dissociative trance disorder a dissociative disorder characterized by involuntary alterations in consciousness, identity, awareness or memory, and motor functioning that result in significant distress or impairment. The two subtypes of the disorder are distinguished by the individual’s identity state. In possession trance, the individual’s usual identity is replaced by a new identity perceived to be an external force, such as a ghost, another person, or a divine being, and there is loss of memory for the episode of trance. In trance disorder, individuals retain their usual identity but have an altered perception of their milieu. These types of dissociative experiences are common in various cultures and may be part of customary religious practice; they should not be regarded as pathological unless considered abnormal within the context of that cultural or religious group. Also called possession trance disorder; trance and possession disorder (TPD).

dissociation n. see cognitive dissociation.

dissociation reduction the process by which a person reduces the uncomfortable psychological state that results from inconsistency among elements of a cognitive system (see cognitive dissociation). Dissociation can be reduced by making one or more inconsistent elements consistent with other elements in the system, by decreasing the perceived importance of an inconsistent element, or by adding new consistent elements to the system. Finally, self-affirmation theory postulates that merely affirming some valued aspect of the self, even if it is not directly relevant to the inconsistency, can reduce dissociation. See also bolstering of an attitude; forced compliance effect.

distal adj. 1. situated or directed toward the periphery of the body or toward the end of a limb. 2. remote from or mostly distantly related to the point of reference or origin. Compare proximal.

distal effect any influence that particular responses of an organism may have on the environment.

distal 18q- see chromosome 18, deletion of long arm.

distal response a response of an organism that produces an effect in the environment. Compare proximal response.

distal stimulus in perception, the actual object in the environment that stimulates or acts on a sense organ. Compare proximal stimulus.

distance n. the disparity between two values or entities. In statistics, the term often refers to the difference or deviation between a raw score and a mean score.

distance cue any of the auditory or visual cues that enable an individual to judge the distance of the source of a stimulus. Auditory distance cues include intensity of familiar sounds (e.g., voices), intensity differences between the ears, and changes in spectral content. In vision, distance cues include the size of familiar objects and accommodation. See also depth cue.

distance learning the process of acquiring knowledge in a location remote from the teaching source. Distance learning may occur via correspondence coursework, coursework presented over radio or television, computerized software programmed learning, coursework programmed and accessible on the Internet, live Internet hook-up to an instructor, direct live remote television, and live group videoconferencing. Also called distance education.

distance measure see dissimilarity coefficient.

distance paradox see size–distance paradox.

distance perception the ability of a viewer to judge the distance between him- or herself and a visual target. See also depth cue.

distance therapy any type of psychotherapy in which sessions are not conducted face to face because of problems of mobility, geographical isolation, or other limiting factors. Distance therapy includes interventions by telephone, audioconference, or videoconference (known collectively as telepsychotherapy) and the Internet (see t-therapy).

distance vision vision that permits discrimination of objects more than 6 m (20 ft) from the observer.

distance zone the area of physical distance commonly adopted between interacting individuals. Interpersonal distances can be influenced by culture and tend to be relatively small when people are familiar with each other and larger in formal or impersonal interactions. See intimate zone; personal distance zone; public distance zone; social zone. See also proxemics.

distinctiveness effect the finding that people tend to have superior memory for odd or unusual information. The most cited example is the von Restorff effect, originally proposed in 1933 by German psychologist Hedwig von Restorff (1906–1962). Also called the isolation effect or Restorff phenomenon, it refers specifically to superior memory for isolated items. For instance, if most of the words in a list are printed in blue ink, one word printed in red will be better remembered than the blue words; the isolated item is odd only with respect to its immediate con-
distinctness

— that is, it is the only member of a category (because it is printed in a different color than the other items in the list). By contrast, other types of distinctiveness effects occur when an item is distinct with respect to general knowledge. They include, among others, the bizarreness effect (superior memory for offbeat images or sentences as compared to common images or sentences) and the orthographic distinctiveness effect (superior memory for words with unusual letter combinations, as in subpoena, compared to words with more typical letter combinations, as in bookcase).

distinctness n. 1. the quality of being perceived clearly and as separate from other stimuli that is characteristic of an object upon which attention is focused. 2. in tasks requiring selective attention, the extent to which the target is different from distractor stimuli. Performance on selective attention tasks is better when the target is distinct from the distractors.

distorted speech test a test used to evaluate auditory and perceptual processing problems. In such tests, certain elements of the acoustic signal are removed. Examples are filtered speech and time-compressed speech.

distorting-photograph procedure a procedure for assessing body-size perception that asks individuals to indicate their size by adjusting a photographic self-image so that it appears within a range of 20% over or under their actual size. Discrepancy between the body size in the selected image and that in an accurate image is used as an index of perceptual distortion of body size.

distortion n. 1. any inaccuracy of perception, cognition, memory, and so forth, 2. either the unconscious process of altering emotions and thoughts that are unacceptable in the individual’s psyche or the conscious misrepresentation of facts, which often serves the same underlying purpose of disguising that which is unacceptable to or in the self. 3. in psychoanalytic theory, the outcome of the dream-work that modifies forbidden thoughts and wishes to make them more acceptable to the ego. Such distortion of the dream wish through the use of substitutes and symbols means that only an act of interpretation can uncover the true meaning of the dream.

distractibility n. difficulty in maintaining attention or a tendency to be easily diverted from the matter at hand. Excessive distractibility is frequently found in children with learning disorders or attention-deficit/hyperactivity disorder and in people experiencing manic or hypomanic episodes.

distractible speech a speech pattern in which the individual shifts rapidly from topic to topic in response to external or internal stimuli. It is a common symptom in mania. See also flight of ideas.

distraction n. 1. the process of interrupting attention. 2. a stimulus or task that draws attention away from the task of primary interest.

distractor n. a stimulus or an aspect of a stimulus that is irrelevant to the task or activity being performed. In memory studies, an item or task may be used as a distractor before the participant attempts to recall the study material to be remembered; the distractor minimizes the participant’s rehearsal of the material and ensures that it is not currently stored in working memory. For instance, the participant might be given some arithmetic problems to solve as a distractor task between the study and recall phases of an experiment. See also visual attention.

distractor task see brown–peterson distractor technique: distractor.

distress n. 1. the negative stress response, often involving negative affect and physiological reactivity; a type of stress that results from being overwhelmed by demands, losses, or perceived threats. It has a detrimental effect by generating physical and psychological maladaptation and posing serious health risks for individuals. This generally is the intended meaning of the word stress. Compare eustress. 2. a negative emotional state in which the specific quality of the emotion is unspecified or unidentifiable. For example, stranger distress because the infant’s negative behavior, typically crying, allows no more specific identification of the emotion. —distressing adj.

distress tolerance the level of either (a) one’s unwillingness to experience emotional distress as part of pursuing desired goals or (b) one’s inability to engage in goal-directed behaviors when experiencing distress. Low distress tolerance is related to a range of disorders, including borderline personality disorder, substance abuse, and eating disorders; some treatments (e.g., dialectical behavior therapy) are designed in part to raise an individual’s level of distress tolerance by habituating him or her to the experience of adapting to distress and other negative emotions.

distributed actions theory a model of leadership that assumes that group effectiveness and member satisfaction increase when certain key functions of a leader, such as decision making, task orientation, initiating structure, and the improvement of intermember relations, are not the sole responsibility of the leader but are instead distributed throughout the group. See also leadership theories: participative leadership.

distributed attention see spatial attention.

distributed cognition a model for intelligent problem solving in which either the input information comes from separated and independent sources or the processing of this input information takes place across autonomous computational devices. Agent-based problem solving is sometimes described as distributed cognition.

distributed knowledge see distributed representation.

distributed practice a learning procedure in which practice periods for a particular task are separated by lengthy rest periods or lengthy periods of practicing different activities or studying other material, rather than occurring close together in time. In many learning situations, distributed practice is found to be more effective than massed practice. Also called spaced learning: spaced practice. See also spacing effect.

distributed-practice effect see spacing effect.

distributed processing information processing in which computations are made across a series of processors or units, rather than being handled in a single, dedicated central processor. See also parallel distributed processing: parallel processing.

distributed representation in information processing, a system of representation in which information pertaining to a given unit of knowledge is carried by many
separate components of the system, rather than being stored together as a single entity.

**distribution** n. the relation between the values that a variable may take and the relative number of cases taking on each value. A distribution may be simply an empirical description of that relationship or a mathematical (probabilistic) specification of the relationship. For example, it would be helpful in examining the distribution of scores for a college exam to view the frequency of students who achieved various percentages correct on the exam. In a normal distribution, most of the scores would fall in the middle (i.e., about 70% correct or a score of C), with fewer students achieving a D (i.e., 60%–69% correct) or a B (i.e., 80%–89% correct) and even fewer earning 59% or less (i.e., an F) or 90% to 100% (e.g., an A). See also frequency distribution; probability distribution.

**distributional redundancy** in psychological aesthetics, the development of uncertainty in an artistic pattern by making some elements occur more frequently than others. Distributional redundancy is one of two kinds of internal restraint in pattern variation, the other being correlational redundancy, in which certain combinations of elements are made to occur more frequently than others.

**distribution-free test** see nonparametric test.

**distribution function** see cumulative distribution function.

**distributive analysis and synthesis** an approach to psychotherapy that developed within psychobiology. In the first stage, a systematic analysis is made from information gained from the client about past and present experience and distributed into such categories as symptoms and complaints, assets and liabilities, and pathological or immature reactions. In the second stage, this study is used as a prelude to a constructive synthesis built on the client’s own strengths, goals, and abilities. [developed by Adolf Meyer]

**distributive bargaining** a form of bargaining seen in adversarial situations in which the parties involved must allocate limited resources, such that one party’s gain necessarily entails the other’s loss. The parties make demands of each other by indicating their preferred outcomes, using such contentious tactics as threats and arguments, and insist that they remain committed to their positions. Also called competitive bargaining. Compare integrative bargaining.

**distributive justice** 1. the belief that rules can be changed and punishments and rewards distributed according to relative standards, specifically according to equality and equity. In the equality stage (ages 8 to 10), children demand that everyone be treated in the same way. In the equity stage (ages 11 and older), children make allowances for subjective considerations, personal circumstances, and motive. Compare immanent justice. [postulated by Jean Piaget] 2. see organizational justice.

**disturbance of association** interruption of a logical chain of culturally accepted thought, leading to apparently confused and haphazard thinking that is difficult for others to comprehend. It is one of the fundamental symptoms of schizophrenia described by Eugen Bleuler. See also schizophrenic thinking; thought disorder.

**disturbance term** see error term.

**disulfiram** n, a drug used as an aversive agent in managing alcohol abuse or dependence. Disulfiram inhibits the activity of acetaldehyde dehydrogenase, an enzyme responsible for the metabolism of alcohol (ethanol) in the liver. Consumption of alcohol following administration of disulfiram results in accumulation of acetaldehyde, a toxic metabolic product of ethanol, with such unpleasant effects as nausea, vomiting, sweating, headache, a fast heart rate, and palpitations. Because of the serious nature of some of these effects (which can include damage to the liver and heart), informed consent is required before use of disulfiram. Disulfiram by itself is rarely effective in managing alcoholism and should be administered only in concert with a carefully designed behavioral regimen. U.S. trade name: Antabuse.

