any of various pathological conditions, such as multiple sclerosis, resulting from destruction of the myelin sheath covering nerve fibers in the central and peripheral nervous systems.
demyelination n. the loss of the myelin sheath that covers nerve fibers.
demyelination plaque see PLAQUE.
denasality n. see HYPONASALITY.
dendrite n. see HYPONASALITY.

demonstration experiment a demonstration, often by a teacher in a classroom, of a well-established fact. Demonstration experiments are usually not experiments in the technical sense of comparing experimental to control conditions after randomization.
demoralization n. a sense of threat to or a breakdown of values, standards, and mores in an individual or group, such as may occur in periods of rapid social change, extended crises (e.g., war, economic depression), or personal traumas. A demoralized person may be disheartened and feel helpless, bewildered, and insecure.—demoralize vb.
demoralization hypothesis the idea that effective psychotherapy depends on the therapist overcoming the client’s state of demoralization, which can be achieved by encouraging the client to confide, explaining his or her symptoms, and providing a therapeutic ritual through which these may be resolved. Such an approach is held to be a common factor underlying the success of various therapies. [proposed by Jerome D. Frank]
demotivation n. negative imagery or negative self-talk that emphasizes why one cannot do well in a task and thus discourages any attempt to perform it.
demyelinating disease any of various pathological conditions, such as multiple sclerosis, resulting from destruction of the myelin sheath covering nerve fibers in the central and peripheral nervous systems.
demyelination n. the loss of the myelin sheath that covers nerve fibers.
demyelination plaque see PLAQUE.
denasality n. see HYPONASALITY.
dendrite n. see HYPONASALITY.

demonstration experiment a demonstration, often by a teacher in a classroom, of a well-established fact. Demonstration experiments are usually not experiments in the technical sense of comparing experimental to control conditions after randomization.
demoralization n. a sense of threat to or a breakdown of values, standards, and mores in an individual or group, such as may occur in periods of rapid social change, extended crises (e.g., war, economic depression), or personal traumas. A demoralized person may be disheartened and feel helpless, bewildered, and insecure.—demoralize vb.

demotivation n. negative imagery or negative self-talk that emphasizes why one cannot do well in a task and thus discourages any attempt to perform it.
demyelinating disease any of various pathological conditions, such as multiple sclerosis, resulting from destruction of the myelin sheath covering nerve fibers in the central and peripheral nervous systems.
demyelination n. the loss of the myelin sheath that covers nerve fibers.
demyelination plaque see PLAQUE.
denasality n. see HYPONASALITY.
dendrite n. see HYPONASALITY.

dental lisp  see LISP.

dental pattern  the species-specific arrangement of teeth by type (i.e., incisors, canines, bicuspids, and molars) in each quadrant of the mouth, from front to back.

dental phobia  a persistent and irrational fear of dentists or of dental treatment, resulting in the avoidance of dental care or marked distress and anxiety during dental visits. It may be related to a prior negative dental experience, fear of pain, perceived lack of control, or feelings of helplessness or embarrassment.

dentate gyrus  a strip of gray matter that is part of the HIPPOCAMPAL FORMATION, connecting the ENTORHINAL CORTEX with the CA3 region of the HIPPOCAMPUS proper. It comprises the granular layer, which is densely packed with the bodies (somas) of elongated neurons called GRANULE CELLS; the molecular layer, which contains the dendrites of the granule cells and is divided into outer, middle, and inner sublayers; and the polymorphic layer (or hilus), which contains the axons of the granule cells (see MOSSY FIBER). At the border between the granular and polymorphic layers is the subgranular zone, one of only two currently known areas in the adult brain in which new neurons are formed (the other is the SUBVENTRICULAR ZONE in the lateral ventricles). This multistage creation process, called NEUROGENESIS, is modulated by many factors (e.g., age, environmental stimuli, hormones, neurotransmitters, NEUROTROPHEINS, stress) and essential to several activities, notably information processing and learning, memory formation, spatial representation, and affect regulation. Structural and functional abnormalities of the dentate gyrus are associated with an increasing number of pathologies, including Alzheimer’s disease, autism, epilepsy, depression and other mood disorders, schizophrenia, and substance abuse and dependence. Consequently, novel therapeutic approaches focused on enhancing the rate of neurogenesis and the successful survival of newborn neurons are being explored.

dentate nucleus  a cluster of cell bodies in the CEREBELUM believed to be associated with skilled and rapid movement.

denti- (dent-)  combining form: teeth.

deoxycorticosterone  n. a potent MINERALOCORTICOID hormone synthesized by the adrenal glands. It is a precursor of CORTICOSTERONE.

deoxycortisol  n. a compound that is related to glucose but cannot be metabolized. It is used, in various forms, to label cells for histological examination or imaging techniques; for example, radiolabeled 2-deoxycortisol is used in POSTERIOR EMISION TOMOGRAPHY.

deoxyribonucleic acid  see DNA.

Depacon  n. a trade name for valproate sodium. See VALPROIC ACID.

Depakene  n. a trade name for VALPROIC ACID.

Depakote  n. a trade name for DIVALPROEX SODIUM.

dependence  n. 1. the state of having some reliance on or ASSOCIATION with another entity or event, as when one variable is formed from another variable in an analysis. For example, dependence would be seen if a researcher included IQ formed from mental age over actual age, in an analysis that already has age as a variable. 2. a state in which assistance from others is expected or actively sought for emotional or financial support, protection, security, or daily care. The dependent person leans on others for guidance, decision making, and nurturance. Whereas some degree of dependence is natural in interpersonal relations, excessive, inappropriate, or misdirected reliance on others is often a focus of psychological treatment. Personality, social, and behavioral psychology, as well as psychoanalytic theory, all contribute different perspectives to the study and treatment of pathological dependence. 3. see SUBSTANCE DEPENDENCE. 4. in OPERANT CONDITIONING, a causal relation between a response and a consequence, which results in a CONTINGENCY. 5. see STATISTICAL DEPENDENCE. Also called dependency. —dependent adj.

dependency court  in the United States, a court dealing with all issues concerned with child abuse and neglect; such issues are brought to the attention of the court by a government agency (typically Child Protective Services), which intervenes on behalf of the child by filing a petition alleging abuse or neglect.

dependency need  any personal need that must be satisfied by others, including the need for affection, love, shelter, physical care, food, warmth, protection, and security. Such needs are considered universal and normal for both sexes and at all ages, though excessive dependence can be maladaptive. See also CODEPENDENCY; MORBID DEPENDENCY.

dependency ratio  a measure of the portion of a population that is composed of people who are not in the work force and depend on others for support versus people who are in the work force and are self-sufficient. The dependency ratio is often defined in terms of age groups, with those who either are too young to work or are retired being set against those who are in their prime earning years; it is then calculated as the number of individuals aged below 15 or above 64 divided by the number of individuals aged 15 to 64.

dependent events  in probability theory, EVENTS that have a relationship such that the outcome of one affects the outcome of the other. For example, overeating and being overweight are dependent events, whereas shoe size and political party preference are most likely not. Compare INDEPENDENT EVENTS.

dependent groups  see DEPENDENT SAMPLES.

dependent model  see INTEGRATED MODEL.

dependent-part quality  in GESTALT PSYCHOLOGY, the quality that a part of a larger whole derives by virtue of the part–whole relationship.

dependent personality disorder  in DSM–IV–TR and DSM–5, a personality disorder manifested in a long-term pattern of passively allowing others to take responsibility for major areas of life and of subordinating personal needs to the needs of others, due to lack of self-confidence and self-dependence. It was formerly known as passive-dependent personality.

dependent samples  sets of data that are related owing to their having been collected from the same group on two or more occasions (as with a pre- and posttest), or from two or more sets of individuals who are related or otherwise closely associated (e.g., parents and their children). Also called correlated samples; dependent groups; related samples. Compare INDEPENDENT SAMPLES.

dependent-samples t test  a T TEST used to analyze data from two or more sets of associated individuals or from one set of individuals measured on different occasions (e.g., pre- and posttreatment). Also called re-
dependent variable

**lated-samples t test:** repeated measures t test. See WITHIN-SUBJECTS DESIGN. Compare INDEPENDENT-SAMPLES T TEST.

**dependent variable (DV)** the outcome that is observed to occur or change after the occurrence or variation of the INDEPENDENT VARIABLE in an experiment, or the effect that one wants to predict or explain in CORRELATIONAL RESEARCH. Dependent variables may or may not be related causally to the independent variable. Also called **criterion variable:** effect variable; outcome variable; response variable.

depersonalization n. a state of mind in which the self appears unreal. Individuals feel estranged from themselves and usually from the external world, and thoughts and experiences have a distant, dreamlike character. In its persistent form, depersonalization is observed in such disorders as depression, hypochondriasis, dissociative states, temporal lobe epilepsy, and early schizophrenia. It also often occurs as a result of a traumatic experience. The extreme form is called depersonalization syndrome.

depersonalization disorder a DISSOCIATIVE DISORDER characterized by one or more episodes of depersonalization severe enough to impair social and occupational functioning. Onset of depersonalization is rapid and usually manifested in a sensation of self-estrangement, a feeling that one’s extremities are changed in size, a sense of being mechanical, a perception of oneself as if from a distance, and, in some cases, a feeling that the external world is unreal (DEREALIZATION).

depersonalization syndrome see DEPERSONALIZATION.

depersonification n. 1. treatment of another person as something other than the unique individual that he or she really is. For example, parents may treat their child as an extension of themselves, which leads to the child having a distorted sense of self. 2. in psychoanalytic theory, a stage in the maturation of the SUPEREGO that follows INTROJECTION of parental IMAGES and leads to integration of parental values as abstract ideas. —depersonify vb.

deleptive treatment a type of treatment that involves deliberately weakening the organism and thereby (it is supposed) depleting it of some substance believed to be harmful, as by bleeding, purging, blistering, or making the patient vomit. Deleptive treatment originated in the time of Greek physician Hippocrates (c. 460–c. 377 BCE) and was practiced for many centuries. More recently, certain psychiatric disorders have been treated by deleptive therapies, as in various shock therapies.

Deplin n. a trade name for L-METHYLFOLATE.

deployment psychology a branch of MILITARY PSYCHOLOGY devoted to understanding and addressing the unique mental and behavioral health needs of members of the armed forces and their families during and after members’ postings to combat zones and other operational environments. Research in this area focuses on (a) the psychosocial effects on military personnel and their families of combat exposure and of injuries sustained in combat, including disfigurement, amputation, sensory loss, TRAUMATIC BRAIN INJURY, and other severe wounds; (b) barriers to accessing mental health care in the military and the efficacy of existing prevention and intervention programs; (c) the psychology of trauma and promotion of RESILIENCE among military personnel and their families; and (d) the process of readjusting to family, community, and general civilian life for returning military personnel. Similarly, clinical services focus on (a) treating posttraumatic stress disorder, anxiety disorder, adjustment disorder, depression, substance abuse, and other mental health disorders common among returning military personnel; (b) mitigating the negative effects of these disorders on the families of those affected; (c) mitigating the stress experienced by families while military personnel are deployed; (d) teaching effective coping skills—such as anger management, conflict resolution, and communication techniques—to returning soldiers and their families to better prepare them to handle interpersonal difficulties that may arise; and (e) using STRESS-INOCULATION TRAINING and other strategies during deployment to enhance the psychological well-being of soldiers and thus prevent the subsequent development of serious problems.

depolarization n. a reduction in the electric potential across the plasma membrane of a cell, especially a neuron, such that the inner surface of the membrane becomes less negative in relation to the outer surface. Depolarization occurs when the membrane is stimulated and sodium ions (Na+) flow into the cell. If the stimulus intensity exceeds the excitatory threshold of the neuron, an ACTION POTENTIAL is created and a nerve impulse propagated. Compare HYPERPOLARIZATION.

Depo-Provera n. a trade name for medroxyprogesterone acetate, an ANTIANDOGEN used as a long-acting contraceptive for women and in the treatment of sex offenders. See CHEMICAL CASTRATION.

deprenyl n. see SELEGILINE.

depressant 1. adj. having the quality of diminishing or retarding a function or activity of a body system or organ. 2. n. any agent that has this quality, especially a CNS DEPRESSANT.

depressed skull fracture a skull fracture in which part of the skull is pressed in toward the brain. In some cases, skull fragments may enter the brain tissue.

depression n. 1. a negative affective state, ranging from unhappiness and discontent to an extreme feeling of sadness, pessimism, and despondency, that interferes with daily life. Various physical, cognitive, and social changes also tend to co-occur, including altered eating or sleeping habits, lack of energy or motivation, difficulty concentrating or making decisions, and withdrawal from social activities. It is symptomatic of a number of mental health disorders. 2. in psychiatry and psychology, any of the DEPRESSIVE DISORDERS. —depressed adj.

depression stage the fourth of the five STAGES OF GRIEF described by Elisabeth KÜHNER-ROSS. It is characterized by feelings of sadness, loss, regret, or uncertainty that typically represent, consciously or nonconsciously, some level of acceptance in facing one’s own or another’s impending or actual death or some other great loss or trauma.

depressive anxiety in psychoanalytic theory, anxiety provoked by fear of one’s own hostile feelings toward others. It is based on the theory that depression is hostility turned inward.

depressive disorder in DSM–IV–TR and DSM–5, any of the mood disorders that typically have sadness as the predominant symptom. They primarily include MAJOR DEPRESSIVE DISORDER and DYSTHYMIC DISORDER.

depressive episode see MAJOR DEPRESSIVE EPISODE.
depressive neurosis a former name for DYSTHIMIC DISORDER.

depressive personality disorder a diagnosis in the appendix of DSM-IV–TR (i.e., proposed but not given official recognition in the manual) that is characterized by glumness, pessimism, a lack of joy, the inability to experience pleasure, and motor retardation. Feelings of loss, a sense of giving up, and an orientation to pain are notable. There are vegetative signs, despair regarding the future, and a disheartened outlook.Clinicians attempt to differentiate this disorder from DYSTHIMIC DISORDER. Mention of the diagnosis has been removed from DSM–5.

depressive position in the OBJECT RELATIONS THEORY of Melanie Klein, the stage of infant development that reaches its peak at about 6 months of age. In the depressive position, the infant begins to perceive the GOOD OBJECT and BAD OBJECT as a single whole and feels guilt for having attacked the good object during the preceding PARANOID-SCHIZOID POSITION. In this—Klein’s most mature—phase of primary psychological organization, the infant fears that he or she will lose or destroy the good object and attempts to make REPARATION for earlier hostility. It is thought that maintenance of the depressive position fluctuates throughout the lifespan and that the lack of capacity for this position is tied to severe pathology.

depressive reaction see REACTIVE DEPRESSION.

depressive spectrum the range of severity and disparate symptoms that characterize DEPRESSIVE DISORDERS. The underlying concept is that depression is a continuum of related disorders, rather than a single diagnostic entity.

depressor nerve an afferent nerve that depresses motor or glandular activity when stimulated, for example, a nerve that causes a fall in blood pressure via a brainstem reflex.

depreciation n. 1. the removal, denial, or unavailability of something needed or desired. See CULTURAL DEPRIVATION. 2. In CONDITIONING, reduction of access to or intake of a REINFORCER. —deprive vb.

depression index a measure of the degree of inadequacy in a child’s intellectual environment with respect to such variables as achievement expectations, incentives to explore and understand the environment, provision for general learning, emphasis on language development, and communication and interaction with significant adult role models.

deprogramming n. the process by which people who have adopted profusely new sets of attitudes, beliefs, and values have their original attitudes, beliefs, and values restored. Deprogramming techniques are typically used on people who have left or been removed from highly coercive social groups, such as religious cults. See also BRAINWASHING.

depth cue any of a variety of means used to inform the visual system about the depth of a target or its distance from the observer. Monocular cues require only one eye and include signals about the state of the CIARY MUSCLES, ATMOSPHERIC PERSPECTIVE, LINEAR PERSPECTIVE, and occlusion of distant objects by near objects. Binocular cues require integration of information from the two eyes and include signals about the CONVERGENCE of the eyes and BINOCULAR DISPARITY.

depth-first search a GRAPH search strategy, equivalent to BACKTRACK SEARCH, that considers states in a graph recursively. The search is often organized by a “stack” or “last in is first out” data structure.

depth from motion a DEPTH CUE obtained from the distance that an image moves across the retina. Motion cues are particularly effective when more than one object is moving. Depth from motion can be inferred when the observer is stationary and the objects move, as in the KINETIC DEPTH EFFECT, or when the objects are stationary but the observer’s head moves, inducing MOTION PARALLAX.

depth from shading a DEPTH CUE obtained from the pattern of light and shadow on an illuminated solid object. The shading alone, without any outline of an object, can also convey a sense of three-dimensional depth.

depth interview an interview designed to reveal an individual’s deep-seated feelings, attitudes, opinions, and motives by encouraging him or her to express them freely without fear of disapproval or concern about the interviewer’s reactions. Such interviews may be conducted, for example, in counseling and as part of qualitative market research. They tend to be relatively lengthy, unstructured, one-on-one conversations.

depth-of-processing hypothesis the theory that the strength of memory depends on the degree of cognitive processing the material receives. Depth has been defined variously as ELABORATION, the amount of cognitive effort expended, and the distinctiveness of the MEMORY TRACE formed. This theory evolved from an expanded empirical investigation of the LEVELS-OF-PROCESSING MODEL OF MEMORY. [explored in 1972 by Canadian psychologist Fergus J. M. Craik (1915—) and Robert S. Lockhart and in 1975 by Craik and Endel Tulving]

depth-oriented brief therapy a form of brief psychotherapy that applies principles of CONSTRUCTIVIST PSYCHOTHERAPY in a time-limited fashion.

depth perception awareness of three-dimensionality, solidity, and the distance between the observer and the object. Depth perception is achieved through such cues as ATMOSPHERIC PERSPECTIVE, MOTION PARALLAX, visual ACCOMMODATION, BINOCULAR DISPARITY, and CONVERGENCE. See also VISUAL CLIFF.

depth psychology a general approach to psychology and psychotherapy that focuses on unconscious mental processes as the source of emotional disturbance and symptoms, as well as of personality, attitudes, creativity, and lifestyle. Typical examples are CLASSICAL PSYCHOANALYSIS and PSYCHODYNAMIC PSYCHOTHERAPY, but others include Carl Jung’s ANALYTIC PSYCHOLOGY and Alfred Adler’s INDIVIDUAL PSYCHOLOGY.

depth therapy any form of psychotherapy, brief or extended, that involves identifying and working through unconscious conflicts and experiences that underlie and interfere with behavior and adjustment. Compare SURFACE THERAPY.