**disuse supersensitivity** a condition in which target cells, on losing neural input through either denervation or chronic application of an antagonist drug, produce more than the normal number of receptor molecules, resulting in an exaggerated response when a neurotransmitter is applied. When this condition results from denervation, it is also called denervation sensitivity.

**disuse theory of aging** the theory that some decline in psychological abilities with aging may be due to the lack of use of those abilities. According to this theory, as adults grow older, they engage their minds less and less with the types of tasks that are found on most psychological tests, particularly tests assessing cognitive functioning.

**disynaptic arc** a neural arc in which there is an interneuron between a sensory neuron and a motor neuron, requiring a neural signal to cross two synapses to complete the arc. See also reflex arc.

**diuretic** n. a substance that increases the flow of urine. Diuretics may be endogenous agents (e.g., dopamine) or prescription or nonprescription drugs (e.g., thiazide diuretics). Many diuretics (including thiazides) work by inhibiting or blocking the reabsorption of sodium and potassium ions from the kidney filtrate, so that less water is reabsorbed across the kidney tubules. Others, called osmotic diuretics, increase the osmolality of the filtrate. Both mechanisms result in increased urine volume. Some diuretics may produce adverse effects with psychological implications, for example, lassitude, weakness, vertigo, sexual impotence, headaches, polydipsia (intense thirst), irritability, or excitability.

**diurnal adj.** 1. daily; that is, recurring every 24 hours. See biological clock; circadian rhythm. 2. occurring or active during daylight hours. Compare nocturnal. —diurnality n.

**diurnal enuresis** see enuresis.

**diurnal mood variation** a feature of some bipolar disorders and depressive disorders in which daily, predictable emotional fluctuations occur. Typically, this pattern consists of an elevation of mood during the daytime and evening hours and a depression of mood during the overnight and morning hours. See also seasonal affective disorder.

**diurnal rhythm** see circadian rhythm.

**divagation** n. rambling, digressive speech, writing, or thought. See also disorganized speech.

**divalproex sodium** an anticonvulsant drug, derived from valproic acid, originally used in the treatment of absence seizures and now used primarily for the stabilization of mania and for prophylaxis in individuals with bipolar
As a helpful assistant, I can provide the natural text representation of the document you've shared.

**divergence**

Disorder. It has also been used in the treatment of various other conditions, including autism, migrainous neuralgia and other forms of headache, other chronic pain syndromes, and mood symptoms associated with borderline personality disorder. Liver damage and reduction in blood platelets (thrombocytopenia) may occur with use of the drug, so blood count and liver function should be monitored, particularly in the early course of treatment and particularly in children, as most fatalities due to liver failure have occurred in children. Because of its possible association with NEURAL TUBE defects, divalproex sodium should not be prescribed during pregnancy. The drug has significant interactions with antidepressants, antipsychotics, anxiolytics, and numerous other classes of medication. U.S. trade name: Depakote.

**divergence** *n.* the rotation of the two eyes outward when shifting fixation from a nearby target object to one that is far away. A permanent divergence of one eye is termed EXOTROPIA. See also VERGENCE. —**divergent** adj.

**divergent evolution** the process by which populations become increasingly different from each other through different SELECTION PRESSURES acting in different habitats. Divergent evolution is a major way in which new species are formed. It contrasts with CONVERGENT EVOLUTION, in which different species become more similar to each other through adaptation to similar habitats.

**divergent production** the capacity to produce novel solutions to a problem. It is one of the abilities recognized in the STRUCTURE OF INTELLECT MODEL. Compare CONVERGENT PRODUCTION.

**divergent strabismus** see EXOTROPIA; STRABISMUS.

**divergent thinking** creative thinking in which an individual solves a problem or reaches a decision using strategies that deviate from commonly used or previously taught strategies. This term is often used synonymously with LATERAL THINKING. Compare CONVERGENT THINKING. [defined in 1967 by Joy Paul Guilford]

**divergent validity** see DISCRIMINANT VALIDITY.

**diversion program** a program that may be available in some circumstances for individuals, especially juveniles and young adults, who have been arrested for the first time or for certain crimes. After the defendant has been formally charged with a crime and has entered a plea, he or she may be sent to a diversion program (e.g., for drug treatment) instead of proceeding to trial; the charges are dropped or reduced if the individual successfully completes the program. Under federal sentencing guidelines, a diversion program for adults counts as a sentence if the defendant pleaded guilty, whereas juveniles who have successfully completed diversion programs do not have their crimes included in their permanent record. In deferred prosecution, individuals may be required to complete the same types of programs (e.g., alcohol treatment, community service), but they are granted a conditional amnesty by the prosecutor before they enter a plea; if they do not complete the agreed-upon programs, they return to court for a trial and sentencing for the original crime, but if they do, the charges are dropped and are not made part of the defendant’s police record.

**diversity** *n.* the wide range of variation of living organisms in an ecosystem. When describing people and population groups, diversity can include such factors as age, gender, sexuality, race, ethnicity, nationality, and religion, as well as education, livelihood, and marital status. See CULTURAL DIVERSITY.

**diversity training** personnel training programs that help employees to appreciate and deal effectively with cultural, ethnic, racial, gender, sexual orientation, and other differences among people.

**diversive exploration** EXPLORATORY BEHAVIOR used as a means of seeking novel or otherwise activating stimuli and thus increasing arousal. Compare INSPECTIVE EXPLORATION. [defined by Daniel E. Berlyne]

**divided attention** attention to two or more channels of information at the same time, so that two or more tasks may be performed concurrently. It may involve the use of just one sense (e.g., hearing) or two or more senses (e.g., hearing and vision).

**divided brain** see SPLIT BRAIN.

**divided consciousness** Ernest R. Hilgard’s characterization of DISSOCIATION as a state in which one stream of mental activity (e.g., perception, memory, planning) proceeds outside of phenomenal awareness and apparently outside of voluntary control. In his NEODISSOCIATION THEORY, Hilgard proposed that this state could be best studied through HYPONOSIS. See also COCONSCIOUSNESS; UNITY OF CONSCIOUSNESS.

**divination** *n.* the purported art or practice of discerning future events or hidden knowledge by supernatural means. The numerous forms of divination include ASTROLOGY, ALCURY, CRYSTAL GAZING, LECANOMANCY, NECROMANCY, NUMEROLOGY, ONEROMANCY, PALMISTRY, and RHABDOMANCY. —**divinatory** adj. —**divine** vb.

**divine right** the theory or presumption that monarchs derive their authority to govern directly from God and not from the governed or any entity representative of them. The theory saw its heyday under the reigns of the English kings James I (1603–1625) and Charles I (1625–1649) and the French king Louis XIV (1643–1715). Also called divine right of kings. See also SOCIAL CONTRACT.

**diviner’s sage** see SALVIA.

**divorce** *n.* the legal dissolution of marriage, leaving the partners free to remarry. Divorce may significantly influence well-being, with many individuals experiencing depression, loneliness and isolation, self-esteem difficulties, or other psychological distress. Parental divorce also has been shown to have negative consequences on the psychosocial adjustment of children and adolescents. See also EMOTIONAL DIVORCE; MATEIAL SEPARATION. —**divorcee** *n.*

**divorce counseling** counseling provided to individuals and their family members to help them cope with the problems resulting from divorce. In either family or individual sessions, family members may be encouraged to let go of the past and learn to deal with their present emotions. Spouses seen either individually or together may explore what their own contributions to the breakup may have been, so as to decrease blame and increase the probability that they can interact effectively in the future.

**divorce mediation** counseling aimed at resolving issues for couples facing separation or divorce. The mediator remains impartial while assisting in negotiations to come to an agreed settlement over such issues as financial arrangements, child custody and visitation, and child support. Divorce mediation attempts to avoid confrontation and undue litigation prior to final settlement.
dizygotic twins (DZ twins) twins, of the same or different sex, that have developed from two separate ova fertilized by two separate sperm. DZ twins are genetically as much alike as ordinary full siblings born as SINGLETONS, with each individual inheriting a random half of each parent’s genes. On average, DZ twins are approximately half as genetically similar to one another as MONOZYGOTIC TWINS. For every 1,000 pregnancies, there are, on average, 7 to 12 DZ twins. Also called fraternal twins. See also TWIN STUDY.

dizziness n. a sensation of light-headedness or unsteadiness, sometimes with nausea and a fear of fainting. See VERTIGO.

D–KEFS abbreviation for DELIS–KAPLAN EXECUTIVE FUNCTION SYSTEM.

DL abbreviation for difference limen. See DIFFERENCE THRESHOLD.

D-love n. see DEFICIENCY LOVE.

dlPFC abbreviation for DORSOLATERAL PREFRONTAL CORTEX.

DMN 1. abbreviation for DEFAULT-MODE NETWORK. 2. abbreviation for DORSOMEDIAL NUCLEUS.

dMRI abbreviation for DIFFUSION MAGNETIC RESONANCE IMAGING.

DMS abbreviation for DIACRITICAL MARKING SYSTEM.

DMT dimethyltryptamine: a HALLUCINOGEN belonging to the indolealkylamine family, to which LSD, PSilocin, and DET also belong.

DMTS abbreviation for DELAYED MATCHING TO SAMPLE.

DNA deoxyribonucleic acid: one of the two types of NUCLEIC ACID found in living organisms; it is the principal carrier of genetic information in chromosomes and, to a much lesser extent, in MITOCHONDRIA. Certain segments of the DNA molecules constitute the organism’s genes. Structurally, DNA consists of two intertwined, helically coiled strands of nucleotides—the double helix. The nucleotides each contain one of four bases: adenine, guanine, cytosine, or thymine. Each base forms hydrogen bonds with the adjacent base on the other, sister strand, producing consecutive base pairs arranged rather like the “rungs” on a helical ladder. Adenine (A) is always paired with thymine (T), and guanine (G) with cytosine (C). DNA can undergo self-replication in such a way that each strand serves as the template for the assembly of a complementary matching strand, resulting in two molecules exactly like the original helix in terms of base pairing. The sequence of bases in the DNA of genes contains information according to the GENETIC CODE. Each gene specifies the manufacture of a particular protein or ribosome. Because of DNA’s ability to conserve its base sequence when replicating, the genetic instructions it carries are also conserved, both during cell division within a single organism and for that organism’s offspring following reproduction. Compare RNA. See also RECOMBINANT DNA.

DNA methylation an epigenetic mechanism that involves the addition of a methyl group to the cytosine or adenine bases of DNA and that suppresses expression of particular genes under particular circumstances. It is crucial in normal cellular development and differentiation. Errors in DNA methylation have been associated with cancer and other diseases. See EPIGENETICS.