Deracyn n. a trade name for ADINAZOLAM.

derailment n. a symptom of thought disorder, often occurring in individuals with schizophrenia, marked by frequent interruptions in thought and jumping from one idea to another unrelated or indirectly related idea. It is usually manifested in speech (speech derailment) but can also be observed in writing. Derailment is essentially equivalent to LOOSENING OF ASSOCIATIONS. See COGNITIVE DERAILEMENT; THOUGHT DERAILEMENT.
derangement

**derangement n.** 1. disturbance in the regular order or normal functioning of something. 2. loosely, mental illness or mental disturbance.

derealization n. a state characterized by a diminished feeling of reality; that is, an alteration in the perception or cognitive characterization of external reality so that it seems strange or unreal (“This can’t be happening”), often due to trauma or stress. It may also occur as a feature of schizophrenia or of dissociative disorders. See also DEPERSONALIZATION.

derefection n. a common technique used to allay anxiety or stop inappropriate behavior by diverting attention to a different topic and away from the self. It is used to reduce excessive self-concern and shyness and is a central component in MORITA THERAPY.

dereism n. mental activity that is not in accord with reality, experience, or logic. It is similar to AUTISTIC THINKING. Also called dereistic thinking.

derivation sample see CROSS-VALIDATION.

derivative n. in calculus, a measure of the change in a variable that results from change in another variable. Compare INTEGRAL.

derived ideas ideas that have causes outside the mind and thus derived from external sources, such as particular sense impressions. René DESCARTES distinguished between derived ideas and INNATE IDEAS, which arise from processes of thought that occur naturally in the mind. According to Descartes, derived ideas are less clear and distinct, and less obviously trustworthy, than innate ideas. See CARTESIANISM; CARTESIAN SELF.

derived need see SECONDARY NEED.

derived property in GESTALT PSYCHOLOGY, a property taken on by a part of a whole by virtue of its being in a particular configuration or context. For example, if three non-collinear dots are seen as forming a triangle, each dot then has the derived property of being a vertex of the triangle.

derma n. the skin, particularly the DERMIS.

dermal sensation see CUTANEOUS EXPERIENCE.

dermal sensitivity the cutaneous sensations detected by nerve receptors in the skin.

dermato- (dermo-) combining form skin.

dermatoglyphics n. the study of the patterns of lines on the skin of the fingers, palms, and soles. The technique is used in the diagnosis of certain kinds of chromosomal abnormalities, based on observations that some patterns are associated with certain types of birth defects or disorders. For example, people with Down syndrome have a single crease across the palm and a single crease on the skin of the little (fifth) finger. [coined in 1926 by U.S. anatomist Harold Cummins (1894–1976)]

dermatographism n. a kind of hives due to physical allergy in which a pale raised welt or wheal with a red flare on each side appears when the skin is scratched with a dull instrument. Also called autographism: dermatographia.

dermatological disorder any disorder or disease of the skin. See also PSYCHOCUTANEOUS DISORDER.

dermatome n. 1. an area of skin that is innervated primarily by fibers from the dorsal root of a particular SPINAL NERVE. 2. a surgical instrument for removing thin slices of skin to be used as skin grafts or for removing lesions.

dermis n. the layer of skin beneath the outermost layer (EPIDERMIS). The dermis contains blood and lymphatic vessels, nerves and nerve endings, and the hair follicles. —dermal adj.

dermographia n. see DERMATOGRAPHISM.

dermo-optical perception (DOP) an alleged ability to see by touch alone, often associated with identifying the color of objects. U.S. psychologist Richard P. Youtz (1910–1986) suggested that people with this ability detect colors by means of temperature differences due to reflection of hand heat or other heat from the object. Also called cutaneous perception of color.

DES 1. abbreviation for DIETHYLSTILBESTROL. 2. abbreviation for DYSEXECUTIVE SYNDROME.

descending pathway 1. a NEURAL PATHWAY from a higher center that modulates sensory input, such as tracts from the cerebral cortex to the spinal cord that gate pain input (see SPINAL GATE). 2. see DESCENDING TRACT.

descending reticular system part of the RETICULAR FORMATION that receives information from the hypothalamus and is involved in activity of the autonomic nervous system. It also plays a role in motor activity.

descending tract a bundle of nerve fibers that carries motor impulses from the brain to the spinal cord. There are three major descending tracts: the CORTICOSPINAL TRACT, VESTIBULOSPINAL TRACT, and reticulospinal tract. Also called descending pathway. Compare ASCENDING TRACT.

descent group any social group, such as a CLAN, PHRATRY, or SEPT, in which membership depends on real or supposed descent from a common ancestor. The group may be defined by UNILATERAL DESCENT (as in a PATRIARCHY or MATRIARCHY) or BILATERAL DESCENT. See also KINSHIP NETWORK.

deschooling n. an informal movement in the late 1960s and 1970s that criticized the formal educational system for emphasizing a narrow idea of academic knowledge and ignoring people’s real-life experience and the wider social context in which all learning takes place. Such thinkers and polemics as Austrian-born U.S. writer Ivan Illich (1926–2002) sought to separate education from its institutional context and to promote the idea of informal lifelong learning. —deschool vb.

descriptive approach see TOPOGRAPHIC MODEL.

descriptive average an estimate of the center point of a set of values, indicating where information “piles up,” that is sometimes made on the basis of impression or partial data. For example, a teacher could provide a descriptive average (e.g., 75%) that indicates how most people performed on an exam.

descriptive behaviorism an approach to the study of behavior espoused by B. F. SKINNER, who thought that psychology should limit itself to a description of behaviors of organisms, the conditions under which they occur, and their effects on the environment. It requires that theoretical explanations in terms of underlying biological or hypothetical psychological processes be avoided. See BEHAVIORISM; RADICAL BEHAVIORISM.

descriptive discriminant analysis a statistical procedure that distinguishes between two or more groups of a categorical outcome on the basis of several initial explanatory or PREDICTOR VARIABLES. The focus is on a set of standardized weights that link each initial variable to the
grouping variable; high weights (in absolute value) indicate variables that tend to differ across the groups. For example, a researcher may want to study what differentiates those who survive cancer from those who do not by using a set of background variables, such as age, weight, frequency of saturated fat in the diet, and family history of cancer. The descriptive discriminant analysis may reveal negative standardized weights in the moderate to high range, suggesting that within the sample examined more family history of cancer, older age, higher weight, and more saturated fat in the diet are significantly linked with a lower chance of surviving cancer. Compare PREDICTIVE DISCRIMINANT ANALYSIS.

descriptive grammar see PRESCRIPTIVE GRAMMAR.

descriptive norm any of various consensual standards (SOCIAL NORMS) that describe how people typically act, feel, and think in a given situation. These standards delineate how most people actually do behave, whereas INJUNCTIVE NORMS prescribe how they should behave.

descriptive operant in experimental studies of behavior, the formal, physical requirements for reinforcement (see OPERANT). For example, the descriptive operant for pressing a lever might be as follows: Any action on the part of the organism that exerts a force on the lever of 0.2 N through a distance of 5 mm will be reinforced. Compare FUNCTIONAL OPERANT.

descriptive research an empirical investigation designed to test prespecified hypotheses or to provide an overview of existing conditions, and sometimes relationships, without manipulating variables or seeking to establish cause and effect. For example, a survey undertaken to ascertain the political party preferences of a group of voters would be a descriptive study because it is intended simply to identify attitudes rather than systematically infer or analyze influencing factors.

descriptive responsibility the judgment that a defendant has performed an illegal act, as opposed to the judgment that he or she can be ascribed CRIMINAL RESPONSIBILITY. Compare ASCRIPITIVE RESPONSIBILITY.

descriptive science see NORMATIVE SCIENCE.

descriptive statistics procedures for depicting the main aspects of sample data, without necessarily inferring to a larger population. Descriptive statistics usually include the MEAN, MEDIAN, and MODE to indicate CENTRAL TENDENCY, as well as the RANGE and STANDARD DEVIATION that reveal how widely spread the scores are within the sample. Descriptive statistics could also include charts and graphs such as a FREQUENCY DISTRIBUTION or HISTOGRAM, among others. Compare INFERENTIAL STATISTICS.

deseasonalization n. the process of removing short-term cyclical variations in a TIME SERIES to reveal the underlying trend. For example, a marketing researcher may want to investigate whether a particular advertising strategy increased sales, after removing the fluctuations in the data that have to do with the time of year (e.g., holiday sales, summer spending). Compare DETRENDING.

desegregation n. the ending of the physical and social separation of groups in schools, neighborhoods, workplaces, and public settings, through legal mandates and social programs deliberately designed to remove barriers to intergroup contact.

desensitization n. a reduction in emotional or physical reactivity to stimuli that is achieved by such means as DECONDITIONING techniques. See also COVERT DESSENSITIZATION; IN VIVO DESSENSITIZATION; SYSTEMATIC DESSENSITIZATION.

desensitizing n. see DEHOAXING.

desertion n. see ABANDONMENT.

desexualization n. in psychoanalytic theory, the elimination or neutralization of a sexual aim. See also SUBLIMATION. —desexualize vb.

design n. the format of a research study, describing how it will be conducted and the data collected. For example, an EXPERIMENTAL DESIGN involves an INDEPENDENT VARIABLE and at least two groups, a treatment or EXPERIMENTAL GROUP and a CONTROL GROUP, to which participants are randomly assigned and then assessed on the DEPENDENT VARIABLE. A variety of other design types exist, including CORRELATIONAL RESEARCH, QUASI-EXPERIMENTAL DESIGNS, LONGITUDINAL DESIGNS, NATURAL EXPERIMENTS, and OBSERVATIONAL STUDIES, among others.

design and behavior see ARCHITECTURAL PSYCHOLOGY.

designer children see PRESELECTION.

designer drug a drug synthesized or manufactured to have the same or similar effects as a known illicit substance. The intention behind the creation of designer drugs is to circumvent existing legal definitions of controlled substances and thus avoid restrictions on use.

design fluency test any of a group of tests in which participants must generate (within a given time) a series of figures that have specific criteria. The tests were developed to provide clinical information regarding nonverbal capacity for flexibility and planning similar to VERBAL FLUENCY TESTS. For example, participants may be required to produce figures from five lines and must devise new ways to put the lines together in an organized manner to make new figures or designs. Also called FIGURAL FLUENCY TEST.

design for adjustable range the practice of designing equipment so that it can be adjusted to suit the physical characteristics of a large portion of the population. Compare DESIGN FOR THE AVERAGE; UNIVERSAL DESIGN.

design for the average the principle that equipment for human use should be designed for average human dimensions, thereby sacrificing the extreme dimensions (e.g., below the 5th and above the 95th percentiles). Although no truly “average” person exists, this principle is used when adjustable designs cannot be developed and it is impossible or impracticable to design for the extremes. Compare DESIGN FOR ADJUSTABLE RANGE; UNIVERSAL DESIGN.

design matrix a grid of data whose elements denote the presence or absence of each participant (row) in a treatment (column) of an experimental study.

design trade-off the situation in which one attribute of a system or product is made less usable because another attribute has been given priority. An example is the child-resistant safety cap. The press-and-turn requirement may be frustrating at times, but its purpose of preventing a child’s easy access to, and accidental ingestion of, harmful substances is considered to be a greater benefit.

desipramine n. a TRICYCLIC ANTIDEPRESSANT and the principal metabolic product of the demethylation of IMIPRAMINE in the liver. Desipramine is a stronger inhibitor of norepinephrine reuptake than of serotonin reuptake rela-
deskilling

tive to imipramine. In general, it is less sedating and has fewer ANTICHOLINERGIC EFFECTS than imipramine and was frequently used to treat behavior disorders and insomnia in children. However, like all tricyclic antidepressants, it has fallen into relative disuse as safer medications have become available. U.S. trade name: Norpramin.

deskilling n. the redesign of tasks in an organization so that they require less knowledge, skill, and ability and take less time to learn. Deskilling is often a consequence of technological and organizational change; it often results in a loss of employee motivation. —deskill vb.

desmopressin n. a synthetic analog of the pituitary hormone vasopressin that, among other functions, stimulates water retention. Desmopressin is used in pill form or in the form of a nasal spray to treat nocturnal enuresis (bed-wetting) and diabetes insipidus. It possesses more antidiuretic activity (i.e., prevents excessive water loss from the body) and less potential to raise blood pressure than vasopressin. U.S. trade name (among others): DDAVP.

desocialization n. gradual withdrawal from social contacts and interpersonal communication, as commonly occurs in those who have schizophrenia or other severe mental illness.

Desoxyn n. a trade name for METHAMPHETAMINE.

despair n. 1. the emotion or feeling of hopelessness, that is, that things are profoundly wrong and will not change for the better. Despair is one of the most negative and destructive of human affects, and as such it is a primary area for psychotherapeutic intervention. 2. in Erikson's eight stages of psychosocial development, see INTEGRITY versus DESPAIR.

despondency n. a state characterized by feelings of hopelessness and despair. —despondent adj.

destiny and growth beliefs two contrasting sets of beliefs about the outcomes of romantic relationships. Those who endorse destiny beliefs generally believe that relationships succeed or fail because two people are either inherently compatible or not. As a result, when problems occur, destiny theorists are more likely to conclude that the relationship was "not meant to be." People who endorse growth beliefs, in contrast, believe that relationships thrive when partners overcome challenges and obstacles. Thus, when problems arise, they put additional effort into making their relationship work. [First identified by U.S. social psychologist C. Raymond Knece]

destructiveness n. a tendency toward the expression of aggressive behavior by destroying, damaging, or defacing objects. See also SELF-DESTRUCTIVENESS.

destructive obedience compliance with the direct or indirect orders of a social, military, or moral authority that results in negative outcomes, such as injury to innocent victims, harm to the community, or the loss of confidence in social institutions. Examples of destructive obedience include soldiers obeying orders to attack civilians, medical personnel following a doctor's orders even when they know the doctor is mistaken, and participants complying with the experimenter in Stanley Milgram's classic behavioral study of obedience. Compare CONSTRUCTIVE OBEDIENCE.

desymbolization n. the process of depriving symbols, especially words, of their accepted meanings and substituting distorted, neologistic, autistic, or concrete ideas for them.

desynchronization n. in electroencephalography, the replacement of occipital alpha waves by the fast, low-amplitude, irregular wave systems characteristic of alert wakefulness, often because of an external stimulus, usually one that requires active attention. Other brain wave states can be desynchronized as well, for example when activity of delta waves is suppressed by the dreaming sleep. See alpha blocking.

desynchronized sleep see REM SLEEP.

desyrel n. a trade name for TRAZODONE.

DET diethyltryptamine: a synthetic HALLUCINOGEN belonging to the indolealkylamine family, to which LSD, psilocin, and DMT also belong.

detached character a personality characterized by extreme self-sufficiency and lack of feeling for others. Karen D. Horn ej identified the development of such a character as one of three basic neurotic trends used as a defense against basic anxiety. Compare AGGRESSIVE CHARACTER; COMPLAINT CHARACTER.

detached retina the separation of the inner layer of the retina (the neural retina) from the outer pigment epithelium layer. The onset of symptoms, depending on the size and site of the detachment, may include flashes of light followed by a clouding of vision, the appearance of spots or visual artifacts before the eye (known as floaters), or a sudden complete loss of vision. Detached retina is usually treated by surgery. Also called retinal detachment. See also diabetic retinopathy.

detachment n. 1. a feeling of emotional freedom resulting from a lack of involvement in a problem or situation or with a person. 2. objectivity: that is, the ability to consider a problem on its merits alone. Also called INTELLIGENT DETACHMENT. 3. in developmental psychology, the child's desire to have new experiences and develop new skills. This occurs at about 2 years of age, as the child begins to outgrow the period of total attachment to and dependence on the parent or caregiver.

detailed inquiry a phase of a clinical interview during which the therapist gains an understanding of the patient by asking direct questions on diverse topics, starting from mundane questions about everyday life to highly detailed questions, for example, about particular reactions to specific events.

detail perspective a DEPTH CUE related to texture. Features or details on a surface appear closer together on a distant object and farther apart on a near object.

detection task see SIGNAL DETECTION TASK.

detection theory see SIGNAL DETECTION THEORY.

detection threshold see ABSOLUTE THRESHOLD.

deterioration n. progressive impairment or loss of basic functions, such as emotional, judgmental, intellectual, muscular, and memory functions.

deterioration effect an adverse effect or negative outcome from participating in psychotherapy.

deterioration index a pattern of subtest scores on the WISCHLER ADULT INTELLIGENCE SCALE viewed as suggestive of declines from baseline functioning and used in measuring the degree of reduced performance that can be attributed to a variety of pathologies, including schizophrenia, multiple sclerosis, and dementia. Also called deterioration...
tion quotient. See also **DON'T-HOLD FUNCTIONS: HOLD FUNCTIONS**.

deterioration of attention** inconstant and shifting attention and impaired ability to concentrate on external reality.

deterioration quotient** see **DETERIORATION INDEX**.

determinant** *n.* **1.** any internal or external condition that is the cause of an event, **2.** a value that represents the generalized variance in a **MATRIX** of numbers, with large values indicating that the matrix numbers are very dissimilar and thus have more varied information. A determinant can be calculated by multiplying the **EIGENVALUES** of a matrix by one another.

determinant of elaboration** any factor that influences the amount of **ELABORATION** a person engages in when encountering attitude-relevant information. Such factors may regulate ability to elaborate (e.g., distractions in the social context) or motivation to elaborate (e.g., the personal relevance of the **ATTITUDE** (**OBJECT**). See also **ELABORATION-LIKELIHOOD MODEL**.

determination** *n.* **1.** a mental attitude characterized by a strong commitment to achieving a particular goal despite barriers and hardships. **2.** the process of making a decision, reaching a conclusion, or ascertaining the characteristics or exact nature of something, or the end result of such a process. **3.** the precise definition or qualification of the attributes of a concept or proposal (e.g., determination of the dependent variable in an experiment).

determination coefficient** see **COEFFICIENT OF DETERMINATION**.

determiner** *n.* in **LINGUISTICS**, a word that appears with a noun or pronoun and limits (determines) its reference in some way, such as a, the, this, that, some, all, any, every, and so on. Numbers (as in **three cats**) and personal pronouns (as in **her cats**) can also be determiners. See also **ARTICLE-QUANTIFIER**.

determining tendency** a goal or intended result that directs mental processes. For example, when shown the numbers 6 and 4 and asked to add them, a person answers 10, but when asked to subtract them, he or she answers 2: the same stimuli lead to different thoughts as intended ends determine what the mind does with the two numbers.