DNR abbreviation for do not resuscitate. See ADVANCE DIRECTIVE; INFORMED CONSENT.

docility n. the state of being passive or calm, easy to handle, or unlikely to attack. Docility can be induced in a strain of animals through selective breeding but may also occur as part of natural variation within a population. —docile adj.

doctor shopping visiting a number of different physicians in an attempt to obtain prescriptions for a drug or drugs that one abuses.

doctrine n. a teaching, dogma, or tenet of a system of belief or a body of such teachings. —doctrinal adj.

doctrine of causes the belief of ARISTOTLE that causality of an object had four different modes or types—formal, final, material, and efficient—corresponding roughly to its form, its goal, the substance of which it was made, and the work done to produce it.

doctrine of double effect (DDE) see PRINCIPLE OF DOUBLE EFFECT.

doctrine of formal discipline a pedagogical theory, now discredited, that was based on the old idea that the mind is divided into general faculties (e.g., reasoning, memory, attention) that, like muscles, could be strengthened through exercise. Training that strengthened a particular faculty was thought to benefit performance on any task that relied on that faculty. For example, students memorized texts and poems because training in memorization, regardless of the content, was thought to increase general memory capacity. See also TRANSFER OF TRAINING.

Doerfler–Stewart test a test originated during World War II for screening for functional hearing loss. It is used to examine a person’s ability to respond to selected two-syllable words in quiet and in the presence of a MASKING noise. [Leo G. Doerfler (1919–2004), U.S. audiologist; J. P. Stewart]

DOES acronym for DISORDERS OF EXCESSIVE SOMNOLENCE.

dogmatism n. 1. the tendency to act in a blindly certain, assertive, and authoritative manner in accordance with a strongly held set of beliefs. 2. a personality trait characterized by this tendency. The belief system of such an individual is strongly held and resistant to change. Nevertheless, it often contains elements that are isolated from one another and thus may contradict one another. See ROKEACH DOGMATISM SCALE. [first proposed by U.S. psychologist Milton Rokeach (1918–1988)] —dogmatic adj.

dol n. a unit of pain sensation. One dol equals twice the threshold value.

dolichocephalic adj. see CEPHALIC INDEX. —dolicocephaly n.

dolichomorphic adj. denoting a body that is tall and thin. —dolichomorphy n.

doll play in PLAY THERAPY, the use of dolls and figurines, which may represent individuals familiar to the child, to facilitate the expression of feelings, to enact stories that express emotional needs, or to reveal significant family relationships. Also called PROJECTIVE DOLL PLAY.

Dolophine n. a trade name for METHADONE.

dolorimeter n. a device for the measurement of pain. —dolorimetry n.

DOM dimethylxenmethamphetamine: a synthetic HALLU-
domain

CINOGEN that is also called STP for serenity, tranquility, and peace, which the substance is said to induce. It is a member of the phenylisopropylamine family, to which MDMA and MDA also belong.

domain n. 1. the class of events or entities that constitutes the subject matter of a science or other discipline. 2. a field of mastery, dominance, or endeavor. 3. in Biological taxonomy, the highest category used in some classification systems, comprising one or more kingdoms. Three domains are recognized: Archaea (archaebacteria), Bacteria, and Eukarya (including animals, plants, fungi, and protists). 4. in set theory, the set of elements over which a function is defined.

domain-free problem in the literature on problem solving, a problem that can be solved without knowledge of a particular content domain, such as mathematics or science.

domain-general ability a cognitive ability, such as general intelligence or speed of information processing, that influences performance over a wide range of situations and tasks. Compare DOMAIN-SPECIFIC ABILITY.

domain identification the process by which individuals tacitly form a relationship between themselves and some field or pursuit, such as the academic, occupational, or athletic domain. Identification with the academic domain, for example, occurs for adolescents who value the rewards offered by success in educational settings, who feel they have the skills and resources needed in school, and who feel that others value achievements in this domain.

domain-referenced test an assessment that covers a specific area of study such that a score will reveal how much of this area has been mastered. This is similar to a criterion-referenced test, in which a content area is mapped and scores reflect whether a particular standard or criterion has been achieved. Thus, if an individual got 90% of the items correct in a domain-referenced or criterion-referenced test, this would be a high score indicative of his or her deep knowledge and understanding of the content covered in the test. These kinds of tests are contrasted with norm-referenced tests, in which scores indicate how well a test taker performed on the items relative to others who took the test.

domain-specific ability a cognitive ability, such as face recognition, that is specific to a task and under control of a specific function of the mind, brain, or both. Compare DOMAIN-GENERAL ABILITY.

domain-specific knowledge specialized knowledge of a topic, such as knowledge of chess, baseball, or music.

domestication n. the selective breeding of animals so that they can live in close association with human beings. All domestic livestock, as well as pets and laboratory mice and rats, have been selectively bred to exhibit features that allow close association with human beings, typically by becoming more docile and less aggressive than wild animals.

—domesticate vb.

domestic partnership two people who live together in a stable, intimate relationship and share the responsibilities of a household in the same way that a married couple would. Some states and countries in the United States and some other countries provide legal and economic rights to domestic partners (e.g., insurance and death benefits) that are similar to those granted to married couples. See COMMON-LAW MARRIAGE; SAME-SEX MARRIAGE.

domestic violence any action by a person that causes physical harm to one or more members of his or her family unit. For example, it can involve battering of one partner by another (partner abuse), violence against children by a parent, or violence against elders by younger family members. See also BATTERED WOMEN; CHILD ABUSE; ELDER ABUSE; INTIMATE PARTNER VIOLENCE.

domiciliary care inpatient institutional care provided because care in the individual’s home is not available or not suitable. See also RESIDENTIAL CARE.

dominance n. 1. the exercise of influence or control over others. Compare SUBMISSION. See also ANIMAL DOMINANCE. 2. an older term for the tendency for one hemisphere of the cerebral cortex to exert greater influence than the other over certain key functions, such as speech production or manual tasks. Also called hemispheric dominance: lateral dominance. See HEMISPHERIC LATERALIZATION. 3. in genetics, the ability of one allele to determine the phenotype of a heterozygous individual. See DOMINANT ALLELE. —dominant adj.

dominance aggression a form of aggression in non-human animals that involves one individual maintaining a higher status over another through threats or actual attacks. See ANIMAL DOMINANCE.

dominance hierarchy 1. a system of stable linear variations in prestige, status, and authority among group members. It is the pecking order of the group, which describes who is influential and who submits to that influence. See also STATUS RELATIONS. 2. any ordering of motives, needs, or other psychological or physical responses based on priority or importance. An example is Maslow’s motivational hierarchy.

dominance need the need to dominate, lead, or otherwise control others. It is motivated by the desire for power, knowledge, prestige, or creative achievement. [proposed by Henry Alexander Murray]

dominance–submission a key dimension of interpersonal behavior, identified through factor analysis, in which behavior is differentiated along a continuum ranging from high dominance (active, talkative, extraverted, assertive, controlling, powerful) to high subordination (passive, quiet, introverted, submissive, weak). Also called ascendance–submission.

dominance–subordination a form of social relationship within groups with a leader or dominant member who has priority of access to resources over other subordinate members of the community. Among nonhuman animals, dominance–subordination relationships are highly organized in troops of baboons, in which dominant males have more access to food resources and mates than do subordinate males and all males often appear to have dominance over females. In hyena groups, the relationship is reversed, with males subordinate to females.

dominant allele the version of a gene (see ALLELE) whose effects are manifest in preference to another version of the same gene (the recessive allele) when both are present in the same cell. Hence, the trait determined by a dominant allele (the dominant trait) is apparent even when the allele is carried on only one of a pair of homologous chromosomes. The term autosomal dominant is used to describe this pattern; for example, Huntington’s disease is an autosomal dominant disorder.
dominant eye the eye that is used preferentially or through which stimulation is preferentially effective.

dominant hemisphere formerly, the hemisphere regarded as having primary control of speech or manual preference (handedness). See HEMISPHERIC LATERALIZATION.

dominant ideology thesis in Marxist theory, the view that the ruling class consolidates its position in society by enforcing its ideology on subordinate classes, who come to accept it uncritically. See HEGEMONY.

dominant wavelength a single wavelength that when mixed with white will match a given hue.

dominatrix n. a woman who takes the dominant role in sexual activity, often associated with BONDAGE AND DISCIPLINE or SADO-MASOCHISM.

Donders's law the principle that the position of the eyes in looking at an object is independent of their movement to that position. [Franciscus Cornelis DONERS]

Donders's method a method of separating out hypothetical stages of mental processing by requiring participants to perform a set of reaction time tasks in which each successive task differs from its predecessor by the addition of a single mental stage. The time required to complete a particular stage of processing can be inferred by subtracting from the reaction time in one task the reaction time in the preceding task. For example, Task A, in which a person responds to one signal by pressing one key and another to pressing another key, adds a response-decision stage to Task B, in which a person responds to one signal by pressing a key and makes no response to the other signal. Also called subtraction method. See also CHRONOMETRIC ANALYSIS; CHOICE REACTION TIME. [Franciscus Cornelis DONERS]

donepezil n. an acetylcholinesterase inhibitor used as a COGNITIVE ENHANCER in the management of mild to moderate dementia. By inhibiting the degradation of acetylcholine in the SYNAPTIC CLEFT, donepezil increases available levels of acetylcholine in the BASAL NUCLEUS OF MEYERN, thought to be associated with improved memory and other aspects of cognitive functioning. U.S. trade name: Aricept.

dong quai an herbal agent derived from the plant Angelica sinensis, native to mountainous regions of China, Korea, and Japan, with extensive folk use in Asia, America, and western Europe for a variety of conditions but particularly as a remedy for AMINORRHEA, DYSMENORRHEA, and other menstrual irregularities. It also is reputed to ameliorate the physical and psychological symptoms associated with premenstrual syndrome and menopause. The limited research that has been done on dong quai is inconclusive, providing conflicting results on its effectiveness for any of these uses. Side effects include abdominal bloating, diarrhea and other gastrointestinal disturbances, fever, photosensitivity, and increased bleeding. Additionally, the plant contains numerous phytoestrogens (see ESTROGEN) and coumarin-like compounds and may therefore interact with pharmaceutical estrogenic compounds and prescribed blood thinners.

Don Juan a man who ruthlessly seduces women, concerned only with sexual conquest, after which he loses interest in them (Don Juanism). The original Don Juan was a legendary Spanish libertine, the subject of literature and Mozart’s opera Don Giovanni. In contrast to men with a CASANOVA COMPLEX, who adore women, a Don Juan may think of women as prey. See also SATYRIASIS.

donor insemination see ARTIFICIAL INSEMINATION.

don’t-hold functions cognitive abilities, such as those involved in digit–symbol association (see DIGIT SYMBOL), that often decline in normative aging as observed on intellectual or cognitive tests (e.g., the WECHSLER ADULT INTELLIGENCE SCALE). They also show declines in conditions that affect cognitive functioning, such as traumatic brain injury, schizophrenia, or dementia. In these conditions, don’t-hold functions are much more likely to be affected, or to be affected first, than are HOLD FUNCTIONS, which often rely on long-term knowledge such as vocabulary.

door-in-the-face technique a two-step procedure for enhancing COMPLIANCE in which an extreme initial request is presented immediately before a more moderate target request. Rejection of the initial request makes people more likely to accept the target request than would have been the case if the latter had been presented on its own. See also FOOT-IN-THE-DOOR TECHNIQUE; LOW-BALL TECHNIQUE; THAT’S-NOT-ALL TECHNIQUE.

DOP abbreviation for DERM-OPTICAL PERCEPTION.

dopa (DOPA) n. 3,4-dihydroxyphenylalanine: an amino acid that is a precursor to DOPAMINE and other catecholamines. See also LEVODOPA.

dopac (DOPAC) n. dihydroxyphenylacetic acid: the major metabolite of DOPAMINE. It is analyzed as an index of dopamine activity in regions of the brain.

dopa decarboxylase the intermediate enzyme in the metabolism of CATECHOLAMINES from the dietary amino acid tyrosine. Tyrosine is transformed to L-dopa (3,4-dihydroxyphenylalanine; see LEVODOPA) by the enzyme tyrosine beta-hydroxylase to NOREPINEPHRINE and subsequently—in specialized cells in the adrenal medulla and other sites, via the action of the enzyme phenylethanolamine N-methyltransferase—to EPINEPHRINE. Also called aromatc L-amino acid decarboxylase.

dopamine (DA) n. a CATECHOLAMINE neurotransmitter that has an important role in motor behavior and is implicated in numerous mental conditions and emotional states (see CATECHOLAMINE HYPOTHESIS; DOPAMINE HYPOTHESIS). It is found in DOPAMINERGIC neurons in the brain and elsewhere. It is synthesized from the dietary amino acid tyrosine, which in the first, rate-limiting stage of the reaction is converted to L-dopa (3,4-dihydroxyphenylalanine; see LEVODOPA) by the enzyme TYROSINE HYDROXYLASE. L-dopa is then transformed into dopamine by the enzyme DOPA DECARBOXYLASE. In nondopaminergic neurons and the adrenal medulla, dopamine is further metabolized to form norepinephrine and epinephrine, respectively. Destruction of the dopaminergic neurons in the SUBSTANTIA NIGRA is responsible for the symptoms of Parkinson’s disease (e.g., rigidity, tremor). Blockade of the actions of dopamine in other brain regions accounts for the therapeutic activities of many antipsychotic drugs.

dopamine hypothesis the influential theory that schizophrenia is caused by an excess of dopamine in the brain, due either to an overproduction of dopamine or a deficiency of the enzyme needed to convert dopamine to DOPAMINE.
norepinephrine (adrenaline). There is some supporting pharmacological and biochemical evidence for this hypothesis, and it is still widely discussed and promoted, particularly in a revised form that postulates the involvement in schizophrenia of both an increased mesolimbic and a decreased prefrontal dopaminergic activity. See also GLUTAMATE HYPOTHESIS.

dopamine receptor a receptor molecule that is sensitive to dopamine and chemically related compounds. Dopamine receptors are located in parts of the nervous system, such as the BASAL GANGLIA, and also in blood vessels of the kidneys and mesentery, where binding of dopamine to its receptors results in widening (dilation) of the arteries. There are several subtypes of dopamine receptors, designated D1, D2, and so on. See DRD2 gene.

dopamine-receptor agonist any drug or other agent that binds to and directly activates dopamine receptors, producing physiological effects that mimic those of the neurotransmitter dopamine. BROMOCRIPTINE is an example. Because PARKINSONISM is associated with a deficiency of dopamine in the brain, drugs that help to maintain adequate levels of dopamine are valuable in treating the disorder. Dopamine-receptor agonists are used to manage some of the drug-induced parkinsonian symptoms associated with use of antipsychotic drugs; they are also used in the treatment of Parkinson’s disease, GALACTORRHEA, and prolactin-secreting tumors of the pituitary gland. Also called dopaminergic agent.

dopamine-receptor antagonist any substance that reduces the effects of the neurotransmitter dopamine by competitively binding to, and thus blocking, dopamine receptors. Classically, the clinical use of dopamine antagonists in mental health has been to modulate the symptoms of schizophrenia and other psychotic conditions. All conventional (typical or first-generation) ANTIPSYCHOTIC drugs are thought to act via antagonism or partial agonism of the postsynaptic dopamine D2 receptor. Most second-generation (atypical) antipsychotics possess some degree of antagonistic activity at that receptor. Other dopamine-receptor antagonists are used to prevent or treat nausea and vomiting.

dopaminergic adj. responding to, releasing, or otherwise involving dopamine. For example, a dopaminergic neuron is any neuron in the brain or other parts of the central nervous system for which dopamine serves as the principal neurotransmitter. Four major tracts (called dopaminergic pathways) of dopamine-containing neurons are classically described: the mesocortical pathway (see MESOCORTICAL SYSTEM), damage to which is associated with depression and attention-deficit/hyperactivity disorder; the MESOLIMBIC SYSTEM, in which excess dopamine activity is hypothesized to be associated with positive and negative symptoms of schizophrenia; the NIGROSTRIATAL TRACT, which is involved in motor functions and Parkinson’s disease; and the TUBEROINFUNDIBULAR TRACT, a local circuit from the hypothalamus to the pituitary that is involved in the regulation of the pituitary hormone prolactin.

dopaminergic agent see DOPAMINE-RECEPTOR AGONIST.

dopamine system a richly defined and extensive neurochemical regulatory system in the mammalian brain. There are four identified dopamine subdivisions: tuberoinfundibular (hormonal regulation); nigrostriatal (motor function); mesolimbic (reinforcement of behavior); and mesocortical (higher order cognitive activities).

Dopar n. a trade name for LEVODOPA.

Doppelganger phenomenon the delusion that one has a double or twin, who looks and acts the same as oneself (German, “double walker”). See also AUTOSCOPY.

Doppler effect the apparent increase or decrease in wavelength or frequency observed when a source of electromagnetic radiation or sound approaches or recedes from the observer or listener, producing a change in hue or pitch. The total Doppler effect may result from motion of the source, observer, or medium (such as a sound wave). [Christian Andreas Doppler (1803–1853), Austrian mathematician]

Dora case one of Sigmund Freud’s earliest and most celebrated cases, reported in Fragment of an Analysis of a Case of Hysteria (1905). The study of this woman’s multiple symptoms (headaches, loss of speech, suicidal thoughts, amnesic episodes) contributed to his theory of REPRESSION and the use of DREAM ANALYSIS as an analytic tool. It was also the first case in which he suggested the concept of TRANSFERENCE.

Doral n. a trade name for QUAZEPAM.

Doriden n. a trade name for GLUTETHIMIDE.

dorsal adj. denoting the hind region or the back surface of the body. In reference to the latter, this term sometimes is used interchangeably with POSTERIOR. Compare VENTRAL. —dorsally adv.

dorsal anterior cingulate cortex see ANTERIOR CINGULATE CORTEX.

dorsal column any of various tracts of sensory nerve fibers that run through the white matter of the spinal cord on its dorsal (back) side. See CUNEATE FASCICULUS; GRACILE FASCICULUS. See also LEMNISCAL SYSTEM.

dorsal column system a SOMATOSENSORY SYSTEM that transmits most touch information via the dorsal columns of the spinal cord to the brain.

dorsal horn either of the upper regions of the H-shaped pattern formed by the PERIAQUEOUS GRAY in the spinal cord. The dorsal horns extend toward the dorsal roots and mainly serve sensory mechanisms. Also called posterior horn. Compare VENTRAL HORN.

dorsal posterior cingulate cortex see POSTERIOR CINGULATE CORTEX.

dorsal root any of the SPINAL ROOTS that convey sensory nerve fibers and enter the spinal cord dorsally on the back surface of each side. Also called posterior root; sensory root. Compare VENTRAL ROOT. See also BELL–MAGENDIE LAW.

dorsal stream a series of cortical maps that originate in the STRIATE CORTEX (primary visual cortex) of the occipital lobe and project forward and upward into the parietal lobe. Known informally as the “where” or “how” pathway, the dorsal stream is involved in processing object motion and location in space. Also called ACTION STREAM. Compare VENTRAL STREAM.

dorsal tegmental bundle a bundle of nerve fibers from the LOCUS CERULEUS that, together with the central tegmental tract, forms the MEDIAL FOREBRAIN BUNDLE.

dorsiflexion n. flexing the ankle or wrist so that the foot or hand moves toward its upper (dorsal) surface.
dorsolateral adj. located both dorsally (toward the back) and laterally (toward the side). —dorsolaterally adv.

dorsolateral column a tract of motor fibers that descend in the dorsolateral part of the spinal cord, terminating on motor neurons. The cell bodies of these fibers lie in the motor cortex, and the fibers descend on the same side until they cross over (decussate) at the pyramids of the medulla oblongata.

dorsolateral prefrontal cortex (DLPFC) a region of the brain located near the prefrontal cortex (Broadmann’s areas 9 and 46) in humans, involved in working memory, voluntary attentional control, and speech production. Damage to this region results in an inability to select task-relevant information and to freely shift attention based on external cues.

dorsomedial nucleus (DMN) a mass of tissue projecting from the thalami to the frontal lobes. It is mainly implicated in memory function but is also associated with the emotional expressions of anxiety and fear. Also called mediodorsal nucleus.

dorsolateral adj. oriented or directed from the back (dorsal) region of the body to the front (ventral) region. Compare ventrodorsal. —dorsolaterally adv.

dose–response relationship a principle relating the potency of a drug to the efficacy of that drug in affecting a target symptom or organ system. Potency refers to the amount of a drug necessary to produce the desired effect; efficacy refers to the drug’s ability to act at a target receptor or organ to produce the desired effect. Dose–response curves may be graded, suggesting a continuous relationship between dose and effect, or quantal, wherein the dose–response curves may be graded, suggesting a continuous relationship between dose and effect, or quantal, wherein the desired effect is an either–or phenomenon, such as prevention of arrhythmias. There is considerable variability among individuals in response to a given dose of a particular drug.

dot figure an arrangement of dots that is interpreted as forming a structure that changes shape over time, depending on which dots are seen as grouped together.

dot plot see scatterplot.

dotting test a pencil-and-paper motor test in which the participant makes as many dots as possible in a given time period, either randomly (tapping test) or within small circles (aiming test).

double n. in psychodrama, an individual, one of the auxiliary ego(s), who speaks or acts out the presumed inner thoughts of the protagonist (i.e., the person presenting the problem to be explored). The technique is known as doubling.

double alternation in experimental research, a pattern in which two consecutive events of one kind alternate with two consecutive events of another kind. For example, in an operant conditioning experiment, two consecutive reinforced (R) trials may alternate with two consecutive nonreinforced (N) trials, yielding the pattern RRNNR-RNN. . . . See also single alternation.

double approach–avoidance conflict a complex conflict situation arising when a person is confronted with two goals or options that each have significant attractive and unattractive features. See also approach–avoidance conflict.