The term, introduced by German psychologist Narziss Ach (1871–1946) and derived from the earlier concept of **Aufgabe**, is essentially equivalent to the modern **MENTAL SET**.

determinism** *n.* the philosophical position that all events, physical or mental, including human behavior, are the necessary results of antecedent causes or other forces. Determinism, which requires that both the past and the future are fixed, manifests itself in psychology as the position that all human behaviors result from specific, efficient causal antecedents, such as biological structures or processes, environmental conditions, or past experience. The relationships between these antecedents and the behaviors they produce can be described by generalizations much like the laws that describe regularities in nature. Determinism contrasts with belief in **FREE WILL**, which implies that individuals can choose to act in some ways independent of antecedent events and conditions. Those who advocate free-will positions often adopt a position of **SOFT DETERMINISM**, which holds that free will and responsibility are compatible with determinism. Others hold that free will is illusory, a position known as **HARD DETERMINISM**. Of contemporary psychological theories, **BEHAVIORISM** takes most clearly a hard determinist position. See also **CAUSALITY**: **GENETIC DETERMINISM**: **PHYSICAL DETERMINISM**: **PSYCHIC DETERMINISM**: **PSYCHOLOGICAL DETERMINISM**. Compare **INDETERMINISM**. —**determinist adj.** —**deterministic adj.**

deterministic model** a mathematical function in which the outcome can be exactly established. In other words, the model explains all of the variance in a **DEPENDENT VARIABLE** and no **ERROR TERM** is needed. This contrasts with a **STOCHASTIC MODEL**, from which a range of possible values may result.

deterministic process** see **STOCHASTIC PROCESS**.

deterministic psychology** any psychology that assumes **DETERMINISM**, most notably **BEHAVIORISM**.

deterrence** *n.* the notion that punishing an individual who has committed an undesirable act, particularly a criminal one, will deter that person, as well as others, from committing such acts in the future. —**deter vb.** —**deterrent n., adj.**

deterrent therapy** see **AVERSION THERAPY**.

detour problem** in studies of problem solving, any problem or task that must be solved or performed indirectly, often because the most direct solution is ineffective or blocked. Also called **Umweg problem**.

detoxification** *n.* a therapeutic procedure, popularly known as **detox**, that reduces or eliminates toxic substances (e.g., alcohol, opioids) in the body. The procedure may be metabolic (by converting the toxic substance to a less harmful agent that is more easily excreted), or it may require induced vomiting, gastric lavage (washing), or dialysis, depending upon the nature of the poison and other factors. In many cases, detoxification occurs in a clinic, hospital unit, or residential rehabilitation center devoted to treating individuals for the toxic effects of alcohol or drug overdose and to managing their acute withdrawal symptoms; these facilities may also provide professional- or peer-run social support during the detox process (known as **social setting detoxification**). In the absence of this type of assistance, an individual who actively tries to manage his or her own withdrawal from a substance is said to be engaged in **self-detoxification**.

detrending** *n.* the practice of removing a specific existing pattern from data, often collected in a **TIME SERIES**, in order to reveal other expected patterns or sequences in the data. **DESEASONALIZATION** is a similar process but removes the effect of seasonal shifts in the data.

detumescence** *n.* the reduction of a swelling, especially in the genital organs of either sex following orgasm. Compare **TUMESCENCE**. —**detumescent adj.**

Detussin** *n.* a trade name for a combination of **HYDROCODONE** and **PSEUDOEPHEDRINE**.

deu t an color blindness** a type of color blindness in which green hues are perceived imperfectly or green is confused with red. In some cases, the condition results from an ability to perceive only two distinct hues, blue and yellow.

deutan color blindness** a type of color blindness in which the green part of the spectrum is perceived inadequately. In testing for deutanomaly, an unusual amount of green would be required in a red–green mixture to match a given yellow.

deutanop a nia** *n.* red–green color blindness in which the
deutero-

deficiency is due to absence of the cone PHOTOPIGMENT sen-
titive to green light, resulting in loss of green sensitivity
and confusion between red and green (see DICROMATISM).
The condition may be unilateral (i.e., color vision may be
normal in one eye). See also PROTANOGIA.

deutero- (deuter-: deut-) combining form second or sec-
ondary. See COLOR BLINDNESS.

deutoplasm n. a substance, rich in protein and fat, that
is laid down within the yolk of an egg cell to serve as nour-
ishment for the embryo. It is absent from the egg cells of
mammals, whose embryos absorb nutrients from their
mothers via the placenta.

deviation n. a defense mechanism that involves deny-
ing the importance of something or someone, including
the self. —deviate vb.

deviation n. the progressive series of changes in
structure, function, and behavior patterns that occur over
the lifespan of a human being or other organism. —devel-
opmental adj.

devolutionary acceleration an abnormal or preco-
cious growth in one or more functions (e.g., language).

devolutionary age (DA) a measure of development
expressed in an age unit or AGE EQUIVALENT. For example, a
4-year-old child may have a developmental age of 6 in ver-
bal skills.

devolutionary amblyopia a condition affecting cen-
tral vision in which the early development of neural cir-
cuits for fine-pattern discrimination is disrupted due to
inadequate detail in foveal imagery. There are two forms of
developmental amblyopia: anisometropic amblyopia, in
which the two eyes have differing powers of refraction, and
strabismic amblyopia, in which the image from one eye is
favored because of imbalance in the extrinsic EYE MUSCLES.

memories of past events (i.e., impaired
expression

functional performance or daily living activities is also observed. How-
ever, the difficulties are not due to intellectual disability or to a
neurological disorder affecting movement (e.g., cere-
bral palsy). See also DEVELOPMENTAL DYSPRAXIA.

devolutionary crisis see MATURATIONAL CRISIS.

devolutionary delay delay in the age at which develop-
omental milestones are achieved by a child or delay in the
development of communication, social, and daily living
skills. It most typically refers to delays that are meaningful
but do not constitute substantial handicap in infants, tod-
ders, and preschool children. Such individuals are often el-
igible for early intervention or preschool services to
ameliorate these delays.

devolutionary disability a developmental level or
status that is attributable to a cognitive or physical impairment,
or both, originating before the age of 22. Such an
impairment is likely to continue indefinitely and results in
substantial functional or adaptive limitations. Examples of
developmental disabilities include, but are not limited to,
intellectual disability, pervasive developmental disorders,
learning disorders, developmental coordination disorder,
communication disorders, cerebral palsy, epilepsy, blind-
ness, deafness, mutism, and muscular dystrophy. Also
called development disorder.

devolutionary dysgraphia see DISORDER OF WRITTEN
EXPRESSION.

development dyslexia a form of DYSLEXIA that is ap-
parent during an early developmental age or phase and
manifested as difficulty in learning to read and spell single
words.

devolutionary dysphasia language difficulty or de-
layed language acquisition believed to be associated with
brain damage or cerebral maturation lag. It is character-
ized by defects in expressive language and articulation and
in more severe cases by defects in comprehension of lan-
guage. Also called developmental aphasia.

devolutionary dyspraxia DYSPRAXIA present since
birth and manifested during an early developmental age or
phase as difficulty in performing coordinated movements.
Compare ACQUIRED DYSPRAXIA.

devolutionary factors the conditions and variables
that influence emotional, intellectual, social, and physical
development from conception to maturity. Examples in-
clude parental attitudes and stimulation, peer relations-
ships, learning experiences, recreational activities, and
hereditary predispositions.

devolutionary function 1. the form that develop-
ment takes over time. Different aspects of development
(e.g., physical vs. cognitive) may show different patterns of
change over time. 2. the role played by an entity (e.g., a
gene), activity (e.g., play), stage (e.g., adolescence), or other
phenomenon in the development of an organism.
developmental immaturity the status of a child who exhibits a delay (usually temporary) in reaching developmental landmarks without clinical or historical evidence of damage to the central nervous system. The child may appear younger than his or her chronological age in physical development, gross and fine motor abilities, language development, social awareness, or any combination of these. See also DEVELOPMENTAL DELAY; DEVELOPMENTAL RETARDATION.

developmental invariance a pattern of development in which a skill reaches adult competence early in life and remains stable thereafter. For example, certain sensory and perceptual skills (e.g., vision) function at a high level early in life.

developmental language disorder any disorder in which the development of language skills is impaired. See EXPRESSIVE LANGUAGE DISORDER; MIXED RECEPTIVE-EXPRESSIVE LANGUAGE DISORDER; SPECIFIC LANGUAGE IMPAIRMENT.

developmental levels the stages into which the human lifespan is typically divided: (a) neonatal period; (b) infancy; (c) early, middle, and late childhood; (d) adolescence; and (e) early, middle, and late adulthood.

developmental measure any assessment used to measure an age-associated dimension, such as motor development in young children. The BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT is an example of a developmental measure.

developmental milestone any aspect of physical, cognitive, social, or emotional development that is significant and predictable, such that children throughout the world develop this ability, characteristic, or behavior at about the same time. Developmental milestones include presence of first teeth and language acquisition.

developmental norm the typical skills and expected level of achievement associated with a particular stage of development.

developmental orientation 1. in service-planning processes, an emphasis on the skills, abilities, and strengths of young people with disabilities in relation to expected developmental attainments and performance of young people without disabilities. 2. see DEVELOPMENTAL THEORY. Compare DEFECT ORIENTATION.

developmental pharmacokinetics see PHARMACOKINETICS.

developmental psycholinguistics see PSYCHOLINGUISTICS.

developmental psychology the branch of psychology that studies the changes—physical, mental, and behavioral—that occur from conception to old age and investigates the various biological, neurobiological, genetic, psychological, social, cultural, and environmental factors that affect development throughout the lifespan. Since its emergence as a formal discipline in the late 19th century, the field has broadened its focus from one that largely emphasized infant, child, and adolescent development to one, beginning in the 1920s, that also accounted for adult development and the aging process and, more recently, prenatal development. As such the term developmental psychology is now often considered virtually synonymous with LIFESPAN DEVELOPMENTAL PSYCHOLOGY. Over the years, numerous currents of thought and investigation have informed or shaped the field’s direction, such as the CHILD STUDY MOVEMENT, psychoanalytic theory, learning theory, evolutionary theory, the development of intelligence measures (e.g., STANFORD-BINET INTELLIGENCE SCALE), genetic studies, TWIN STUDIES, research using LONGITUDINAL DESIGNS and CROSS-SECTIONAL DESIGNS, professional organizations and academic journals (e.g., Developmental Psychology, Psychology and Aging) devoted to understanding various aspects of the lifespan, and the explosion of brain research in recent decades. See also GENETIC PSYCHOLOGY.

developmental psychopathology the scientific study of the origins and progression of psychological disorders as related to the typical processes of human growth and maturation. Central to this field is the belief that studying departures from developmental NORMS will enhance understanding of those norms, which will in turn enhance the conceptualization and treatment of mental illness.

developmental quotient (DQ) the DEVELOPMENTAL AGE, or a substitute measure of development, divided by the CHRONOLOGICAL AGE.

developmental readiness a student’s state of psychological and intellectual preparedness for a given task, subject, or grade level.

developmental reading disorder see READING DISORDER.

developmental retardation abnormally slow maturation in any or all areas—intellectual, motor, perceptual, linguistic, or social. See also DEVELOPMENTAL DELAY; DEVELOPMENTAL IMMaturity.

developmental scale a measurement instrument used to assess the degree to which an individual has progressed through the typical DEVELOPMENTAL MILESTONES.

developmental schedules normative timetables of when certain aspects of physical and behavioral development typically occur (see DEVELOPMENTAL MILESTONE).

developmental science the interdisciplinary study of changes in the biopsychosocial dimensions of individuals over their lifespan and into successive generations.

developmental sequence the order in which changes in structure or function occur during the process of development of an organism.

developmental stage a period of development during which specific abilities, characteristics, or behavior patterns appear.

developmental systems approach the view that development is the result of bidirectional interaction between all levels of biological and experiential variables, from the genetic through the cultural. Also called developmental contextual model. See also BIDIRECTIONALITY OF STRUCTURE AND FUNCTION; TRANSACTIONAL MODEL OF DEVELOPMENT.

developmental task any of the fundamental physical, social, intellectual, and emotional achievements and abilities that must be acquired at each stage of life for normal and healthy development. Because development is largely cumulative, the inability to master developmental tasks at one stage is likely to inhibit development in later stages.

developmental teaching model a general approach in education based on the work of Jean PIAGET and others, emphasizing logical reasoning and the enhancement of intellectual development. There is an effort to orient school...
Developmental Test of Visual–Motor Integration

Developmental Test of Visual–Motor Integration (VMI) a measure of visuomotor development that requires the participant to copy onto blank pieces of paper geometric designs increasing in difficulty from a straight line to complex figures. The VMI is used to identify problems with visual perception, motor coordination, and visual–motor integration. It is available in two versions: the Short Format, containing 15 designs and appropriate for children ages 2 to 8 years, and the Full Format, containing 24 designs and appropriate for children of all ages and adults. [originally developed in 1967 by U.S. psychologists Keith E. Beery (1932–2010) and Norman A. Buktenica (1930– 1)]

developmental theory 1. any theory based on the continuity of human development and the importance of early experiences in shaping personality. Examples are the psychoanalytic theory of psychosexual development, Erikson’s eight stages of psychosocial development, learning theories that stress early conditioning, and role theories that focus on the gradual acquisition of different roles in life. 2. the proposition that intellectual disability is due to slower than normal development of cognitive processes but that such processes are not otherwise qualitatively different from those of people without intellectual disability. Also called developmental orientation. Compare DEFECT THEORY.

developmental therapy a method of treatment for children and adolescents with emotional, social, or behavioral problems. A series of graded experiences is used, for example, to help clients improve their interactions with others or manage anger.

developmental toxicology the study of the effects of toxic (poisonous) substances on the normal development of infants and children: specifically, the study of the adverse effects of certain agents administered to them or to which they may have been exposed in utero.

developmental trauma disorder (DTD) a new diagnosis for children who have been exposed in early life to multiple adverse interpersonal events, such as sexual or physical abuse, parental substance abuse, domestic or community violence, neglect, and abandonment. These experiences, termed complex trauma, have a pervasive and long-range influence on children’s emotional, cognitive, behavioral, and psychological functioning that many clinicians believe is not adequately captured by POST-TRAUMATIC STRESS DISORDER or any other existing diagnosis.

Six domains of potential impairment related to complex trauma exposure have been delineated: (a) affect regulation, including difficulty modulating anger and self-destructiveness; (b) information processing, including difficulties with attention, concentration, learning, and consciousness (e.g., amnesias and dissociation); (c) self-concept, including guilt and shame; (d) behavioral control, including aggression and substance abuse; (e) interpersonal relationships, including problems with trust and intimacy; and (f) biological processes, including SOMATIZATION and delayed sensorimotor development. This multifaceted dysregulation can disrupt typical maturation, potentially leading to wide-ranging developmental delays and to persistently altered attributions and expectancies about the self, relationships, and others.
ters visual or audio instructions for muscle relaxation and visualization of feared stimuli arranged in a hierarchical order. See also COVERT DESENSITIZATION; SYSTEMATIC DESSENSITIZATION.

devil’s trumpet see JIMSONWEEED.

DEX abbreviation for Dysexecutive Questionnaire. See DYSEXECUTIVE SYNDROME.

dexamethasone n. a synthetic analog of CORTISOL, with similar biological action. It is used to treat nausea and vomiting and as an anti-inflammatory agent. U.S. trade name (among others): Decadron.

dexamethasone suppression test (DST) a test of the ability of dexamethasone, a synthetic analogue of CORTISOL, to inhibit the secretion of CORTICOTROPIN and hence suppress levels of cortisol in the blood. In the test, dexamethasone is administered, and after a waiting period, cortisol levels are assessed. In normal individuals, cortisol levels will be suppressed by dexamethasone. If cortisol is still elevated, the individual is categorized as a nonsuppressor. The test is a common research tool, but its primary clinical use is to aid in the diagnosis of Cushing’s syndrome.

dexamphetamine n. see DEXTROAMPHETAMINE.

Dexedrine n. a trade name for DEXTROAMPHETAMINE.

dexterity test a manual test of speed and accuracy.

dextrality n. a tendency to use the right hand, arm, or leg in motor activities. See also RIGHT-HANDEDNESS. Compare SINISTRALITY.

dextro- (dext-) combining form on or toward the right.

dextroamphetamine n. a sympathomimetic agent and CNS STIMULANT that is the dextrorotated form of the amphetamine molecule. It is used in the treatment of narcolepsy and attention-deficit/hyperactivity disorder. Like all amphetamines, it is prone to abuse and dependence. Also called dexamphetamine. U.S. trade names (among others): Dexedrine; Adderall (in combination with AMPHETAMINE).

dextromethorphan n. a synthetic OPIOID used clinically as a cough suppressant. Its mechanism of action is unknown, but it does bind to NMDA RECEPTORS and to SIGMA RECEPTORS. Dextromethorphan is a common ingredient in over-the-counter cough and cold preparations and is increasingly a drug of abuse, particularly among adolescents. Because it is metabolized extensively by the CYTOCHROME P450 (CYP) 2D6 liver enzyme, it is used in pharmacology as a comparison when calculating the degree to which certain drugs inhibit CYP enzymes. It should not be taken by individuals who are taking MONOAMINE OXIDASE INHIBITORS, and it should be used with caution by those taking inhibitors of the CYP2D6 enzyme (i.e., fluoxetine, paroxetine) because unexpectedly high plasma concentrations of either drug may occur (see ENZYME INHIBITION). Examples of some common U.S. proprietary products that include dextromethorphan are Coricidin, Ny-Quil, Robitussin, TYLENOL PM, and Vicks 44. Dextromethorphan is also used in combination with quinidine to treat PSEUDOMONAL INFECTION (U.S. trade name: Neudexta).

dextroinstinal adj. oriented or directed from the right side of the body to the left side.

df symbol for DEGREES OF FREEDOM.

Dharma n. 1. in Hinduism, the principle of natural law that sustains and governs the cosmos. In a narrower sense, the term denotes the social laws and customs that must be followed to achieve the right path of spiritual advancement. 2. in Buddhism, the cosmic law underlying the world of humans and, above all, the functioning of karmic rebirth (see KARMA). The term has multiple other meanings, including the truth as set out in the teachings of the Buddha, norms of behavior and ethical rules, the manifestation of reality, and the content of human thought. [Sanskrit, literally: “carrying, holding”]

dhat n. a CULTURE-BOUND SYNDROME specific to India. Dhat involves severe anxiety and hypochondriacal concerns about the discharge of semen, whisth discoloration of the urine, and feelings of weakness and exhaustion. It is similar to SHEN-K’UEI.