double approach–approach conflict see approach–approach conflict.

double aspect theory the position that mind and body are two attributes of a single substance (see mind–body problem). This view is particularly associated with Baruch Spinoza, who held that there is one (and only one) infinite substance, which he identified as God (see pantheism).

double-avoidance conflict see avoidance–avoidance conflict.

double bind a situation in which an individual receives contradictory messages from another person. For example, a parent may respond negatively when his or her child approaches or attempts to engage in affectionate behavior but then, when the child turns away or tries to leave, reaches out to encourage the child to return. Double-binding communication was once considered a causative factor in schizophrenia. [proposed by British anthropologist Gregory Bateson (1904–1980)]

double blind see blind.

double bootstrapping a procedure in which samples are randomly drawn, with replacement, from an initial data set and their parameters and standard errors are estimated and averaged across the set of samples. This is then followed by another random sampling of the data, again with replacement, after which parameter estimates and standard errors are obtained a second time. Double bootstrapping usually is less biased than using a single set of bootstrapping samples.

double consciousness 1. a condition in which two distinct, unrelated mental states coexist within the same person. This may occur, for example, in an individual with a dissociative identity disorder. Also called dual consciousness. 2. a condition described by U.S. educator, scholar, and activist W. E. B. Du Bois (1868–1963) as one in which African Americans experience themselves through their own consciousness as well as through their awareness of how they are perceived by White Americans.

double deception in deception research, an apparent debriefing after the experiment, which is itself a further play.

double depression a condition in which a person with dysthymic disorder—chronically low or irritable mood—experiences a concurrent major depressive episode. Symptoms commonly include hopelessness, low internal locus of control, low self-esteem, difficulty sleeping, and anhedonia. Severe hopelessness in particular has been implicated as the key distinguishing feature of double depression. Other distinctions (e.g., from dysthymic disorder alone, minor depressive disorder, single-episode depression), however, are more controversial among researchers and practitioners. Some claim that there are few if any legitimate clinical differences between double depression and other depressive conditions, whereas others argue that individuals with double depression have more severe symptoms, greater comorbidity, greater psychopathology in first-degree relatives, and a poorer prognosis; are less responsive to psychotherapy and other treatment; and otherwise differ in psychosocial functioning, family history, and degree of impairment.

double dissociation a research process for demonstrating the action of two separable psychological or biological systems, such as differentiating between types of memory or the function of brain areas. One experimental variable is found to affect one of the systems, whereas a second variable affects the other. The differentiating varia-
double entendre

bles may be task related, pharmacological, neurological, or individual differences. For example, double dissociation has been used to separate DECLARATIVE MEMORY from PROCEDURAL LEARNING. [developed by Hans-Lukas Teuber]

double entendre a word, phrase, or sentence that could be interpreted in two ways, especially when one of the possible meanings is a sexual one. See also AMBIGUITY; PUN. [French: “double understanding” or “double meaning”]

double helix see DNA.

double image 1, a duplicate retinal image that occurs as a result of eye defects. 2, a duplicate image of a distant object when fixating on near objects or of a near object when fixating on distant objects. See also DIPLOPIA; DOUBLE VISION.

double insanity see FOLIE À DEUX.

double personality see DUAL PERSONALITY.

double predestination see PREDESTINATION.

double-simultaneous stimulation a test used in studies of parietal lobe lesions in which two sensory stimuli (typically one on each side of the body) are presented to an individual simultaneously.

double-simultaneous tactile sensation the ability of a person to perceive two tactile sensations in different areas at the same time, for example, when touched simultaneously on the left and right hands or the right hand and left side of the face. An inability to perceive one or both of the simultaneous tactile sensations is referred to as tactile extinction. See also FACE–HAND TEST.

double standard the hypocritical belief that a code of behavior is permissible for one group or individual but not for another. For example, a double standard is held by the man who believes that free sexual expression is acceptable for another. For example, a double standard is held by the man who believes that free sexual expression is acceptable for another, while insisting on his daughter’s virginity while encouraging or ignoring his son’s philandering.

double vision the perception of a single object as a separate image by each eye. Double vision is referred to medically as DIPLOPIA.

double-Y condition see XY SYNDROME.

doubling n. see DOUBLE.

doubt n. 1, lack of confidence or an uncertainty about something or someone, including the self. Doubt may center on everyday concerns (Can I accomplish this task?), issues of daily living (Can I change this ingrained habit?), or the very meaning of life itself (see EXISTENTIAL ANXIETY; EXISTENTIAL CRISIS). It is a perception, typically with a strong affective component, that is frequently a focus during psychotherapeutic intervention. 2, in ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, see AUTONOMY VERSUS SHAME AND DOUBT.

doubting obsession extreme feelings of uncertainty about even the most obvious matters. Doubting obsession is commonly associated with OBSESSIVE-COMPULSIVE DISORDER and often results in checking rituals (e.g., repeatedly looking to see if the door is locked) as a means of reducing doubt-related anxiety. It was originally named doubting mania by French psychiatrist Jean-Pierre Falret (1794–1870).

doula n. a professional trained in giving social support to families before, during, and after the birth of a child—that is, during pregnancy, labor, and birth and at home during the first few days or weeks after birth. Unlike a MIDWIFE, a doula is not a medical professional and acts only as a labor coach during the actual delivery.

downer n. slang for a SEDATIVE, HYPNOTIC, AND ANXIOLYTIC DRUG.

down-regulation n. a decrease in the number of RECEPTOR molecules in a given area. Compare UP-REGULATION.

Down syndrome a chromosomal disorder characterized by an extra chromosome 21 and manifested by a round flat face and eyes that seem to slant (the disorder was formerly known as MONGOLISM). Brain size and weight are below average; affected individuals usually have mild to severe intellectual disability and have been characterized as having docile, agreeable dispositions. Muscular movements tend to be slow, clumsy, and uncoordinated. In many cases, growth is stunted, the tongue is thick, and the fingers are stubby. Affected individuals may have heart defects and respiratory insufficiencies or anomalies that are often corrected during infancy by surgery. However, lifespan is reduced compared with that in the general population, and affected individuals typically show early onset of Alzheimer’s disease. Down syndrome is one of the most common physiological causes of intellectual disability. Also called Langdon Down’s disease: trisomy 21. See also AUTOSOMAL TRISOMY OF GROUP G. [described in 1866 by John Langdon Haydon Down (1828–1896), British physician]

down through a technique for testing CLAIRVOYANCE in which the participant is asked to state the order of a stacked deck of ZENER CARDS from top to bottom. Compare UP THROUGH. See also BASIC TECHNIQUE; SCREEN TOUCH MATCHING.

downward communication the transmission of information from individuals who occupy relatively high-status positions within a group or organization to those who occupy subordinate positions. Such communications tend to be informational and directive, whereas UPWARD COMMUNICATIONS request information, provide factual information, or express grievances. Communication tends to flow downward in hierarchically organized groups. See CHANNELS OF COMMUNICATION; COMMUNICATION NETWORK.

downward drift hypothesis see DRIFT HYPOTHESIS.

downward mobility the movement of a person or group to a lower social class. See also SOCIAL MOBILITY. Compare UPWARD MOBILITY.

downward social comparison see SOCIAL COMPARISON THEORY.

dowry n. in some cultures, money or assets bestowed on the groom by the bride’s family on marriage. Compare BRIDE PRICE.

dowsing n. a purported technique for finding sites to dig for water or minerals. A forked stick (divining rod) is held by a person in such a way that a downward movement of the stick indicates a likely site. See also RHAIDO-MANCY. —dowse vb. —dowsed n.

doxepin n. a TRICYCLIC ANTIDEPRESSANT, among the most sedating and most anticholinergic of these agents. Although it currently has little use as an antidepressant, it may be used in relatively low doses as a hypnotic, for treatment of insomnia, or in the management of neuromuscular or musculoskeletal pain. It is also available as a topical
treatment for management of dermatologic conditions. U.S. trade names: Adapin; Silenor; Sinequan.

doxylamine n. an ethanamine ANTIHISTAMINE with significant sedative properties that is included in numerous nonprescription sleep aids. Like all antihistamines, it may lose its efficacy with repeated use. Overdose is characterized by symptoms of anticholinergic toxicity, including raised temperature, a rapid heart rate, and delirium.

dPCC abbreviation for dorsal POSTERIOR CINGULATE CORTEX.

DPE abbreviation for DELIBERATE PSYCHOLOGICAL EDUCATION.

d prime (symbol: $d'$) a measure of an individual's ability to detect signals; more specifically, a measure of sensitivity on discrimination tasks (receiver-operating characteristic curve). In practice, $d'$ has proved to be sufficient bias free to the "best" measure of psychophysical performance. It is essentially a STANDARIZED SCORE and is computed as $d' = \sqrt{\frac{(H - F)}{\sigma^{2}}}$. A value of $d' = 3$ is close to perfect performance; a value of $d' = 0$ is chance ("guessing") performance.

DQ abbreviation for DEVELOPMENTAL QUOTIENT.

DRA abbreviation for DIFFERENTIAL REINFORCEMENT OF ALTERNATIVE BEHAVIOR.

Dracmine n. a trade name for DIMENHYDRINATE.

dream therapy in GROUP THERAPY, the use of theater techniques to gain self-awareness and increase self-expression.

dramatics n. 1. the art or practice of stagecraft and theatrical performance. 2. the use of drama as a rehabilitation technique, using published or original scripts with patients as performers. See also PSYCHODRAMA. 3. see CREATIVE DRAMATICS.

dreamatization n. 1. ATTENTION-GETTING behavior, such as exaggerating the symptoms of an illness to make it appear more important than the occurrence of the same illness in another person. 2. in psychoanalytic theory, the expression of repressed wishes or impulses in dreams. — dreamatize vb.

dream deprivation a technique, originally used in psychotherapy, in which the content of dreams is interpreted to reveal underlying motivations or symbolic meanings and representations (i.e., LUCID DREAM).

dream analysis a technique, originally used in psychoanalysis but now also used in some other psychotherapies, in which the content of dreams is interpreted to reveal underlying motivations or symbolic meanings and representations (i.e., LATENT CONTENT). Dream analysis is aided by such techniques as FREE ASSOCIATION. Also called dream interpretation.

dream anxiety disorder see NIGHTMARE DISORDER.

dream censorship in psychoanalytic theory, the disguising in dreams of unconscious wishes that would be disturbing to the ego if allowed conscious expression. According to Sigmund FREUD, the thoroughness of dream disguise varies directly with the strictness of the censorship. See CENSOR.

dream content the images, ideas, and impulses expressed in a dream. See LATENT CONTENT; MANIFEST CONTENT.

dream deprivation a research technique designed to study the effects of reduced REM SLEEP on REM dreaming. After being routinely awakened during this stage of sleep,
participants tend to compensate with longer periods of REM sleep on subsequent nights, a finding that may point to homeostatic compensation for REM-dream deprivation. The technique is a specifically focused subtype of REM-sleep deprivation.