DHE 45 a trade name for DIHYDROERGOTAMINE.

DHT abbreviation for DIHYDROXYTRYPTAMINE.

di- prefix twice or double.

dia- prefix through, across, or apart.

diabetes insipidus a metabolic disorder marked by a deficiency of VASOPRESSIN (antidiuretic hormone), which promotes the reabsorption of water from the kidney tubules. The patient experiences excessive thirst and excretes large amounts of urine but without the high level of sugar found in the urine of people with diabetes mellitus. See also NEPHROGENIC DIABETES INSIPIDUS.

diabetes mellitus a metabolic disorder caused by ineffective production or utilization of the hormone INSULIN. Because of the insulin disruption, the patient is unable to oxidize and utilize carbohydrates in food. Glucose accumulates in the blood, causing weakness, fatigue, and the appearance of sugar in the urine. Fat metabolism is also disrupted so that end products of fat metabolism (ketones) accumulate in the blood. There are two major types of the disorder. Type 1 diabetes, formerly called insulin-dependent diabetes mellitus (IDDM), is characterized by a complete or near complete absence of endogenous insulin secretion, requiring patients to take daily insulin injections and to carefully manage the timing and size of their daily food intake to control their blood glucose levels; because this type usually occurs during childhood or early adolescence, it was formerly also called juvenile-onset diabetes (or juvenile diabetes). Type 2 diabetes, formerly called non-insulin-dependent diabetes mellitus (NIDDM), is characterized by reduced secretion of or resistance to insulin in the body and may be manageable through diet alone. In the past, it typically occurred in adulthood (and was formerly also called adult-onset diabetes); however, with the rise in childhood obesity, a significant risk factor for the disorder, Type 2 diabetes is increasingly seen in children as well as adults.

diabetic enteropathy a gastrointestinal complication of diabetes mellitus, marked by intermittent occurrence of nocturnal fecal incontinence. The condition is often associated with autonomic and peripheral neuropathy and is regarded as one of several manifestations of visceral neuropathy in people with diabetes. See also GASTRIC NEUROPATHY.

diabetic gastropathy any disorder of the stomach or related digestive organs that is due primarily to the effects of diabetes on the autonomic nervous system. See also GASTRIC NEUROPATHY.

diabetic retinopathy deterioration of the retina as a
complication of diabetes mellitus, marked by tiny aneu-
rysms of the retinal capillaries. These first appear as small
venous dilations and red dots, observed during ophthalmol-
ogical examination; they progress to retinal hemorrhages
and exudates that impair vision. New, abnormal vessels
may form in the vitreous cavity and may also hemorrhage.
Detached retina is a complication. Treatment includes
control of diabetes and hypertension, laser photocoagula-
tion, and vitreous surgery.

diacetylmorphine n. the chemical name for heroin. A
synthetic analog of morphine (produced by substituting
acetyl groups for hydroxyl groups at two positions on the
morphine molecule), it is, like morphine and codeine, a
pure opioid agonist, activating receptors for endorphins
and enkephalins (see endogenous opioid). Diacetylmor-
phine has a rapid onset of action and a duration of action
similar to that of morphine; however, it is three times more
potent than morphine. In Great Britain and Canada, it is
used clinically in the management of severe pain—for ex-
ample, in terminally ill patients—but it is not legally avail-
able in the United States due to concerns about its potential
for abuse. Also called diamorphine. See opioid analges-
ic.

diachronic linguistics the study of languages as they
change over time, as practiced in philology or compar-
tive linguistics. This is often contrasted with synchronic
linguistics, the study of languages or (more often) a partic-
ular language at a single point in time, with no reference to
historical or developmental factors. The synchronic ap-
proach to language is the basis of linguistic structural-
ism. [introduced by Swiss linguist Ferdinand de Saussure
(1857–1913)]

diachronic universal see psychological universal.

diacritical marking system (DMS) a unified ar-
rangement or series of symbols used to denote phonetic
sounds.

diadochokinesis n. the ability to rapidly perform repeti-
tive muscular movements, such as finger tapping or purs-
ing and retracting the lips. This ability is often examined
during clinical assessments of motor behavior.

diagnosis (Dx) n. (pl. diagnoses) 1. the process of iden-
tifying and determining the nature of a disease or disorder
by its signs and symptoms, through the use of assessment

techniques (e.g., tests and examinations) and other avail-
able evidence. 2. the classification of individuals on the
basis of a disease, disorder, abnormality, or set of charac-
teristics. Psychological diagnoses have been codified for
professional use, notably in the DSM–IV–TR and DSM–5. 3.
the decision or statement itself that results from this pro-
cess or classification, as in “She was given a diagnosis of
schizoaffective disorder.”—diagnostic adj.

diagnosis-related groups (DRGs) an inpatient or
hospital classification used as a financing tool to reimburse
health care providers. Each of the DRGs (of which there
are currently over 500) has a preset price based on diagno-
sis, age and sex of patient, therapeutic procedure, and
length of stay.

diagnostic Adaptive Behavior Scale (DABS) a stan-
ardized assessment measuring the conceptual, social,
and practical skills needed for daily functioning. The pre-
ence of significant limitations in these domains is neces-
sary to establish a diagnosis of intellectual disability. This
scale is used with individuals ages 4 to 21 years and in-
cudes 500 items that the administrator can draw from in
an hour-long interview with an individual’s parents,
teachers, or case manager. [developed by the American As-
sociation on Intellectual and Developmental Disabili-
ties]

Diagnostic and Statistical Manual of Mental
Disorders see DSM–IV–TR; DSM–5.

diagnostic audiology see audiology.

diagnostic baseline the entry or pretreatment levels of
symptoms, used in identifying or treating diseases or dis-
orders. Such levels are also used to assign patients or partici-
pants in a study to correlational groups.

diagnostic center a facility equipped with skilled per-
sonnel and appropriate laboratory and other equipment for
evaluating the condition of a patient and determining the
cause of his or her physical or psychological disorder. The
diagnostic center may be separate or part of a larger health
care facility.

diagnostic educational tests tests designed to iden-
tify and measure academic deficiencies. Examples include
the peabody picture vocabulary test, the iowa tests of
basic skills, and the nelson–denny reading test. Also
called educational tests.

diagnostic formulation a comprehensive evaluation
of a patient, including a summary of his or her behavioral,
emotional, and psychophysiological disturbances. Diagno-

tic formulation includes the most significant features of
the patient’s total history; the results of psychological and
medical examinations; a tentative explanation of the origin
and development of his or her disorder; the diagnostic clas-
sification of the disorder; a therapeutic plan, including
basic and adjunctive treatments; and a prognostic evalua-
tion based on carrying out this plan.

diagnostic interview an interview in which a health
or mental health professional explores a patient’s present-

ing problem, current situation, and background, with the
aim of formulating a diagnosis and prognosis as well as de-
veloping a treatment program.

Diagnostic Interview Schedule (DIS) a structured in-
terview assessing an individual’s current and past
symptoms of psychiatric disorders, such as depression,

schizophrenia, and substance dependence. Designed to be
an objective diagnostic instrument requiring a minimum
of clinical judgment, the DIS consists of a predetermined
set of questions that are asked in a specific order. It was
originally developed in the late 1970s by the national insti-
tute of mental health for use in the epidemiologic
catchment area survey. The diagnostic interview sched-
ule for children (DISC) is also available.

diagnosticity n. the informational value of an interac-
tion, event, or feedback for someone seeking self-knowl-
edge. Information with high diagnosticity has clear
implications for the self-concept, whereas information
with low diagnosticity may be unclear, ambiguous, or in-
naccurate. The desire for highly diagnostic information
about the self is called the self-assessment motive.

diagnostic orphan a person who manifests one or two
symptoms of a disorder but who does not qualify for a for-
mal diagnosis. For example, someone who exhibits only a
few symptoms indicating a dependence on alcohol and
who therefore would not qualify for a formal DSM–IV–TR
diagnosis of alcohol dependence is a diagnostic orphan.

diagnostic overshadowing the failure, when assess-

308
ing an individual with multiple disabilities, to discern the presence of one disability because its features are attributed to another, primary disability. In particular, the term refers to the failure to recognize a mental disorder in a person with intellectual disability because characteristics of that mental disorder are erroneously attributed to the intellectual disability. See also DUAL DIAGNOSIS.

diagnostic prescriptive education the concept that effectiveness of classroom teaching of children with disabilities depends in large part on the teacher’s understanding of the disabilities. For example, the more the teacher and educational administrators know about hydrocephalus, the more effectively they can design and individualize an appropriate educational program for students with this particular disability.

diagnostics pl. n. 1. the practice of diagnosis. 2. procedures for evaluating how much a model differs from expected patterns and ASSUMPTIONS. For example, diagnostics may reveal how much a set of data departs from assumptions of NORMALITY, LINEARITY, and HOMOGENEITY OF VARIANCE, possibly showing skewed, curvilinear, and unequal variances across levels of another variable, respectively. See also REGRESSION DIAGNOSTICS.

diagnostic test any examination or assessment measure that may help reveal the nature and source of an individual’s physical, mental, or behavioral problems or anomalies. In medical research, a diagnostic test would be expected to show SENSITIVITY (i.e., correctly identifying individuals with a certain illness) and SPECIFICITY (i.e., correctly identifying those who do not have a specific illness).

dialect n. 1. a variety of a language that is associated with a particular geographical region, social class, or ethnic group and has its own characteristic words, grammatical forms, and pronunciation. Dialects of a language are generally mutually intelligible. Compare ACCENT; REGISTER. 2. among nonhuman animals, a variant of the standard form of communication that is specific to a population or a geographical region. For example, cardinals in different parts of North America have regional differences in song. —dialectal adj.

dialectic n. 1. in general, any investigation of the truth of ideas through juxtaposition of opposing or contradictory opinions. 2. the conversational mode of argument attributed to Socrates, in which knowledge is sought through a process of question and answer. 3. in the work of German philosopher Georg Wilhelm Friedrich Hegel (1770–1831), the pattern of statement, contradiction, and reconciliation (THESIS, ANTHESIS, and SYNTHESIS) that he held to govern thought processes and the progress of human history. See also DIALECTICAL MATERIALISM. —dialectical adj.

dialectical behavior therapy (DBT) a flexible, stage-based therapy that combines principles of BEHAVIOR THERAPY, COGNITIVE BEHAVIOR THERAPY, and MINDFULNESS. It establishes a “dialectic” between helping individuals to accept the reality of their lives and their own behaviors on the one hand and helping them learn to change their lives, including dysfunctional behaviors, on the other. Its underlying emphasis is on helping individuals learn both to regulate and to tolerate their emotions. DBT is designed for especially difficult-to-treat patients, such as those with BORDERLINE PERSONALITY DISORDER. [developed by U.S. clinical psychologist Marsha Linehan (1943–)]

dialectical materialism in the philosophy of Karl MARX, the principle that accounts for the progress of history and the succession of economic and government systems. The process is one in which the clash of the prevailing system (the THESIS) with an insurgent system (the ANTHESIS) results in a new system (the SYNTHESIS). This movement is driven by purely material factors, most notably those attending the control of the means of production. Marx’s dialectical account of history thus inverts what may be referred to as the dialectical idealism of German philosopher Georg Wilhelm Friedrich Hegel (1770–1831). See also CLASS THEORY; MARXISM.

dialectical operations mechanisms by which development occurs as a result of interactions between the individual and the environment. Rather than emphasizing universal stages of development, theorists taking a dialectical perspective, such as Lev VYGOTSKY, argue that development takes place as individuals both react to and influence their social environment. Models of this sort are based on the theories of German philosopher Georg Wilhelm Friedrich Hegel (1770–1831).

dialectical teaching a method that engages students in a critical examination of their reasoning through repeated questioning of their answers, much as Socrates is portrayed as doing in the Platonic dialogues. Also called dialectical method.

dialectology n. the branch of linguistics concerned with the study of DIALECTS.

Diallinas–Amalric syndrome a familial condition thought to be an autosomal recessive trait in which deafness is associated with defects in central vision. Also called Amalric’s syndrome: deaf mutism–retinal degeneration syndrome. [described in 1959 by Nicolaos Pindaros Diallinas, Greek ophthalmologist, and in 1960 by Pierre Amalric (1923–1999), French ophthalmologist]

dialogue (dialog) n. 1. in general, an exchange of ideas between two or more people. 2. in GESTALT THERAPY, a technique in which the client engages in an imaginary conversation (a) with a body part from which he or she feels alienated; (b) with a person, such as a parent, who is pictured sitting in an empty chair (see EMPTY-CHAIR TECHNIQUE); or (c) with an object associated with a dream. The technique often elicits strong feelings. Also called dialogue technique.

dialysis dementia an aluminum-induced brain disease affecting patients undergoing long-term dialysis. Major symptoms are progressive mental deterioration, personality changes, and speech impairment, with such neurological signs as seizures, DYSARTHRIA, dysphonia (difficulty in naming objects), and DYSPRAXIA.

diamorphine n. see diACETYLmorphine.

dianetics n. a controversial therapeutic technique claiming to treat, according to its founder, “all inorganic mental ills and all inorganic psychosomatic ills, with assurance of complete cure.” Dianetics has been largely discredited within the fields of psychology and psychiatry. [introduced in 1950 by L(lafayette) Ron(ald) Hubbard (1911–1986), U.S. science-fiction writer and subsequent founder of SCIENTOLOGY]

dianoia n. in philosophy, reasoning based on sensory perception and experience, especially as contrasted with the purely intellectual operation of the NOUS. Compare NOESIS. See also UNDERSTANDING. —dianoetic adj.

diaphragm n. 1. a muscular sheet that separates the
thoracic and abdominal cavities. 2. a cup-shaped contraceptive device made from a layer of thick latex rubber fitted over a round or spiral spring. The diaphragm is filled with a contraceptive jelly and inserted in the vagina so that it forms a barrier between the cervix and any spermatozoa that enter the vagina during coitus. The spring holds it in place. The diaphragm has been used by women since 1882. —diaphragmatic adj.

diary method a technique for compiling detailed data about an individual who is being observed or studied by having the individual record his or her daily behavior and activities. Also called diary survey.

diastolic blood pressure the pressure of blood flowing in a major artery while the heart rests briefly between contractions. On blood pressure readings, it is the smaller number, usually noted after the systolic blood pressure.

diathesis n. any susceptibility to or predisposition for a disease or disorder. See also genetic predisposition.

diathesis-stress model the theory that mental and physical disorders develop from a genetic or biological predisposition for that illness (diathesis) combined with stressful conditions that play a precipitating or facilitating role. Also called diathesis-stress hypothesis (or paradigm or theory). See also Stress-Vulnerability model.

diatomic adj. pertaining to a musical scale with an octave span and intervals of five tones and two semitones. Compare chromatic.

diazepam n. a long-acting BENZODIAZEPINE that is used for the management of alcohol withdrawal and as an anticonvulsant, anxiolytic, and muscle relaxant. It is broken down in the liver to produce a number of metabolites (metabolic products) of varying half-lives, including the active compounds desmethyldiazepam (nordiazepam) and oxazepam. Its complex metabolism and lengthy half-life make diazepam unsuitable for use in older adults and those with liver disease. U.S. trade name (among others): Valium.

diazepam-binding inhibitor (DBI) an endogenous NEUROPEPTIDE that binds to molecular receptors for benzodiazepines. It counters the effectiveness of these drugs, thus increasing anxiety, and may be involved in the development of drug dependence.

dibenzoazepine n. any member of a class of chemically related compounds that include clozapine, the first atypical antipsychotic introduced into clinical medicine. This class is structurally similar to the dibenzoazepines.

dibenzoazepine n. any member of a class of chemically related compounds that include quetiapine, an atypical antipsychotic. This class is structurally similar to the dibenzoazepines and the dibenzoazepines.

dibenzoazepine n. any member of a class of chemically related compounds that include loxapine, one of the older antipsychotics that does not belong to the phenothiazine class. This class is structurally similar to the dibenzoazepines.

DIC abbreviation for deviation information criterion.

DICe model dissociable interactions and conscious experience model: a cognitive model proposing that linguistic, perceptual, and other kinds of knowledge are processed by independent memory modules, with consciousness operating as an awareness system that serves as a gateway to an executive system. Access to various types of knowledge depends on intact interactions between the consciousness awareness system and other components of the model. The model considers certain impairments (e.g., amnesia, alexia) as examples of “disconnects” in this interactive process. See Modularity. [Devised by U.S. psychologist Daniel L. Schacter (1952—)].

dichoptic stimulation the simultaneous presentation of different stimuli to each of the eyes. Dichoptic stimulation usually causes binocular rivalry.

dichorionic adj. relating to the presentation of different odorants in each nostril via an olfactometer.

dichorial twins a set of twins that had separate chorionic membranes as embryos. They include DIZYGOTIC TWINS as well as monochorial twins that separate shortly after fertilization. Compare monochorial twins.

dichotic adj. affecting or relating to the left and right ears differently, as with the presentation of different sounds to each ear. Compare diotic: monotic.

dichotic listening the process of receiving different auditory messages presented simultaneously to each ear. Listeners experience two streams of sound, each localized at the ear to which it is presented, and are able to focus on the message from one ear while ignoring the message from the other ear. See also INTERAURAL RIVALY.

dichotomized variable an item or score that initially had a set of continuous values (e.g., age) but was then separated into two possible values (e.g., younger or older). It may be useful to create a dichotomized variable when there are truncated data.

dichotomous thinking the tendency to think in terms of polar opposites—that is, in terms of the best and worst—without accepting the possibilities that lie between these two extremes. The term has been used to characterize the tendency of people with major depressive disorder to view mildly negative events as extremely negative, but the potential role of such thinking in other conditions (e.g., eating disorders, personality disorders) is also under investigation. Also called polarized thinking.

dichotomous variable a variable that can have only one of two values (typically, 0 or 1) to designate membership in one of two possible categories, such as female versus male or Republican versus Democrat. Also called binary variable. See also POLYCHOTOMOUS VARIABLE.

dichromatism (dichromacy; dichromasy; dichromatopsy) n. partial color blindness in which the eye contains only two types of cone photopigment instead of the typical three: Lack of the third pigment leads to confusion between certain colors. Red-green color blindness (see DEUTERANOPIA; PROTANOPIA) is the most common, whereas the blue-green variety (see TRITANOPIA) is relatively rare. Another type, yellow-blue (see TETRANTANOPIA), has been proposed, but its existence has yet to be firmly established. See also ACHROMATISM; MONOCHROMATISM; TRICHROMATISM. —dichromatic adj.

dichromatic adj. distinguishing only two colors.

didactic group therapy an early form of group psychotherapy based on the theory that institutionalized individuals will respond most effectively to the active guidance
of a professional leader. In one form of didactic group therapy, the group members bring up their own problems and the therapist leads the discussion, often giving his or her own interpretations. In another form, the therapist presents a short lecture based on printed material designed to stimulate the members to break through their resistances and express themselves. The didactic approach is also used in self-help groups.

**didactic teaching** 1. a technique in which behavioral and therapeutic concepts and techniques are explained to clients, and instructions are given in both verbal and written form. Such instruction is common in many forms of therapy, with the exception of **psychodynamic psychotherapy and psychoanalysis**. 2. a component of many undergraduate and graduate psychology courses and multidisciplinary psychotherapy training.

**diencephalic amnesia** amnesia caused by lesions of the **diencephalon** due to infarction of the paramedian artery, trauma, diencephalic tumors, and **Wienerke-Korsakoff syndrome**.

**dienecephalon** n. the posterior part of the **forebrain** that includes the **thalamus**, **epithalamus**, and **hypothalamus**. —dienecephalic adj.

**diestrus** n. in the polyestrous mammalian female, a period of sexual inactivity between two **estrous cycles**, during which the reproductive system prepares for potential conception and gestation.

**diet** n. 1. food substances and liquids habitually consumed by an organism. 2. a prescribed course of eating and drinking for a particular reason (e.g., a low-cholesterol diet). —dietary adj.

**dietary neophobia** avoidance of new foods. A nonpathological form is commonly seen in children who display a reluctance to try unfamiliar food. Acceptance of novel diets may be facilitated through observation of others eating similar foods or, in some cases, by simply observing others eating familiar foods. In some nonhuman primates, parents or other caretakers appear more likely to offer or share foods that are novel to their young than foods that are familiar to them.

**dietary selection** the ability of an organism to choose foods that maintain a good nutritional balance of calories, fats, protein, minerals, and vitamins. Many species appear to be able to self-select an appropriate diet, perhaps due to infarction of the paramedian artery, trauma, diencephalic tumors, and **Wienerke-Korsakoff syndrome**.

**dieting** n. the deliberate restriction of the types or amounts of food one eats, usually in an effort to lose weight or to improve one’s health. Dieting is viewed by some medical and mental health professionals as a solution to obesity and by others as a primary pathology associated with **eating disorders**.

**DIF** abbreviation for **Differential Item Functioning**.

**difference canon** see **Method of Difference**.

**difference hypothesis** see **Defect Theory**.

**difference judgment** a judgment that two similar stimuli are not identical. The minimum difference between the stimuli necessary to make such a judgment is called the **difference threshold**.

**difference score** (symbol: Δ) an index of dissimilarity or change between observations from the same individual across time, based on the measurement of a construct or attribute on two or more separate occasions. For example, it would be helpful to calculate a difference score for a person’s weight at the beginning of a diet and exercise program and the final weight 6 months later. Also called **change score**; **gain score**.

**difference threshold** the smallest difference between two stimuli that can be consistently and accurately detected on 50% of trials. Also called **difference limen** (DL); **just noticeable difference** (JND; JND). See also **Weber’s Law**.

**difference tone** see **Combination Tone**.

**Differential Ability Scales (DAS)** an individual test designed to yield a broad index of intelligence. Updated in 2007 as **DAS-II**, it now comprises 20 cognitive subtests divided into two age-based batteries: the **Early Years Cognitive Battery** and the **School-Age Cognitive Battery**. Each battery is further divided into core and diagnostic subtests. The core subtests are good measures of g (see **General Factor**), whereas the diagnostic subtests measure such abilities as short-term memory and processing speed. Six of the core subtests at the school-age level yield separate scores for verbal ability, nonverbal reasoning, and spatial ability. [developed in 1990 by British psychologist Colin D. Elliott (1937–)].

**difference accuracy** the ability to determine accurately in what way and to what extent a person’s traits differ from a **stereotype** associated with his or her age group, ethnic group, professional group, or other relevant group. Compare **stereotype accuracy**.

**differential amplifier** an electrical device that amplifies the voltage difference between two input leads. In neural research, potential changes may be as small as 1 μV, and electrical resistances and sources of interference may be greater than the voltages being studied. Thus, complex electronic equipment, such as a differential amplifier, is required.

**Differential Aptitude Tests (DAT)** a battery of tests designed for use in the educational and vocational counseling of students in grades 7 to 12 as well as adults. The battery—which measures abstract reasoning, mechanical reasoning, verbal reasoning, language usage, numerical ability, spatial relations, and perceptual speed and accuracy—pinpoints mental strengths and weaknesses and predicts success both in school and in the workplace. The DAT is in its fifth edition, published in 1990. [originally developed in 1947 by U.S. psychologists George Kettner Bennett...
differential association

(1904–1975), Harold G. Seashore (1906–1965), and Alexander G. Wesman (1914–1973)

differential association 1. the theory that an individual's behavior is influenced by the particular people with whom he or she associates, usually over a prolonged period. This concept was proposed to explain why people living in a neighborhood with a high crime rate were more likely to commit crimes themselves. Moreover, it was suggested that association with a particular type of criminal determined what kind of criminal one became. [proposed by U.S. criminologist Edwin H. Sutherland (1883–1950)]

2. the different effects that individual factors—such as medicines, genes, catalysts, traits, and the like—may contribute to a phenomenon, structure, or outcome.

differential conditioning a CLASSICAL CONDITIONING experiment in which two or more stimuli are used, each paired with different outcomes. Most commonly, one stimulus (the positive conditioned stimulus, e.g., a tone) is paired with an unconditioned stimulus (e.g., food), and another (e.g., a tone) is not paired. The usual outcome is that a CONDITIONED RESPONSE is elicited by the positive conditioned stimulus but not by the other stimulus.

differential diagnosis 1. the process of determining which of two or more diseases or disorders with overlapping symptoms a particular patient has. 2. the distinction between two or more similar conditions by identifying critical symptoms present in one but not the other.

differential effect in parapsychology experiments using ZENER CARDS or similar targets, the finding that a participant shows an above-chance difference in performance under two contrasting conditions of testing (e.g., with two different targets). See also DECLINE EFFECT; FOCUSING EFFECT; POSITION EFFECT; PREFERENTIAL EFFECT; SHEEP-GOAT EFFECT.

differential emotions theory a theory proposing the existence of a large but limited set of specific emotions that appear without social learning at the age when the emotions can first play an adaptive role in the behavior of the child. [proposed by Carroll E. Izard]

differential extinction the extinction of one or more responses established through conditioning while related conditioned responses remain.

differential fertility the fertility rate of any group (e.g., an ethnic or socioeconomic group) in relation to that of another group.

differential growth the growth of an organ at a rate different from that of other organs in the body.

differential inhibition a decreased tendency to respond to stimuli resembling the original conditioning stimulus.

differential item functioning (DIF) the circumstance in which two individuals of similar ability do not have the same probability of answering a question in a particular way. This often is examined to assess whether men and women or individuals of different ethnicity are likely to provide disparate answers on a test. If so, the fairness of the test can be called into question.

differential-organization theory see LAG EFFECT.

differential psychology the branch of psychology that studies the nature, magnitude, causes, and consequences of psychological differences between individuals and groups, as well as the methods for assessing these differences. See also INDIVIDUAL DIFFERENCES.

differential reinforcement in conditioning, the REINFORCEMENT of only selected behavior. For example, one might reinforce lever presses that are more than 1 second in duration but not reinforce those that are less than 1 second in duration.

differential reinforcement of alternative behavior (DRA) the reinforcement of a particular behavior as a means of decreasing another, targeted behavior. It combines EXTINCTION of the targeted response with competition from the reinforced alternative.

differential reinforcement of high rate (DRH) a SCHEDULE OF REINFORCEMENT in which reinforcement depends on fast responses to stimuli. It often requires the interval between responses to be less than an allowed maximum.

differential reinforcement of low rate (DRL) a SCHEDULE OF REINFORCEMENT in which reinforcement is given only when the rate of response to stimuli is low. It often requires the interval between responses to be greater than an allowed minimum. Also called differential reinforcement of long response times.

differential reinforcement of other behavior (DRO) a procedure in which REINFORCEMENT is provided if a particular response does not occur for a fixed period of time. It is used to decrease the rate of the targeted response. Also called omission training.

differential relaxation a technique for exerting only the amount of muscular tension or energy required to perform an activity successfully. For example, an individual driving an automobile can practice easing and releasing contracted muscles that are not primarily involved in the act of driving (e.g., the shoulders and upper back or the neck and facial muscles) and thus permit more appropriate focus and engagement of those muscles directly involved (e.g., in the hands, arms, legs, and lower back).

differential validity 1. the accuracy of a battery of tests in discriminating between a person's subsequent success in two or more different criterion tasks. 2. differences in VALIDITY COEFFICIENTS across groups. For example, the correlation between test scores and job performance may differ for males and females.

differentiation n. 1. sensory discrimination of differences among stimuli. For example, wines that at first taste are identical may, with experience, be readily distinguished. 2. a conditioning process in which a limited range of behavior types is achieved through selective REINFORCEMENT of only some forms of behavior. Also called RESPONSE DIFFERENTIATION. 3. in embryology, the process whereby cells of a developing embryo undergo the changes necessary to become specialized in structure and function so that they or their successors can form tissues, such as muscle, neurons, or bone. 4. in mathematics, the process used in calculus for obtaining the differential coefficient of a function or variable. 5. in attitudes research, see COMPLEXITY OF AN ATTITUDE.

differentiation–dedifferentiation hypothesis two complementary proposals about the development of intelligence. In one, U.S. psychologist Henry E. Garrett (1894–1973) proposed in 1918 that intelligence begins as a fairly unified, general ability that then differentiates into separate, albeit related, abilities as children develop. This
proposals has come to be called the age differentiation hypothesis. According to the other proposal, put forth by U.S. psychologist Benjamin Balinsky in 1941, a process occurs after age 65 during which the separate abilities developed in childhood become increasingly intercorrelated as a result of decreasing fluid intelligence (see CAIETTL–HORN THEORY OF INTELLIGENCE); at this time, intelligence dedifferentiates and returns to a single factor of general ability. This proposal has become known as the age dedifferentiation hypothesis. Both proposals have garnered much debate over the years, but the evidence for each remains limited.

differentiation theory the theory that perception can be understood as an incremental filtering process enabling environmental noise (i.e., dispensable, incidental information) to be screened out while one learns to distinguish the essential characteristics of sensory patterns.

diffraction n. the bending or scattering of waves as they pass through an aperture or around the edge of a barrier. Diffraction most often refers to this phenomenon in light waves, but it may occur with waves of any type, including sound waves, radio waves, water waves, and so forth.

diffraction grating a piece of glass or metal containing closely spaced parallel slits or transparencies, used to separate light into its component wavelengths.

diffuse axonal injury (DAI) widespread stretching and degradation (e.g., acute tearing or delayed biochemically mediated degeneration) of the white matter nerve fibers of the brain, caused by any incident resulting in sudden, significant acceleration or deceleration forces to the head. DAI typically is caused by motor vehicle accidents and is a frequent form of TRAUMATIC BRAIN INJURY.

diffuse bipolar cell a RETINAL BIPOLAR CELL that receives input from several receptors. Compare MIDGET BIPOLAR CELL.

diffuse-status characteristic in EXPECTATION-STATES THEORY, any of certain general personal qualities, such as age, sex, and ethnicity, that people intentionally and unintentionally consider when estimating the relative competence, ability, and social value of themselves and others. Unlike SPECIFIC-STATUS CHARACTERISTICS, diffuse-status characteristics have no particular relevance in the given setting. See STATUS GENERALIZATION.

diffuse thalamic projection system (DTPS) a set of thalamic nuclei that project numerous fibers to all parts of the cerebral cortex. It is the projection system for the RETICULAR FORMATION and sets the tone of the cerebral cortex. See THALAMUS.

diffusion n. 1. the process by which knowledge, innovation, language, or cultural characteristics are spread within or between cultures or communities. 2. in biology, see PASSIVE TRANSPORT. 3. more generally, any process by which something becomes spread or distributed throughout something else. —diffuse vb.

diffusion magnetic resonance imaging (dMRI) a variant of MAGNETIC RESONANCE IMAGING (MRI) in which the molecular diffusion of water or metabolites in the body is measured, resulting in high-resolution images of tissue microstructure. dMRI allows noninvasive evaluation of diffusion in vivo without affecting the diffusion itself. It is used in the study of ischemia, the evaluation of cancer treatments, and the management of acute stroke.

diffusion model a model of reaction time and accuracy proposing that an individual accumulates evidence continuously, rather than in discrete steps, until a response criterion is reached. [proposed in 1978 by U.S. psychologist Roger Ratcliff (1947– )]

diffusion of responsibility the diminished sense of responsibility often experienced by individuals in groups and social collectives. The diffusion has been proposed as a possible mediator of a number of group-level phenomena, including the BYSTANDER EFFECT, CHOICE SHIFTS, DEINDIVIDUATION, SOCIAL LOADING, and reactions to SOCIAL DILEMMAS. See also CONFUSION OF RESPONSIBILITY. [first described in 1970 by U.S. social psychologists John M. Darley (1938– ) and Bibb Latané (1937– )]

diffusion of treatments a situation in which research participants adopt a different intervention from the one they were assigned because they believe the different intervention is more effective. When diffusion of treatments occurs, the INTERNAL VALIDITY of a study is called into question, as it would be difficult to attribute a specific outcome to a specific intervention. For example, participants in a weight-reduction program may be assigned to a low-carbohydrate intervention, a low-fat intervention, a low-calorie intervention, or a control group that only receives educational material on losing weight. If some participants in the control condition found out that those in one of the other conditions were losing more weight and they adopted that intervention, there would be diffusion of treatments.

diffusion process in consumer psychology, the process by which the general public comes to accept a new concept or product. The process often compared to a stone dropped into a pond that produces waves that spread outward to cover the entire pond. The diffusion process depends on acceptance by an initial core of people, whose influence then ripples outward through the surrounding population.

diffusion status see IDENTITY STATUS MODEL.

diffusion tensor imaging (DTI) a variant of DIFFUSION MAGNETIC RESONANCE IMAGING that traces the flow of water in the brain to visualize white matter structures. It is useful in mapping connections between different areas of the brain and can provide valuable detail about these areas and connections. It is utilized in the study of language development, the aging brain, and such disorders as dyslexia, epilepsy, stroke, multiple sclerosis, and schizophrenia.

digestion n. the process by which food is broken down so that it may be absorbed and assimilated by the body, thus providing energy and nutrients.

digestive type a constitutional body type in which the alimentary system dominates other systems (see ROSTAN TYPES). It corresponds to the PYKNIC TYPE in KRETSCHEMER TYPOLOGY.

digital adj. 1. relating to the representation of information in discrete or numerical (typically binary) form. Compare ANALOG, 2. of or relating to the fingers or toes.

digital computer an electronic device that processes information, including making numeric calculations. It is called “digital” because the machine’s primary mechanisms include counting, comparing, and rearranging digits in its memory and processing modules. The (digital) unit for these computations is called a BIT. Compare ANALOG COMPUTER.
digital divide

digital divide any significant gap between groups of individuals in their access to and skilled use of computers, the Internet, smartphones, and other information and communication technologies. For example, there is a digital divide between older adults and younger people: Because the former have been without computers for most of their lives, they tend to be less knowledgeable about the use of such technology than the latter, who have grown up with the technology. The digital divide is an increasing concern as more and more information is collected and disseminated electronically. A related concern is digital acceptance, or how information gathered through digital means is perceived. For example, some social science researchers routinely collect data via online surveys and other Internet-based methods, whereas other researchers do not consider the information obtained from such methods to be as valuable as that collected from more traditional (i.e., nonelectronic) sources.

digital subtraction angiography angiography to visualize blood vessels that have been injected with contrast medium in which minimization or elimination of the background and other soft tissues by computer results in a clear image.

digitized speech speech that has been coded in digital form, usually for storage in a computer or transmission over a computer network.

digit span the number of random digits from a series that a person can recall following a single auditory presentation. A span of 5 to 9 digits (see Seven Plus Minus Two) is considered typical for an adult.

Digit Span an attentional subtest in the WECHSLER ADULT INTELLIGENCE SCALE that assesses the ability of an individual to repeat a series of digits of increasing length. Digit Span Forward assesses the number of digits an individual is able to repeat immediately following their presentation, in the exact order they were presented. Digit Span Backward assesses the number of digits an individual is able to repeat immediately following their presentation, but in reverse order. The former is regarded as a measure of immediate memory; the latter provides a measure of working memory.

Digit Symbol a performance subtest in the WECHSLER ADULT INTELLIGENCE SCALE that measures the time taken to indicate digits associated with abstract symbols using a substitution key. It is a measure of fluid abilities (see CATTELL–HORN THEORY OF INTELLIGENCE) and performance and is negatively correlated with adult age. Also called Digit Symbol Substitution.

diglossia n. the situation in which two varieties of a language coexist and have distinct social functions within a community; these are usually characterized by high (H) and low (L) uses, H being associated with formality and literacy, and L with everyday colloquial usage. See also CODE SWITCHING; MULTILINGUALISM; VERNACULAR. [First described in 1959 by U.S. linguist Charles Ferguson (1921–1998)]

digraph n. a combination of two letters or other symbols used to represent a single speech sound, for example, ph in digraph or in head. The corresponding term trigraph refers to three letters or symbols, for example, thi in Matthew. See also DIPHTHONG.

dihydromorphine n. a semisynthetic opioid analgesic used primarily in research on opioid receptors. It is also a metabolite (metabolic product) of dihydrocodeine.

dihydrotestosterone n. a potent androgenic hormone produced by the metabolic breakdown of testosterone, many of whose effects it mediates in target tissues. It is important in the development of reproductive organs in the male fetus and of male secondary sex characteristics. A semisynthetic form is used therapeutically (see STANOLONE).

dihydroxyphenylacetic acid see DOPAC.

3,4-dihydroxyphenylalanine see DOPA.

dihydroxytryptamine (DHT) n. a serotonergic neurotransmitter used experimentally to decrease serotonin neurotransmission and to investigate the effects of this depletion on brain activity and behavior.