**dream ego** in the ANALYTIC PSYCHOLOGY of Carl JUNG, a fragment of the conscious ego that is active during the dream state.

**dream incorporation** the integration of a stimulus, such as a muscle cramp or the sound of a telephone ringing, into the content of a dream. Such a dream is referred to as an incorporation dream.

**dream interpretation** see DREAM ANALYSIS.

**dream stimulus** any of various stimuli that may initiate dream content, such as external stimulation, internal sensory stimulation, mental images, feelings, or memories.

**dream suggestion** a specialized hypnotic technique in which the client is instructed to dream about a problem or its source, either during the hypnotic state or posthypnotically, during natural sleep. The technique is sometimes used as an aid in HYPNOTHERAPY.

**dream-work** n. in psychoanalytic theory, the transformation of the latent content of a dream into the manifested content experienced by the dreamer. This transformation is effected by such processes as condensation, symbolization, displacement, and dramatization.

**dreamy state** a brief altered state of consciousness similar to a dream, during which the individual experiences visual, olfactory, or auditory hallucinations.

**dressing aid** an ASSISTIVE TECHNOLOGY device that helps people with disabilities to dress independently. Dressing aids include buttonhooks, specially designed fasteners (e.g., Velcro strips), grabbers, and other devices.

**dressing apraxia** an inability to dress oneself normally, sometimes associated with brain damage. For example, an individual may put on clothing so that it covers only the right side of the body, neglecting the left side.

**DRGs** abbreviation for Diagnosis-related groups.

**DRII** abbreviation for Differential reinforcement of high rate.

**drift** n. 1. a reduction in variation in genetic traits that can occur when sampling from continually smaller groups, such that some traits ultimately become excluded from possibility. 2. a reduction in the reliability of technical instruments or in the accuracy of observers over time. See INSTRUMENT DRIFT; OBSERVER DRIFT.

**drift hypothesis** a sociological concept purporting to explain the higher incidence of schizophrenia in urban poverty centers, suggesting that during the preclinical phase people tend to drift into poverty and social isolation. Also called downward drift hypothesis. See also SOCIOGENIC.

**drifting attention** a disorder marked by a tendency to maintain attention for a short period, when alerted, but then to drift back to a somnolent state. It is caused by disturbance of the subcortical alerting mechanisms, which usually indicates pathological involvement of the midbrain or thalamic portion of the reticular activating system. See also WANDERING ATTENTION.

**drill** n. the methodical repetition of a physical or mental response or response sequence for the purpose of learning. Drill may be necessary when the material to be learned does not yet represent to the individual an integrated or internally coherent entity. For example, an individual learning a foreign language may need to use drill. Drill is also necessary to produce AUTOMATIZATION of a behavior or skill.

**drinking aid** an ASSISTIVE TECHNOLOGY device that permits an individual with a disability to ingest liquids without the help of another person. Drinking aids include terry-cloth tumbler jackets, wooden or metal glass holders, various built-in and flexible sipping straws, coasters with suction-cup attachments, and cups designed for drinking while lying down.

**drinking episode** a continuous period of drinking, often but not always short-lived.

**drinkometer** n. a device used in nonhuman animal experiments to record the number of times an animal licks a drinking tube. Also called **lickometer**.

**drive** n. 1. a generalized state of readiness precipitating or motivating an activity or course of action. Drive is hypothetical in nature, usually created by deprivation of a needed substance (e.g., food), the presence of negative stimuli (e.g., pain, cold), or the occurrence of negative events. Drive is said to be necessary for stimuli or events to serve as reinforcers. 2. in the classical psychoanalytic theory of Sigmund Freud, a concept used to understand the relationship between the psyche and the soma (mind and body): drive is conceived as having a somatic source but creating a psychic effect. Freud identified two separate drives as emerging from somatic sources: LIBIDO and agression. See also motivation; object relations. 3. see carver and white's bis/bas scales.

**drive discrimination** the ability of an organism to differentiate between various psychological, emotional, and physiological needs and to direct responses accordingly, such as drinking when thirsty or eating when hungry. [defined by Edward C. TOLMAN]

**drive displacement** the activation of one drive when another drive is thwarted: for example, eating chocolate when one is prohibited from smoking a cigarette.

**drive-induction theory** the theory that reinforcement is a function of the degree of drive induced by a given reinforcer. According to this theory, it is the arousal or excitement produced by consummating a reinforcer (e.g., eating, drinking, mating) that produces reinforcement of behavior, not the reduction of the drive state that the reinforcer may produce. Drive-induction theory was proposed as an alternative to **drive-reduction theory**. Also called consummatory response theory of reinforcement. [introduced by U.S. learning theorist Frederick Sheffield (1914–1994)]

**drive-reduction theory** a theory of learning in which the goal of motivated behavior is a reduction of a drive state. It is assumed that all motivated behavior arises from drives, stemming from a disruption in homeostasis, and that responses that lead to reduction of those drives tend to be reinforced or strengthened. See also hull's mathematically-deductive theory of learning. Compare drive-induction theory. [proposed by Clark L. HULL]

**driver training** in rehabilitation, the training of individuals with disabilities to operate an automobile equipped with assistive technology devices, such as customized or
adapted controls. For example, a previously trained driver may have to learn to maneuver a vehicle with hand-operated accelerator and brakes or a gearshift extension for left-hand rather than right-hand use.

drive state see DRIVE.

drive stimulus in Clark L. Hull’s theories of learning, any of the hypothetical nerve impulses produced by a drive state. Behaviors that reduce these impulses are reinforced or strengthened. See DRIVE-REDUCTION THEORY; HULL’S MATHEMATICO-DEDUCTIVE THEORY OF LEARNING.

drive strength the intensity of a drive, particularly as quantified in hull’s matematico-deductive theory of learning as the number of hours of deprivation of a need.

drive theory see CLASSICAL PSYCHOANALYSIS.

DRL abbreviation for DIFFERENTIAL REINFORCEMENT OF LOW RATE.

DRO abbreviation for DIFFERENTIAL REINFORCEMENT OF OTHER BEHAVIOR.

dromomania n. an abnormal drive or desire to travel that involves spending beyond one’s means and sacrificing job, partner, or security in the lust for new experiences. People with dromomomania not only feel more alive when traveling but also start planning their next trip as soon as they arrive home. Fantasies about travel occupy many of their waking thoughts and some of their dreams. The condition was formerly referred to as vagabond neurosis.

dronabinol n. see TETRAHYDROCANNABINOL.

drone n. see MEPHEDRONE.

droperidol n. an antipsychotic agent of the BUTYROPHENE class that is used in premedication for surgery and to maintain surgical anesthesia. It is occasionally used for the emergency treatment of acute psychotic agitation. Because of its extremely rapid onset of action, it has few other mental health applications. U.S. trade name: Inapsine.

drop-in center a facility, often associated with a substance abuse program, where professional support and advice can be obtained without an advance appointment. A drop-in center also serves as a gathering place providing social, educational, and recreational activities.

dropout n. 1. a student who leaves school before graduating. 2. a patient or client who terminates treatment before it is completed.

Drosophila n. a genus of small fruit flies consisting of about a thousand species commonly known as vinegar flies. The species Drosophila melanogaster is used extensively in genetic investigations, including studies of the genetic components of behavior; for example, U.S. behavioral geneticist Jerry Hirsch (1922–2008) studied the relationship between variations in certain chromosomes in D. melanogaster and differences in GEOSTAT.

drowsiness n. a state of low alertness characterized by lowered frontal lobe (executive) functioning, difficulty in exerting mental effort, and an involuntary tendency for rapid skeletal muscle inhibition to occur. Electroencephalography shows intermittent sleep brain waves, including DELTA WAVES. See also HYPERSONOMIA; SOMNOLENCE.

DRS 1. abbreviation for DEMENTIA RATING SCALE. 2. abbreviation for DISABILITY RATING SCALE.

drug n. any substance, other than food, that influences motor, sensory, cognitive, or other bodily processes. Drugs generally are administered for experimental, diagnostic, or treatment purposes but also tend to be used recreationally to achieve particular effects.

drug abuse see SUBSTANCE ABUSE.

Drug Abuse Resistance Education see D.A.R.E.

Drug Abuse Screening Test (DAST) a 28-item, yes-no questionnaire used to screen for drug abuse or dependence. Its questions are based on those of the MICHIGAN ALCOHOLISM SCREENING TEST.

drug abuse treatment see SUBSTANCE ABUSE TREATMENT.

drug addiction see ADDICTION; SUBSTANCE DEPENDENCE.

drug court an alternative to the usual legal processing and penalties for nonviolent drug offenders. Drug court focuses on treatment and rehabilitation rather than punishment.

drug culture the activities and way of life of people who habitually use one or more kinds of drugs of abuse, usually illicit drugs such as hashish, cocaine, heroin, LSD, or other substances that produce altered states of consciousness. Also called drug subculture.

drug dealer a person who sells illegal substances or sells legal substances in an illegal manner (e.g., without a license). Also called a drug pusher.

drug dependence see SUBSTANCE DEPENDENCE.

drug discrimination the ability of an organism to distinguish between the internal states produced by different drugs (or by a particular drug and saline). In a typical experimental procedure, a nonhuman animal is injected with one drug, and a certain response (e.g., pressing the left-hand lever in a two-lever apparatus) is reinforced. When injected with a different drug (or with saline), a different response (e.g., pressing the right-hand lever) is reinforced. Thus, the animal must discriminate between the internal cues produced by the drugs in order to make the correct response.

drug education the process of informing individuals or groups about the effects of various chemical agents on the human body, usually with a special emphasis on the effects of mind-altering substances.

drug holiday discontinuance of a therapeutic drug for a limited period in order to control dosage and side effects and to evaluate the patient’s response with and without it. At one time commonly recommended for children taking METHYLPHENIDATE, drug holidays on weekends or school vacations were thought to prevent growth suppression that was tentatively associated with this agent. Drug holidays are infrequent in modern clinical practice.

drug-induced amnesia see AMNESIA.

drug-induced lactation see GALACTORRHEA.

drug-induced parkinsonism see PARKINSONISM.

drug-induced psychosis a psychotc state resulting from the use or the abuse of illicit or therapeutic substances. Well-described drug-induced psychoses may result from excessive or chronic use of amphetamines, cocaine, or other stimulants; cannabis; LSD; PCP (phencyclidine), or other hallucinogens; and other illicit substances. A variety of medications may produce psychotic symptoms, including anticholinergic drugs at therapeutic doses in suscepti-
Drug interactions

Drug interactions the effects of administering two or more drugs concurrently, which alters the pharmacological action of one or more of them. Pharmacokinetic interactions alter the absorption, distribution, metabolism, and excretion of the drugs; they may induce or inhibit the elimination of these drugs, leading to unexpected increases or decreases in their concentrations in the body. Pharmacodynamic interactions affect the drugs’ activities at target organs or receptor sites; they may be synergistic, enhancing the effectiveness of a drug at a target receptor or organ (see DRUG SYNERGISM), or antagonistic, in which the presence of one drug reduces the effectiveness of another (see ANTAGONIST).