Dilantin n. a trade name for PHENYTOIN.

dilation n. the process of enlargement, usually of an aperture, such as the pupil of the eye.

dilator n. 1. a muscle or nerve that causes opening or enlargement of a bodily structure. 2. an instrument for opening up an orifice or passage in the body. 3. a drug or other agent that causes dilation or enlargement of an organ or opening. See VASODILATOR.

dildo n. an artificial penis, made usually of plastic or silicone but occasionally of wood or other materials. A dildo is used in autoerotic practices and other sexual activities. Also called DILISOS. See also VIBRATOR.

dilemma n. a situation necessitating a choice between two equally desirable or undesirable alternatives. Psychologists, economists, or sociologists may invent dilemmas and present them to individuals or groups to study decision making. See ETHICAL DILEMMA; PRISONER’S DILEMMA; SOCIAL DILEMMA.

dilution effect 1. the reduction in the average probability that any one individual animal will be preyed on when many animals carry out the same activity at the same time. For example, young birds may leave a nesting colony en masse, or insects may emerge synchronously; as a result, predators are able to take proportionally fewer prey. See also ANTIPREDATOR BEHAVIOR; CONFUSION EFFECT. 2. the protection against disease transmission that may occur when the presence of incompetent reservoirs (i.e., organisms that do not efficiently transmit a particular pathogen) dilutes the effect of competent reservoirs; in this situation, a decrease in biodiversity may lead to an increase in the transmission of a pathogen. In contrast, the amplification effect occurs when an increase in biodiversity leads to an increase in disease transmission.

dimenhydrinate n. a nonprescription antihistamine at H1 receptors that is commonly taken to suppress symptoms of motion sickness. U.S. trade name (among others): Dramamine.

dimension n. in statistics, a factor or component that is applied in measuring a set of variables. For example, some intelligence scales are considered to have two important dimensions consisting of verbal and nonverbal intelligence.
dimensionality  n. the number of dimensions applied in measuring a construct. In factor analysis and principal components analysis, it is important to assess the dimensionality of a set of items on a scale in order to form cohesive subscales that each describe a similar set of items.

dimensional theory of emotion any theory postulating that emotions have two or more fundamental dimensions. There is universal agreement among theories on two fundamental dimensions—pleasantness-unpleasantness (hedonic level) and arousal-relaxation (level of activation)—but considerable differences in labeling others.

dimensions of consciousness variables along which the overall quality of a person’s consciousness can be assessed, including mood and feeling tone, internal or external focus of attention, changes in spatial awareness, a sense of flow or difficulty, degree of self-awareness, and degree of self-identification with groups or individuals.

dimer  n. a complex in which two macromolecular subunits (e.g., of a protein) are bound together. —dimeric adj.

dimethoxymethylamphetamine n. see DOM.

dimethyl ketone see acetone.

dimethyltryptamine n. see DMT.

diminished capacity a legal defense in which a mental abnormality due to either intoxication (see intoxication defense) or mental defect, is claimed to have limited the defendant’s ability to form the requisite criminal intent (see mens rea) for the crime with which he or she is charged.

diminished responsibility a form of affirmative defense in which evidence of mental abnormality is presented to mitigate or reduce a defendant’s accountability for an act. It is distinct from an insanity defense, which takes an all-or-none perspective with regard to criminal responsibility. Also called limited responsibility. See also partial insanity.

diminutive visual hallucination see leliputian hallucination.

dimming effect 1. the effect of a bright light in a scene with fainter elements. The faint elements appear dimmer in the presence of the light source than they do when the light source is absent. 2. the increase in brightness of an afterimage that results from dimming its background.

dimorphism  n. the existence among members of the same species of two distinct forms that differ in one or more characteristics, such as size, shape, or color. Compare monomorphism. See also sexual dimorphism. —dimorphic adj.

DIMS abbreviation for disorders of initiating and maintaining sleep.

DIN color system a European system for representing colors by their attributes of hue, luminous intensity, and saturation (from German Farbe [D]eutche [I]ndustrie-N[orm], German Industry Standard). It is similar to the U.S. Munsell color system.

dinitrogen monoxide see nitrous oxide.

Dionysian adj. describing a state of mind that is irrational, sensational, disordered, and even drunken or mad (from Dionysus, Greek god of wine, intoxication, and ritual madnes or ecstasy). This modern use of the term was originated by Friedrich Nietzsche, who drew a contrast between the Dionysian and the APOLLONIAN sides of human nature. He felt that a Dionysian attitude would counter the enervating effects of the Apollonian attitude then dominant in morality, religion, and philosophy.

diopter  n. a unit of the power of a lens, equal to the reciprocal of its focal length in meters. A lens of 1 diopter will focus parallel rays of light to a point 1 m behind the lens.

dioptrics  n. the field of optics concerned with the refraction of light. Compare catoptrics.

diotic adj. denoting or relating to the presentation of the same sound to both ears. Compare dichotic monotic.

diphenhydramine  n. a sedating antihistamine at H1 receptors that also possesses activity at cholinergic and other receptor sites. It is used generally to suppress allergic responses and, in mental health, as a sedative and hypnotic or to suppress the parkinsonian symptoms induced by conventional antipsychotic drugs. U.S. trade name (among others): Benadryl.

diphenylbutylpiperidine  n. any member of a class of chemically related compounds that include the conventional antipsychotic pimozide.

diphenylmethane  n. any of a class of sedating antihistamines at H1 receptors that are used primarily as anxiolytics. They also prevent cardiac fibrillation and have local anesthetic effects. The prototype is hydroxyzine.

diphthong  n. a speech sound in which one vowel glides imperceptibly into another, as in the English words boy or great.

diplacusis  n. a condition in which one tone is heard as two.

diplegia  n. a paralysis that affects corresponding parts on both sides of the body (e.g., both arms). —diplegic adj.

diplo- (dipl-) combining form double or doubled.

diploid adj. denoting or possessing the normal number of chromosomes, which in humans is 46: the 22 homologous pairs of autosomes plus the male or female set of XY or XX sex chromosomes. Compare haploid.

diplomate  n. see board certified.

diplopia  n. a visual disorder in which images from the two eyes are seen separately and simultaneously. Diplopia is usually due to weak or paralyzed eye muscles, resulting in a failure of coordination and focus. It may also be a functional symptom or result from brain injury (cerebral diplopia). See also double vision.

dipsomania  n. an obsolete term for compulsive alcoholic drinking, particularly episodic binge drinking. —dipsomaniac  n.

direct aggression  aggressive behavior directed toward the source of frustration or anger. Compare displaced aggression.

direct attitude measure any procedure for assessing attitudes that requires a person to provide a report of his or her attitude. Traditional approaches to attitude measurement, such as the likert scale, semantic differential, and Thurstone attitude scales, are examples of direct attitude measures. See also explicit attitude measure; implicit attitude measure. Compare indirect attitude measure.

direct-contact group see face-to-face group.

direct coping active, focused confrontation and man-
direct correlation

agreement or resolution of stressful or otherwise problematic situations. See also ACTIVE COPING.

direct correlation see POSITIVE CORRELATION.

direct dyslexia a form of acquired DYSLEXIA characterized by an ability to read words aloud but an inability to understand what is being read. Some have suggested this is a parallel to developmental HYPERLEXIA.

directed attention see SELECTIVE ATTENTION.

directed discussion method dialogue between two or more people about a specific topic in which one person's role is to keep the dialogue focused on a certain path or moving in a certain direction. That person may be a teacher, group leader, or mediator. In an educational setting, for example, a professor would provide curriculum-directed focus based on experience, while the students would contribute varied perspectives and broad-ranging information from their research.

directed forgetting in memory trials, forgetting that happens due to an item being accompanied by a forget cue, that is, a stimulus that signifies that the item will not be included in the memory test. A remember cue signifies that an item will be included.

directed graph see GRAPH.

directed masturbation a behavioral treatment for women with ANORGASMA or FEMALE ORGASMIC DISORDER to improve the consistency, strength, and number of orgasms experienced in intercourse. Directed masturbation also is used to alter deviant sexual preferences in individuals who engage in pedophilia, rape, and child molestation. The procedure consists of weekly therapy sessions as well as extratherapy sensuality and masturbatory exercises to be practiced by the client, including visual examination of the genitalia and whole body, focused genital exploration and touching, and increasingly intense manual stimulation supplemented with erotica and fantasy. Sexual enrichment workshops, communication skills training, sexual counseling, and KEGEL EXERCISES may also be used. Despite the clinical popularity of directed masturbation for treating orgasmic dysfunction, empirical support for its effectiveness has been plagued by methodological problems (e.g., small sample sizes, confounded treatments, lack of objective outcome measures), and the technique has yet to gain widespread acceptance as an EVIDENCE-BASED PRACTICE. [Formally developed in 1972 by U.S. psychologists Joseph LoPiccolo (1941–) and W. Charles Lobitz] 

directed movement movement targeted toward achieving a specific goal.

directedness n. the sense of unified purpose that provides the mature individual with enduring motivation, continuity, and orientation to the future. [First described by Gordon W. ALLPORT]

directed reverie in individual and group therapy, a technique in which the therapist directs the client to experience a dream or something that happened in early life by creating and then describing a mental image of that dream or event. See also GUIDED AFFECTIVE IMAGERY.

directed thinking controlled, purposeful thinking that is focused on a specific goal, such as the solution to a problem, and guided by the requirements of that goal. See also CRITICAL THINKING.

direct glare interference with vision caused by bright light from a source in the visual field, as opposed to reflected glare, which is interference caused by light reflected from a surface.

directional confusion difficulty in distinguishing left from right and, in some cases, difficulty with other spatial relationships, such as that of UPTOWN and DOWNTOWN. Some directional confusion is common up to the age of 6 or 7, especially during the early stages of reading, writing, and spelling, and also in people with MIXED LATERALITY. Persistent directional confusion may indicate MINIMAL BRAIN DYSFUNCTION or a history of forced conversion from left-handedness to right-handedness.

directional hypothesis a scientific prediction stating (a) that an effect will occur and (b) whether that effect will specifically increase or specifically decrease, depending on changes to the INDEPENDENT VARIABLE. For example, a directional hypothesis could predict that depression scores will decrease following a 6-week intervention, or conversely that well-being will increase following a 6-week intervention. Also called directional alternative hypothesis: one-tailed hypothesis. Compare NONDIRECTIONAL HYPOTHESIS.

directionality problem in CORRELATIONAL RESEARCH, the situation in which it is known that two variables are related although it is not known which is the cause and which is the effect.

directional test a statistical test of a DIRECTIONAL HYPOTHESIS. Also called directional alternative hypothesis test: directional hypothesis test: one-tailed test. Compare NONDIRECTIONAL TEST.

direction perception the ability to determine the location in space of a moving visual target or of an auditory stimulus.

directions test a type of intelligence test that measures the participant’s ability to follow instructions on a series of tasks. Most directions tests only implicitly measure this ability, typically resulting in a reduced score only if their directions are misunderstood.

directive n. a command, suggestion, or order specifying the type of action that should be performed. In therapeutic contexts, a directive is a specific statement by the therapist that enjoins the client to act, feel, or think in a particular way when he or she confronts a particular problem or situation. The use of directives varies depending on therapeutic method; in some modes (e.g., psychoanalysis), directives occur rarely if at all, whereas in others (e.g., behavior therapy), they occur more frequently.

directive counseling an approach to counseling and psychotherapy in which the therapeutic process is directed along lines considered relevant by the counselor or therapist. Directive counseling is based on the assumption that the professional training and experience of the counselor or therapist equip him or her to manage the therapeutic process and to guide the client’s behavior. Also called directive therapy. See also ACTIVE THERAPY.

directive discipline a field of study, particularly within the social sciences or humanities, that provides explicit or implicit answers to prescriptive questions regarding society and the conduct of individual lives. For example, philosophy is a directive discipline when it suggests that some ethical system is to be recommended over another. Psychology is a directive discipline to the extent that it describes a
healthy or fully functioning life and may attempt to modify behaviors that fall short of this ideal.

directive group psychotherapy a type of group psychotherapy designed to help members adjust to their environment through educational tasks, group guidance, group counseling, and therapeutic recreation. [developed by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981)]

directive leader a group leader who actively guides the group’s planning, activities, and decision making. In therapeutic groups, for example, a directive leader is one who guides the course of the interaction, assigns various tasks to the group members, and offers verbal interpretations and recommendations. In contrast, nondirective DEMOCRATIC LEADERS refrain from providing direction or interpretation.

directive play therapy a controlled approach to PLAY THERAPY in which the therapist is actively involved, structuring a child’s activities by providing selected play materials and encouraging the child to use them in the enactment of “pretend” situations and the expression of feelings. Compare NONDIRECTIVE PLAY THERAPY.

directive therapy see DIRECTIVE COUNSELING.

direct marketing promoting a product by means of communication strategies addressed directly to individuals, rather than via the mass media: Direct marketing strategies will usually make use of knowledge of past purchases, demographics, and other factors. Examples are direct mail campaigns, telemarketing, and targeted e-mailing.

direct memory test see EXPLICIT MEMORY TEST.

direct model a representation in which interest centers on how one or more variables specifically correlate with one or more other variables, without the inclusion of a MEDIATOR or intervening variable. For example, a researcher may hypothesize that an individual’s health background relates to his or her coping style, which in turn may be related to the individual’s sense of well-being. A direct model of this research would focus upon how health background relates to well-being, without considering the mediator of coping style.

direct object see OBJECT.

direct observation a method of collecting data in which a researcher simply views or listens to the subjects of the research, without asking specific questions or manipulating any variables. The method of direct observation is useful in EVALUATION RESEARCH or FIELD RESEARCH. See also NATURALISTIC OBSERVATION.

direct odor effect a change in the nervous system caused by direct stimulation of the OLFATORY TRACT and related brain structures. In contrast, an INDIRECT ODOR EFFECT is a change in the central nervous system arising from cognitions, such as expectations, associated with the odor.

director n. in PSYCHODRAMA, the therapist who establishes the scenario or ROLE PLAY and manages the interactions therein.

Directory of Psychological Tests in the Sport and Exercise Sciences a collection of psychological scales, questionnaires, and inventories related to sport and exercise. It provides the source, purpose, description, construction, reliability, validity, norms, availability, and references for each instrument.

direct perception the theory that the information required for perception is external to the observer; that is, one can directly perceive an object based on the properties of the DISTAL STIMULUS alone, unaided by inference, memories, the construction of representations, or the influence of other cognitive processes. See ECOLOGICAL PERCEPTION. Compare CONSTRUCTIVISM. [proposed by James J. GIBSON]

direct realism 1. see NAIVE REALISM. 2. an occasional synonym for DIRECT PERCEPTION.

direct reflex a reflex involving a receptor and effector on the same side of the body.

direct relationship 1. an association between two variables such that they rise and fall in value together. For example, the number of hours studied and the level of test performance form a direct relationship in that as the number of study hours increases, the level of performance also increases, and vice versa. 2. in STRUCTURAL EQUATION MODELING, a correlation or prediction between two variables that does not involve a MEDIATOR or intervening variable. Also called POSITIVE RELATIONSHIP. Compare INDIRECT RELATIONSHIP.

direct replication the process of repeating a study with different data under similar conditions, or of conducting several different studies with the same data. Direct replication is useful for establishing that the findings of the original study are reliable (see RELIABILITY). In contrast, SYSTEMATIC REPLACEMENT uses a different data set and also adjusts the conditions in specific ways.

direct scaling a procedure for developing numerical scales of magnitude of psychophysical factors in which the observer makes judgments of the magnitude of stimuli. This is in contrast to INDIRECT SCALING, in which the magnitude scales are derived from PAIRED COMPARISON judgments.

direct selection a form of NATURAL SELECTION in which some behavioral, physical, or physiological trait in an individual improves the likelihood that its offspring will survive to reproduce. This contrasts with KIN SELECTION, in which the behavior of an organism may not help survival of its direct descendants but may benefit its relatives instead.

direct suggestibility see PRIMARY SUGGESTIBILITY.

direct suggestion 1. a technique in SUPPORTIVE PSYCHOTHERAPY in which attempts are made to alleviate emotional distress and disturbance in an individual through reassurance, encouragement, and direct instructions. 2. a technique in HYPNOTHERAPY in which a client under hypnosis is directed to follow instructions of the therapist either in the session or in his or her daily life.

dirhinic adj. relating to the presentation of the same ODORANT in each nostril via an OLFACTOMETER.

dirt phobia a persistent and irrational fear of dirt, often accompanied by a fear of contamination and a hand-washing compulsion. Fear of dirt is a common obsession associated with OBSESSIVE-COMPULSIVE DISORDER.

DIF abbreviation for DIAGNOSTIC INTERVIEW SCHEDULE.

disability n. a lasting physical or mental impairment that significantly interferes with an individual’s ability to function in one or more central life activities, such as self-care, ambulation, communication, social interaction, sexual expression, or employment. For example, an individual...
disability adjusted life years

who cannot see has a visual disability. See also HANDICAP. —disabled adj.

disability adjusted life years (DALYs) a measure of the influence of disease or injury on the length and quality of a person’s life. It takes into account the potential loss of years due to premature mortality and the value of years lived with disability. One DALY represents one lost year of “healthy” life.

disability evaluation an evaluation of the effect of an impairment (i.e., a loss of function) on an individual’s capabilities, particularly in terms of his or her capacity for gainful employment.

disability laws legislation relating to the treatment of people with mental or physical disabilities. An example in the United States is the 1990 AMERICANS WITH DISABILITIES ACT.

Disability Rating Scale (DRS) a rating scale, used primarily in rehabilitation facilities to monitor the rehabilitative progress of individuals with moderate to severe brain damage, that measures arousal and awareness, cognitive ability, dependency on others, and psychosocial adaptability. Each of the eight items on the scale (eye opening, communication ability, motor response, feeding, toileting, grooming, level of functioning in self-care, and employability) is assigned a value from 0 to 3, 4, or 5. These values are then added together to obtain a total score, which may range from 0 (no disability) to 29 (extreme vegetative state).

[originally developed in 1982 by psychiatrist Maurice Rapaport (1926–2008) and colleagues]

disadvantaged adj. denoting individuals, families, or communities deprived of equal access to society’s resources, especially the necessities of life or the advantages of education and employment.

disaggregation n. the process of breaking down data into smaller units or sets of observations. For example, faculty salary data initially may show a significant difference between male and female earnings. After disaggregating the data into separate levels (e.g., assistant, associate, full professor), however, one may find that there are no significant differences in salary among men and women at the assistant professor level but there are differences at the full professor level. Thus, disaggregating the data reveals a finer pattern. Compare AGGREGATION.

disarranged-sentence test a test or test item whose objective is to put a scrambled sentence in proper order. For example, the individual being tested could be required to reorder “Boy went to the bustling town.” to read “The boy went to the bustling town.”

disaster n. a collectively experienced sudden catastrophic event caused by nature (e.g., hurricane, earthquake, tsunami, tornado), technology (e.g., airplane crash, nuclear plant explosion, mining accident), or human aggression (e.g., acts of terrorism). The effect is often measured in terms of loss of lives, injuries, and property damage and typically overwhelms the community’s resources and ability to respond without outside assistance.

disaster counseling counseling offered to victims and their families, emergency workers, and witnesses during or immediately following a catastrophic event. Individual therapists and counselors and mental health teams are specially trained (e.g., by the American Red Cross) to respond in disaster situations. Their approach may include defusing, debriefing, and other counseling techniques to help traumatized people cope with stress. One aim of the counseling might be to reduce the potential for posttraumatic stress disorder, which may develop after the event.

disaster psychology the specialized domain of training, research, and service provision applied to individuals, communities, and nations exposed to a disaster. A key goal is to reduce initial distress and foster short- and long-term adaptive functioning following a disaster. Within this domain, disaster mental health is the term most widely used in the United States to describe the psychological component in overall disaster response. PSYCHOSOCIAL SUPPORT is the term adopted by the international community and the World Health Organization to refer to the development and implementation of culturally appropriate mental health training and services for communities devastated by a disaster. Disaster mental health specialists may serve as consultants, researchers, and educators in the field. See also CRISIS INTERVENTION; DISASTER COUNSELING.

disavowal n. see DENIAL.

discharge n. 1. in neurophysiology, the firing or activity of a neuron or group of neurons, resulting in an ACTION POTENTIAL. 2. in hospitals and other health facilities, the release of a patient from treatment or other services. 3. the dismissal of an employee. 4. the abrupt reduction in psychic tension that occurs in symptomatic acts, dreams, or fantasies.

discharge of affect the reduction of an emotion by giving it active expression, for example, by crying. [described by Sigmund FREUD]

discharge planning a structured plan to facilitate an individual’s safe and successful transition from an inpatient treatment setting (e.g., hospital, psychiatric unit, drug or alcohol residential treatment center) back into the community. It is part of the continuum of care and may begin development at the time of admission. The process systematically addresses, with the patient’s participation, his or her physical and mental health needs (e.g., prescribed medications, follow-up therapy), but it may also address social services needs (e.g., food, housing, employment, education).

discharge procedure the process of releasing a patient from an inpatient setting back into the community. Common steps in the process include a final clinical interview and evaluation, instructions regarding prescribed medication (if relevant), and discussion of follow-up treatment and services. See DISCHARGE PLANNING.

discharge rate the ratio of the number of patients discharged from a hospital or other institution in a given period to the number admitted. Also called IMPROVEMENT RATE: RECOVERY RATIO.

dischronotaraxis n. an aspect of DISORIENTATION in which there is confusion about time. See also CHRONOTARCISIS.

disciple n. 1. a student under a teacher’s direction, a supporter of a cause, or a follower. 2. one who spreads the doctrine of another.

discipline n. 1. training that is designed to establish desired habits of mind and behavior. 2. control of conduct, usually a child’s, by means of punishment or reward. 3. a field of study.

discomfort anxiety tension and consequent low frustration tolerance that arise from irrational beliefs about
perceived threats to well-being. [proposed in 1979 by Albert Ellis]

disconfirmability n. see FALSIFIABILITY.

disconnection syndrome any neurological disorder resulting from a separation or isolation of cortical areas that usually work together. Several neurobehavioral symptoms, including some apraxias and agnosias, are thought to be attributable to disconnection syndrome. [defined by U.S. neurologist Norman Geschwind (1926–1984)]

discontinuity effect the markedly greater competitiveness of intergroup interactions relative to the competitiveness of interpersonal interactions. DIFFUSION OF RESPONSIBILITY and INGROUP BIAS have been proposed as contributing factors to this effect.

discontinuity hypothesis in GESTALT PSYCHOLOGY, the viewpoint that emphasizes the role of sudden insight and perceptual reorganization in successful problem solving. According to this view, a correct answer is only recognized when its wholeness is perceived as a whole is discovered. Also called discontinuity theory. Compare CONTINUITY HYPOTHESIS. See also AHA EXPERIENCE; ALL-OR-NONE LEARNING; EUREKA TASK.

discontinuous adj. intermittent or disconnected. For example, a sequence of ordinal numbers is discontinuous because it does not have a smooth flow from one value to the next. See also DISCRETE. Compare CONTINUOUS.

discontinuous variable a variable that has distinct, discrete values but no precise numerical flow. For example, gender can be thought of as a discontinuous variable with two possible values, male or female. In contrast, a CONTINUOUS VARIABLE involves numerically precise information, such as height, weight, and miles per hour. Also called discrete variable.

discordance n. 1. the state or condition of being at variance. Affective discordance may be observed, for example, when a person relates a particularly disturbing experience without any facial or vocal indication of distress. 2. in TWIN STUDIES, dissimilarity between a pair of twins with respect to a particular trait or disease. Compare CONCORDANCE. —discordant adj.

discounting principle see ATtribution THEORY.

discourse n. the areas of written, spoken, and signed communication, whether formal (debate) or informal (conversation). The term is most often used in LINGUISTICS, where discourse analysts focus on both the study of language (sentences, speech acts, and lexicons) as well as the rhetoric, meanings, and strategies that underlie social interactions.

discourse analysis in linguistics, the study of structures that extend beyond the single sentence, such as conversations, narratives, or written arguments. Discourse analysis is particularly concerned with the ways in which a sequence of two or more sentences can produce meanings that are different from or additional to any found in the sentences considered separately. An important source of such meanings is the “frame” or format of the discourse (news item, fairytale, joke, etc.) and a recognition of the various norms that this implies. The norms and expectations that govern conversation are a major concern of discourse analysis, as is the structure of conversational language generally. Particular areas of interest here include the distinction between background and foreground information (see FORGROUNDING; GIVEN–NEW DISTINCTION) and the relations between explicit and inferred meanings (see CONVERSATIONAL INFERENCE; IMPLICATURE; PRESUPPOSITION).

discourse routine a highly structured and ritualized conversational act in which the participants have set expectations about turn taking and participation. Discourse routine is important in institutional contexts, such as classroom instruction.

discovery n. in a legal dispute, a motion usually put forward by the defense that the prosecution make available for copy all documents relevant to its case. These include both paper documents and any information stored on computer or video.

discovery learning learning that occurs through solving problems, by formulating and testing hypotheses, and via actual experience and manipulation in attempting solutions.

discovery method teaching that seeks to provide students with experience of the processes of science or other disciplines through inductive reasoning and active experimentation, with minimal teacher supervision. Students are encouraged to organize data, develop and test hypotheses, and formulate conclusions or general principles. The discovery method is associated with the cognitivist school of Jean PIAGET, Jerome Seymour BRUNER, and others.

discovery of new means through active experimentation see TERTIARY CIRCULAR REACTION.

discrepancy evaluation in evaluation research, the search for differences between two or more elements or variables of a program that should be in agreement. Reconciling these differences may then become a major objective in the program’s development.

discrepancy principle see NOVELTY PREFERENCE TASK.

discrepant stimulus a stimulus that varies moderately from a known stimulus or schematic image. For example, a stranger’s face represents a discrepant stimulus for an infant.

discrete adj. separate or distinct; often referring to CATEGORICAL or ORDINAL data that have names or ranks as values. In contrast, CONTINUOUS data have a potentially infinite flow of precise numerical information. See also DISCONTINUOUS.

discrete control see CONTINUOUS CONTROL.

discrete distribution a delineation of separate, distinct values. For example, the number of children in a family can be displayed in a discrete distribution with values of 0, 1, 2, 3, and 4. Compare CONTINUOUS DISTRIBUTION.

discrete measure a measure of a DISCONTINUOUS value, for example, the grade level of a student.

discrete movement task a purposeful movement that has a recognizable beginning and end. Examples include grasping an object, kicking a ball, and shifting the gears of a car. Compare CONTINUOUS MOVEMENT TASK.

discrete trial a defined, limited occasion to engage in some behavior. For example, each trip through a maze by a rat can be considered a discrete trial. Such trials may be contrasted with those in which the behavior in question can occur at any time (see FREE OPERANT).

discrete variable see DISCONTINUOUS VARIABLE.

discernmentary task a relatively unstructured group
task that can be completed using a variety of procedures. See ADDITIVE TASK; COMPENSATORY TASK; CONJUNCTIVE TASK; DISJUNCTIVE TASK.

discriminal dispersion in an experiment involving the differentiation of stimuli, the distribution of responses around a given MEAN.

discriminanda pl. n. (sing. discriminandum) stimuli that can be distinguished from one another.

discriminant analysis a MULTIVARIATE method of data analysis that uses a linear combination of values from a set of quantitative variables to predict differences among a set of predefined categories or groups of another variable. For example, a researcher might use a discriminant analysis to determine whether several measures of personality can differentiate those who pursue different majors in college. If there are more than two outcome categories, MULTIPLE DISCRIMINANT ANALYSIS is used. See also DESCRIPTIVE DISCRIMINANT ANALYSIS; PREDICTIVE DISCRIMINANT ANALYSIS.

discriminant function 1. any of a range of statistical techniques used to situate an item that could belong to any of two or more variables in the correct set, with minimal probability of error. 2. in DISCRIMINANT ANALYSIS more specifically, a linear combination of predictor variables that is used to categorize items into distinct groups. The first discriminant function denotes the linear combination that best distinguishes among the discrete groups, the second discriminant function is the linear combination that is the next best in distinguishing among the groups, and so forth.

discriminant loading a correlation between a variable and an underlying dimension found when trying to predict a categorical outcome from a set of predictor variables. It may range from −1 to +1, where values near either extreme indicate a variable that is able to clearly differentiate among the categories of the outcome.

discriminant validity the degree to which a test or measure diverges from (i.e., does not correlate with) another measure whose underlying construct is conceptually unrelated to it. This is one of two aspects of CONSTRUCT VALIDITY, the other being CONVERGENT VALIDITY. Also called divergent validity.

discriminated avoidance an approach to AVOIDANCE CONDITIONING in which a conditioned stimulus signals the onset of an aversive unconditioned stimulus. By responding to the first stimulus, the organism can prevent the occurrence of the second. By contrast, in nondiscriminated avoidance, there is no warning conditioned stimulus. Also called signaled avoidance.

discriminated operand a conditioned operand that is under stimulus control, that is, a response that is more likely to occur when its DISCRIMINATIVE STIMULUS is present than when it is not present.

discriminating power 1. a measure of the ability of a test to distinguish between two or more groups being assessed. 2. in DISCRIMINANT ANALYSIS, the degree of accuracy with which a set of predictor variables differentiates outcomes into categories.

discrimination n. 1. the ability to distinguish between stimuli or objects that differ quantitatively or qualitatively from one another. 2. the ability to respond in different ways in the presence of different stimuli. In conditioning, this is usually established in experiments by DIFFERENTIAL REINFORCEMENT or DIFFERENTIAL CONDITIONING techniques. See DISCRIMINATION LEARNING; DISCRIMINATION TRAINING.

3. differential treatment of the members of different ethnic, religious, national, or other groups. Discrimination is usually the behavioral manifestation of PREJUDICE and therefore involves negative, hostile, and injurious treatment of the members of rejected groups. By contrast, REVERSE DISCRIMINATION is the favorable treatment of the oppressed group rather than the typically favored group. See also RACIAL DISCRIMINATION; SEX DISCRIMINATION; SOCIAL DISCRIMINATION. —discriminate vb.

discrimination index see INDEX OF DISCRIMINATION.

discrimination learning a conditioning or learning experience in which an individual must learn to make choices between alternative stimuli, some of which may be highly similar. To facilitate the learning, typically one of the stimuli is associated with a reinforcer or goal object and the other is not. For example, a cat may have to learn to find food under a white cup on the left side of an area in which there are white and black cups on both sides. Also called discriminative learning.

discrimination of cues the ability to distinguish between two or more stimuli. Operant or classical DISCRIMINATION TRAINING procedures are often used to allow behavior to reflect this ability.

discrimination reaction time the time it takes a participant in a task to distinguish different stimuli, as in a CHOICE REACTION TIME task. See also SIMPLE REACTION TIME.

discrimination training 1. a procedure in which an OPERANT RESPONSE is reinforced in the presence of a particular stimulus but not in the absence of that stimulus. For example, a rat’s lever-press response might be reinforced when a stimulus light is on but not when the light is off. The rat will eventually learn to press the lever only when the light is on. See DISCRIMINATION OF CUES. 2. in sport, the training of the ability to identify task-relevant cues and their meaning.

discriminative learning see DISCRIMINATION LEARNING.

discriminative response following DISCRIMINATION LEARNING, the choice of a particular stimulus among different stimuli to obtain a particular reward.

discriminative stimulus (symbol: S0) in OPERANT CONDITIONING, a stimulus that increases the probability of a response because of a previous history of DIFFERENTIAL REINFORCEMENT in the presence of that stimulus. For example, if a pigeon’s key pecks are reinforced when the key is illuminated red but not when the key is green, the red stimulus will come to serve as an S0 and the pigeon will learn to peck only when the key is red. Compare NEGATIVE DISCRIMINATIVE STIMULUS.

discursive psychology the study of social interactions and interpersonal relationships with a particular focus on understanding the ways in which individuals construct events via written, spoken, or symbolic communication.

discussion group any group set up to explore problems and questions in a variety of vocational, educational, guidance, therapeutic, and community settings. In schools, a discussion group is usually an instructional technique; in counseling and other therapeutic settings, the focus is emotional and interpersonal; in vocational, guidance, and community settings, the objective may be to stimulate decision-making processes and to channel recommendations to a study or action group.
ponent of old age. Compare in the outside world. Empirical research has shown, how-
tention inward toward the self and away from involvement in society. According to this theory, those happiest in old age have turned their att-
sire of adaptation any of a group of illnesses, including high blood pressure and heart attacks, that are as-
exion (e.g., one that causes disidentification n. a protective mechanism whereby one removes a potentially harmful characteristic or experi-
engagement theory a theory proposing that old age involves a gradual withdrawal of the individual from society and of society from the individual. According to this theory, those happiest in old age have turned their att-
environmental (e.g., one that causes disinhibited feedback theory see SYNAPSE. disinhibited social engagement disorder see RE-
disintegration n. a breakup or severe disorganization of

disease course the progress of a pathological condition or process from inception, manifestation, and diagnosis through treatment and resolution.
disease management an integrated treatment approach for patients with chronic health conditions that seeks to minimize the effects of their condition through illness-specific management, education, and patient support.
disease model 1. any of several theories concerning the causes and course of a pathological condition or process. 2. see MEDICAL MODEL.
disease of adaptation any of a group of illnesses, including high blood pressure and heart attacks, that are associated with or partly caused by long-term defective physiological or psychological reactions to stress. [named and defined by Hungarian-born Canadian endocrinologist Hans Selye (1907–1982)]
disease phobia a persistent and irrational fear of disease in general or of a particular disease. Fear of disease may be a SPECIFIC PHOBIA or a feature of HYPOCHONDRIASIS or OBSESSIVE-COMPULSIVE DISORDER.
disenfranchised grief grief that society (or some element of it) limits, does not expect, or may not allow a person to express. Examples include the grief of parents for stillborn babies, of teachers for the death of students, and of nurses for the death of patients. People who have lost an animal companion are often expected to keep their sorrow to themselves. Disenfranchised grief may isolate the bereaved individual from others and thus impede recovery. Also called hidden grief. See also GRIEF COUNSELING; GRIEF WORK; MOURNING.
disengaged family a family whose members are mutually withdrawn from each other psychologically and emotionally.
disengagement n. the act of withdrawing from an attachment or relationship or, more generally, from an unpleasant situation. —disengaged adj.
disidentification n. 1. a protective mechanism whereby one removes a potentially harmful characteristic or experience (e.g., one that causes STEREOTYPE THREAT) from one’s self-identity as insulation from anxiety or failure. 2. in meditation, a benign separation from one’s sense of self in order to gain self-knowledge. It is a stepping away from self-identity to attempt to observe oneself objectively.
disincentive n. a deterrent. Specifically, in industrial and organizational psychology, it is any factor that tends to discourage effort or productivity and to lower motivation, such as unpleasant working conditions. See also HYGIENE FACTORS.
disinformation n. PROPAGANDA or false information publicly announced or planted in the news media for the purpose of deception.
dishabituation n. the reappearance or enhancement of a habituated response (i.e., one that has been weakened following repeated exposure to the evoking stimulus) due to the presentation of a new stimulus. Dishabituation can be interpreted as a signal that a given stimulus can be discriminated from another habituated stimulus and is a useful method for investigating perception in nonverbal individuals or nonhuman animals. Compare HABITUATION.
dishonest signal among nonhuman animals, a signal that provides misleading information about the size, quality, or intention of an individual. Dishonest signals include alarm calls that scare away other group members, with the result that the animal gains better access to food, and a misleading impression of great vigor that attracts mates. Some have argued that dishonest signals are more compatible with the competitive process of NATURAL SELECTION than are HONEST SIGNALS. See DECEPTION.
disidentification n. a protective mechanism whereby one removes a potentially harmful characteristic or experience (e.g., one that causes STEREOTYPE THREAT) from one’s self-identity as insulation from anxiety or failure. 2. in meditation, a benign separation from one’s sense of self in order to gain self-knowledge. It is a stepping away from self-identity to attempt to observe oneself objectively.
disincentive n. a deterrent. Specifically, in industrial and organizational psychology, it is any factor that tends to discourage effort or productivity and to lower motivation, such as unpleasant working conditions. See also HYGIENE FACTORS.
disinformation n. PROPAGANDA or false information publicly announced or planted in the news media for the purpose of deception.
dishabituation n. the reappearance of responding, in condi-
tioning experiments, the reappearance of responding, which has stopped occurring as a result of exposure to EX-
tinction, when a new stimulus is presented.
disintegration n. a breakup or severe disorganization of

discussion method a teaching method in which both teacher and students actively contribute to the instructional process through classroom dialogue.
disease n. a definite pathological process with organic origins, marked by a characteristic set of symptoms that may affect the entire body or a part of the body and that impairs functioning.
disease n. a persistent and irrational fear of disease in general or of a particular disease. Fear of disease may be a SPECIFIC PHOBIA or a feature of HYPOCHONDRIASIS or OBSESSIVE-COMPULSIVE DISORDER.
disenfranchised grief grief that society (or some element of it) limits, does not expect, or may not allow a person to express. Examples include the grief of parents for stillborn babies, of teachers for the death of students, and of nurses for the death of patients. People who have lost an animal companion are often expected to keep their sorrow to themselves. Disenfranchised grief may isolate the bereaved individual from others and thus impede recovery. Also called hidden grief. See also GRIEF COUNSELING; GRIEF WORK; MOURNING.
disengaged family a family whose members are mutually withdrawn from each other psychologically and emotionally.
disengagement n. the act of withdrawing from an attachment or relationship or, more generally, from an unpleasant situation. —disengaged adj.
disidentification n. 1. a protective mechanism whereby one removes a potentially harmful characteristic or experience (e.g., one that causes STEREOTYPE THREAT) from one’s self-identity as insulation from anxiety or failure. 2. in meditation, a benign separation from one’s sense of self in order to gain self-knowledge. It is a stepping away from self-identity to attempt to observe oneself objectively.
disincentive n. a deterrent. Specifically, in industrial and organizational psychology, it is any factor that tends to discourage effort or productivity and to lower motivation, such as unpleasant working conditions. See also HYGIENE FACTORS.
disinformation n. PROPAGANDA or false information publicly announced or planted in the news media for the purpose of deception.
dishabituation n. the reappearance of responding, in condi-
tioning experiments, the reappearance of responding, which has stopped occurring as a result of exposure to EX-
tinction, when a new stimulus is presented.
disintegration n. a breakup or severe disorganization of
disjoint sets

some structure or system of functioning, for example, of psychic and behavioral functions.