Drug interdiction the interception and confiscation, by police or other law enforcement officials, of illegal drugs while they are being transported.

Drug metabolism the process by which a drug is transformed in the body (in the liver and other organs), usually from a more lipid-soluble form, which makes it more readily absorbed into the body, to a more water-soluble form, which facilitates its excretion. Two phases of drug metabolism are recognized. In Phase I metabolism, the drug is oxidized, reduced, or hydrolyzed—that is, oxygen is added, oxygen is removed, or hydrogen is added, respectively (see CYTOCHROME P450). In Phase II metabolism, functional groups (specific clusters of atoms) are added to drug molecules (e.g., by GLUCURONIDATION).

Drug rehabilitation a combination of interventions designed to enable a person with substance dependence to achieve and maintain abstinence. Also called drug rehab: drug treatment.

Drug screening instrument a brief interview, such as CAGE, or a brief self-report instrument, such as the MICHIGAN ALCOHOLISM SCREENING TEST (MAST) or DRUG ABUSE SCREENING TEST (DAST), that is designed to identify individuals who should be assessed thoroughly for the possibility of substance abuse.

Drug-seeking behavior an attempt to attain a drug or drugs that a person abuses or on which he or she is dependent. Such behavior may include DOCTOR SHOPPING, forging prescriptions, and trading sex for drugs.

Drug subculture see SELF-ADMINISTRATION.

Drug synergism an enhancement of efficacy occurring when two or more drugs are administered concurrently, so that their combined pharmacological or clinical effects are greater than those occurring when the drugs are administered individually. Drug synergism can be metabolic, when the administration of one agent interferes with the metabolism of another, or it can be pharmacological, when the administration of two or more agents results in enhanced receptor binding or other activity at target sites. The enhanced antimicrobial activity of two antibiotics administered together is an example of positive synergism; negative synergism can be seen when the administration of a non-toxic agent with a toxic drug worsens the toxicity of the latter.

Drug therapy see PHARMACOTHERAPY.

Drug tolerance see TOLERANCE.

Drug trafficking see TRAFFICKING.

Drug withdrawal see SUBSTANCE WITHDRAWAL.

Dry eyes see XEROPHTHALMIA.

DS abbreviation for DUAL SCALING.

DSH abbreviation for DELIBERATE SELF-HARM.

DSM–IV–TR the text revision of the fourth edition of the Diagnostic and Statistical Manual of Mental Disorders, prepared by the DSM–IV Task Force of the American Psychiatric Association and published in 2000. The classification presents descriptions of diagnostic categories without favoring any particular theory of etiology. It is largely modeled on the INTERNATIONAL CLASSIFICATION OF DISEASES (9th edition, 1978), developed by the World Health Organization and modified for use in the United States (ICD–9–CM), but it contains greater detail as well as a method of coding on different axes (see MULTIAXIAL CLASSIFICATION). Previous editions were published in 1952 (DSM–I), 1968 (DSM–II), 1980 (DSM–III, a revision of which, DSM–III–R, was published in 1987), and 1994 (DSM–IV). Over that period, the number of identified disorders increased from about 100 to more than 300.

DSM–4 the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders, prepared by the DSM–5 Task Force of the American Psychiatric Association and published in 2013. Changes from the DSM–IV–TR include use of a nonaxial approach to diagnosis with separate notations for psychosocial and contextual factors and disability; organization of diagnoses according to the period (i.e., childhood, adolescence, adulthood, later life) during which they most frequently first manifest; clustering of disorders within chapters according to internalizing factors (e.g., anxiety, depression) and externalizing factors (e.g., impulsive, disruptive conduct); replacement of the NOT OTHERWISE SPECIFIED label with clinician choice of other specified disorder or unspecified disorder; replacement of the GLOBAL ASSESSMENT OF FUNCTIONING SCALE with the World Health Organization’s Disability Assessment Schedule for further study; and consolidation of separate diagnostic areas into spectra (e.g., AUTISM SPECTRUM DISORDER).

Several diagnostic changes in the DSM–5 have met with controversy. Its consolidation of ASPERGER’S DISORDER into autism spectrum disorder, for example, has raised concerns that those who would meet prior criteria for Asperger’s will now instead be diagnosed as having ASD, which many consider a more serious disorder, or not having either disorder, thereby losing eligibility for certain medical and educational services. Moreover, a criticism of its immediate predecessor has been lodged against the DSM–5 as well—that it retains some diagnostic criteria that pathologize normal behaviors (e.g., temper tantrums, overeating) and emotions (e.g., grief, worrying).

DST abbreviation for DEXAMETHASONE SUPPRESSION TEST.

DTD abbreviation for DEVELOPMENTAL TRAUMA DISORDER.

DTI abbreviation for DIFFUSION TENSOR IMAGING.

DTPS abbreviation for DIFFUSE THALAMIC PROJECTION SYSTEM.
D trisomy syndrome see TRISOMY 13.
DTs abbreviation for DELIRIUM TREMENS.
dual-action antidepressant see MULTIFUNCTIONAL ANTIDEPRESSANT.
dual-aspect physicalism a philosophical answer to the MIND-BODY PROBLEM claiming that there are two aspects of reality—physical and experiential—but that the more fundamental aspect is physical.
dual-attitude model the hypothesis that a new attitude toward an object does not replace a former one but rather overrides it, such that two contradictory attitudes about the same object are then held simultaneously by the same individual. One attitude is held explicitly and the other implicitly. The attitude that people endorse depends on whether they have the cognitive capacity to retrieve the explicit attitude (e.g., egalitarianism) and whether this overrides their original implicit view (e.g., prejudice toward certain racial groups). [proposed in 2000 by U.S. psychologists Timothy D. Wilson and Samuel Lindsey and U.S. behavioral oncologist Tonya Y. Schooler]
dual careers the situation in which both spouses or partners in a family or other domestic unit are committed to their careers, rather than one being regarded as the main breadwinner and the other as the main homemaker.
dual coding theory 1. the theory that linguistic input can be represented in memory in both verbal and visual formats. CONCRETE WORDS that readily call to mind a picture, such as table or horse, are remembered better than ABSTRACT WORDS, such as honesty or conscience, which do not readily call to mind a picture, because the concrete words are stored in two codes rather than one. [proposed by Canadian cognitive psychologist Allan U. Paivio (1925–)]
2. the theory that linguistic knowledge in bilingual people is stored in two distinct codes. See COORDINATE BILINGUAL.
3. a theory for explaining the relationship between IMAGERY and performance that suggests there are two ways of gaining information about a skill: the motor channel for encoding human actions and the verbal channel for encoding speech. Using auditory imagery linked with visual imagery is suggested to be the most effective in PERFORMANCE ENHANCEMENT.
dual consciousness see DOUBLE CONSCIOUSNESS.
dual diagnosis the identification of two distinct disorders that are present in the same person at the same time, for example, the coexistence of depression and a substance dependence disorder (e.g., alcohol or drug dependence). See also COMORBIDITY.
dual encoding see DUAL REPRESENTATION.
dual instinct theory in classical psychoanalytic theory, the view that human life is governed by two antagonistic forces: the LIFE INSTINCT, or EROS, and the DEATH INSTINCT, or THANATOS. This was a late theoretical formulation by Sigmund Freud, who held that "the interaction of the two basic instincts with or against each other gives rise to the whole variegation of the phenomena of life" (Beyond the Pleasure Principle, 1920).
dualism n. the position that reality consists of two separate substances, defined by René DESCARTES as thinking substance (mind) and extended substance (matter). In the context of the MIND-BODY PROBLEM, dualism is the position that the mind and the body constitute two separate realms or substances. Dualistic positions raise the question of how mind and body interact in thought and behavior. Compare MONISM. See also CARTESIAN DUALISM. —dualist adj., n. —dualistic adj.
duality of language the concept that language can be represented at two levels: (a) PHONOLOGY, which is the sound that a speaker produces; and (b) meaning, which is a function of SYNTAX and SEMANTICS.
dual memory theory see DUAL-STORE MODEL OF MEMORY.
dual orientation see DUAL REPRESENTATION.
dual personality a personality that is divided into two relatively independent and generally contrasting systems. See DISSOCIATIVE IDENTITY DISORDER.
dual process model of persuasion any of various persuasion theories postulating that attitude change can occur as a result of strategies for processing attitude-relevant information that involve either a very high degree of effort or very little effort. The most prominent theories of this type are the ELABORATION-LIKELIHOOD MODEL and the HEURISTIC-SYSTEMATIC MODEL.
dual process theory 1. the theory that the response made by an individual to a stimulus that permits behavioral control involves two stages: (a) a decision as to whether or not to respond and (b) a choice between alternative responses. 2. in theories of memory, the operation of two different cognitive processes (e.g., recollection and familiarity) in recognition memory. 3. a decision-making theory stating that judgment and reasoning involve two separate processes: intuitive decision making and rational decision making. See SYSTEM 1. [proposed by Daniel KAHNEMAN and Amos TVERSKY]
dual process theory of color vision see OPPONENT PROCESS THEORY OF COLOR VISION.
dual relationship in a therapeutic context, a situation in which a psychologist has more than one type of relationship with a client: The psychologist (a) is concurrently in both a professional role and another role with the same client, (b) is concurrently in a relationship with a person closely associated with or related to the client, or (c) promises to enter into another relationship in the future with the client or a person closely associated with or related to the client. Psychologists are ethically expected to refrain from entering into a dual relationship because it might impair their objectivity, competence, or effectiveness in performing their functions as a psychologist or exploit or harm the client with whom the professional relationship exists. Also called multiple relationship.
dual representation the ability to comprehend an object simultaneously as the object itself and as a representation of something else. For example, a photograph of a person can be represented both as the print itself and as the person it depicts. Also called dual encoding; dual orientation.
dual scaling (DS) a method of assessing relationships and patterns among CATEGORICAL DATA that involves assigning scale values to the elements of the data set. For example, DS may be useful when assessing the relationship between achievement motivation and performance. When achievement motivation is low or high, performance is expected to be low; however, when achievement motivation is moderate, performance is expected to be high. This curvilinear relationship can be analyzed more effectively with DS than with conventional statistical methods.
dual-sto re model of memory

loration, regression), as the latter require assumptions of linearity and would reveal no apparent association between the variables. Also called **optimal scaling**.

**dual-sto re model of memory** the concept that memory is a two-stage process, comprising **short-term memory**, in which information is retained for a few seconds, and **long-term memory**, which permits the retention of information for hours to many years. William James called these stages **primary memory** and **secondary memory**, respectively. Also called **dual memory theory**. See also **modal model of memory**; **multistore model of memory**.

**dual-task competition** a phenomenon observed in experimental techniques examining **dual-task performance**, in which participants are asked to perform two tasks (e.g., speeded reaction time and mental arithmetic) simultaneously. Such tasks require effort (see effortfulness) and tend to compete against each other (see resource competition), resulting in increased error rates and longer reaction time. The decrease in performance is often taken as an index of conscious, voluntary, and attentional capacity limits (see central limited capacity).