**disjoint sets** in set theory, two sets that have no elements in common. The intersection of the groups is empty, and they are mutually exclusive. An example of disjoint sets would be the set of all males and the set of all females.

**disjunctive concept** a concept that is based on possession of any one of a set of attributes. For example, the concept people with black hair or brown hair is a disjunctive concept. Compare CONJUNCTIVE CONCEPT. See also FAMILY RESEMBLANCE.

**disjunctive motivation** striving for substitute or temporary (rather than true and lasting) satisfaction. Compare CONJUNCTIVE MOTIVATION. [defined by Harry Stack SULLIVAN]

**disjunctive task** a group task or project, such as solving a complex problem, that is completed when a single solution, decision, or group member’s recommendation is adopted by the group. This means that the group’s performance tends to be determined by the most skilled member. Compare ADDITIVE TASK; COMPENSATORY TASK; CONJUNCTIVE TASK.

**dismissive attachment** an adult attachment style that combines a positive internal working model of attachment of oneself, characterized by a view of oneself as competent and worthy of love, and a negative internal working model of attachment of others, characterized by one’s view that others are untrustworthy or unpredictable. Individuals with dismissive attachment are presumed to discount the importance of close relationships and to maintain rigid self-sufficiency. Compare FEARFUL ATTACHMENT; PREOCCUPIED ATTACHMENT; SECURE ATTACHMENT.

**disorder** n. a group of symptoms involving abnormal behaviors or physiological conditions, persistent or intense distress, or a disruption of physiological functioning. See also MENTAL DISORDER.

**disorder of written expression** in DSM–IV–TR, a LEARNING DISORDER in which writing skills are substantially below those expected for a person’s chronological age, education, and measured intelligence. The writing difficulties—which may involve errors in grammar, punctuation, and paragraph organization, often combined with extremely poor handwriting and spelling errors—significantly interfere with academic achievement and activities of daily living that require writing skills. In DSM–5, the disorder has been subsumed within a category labeled SPECIFIC LEARNING DISORDER and is no longer considered a distinct diagnosis. Also called developmental dysgraphia.

**disorders of excessive somnolence** (DOES) one of four basic types of SLEEP DISORDERS, differentiated from the other types by the presence of excessive sleepiness for at least 1 month. The equivalent classification in DSM–IV–TR is PRIMARY HYPERSONNIA (or in DSM–5, HYPERSONNIA DISORDER). Diagnosis can involve observation in a SLEEP LABORATORY, in which such criteria as nocturnal awakenings, sleep time, sleep efficiency, breathing patterns, percentage of time in STAGE 2 SLEEP, percentage of time in STAGE 3 SLEEP and STAGE 4 SLEEP, minutes of REM SLEEP, and SLEEP LATENCY are measured.

**disorders of the self** in self psychology, narcissistic problems resulting from insufficient response by others (such as parents) to one’s needs. According to this view, an individual’s self-esteem, vitality, and self-efficacy are maintained by the empathic responsiveness of others; lack of this response can lead to deficiences or inabilities in loving other people and to a focus on oneself. [defined by Austrian-born U.S. psychoanalyst Heinz Kohut (1913–1981)]

**disorders of the sleep–wake cycle schedule** one of four basic types of SLEEP DISORDERS, differentiated from the other types in that it results from a mismatch between one’s internal CIRCADIAN RHYTHM and one’s actual sleep schedule. The equivalent classification in DSM–IV–TR is CIRCADIAN RHYTHM SLEEP DISORDER (or in DSM–5, CIRCADIAN RHYTHM sleep–wake disorder). Rotating work-shift schedules and JET LAG are two common causes of this disorder. Diagnosis can involve observation in a SLEEP LABORATORY, in which such criteria as nocturnal awakening, sleep time, sleep efficiency, breathing patterns, body temperature, minutes of REM SLEEP, and SLEEP LATENCY are measured.

**disorganization** n. loss or disruption of orderly or systematic structure or functioning. For example, thought disorganization is an inability to integrate thought processes; behavior disorganization manifests as self-contradictory or inconsistent behavior.

**disorganized attachment** in the STRANGE SITUATION, a form of INSURENC ATTACHMENT in which infants show no coherent or consistent behavior during separation from and reunion with their parents. Also called DISORIENTED ATTACHMENT.

**disorganized behavior** behavior that is self-contradictory or inconsistent. It may include childlike silliness, purposeless behavior, unpredictable agitation, or extreme emotional reaction (e.g., laughing after a catastrophe). A typical example is dressing in clothing inappropriate for the weather (e.g., wearing several layers on a warm summer day). Disorganized behavior is commonly seen in individuals with schizophrenia.

**disorganized development** disruption in the normal course of ATTACHMENT in which a child does not learn how to deal with separation from or reunion with a parent and reacts inconsistently to the parent. See DISORGANIZED ATTACHMENT.

**disorganized offender** the type of offender who approaches his or her crimes in a frenzied and impulsive manner, is typically of low to moderate intelligence and socially withdrawn, and has a poor work history. Compare ORGANIZED OFFENDER.

**disorganized schizophrenia** in DSM–IV–TR, a subtype of schizophrenia characterized primarily by random and fragmented speech and behavior and by flat or inappropriate affect, frequently associated with grimaces, odd or unusual mannerisms, laughter, and extreme social withdrawal. It tends to be the most severe of the schizophrenia subtypes and is often associated with poor premorbid personality and early and insidious onset. This subtype
disposition

has been eliminated from DSM–5. Historically, and in other classifications, it is known as hebephrenia or hebephrenic schizophrenia.

disorganized speech incoherent speech. This may be speech in which ideas shift from one subject to another seemingly unrelated subject, sometimes described as loosening of associations. Other types of disorganized speech include responding to questions in an irrelevant way, reaching illogical conclusions, and making up words. See neurosis; paralogia.

disorientation n. impaired ability to identify oneself or to locate oneself in relation to time, place, or other aspects of one’s surroundings. Long-term disorientation can be characteristic of neurological and psychological disorders; temporary disorientation can be caused by alcohol or drugs or can occur in situations of acute stress, such as fires or earthquakes. See also confusion; topographical disorientation. —disoriented adj.

disoriented attachment see disorganized attachment.

disparate impact see adverse impact.

disparate sensations 1. different sensory or cognitive responses arising from a single object or idea. 2. the bases for thought and perception, which are integrated by the brain into wholes.

dispersal n. the departure of nonhuman animals from their natal group to join a different group or find mates elsewhere. Dispersal is thought to be important in reducing inbreeding and avoiding competition with older individuals of the same sex. Species vary in terms of whether dispersal is male biased or female biased or whether both sexes disperse. It is a costly behavior, because the dispersing individual is more subject to predation as well as to aggression from other members of the same species. See also philopatry.

dispersion n. the degree to which a set of scores deviate from the mean. Also called spread. See also range; standard deviation; variance.

dispersion matrix see covariance matrix.

dispersion measure an index of variability, or how dispersed a set of values is for a given variable. Common measures of dispersion include the range, which is the highest minus the lowest score, and the standard deviation, which is the average distance of scores from the mean. The larger the dispersion measure, the more spread out the scores.

dispersion parameter an index of the skewness (lopsidedness) or kurtosis (peakedness) of a distribution. The normal distribution thus does not need a dispersion parameter as skewness and kurtosis are not present (i.e., equal zero) in such a distribution. Also called scale parameter.

displaced aggression the direction of hostility away from the source of frustration or anger and toward either the self or a different entity. Displaced aggression may occur, for example, when circumstances preclude direct confrontation with the responsible entity because it is perceived as too powerful to attack without fear of reprisal. Compare direct aggression.

displacement n. the transfer of feelings or behavior from their original object to another person or thing. In psychoanalytic theory, displacement is considered to be a defense mechanism in which the individual discharges tensions associated with, for example, hostility and fear by taking them out on a less threatening target. Thus, an angry child might break a toy or yell at a sibling instead of attacking the father; a frustrated employee might criticize his or her spouse instead of the boss; or a person who fears his or her own hostile impulses might transfer that fear to knives, guns, or other objects that might be used as a weapon. See also displaced aggression; drive displacement; scapegoating. —displace v.

displacement behavior a behavior in which an individual substitutes one type of action for another when the first action is unsuccessful or when two competing motivations are present that lead to incompatible actions. A gull at a territory boundary may direct attack-like actions toward the ground rather than its rival due to simultaneous aggressive and fearful responses to the opponent. A laboratory animal that is frustrated by servings of food that are small and delivered slowly may express displacement behavior by drinking instead of eating. Also called displacement activity.

displacement of affect see transposition of affect.

display n. 1. the presentation of stimuli to any of the senses. 2. more or less stereotyped actions (i.e., actions repeated with little variation) that bring about a response in another individual: an integral part especially of animal communication. Display behavior may be a physical or vocal signal, usually involving stimulation of the visual or auditory senses. It may include body language that would convey a message of courtship to a member of the opposite sex (e.g., a show of plumage or color) or a suggestion that would be interpreted by an opponent as threatening (e.g., bared teeth or hissing noises). Because of their stereotyped nature, displays are thought to have evolved from physiological or behavioral responses to previously direct interactions that have now become symbolic. For example, a human being may be flustered when aggressive or pale when fearful due to vasodilation or vasoconstriction associated with attack or avoidance. These vascular changes have now become predictive of the behavior likely to follow and serve as communication signals. See also display rule.

display–control compatibility in ergonomics, a design principle stating that controls and their corresponding displays should be compatible on such dimensions as direction of movement, color, and location or alignment. See also control function logic; proximity compatibility.

display design in ergonomics, the design of displays for effective transmission of information in different situations. Displays may be static devices (such as signs, labels, and diagrams) or dynamic devices (such as speedometers, clocks, and temperature gauges). The information conveyed may include directions and instructions, safety messages and alerts, and fluctuating information about the state of a particular system (e.g., speed, volume, or temperature). See bar display; object display; integrated display; separated display. See also display–control compatibility.

display rule a socially learned standard that regulates the expression of emotion. Display rules vary by culture; for example, the expression of anger may be considered appropriate in some cultures but not in others. [coined in 1972 by U.S. psychologist Paul Ekman (1934– )]

disposition n. a recurrent behavioral, cognitive, or affec-
dispositional attribution

tive tendency that distinguishes an individual from others. See also PERSONAL DISPOSITION.

**dispositional attribution** the ascription of one’s own or another’s actions, an event, or an outcome to internal or psychological causes specific to the person concerned, such as traits, moods, attitudes, decisions and judgments, abilities, or effort. Also called *internal attribution; personal attribution*. Compare SITUATIONAL ATTRIBUTION.

**dispositional hearing** a proceeding held in juvenile court cases after the court finds that an offense has been committed. It is similar to the sentencing hearing or penalty phase in an adult criminal court.

**disruptive behavior** behavior that chronically threatens and intimidates others or violates social norms. The term is typically applied to the behavior of children, but it can also be used to describe adult behavior.

**disruptive behavior disorder** a set of disorders in which the primary symptom (e.g., violation of social rules and rights of others, defiance, hostile behavior) is severe enough to produce significant impairment in social or occupational functioning. In DSM–IV–TR, disruptive behavior disorders include CONDUCT DISORDER, OPPOSITIONAL DEFiant DISORDER, and disruptive behavior disorder not otherwise specified (i.e., a pattern of behavior, such as aggression or defiance, that results in clinically significant impairment but does not conform to the full diagnostic criteria of the other disorders in this category). DSM–5 uses the rubric disruptive, impulse-control, and conduct disorders to encompass conditions characterized by problems with behavioral and emotional self-control, including not only conduct and oppositional defiant disorders but also INTERMITTENT EXPLOSIVE DISORDER, PYROMANIA, and KLEPTOMANIA, among others. It also includes in this category ANTISOCIAL PERSONALITY DISORDER, cross-listing it under the category for personality disorders.

**disruptive mood dysregulation disorder** in DSM–5, a new diagnosis in children 18 years or younger with persistent irritability and an average of at least three episodes per week of extreme behavioral dyscontrol (e.g., severe rages). It has been established as an alternative to the diagnosis of BIPOLAR DISORDER in children.

**disrupt-then-reframe technique** a persuasion technique for enhancing COMPLIANCE in which one uses an odd request to surprise or confuse another person before following up with a new framing of the same request. In the original investigations of this technique, sellers offered potential buyers a set of note cards for 300 pennies (the odd request) and then broke in on the buyers’ confusion about the price in pennies with a reframed pitch (“that’s $3. It’s a bargain”). The studies reported that nearly twice as many people bought the cards after experiencing the disrupt-and-reframe approach as did those who received only a standard pitch in which the cards were offered for $3. [introduced by U.S. psychologists Barbara Price Davis and Eric S. Knowles (1941– )]

**dissent** n. 1. disagreement with majority opinion or established social norms. 2. disagreement with government policies, especially as expressed through organized protests or social ACTIVISM. See also CIVIL DISOBEDIENCE; PASSIVE RESISTANCE. —dissenter n.

**dissimilarity coefficient** an index of difference or distance between two objects, variables, or samples. It may be based on CORRELATION, with lower values indicating more difference or distance, or VARIANCE, with higher values indicating greater difference or distance. A dissimilarity coefficient often is used in multivariate procedures such as CLUSTER ANALYSIS, MULTIDIMENSIONAL SCALING, and PRINCIPAL COMPONENTS ANALYSIS. Also called distance measure. Compare SIMILARITY COEFFICIENT.

**dissociated learning** see STATE-DEPENDENT LEARNING.

**dissociated state** a reaction to a traumatic event in which the individual splits the components of the event into those that can be faced in the present and those that are too harmful to process. See also DISSOCIATIVE DISORDER.

**dissociation** n. 1. a DEFENSE MECHANISM in which conflicting impulses are kept apart or threatening ideas and feelings are separated from the rest of the psyche. See COMPARTMENTALIZATION. 2. in research, a method used to differentiate processes, components, or variables. For instance, it might involve discovering a variable that influences short-term memory but not long-term memory. See DOUBLE DISSOCIATION.

**dissociative amnesia** in DSM–IV–TR and DSM–5, a DISSOCIATIVE DISORDER characterized by failure to recall important information about one’s personal experiences, usually of a traumatic or stressful nature, that is too extensive to be explained by normal forgetfulness. Recovery of memory often occurs spontaneously within a few hours and is usually connected with removal from the traumatic circumstances with which the amnesia was associated. Formerly called *psychogenic amnesia*. See also FUNCTIONAL AMNESIA.

**dissociative anesthetic** an agent capable of producing amnesia, analgesia, and sedation without inducing loss of consciousness. PCP and KETAMINE were formerly used as dissociative anesthetics.

**dissociative barriers** the psychological mechanisms that prevent individuals from fully remembering a traumatic event. The trauma is presumed to be implicated in the development of a dissociative disorder, and the barriers are theorized to serve a protective function, allowing the traumatized person to avoid knowledge of horrific life events.

**dissociative disorders** any of a group of disorders characterized by a sudden or gradual disruption in the normal integrative functions of consciousness, memory, or perception of the environment. Such disruption may last for minutes or years, depending on the type of disorder. Some of the disorders typically included in this category are DISSOCIATIVE AMNESIA, DISSOCIATIVE FUGUE, DISSOCIATIVE IDENTITY DISORDER, and DEPERSONALIZATION DISORDER.

**dissociative fugue** in DSM–IV–TR, a DISSOCIATIVE DISORDER in which the individual suddenly and unexpectedly travels away from home or a customary place of daily activities and is unable to recall some or all of his or her past. Symptoms also include either confusion about personal identity or assumption of a new identity. No other signs of mental disorder are present, and the fugue state can last from hours to months. Travel can be brief or extended in duration, and there may be no memory of travel once the individual is brought back to the prefugue state. DSM–5 subsumes dissociative fugue as a feature that may or may not occur with DISSOCIATIVE AMNESIA rather than as a separate diagnosis.

**dissociative group** a group with which one wishes not to be associated. Compare ASPIRATIONAL GROUP.
dissociative hysteria a former name for a dissociative disorder.

dissociative identity disorder (DID) a dissociative disorder characterized by the presence in one individual of two or more distinct identities or personality states that each recurrently take control of the individual’s behavior. It is believed to be associated with severe physical and sexual abuse, especially during childhood. Despite an increase in reported cases in the United States since the 1970s, DID remains the subject of considerable controversy, with many disputing its validity as a diagnosis and citing the incidences of childhood abuse reported by diagnosed individuals or their therapists as cases of false memory. DID is still commonly known as multiple personality disorder, a coinage usually attributed to U.S. physician Morton Prince (1854–1929), whose case history of his patient “Miss Beuchamp” (with personalities called Christine, Sally, and “the Idiot,” among other names) was one of the first in-depth examinations of the phenomenon, published in The Dissociation of Personality in 1906. Subsequent case histories, especially the books The Three Faces of Eve (1957) and Sybil (1973) and their film adaptations, contributed to popularizing—some say sensationalizing—the phenomenon during the late 20th century. See also split personality.

dissociative pattern a pattern of behavior consistent with dissociative disorders, as evidenced by disruption in the normal integrative functions of consciousness, memory, or perception of the environment.

dissociative psychosis see hysterical psychosis.

dissociative stupor a profound decrease in or absence of voluntary movement and responsiveness to external stimuli, apparently resulting from acute stress.