**dual-task performance** the concurrent performance of two tasks. In the study of attention, dual-task performance is often examined to explore the nature of processing limitations and the strategies used to coordinate performance. See **dual-task competition**; **secondary task methodology**.

**dual thresholds** a stimulus-threshold theory in which high and low thresholds are postulated. When the lower threshold is exceeded, the observer may believe a stimulus is present but is not sure. When the higher threshold is exceeded, the observer is certain that the stimulus is present.

**dual trace hypothesis** a restatement of the perseveration-consolidation hypothesis of memory formation specifying that short-term memory is represented neurally by activity in reverberating circuits and that stabilization of these circuits leads to permanent synaptic change, reflecting the formation of long-term memory. See **Hebbian synapse**. [proposed in 1949 by Donald O. Hebb]

**Duchenne muscular dystrophy** see **muscular dystrophy**. [Guillaume Benjamin Armand Duchenne (1806–1875), French neurologist]

**Duchenne smile** a smile characterized by bilaterally symmetrical upturning of the lips and activation of the orbicularis oculi muscles surrounding the eyes, which creates a crow’s-foot effect at the corners of the eyes. Duchenne smiles are believed to be authentic smiles, as opposed to posed, voluntary **non-Duchenne smiles** that lack the orbicularis oculi component. [Guillaume Duchenne]

duct n. in anatomy, a tubular canal or passage, especially one that transports a secretion, such as a bile duct or tear duct. Glands with ducts are called **exocrine glands**.

---ductal adj.

**ductless gland** see **endocrine gland**.

**ductus deferens** see **vas deferens**.

**due process** the administration of the law according to established and accepted principles, especially those upholding natural justice and the rights of the accused. In the United States, due process of law is guaranteed by the 5th and 14th Amendments to the U.S. Constitution. Also called **due process rights**.

**due process model** a view of legal process that places a premium on the rights of the accused and the maintenance of fair procedures by which such people are processed within the criminal justice system. Compare **crime control model**.

**dull normal** see **below average**.

**dummy** n. in **double-blind** drug trials, an inert substance that appears identical in all aspects (e.g., dosage form, method of administration) to the active drug under investigation, thereby helping to preserve experimental blinds for both patients and clinical investigators. Since a dummy is completely inert, it has no pharmacological activity, unlike an active **placebo**, which may produce side effects.

**dummy variable** 1. in **regression analysis**, a numerical variable that is created to represent a qualitative fact, which is done by giving a variable a value of 1 or 0 to indicate the presence or absence of a categorical trait. A dummy variable usually represents a **dichotomous variable**, that is, one that can have only two categories. For example, gender could be coded as a 1 to represent female and a 0 to represent male. When a measure has more than two categories, a researcher creates \( k - 1 \) dummy variables to represent the total number of different categories, \( k \), with one of the categories indicated by 0. 2. in mathematics and computer science, a variable that can stand for or be bound to any element from its domain. Also called **indicator variable**.

**dummy variable coding** a method of assigning numerical values to a categorical variable in such a way that the variable reflects class membership. The values of 0 and 1 are used, with 0 typically representing non-membership and 1 typically representing membership. Compare **contrast coding**; **effect coding**.

**Duncan’s multiple range test** (Duncan’s MRT) a **multiple comparisons test** used to follow up on an **analysis of variance** that yields significant results. After obtaining a significant \( F \) ratio, a researcher could conclude that at least one pair of samples is significantly different on the dependent variable and then conduct a Duncan multiple range test on pairs of samples to identify that specific pair. The overall Type I error rate would be protected, which would not be the case if separate \( T \) tests were conducted on all possible pairs. Other types of procedures for following up a significant analysis of variance include the **Scheffé test** and **Tukey’s honestly significant difference test**, among others. [David B. Duncan (1917–2006), U.S. biostatistician]

**Dunn–Bonferroni procedure** a statistical method for assessing whether multiple pairs of samples are significantly different from each other, while protecting the overall Type I error rate by dividing the alpha or significance level by the number of comparisons made. For example, if a researcher wants to investigate whether three samples are significantly different using an alpha of .05, three \( T \) tests could be conducted (i.e., between groups 1 and 2, 2 and 3, and 1 and 3) using an alpha level of .05/3 = .0167 for each comparison; this approach would hold the overall Type I error rate at .05. Also called **Bonferroni test**.

**Dunn’s multiple comparison test**. [James Dunn, U.S. mathematician; Carlo Emilio Bonferroni (1892–1960), Italian mathematician]

**Dunnett’s multiple comparison test** a statistical method for assessing whether a **control group** is significantly different from each of several treatment groups. It is similar to the **Dunn–Bonferroni procedure** but not as
Dunnett's multiple comparison test  see Dunn–Bonferroni procedure.

duplex theory  the theory that vision depends on the activity of two types of receptors: the retinal rods, which are active in dim light; and the retinal cones, which are active in brighter light. Also called duplicity theory.

durable power of attorney  see advance directive.

dura mater  n.  a trade name for fentanyl.

dying process  a progressive and nonreversible loss of vital functions that results in the end of life. The transition from health to death can be swift or extended, predictable or unpredictable, depending on the specific life-threatening condition in question.
dynamic adj. 1. pertaining to force. 2. continuously changing or in flux. 3. describing systems of psychology that emphasize motivation, mental processes, and the complexities of force and interaction. See also DYNAMIC PSYCHOLOGY; PSYCHODYNAMICS.

dynamic anthropology design practice that takes into account the actions and movements expected of product or system users, with the goal of shifting adjustment demands from the user to the product, so that, for example, the angle of a backrest changes automatically when the user moves.

dynamic assessment 1. a process that uses formal DYNAMIC TESTING as well as essays and the like to assess learning ability. 2. an assessment that has the goal of elaborating on the complex reasons for dysfunctions, especially with regard to conflicts.

dynamic calculus a model of motivation based on measurements of innate drives (ERGS) and sentiments. [proposed by Raymond B. Cattell]

dynamic core a postulated brain basis for conscious events, involving a subset of neurons in the THalamocortical system that enables specific conscious experiences. The most information-rich subset of neurons involved may vary dynamically from moment to moment, but the core always maximizes high integration and differentiation of information. See COMPLEXITY HYPOTHESIS. [proposed by U.S. neuroscientist Gerald M. Edelman (1929–2014) and Italian–U.S. neuroscientist Giulio Tononi (1960–)]

dynamic effect law the theory that GOAL-DIRECTED BEHAVIORS become habitualized as they effectively attain the goal. [proposed by Raymond B. Cattell]

dynamic equilibrium the state of a system in which different (often opposing) reactions or other processes occur at the same rate and thus balance each other, such that there is no net change to the overall system. See also DYNAMIC SYSTEM.

dynamic formulation the ongoing attempt to organize the clinical material elicited about a client's behavior, traits, attitudes, and symptoms into a structure that helps the therapist understand the client and plan his or her treatment effectively.

dynamic interactionism a model of personality and behavior in which individual development depends upon continuous, reciprocal interaction with the environment.

dynamic kinesthetic imagery see KINESTHETIC IMAGERY.

dynamic model in psychoanalytic theory, the view that the psyche can be explained in terms of underlying, unconscious drives and instincts that mold the personality, motivate behavior, and produce emotional disorder. Compare ECONOMIC MODEL; TOPOGRAPHIC MODEL. See also METAPSYCHOLOGY.

dynamic psychology 1. any system of psychology that emphasizes MOTIVATION or DRIVE. 2. a theory of psychology emphasizing causation and motivation in relation to behavior, specifically the stimulus–organism–response chain in which the stimulus–response relationship is regarded as the mechanism of behavior and the drives of the organism are the mediating variable. See S-O-R PSYCHOLOGY.

dynamic psychotherapy see PSYCHODYNAMIC PSYCHOTHERAPY.

dynamics n. 1. the study of motion in terms of the forces involved. 2. the forces that bring about motion. See also KINEMATICS.

dynamic self-distribution in GESTALT PSYCHOLOGY, the tendency of the constituents of a whole to arrange themselves in a way that is influenced by the totality and the role of each part in that totality. [attributed to Wolfgang Köhler]

dynamic skill theory see SKILL THEORY.

dynamic social impact theory an extension of SOCIAL IMPACT THEORY that seeks to explain the changes in physiological states, subjective feelings, emotions, cognitions, and behavior that occur as a result of SOCIAL INFLUENCE. The model assumes that this influence is a function of the strength, immediacy, and number of people (or, more precisely, sources) present, and that this influence results in consolidation (growth of the majority), clustering (the emergence of small groups whose members hold similar opinions), correlation (the convergence of group members' opinions on a variety of issues), and continuing diversity (the maintenance of the beliefs of the members of the minority) in groups that are spatially distributed and interacting repeatedly over time. [developed by U.S. social psychologist Bibb Latané (1937–)]

dynamic system a system in which a change in one part influences all interrelated parts. Such a system is described by a set of quantitative variables changing continuously and interdependently in time in accordance with laws captured by some set of equations. Dynamic system models provide an important alternative to symbolic models as a way to understand many psychological phenomena (e.g., coordinated movements, developmental phenomena, and decision making).

dynamic systems theory a theory, grounded in NONLINEAR systems principles, that attempts to explain behavior and personality in terms of constantly changing, self-organizing interactions among many organismic and environmental factors that operate on multiple timescales and levels of analysis. See CHAOS THEORY; COMPLEXITY THEORY.

dynamic testing an approach to the measurement of learning (i.e., both the ability and the potential to learn) that attempts to identify and quantify through progressively more difficult tasks the degree to which an individual's developed ability reflects underlying capacity. [introduced by Lev Vygotsky]

dynamic touch the perception of the characteristics of an object by wielding and manipulating it. People can perceive length and shape by dynamic touch.

dynamic trait a personality trait that involves motivation or putting the individual into action. It is one of three classes of SOURCE TRAITS in CATTELL'S PERSONALITY TRAIT THEORY, the others being ABILITY TRAITS and TEMPERAMENT TRAITS.

dynamic unconscious see UNCONSCIOUS.

dynamic visual display in ergonomics, a visual display that is designed to present fluctuating information, such as changes in temperature, speed, or volume.
dynamogenesis n. 1. the development of force, especially in the muscles or nerves. 2. the SENSORIMOTOR principle that changes in motor responses are correspondent and proportional to changes in sensory activities. 3. the idea that motor responses are evoked by sensory stimulation. Also called dynamogeny.

dynamometry n. the measurement of force expended or power, especially muscular effort or strength. A dynamometer usually consists of a spring that can be compressed by the force applied. For example, a hand dynamometer is a device for measuring manual grip strength by the amount of force applied to a spring by the hands. See grip strength test. —dynamometric adj.

dynorphin n. see endogenous opioid.

dys- prefix 1. diseased or abnormal (e.g., dysgeusia). 2. painful or difficult (e.g., dysmenorrhea).

dysacusia n. a distressing sensation of tones or noises of peripheral origin, such as TINNITUS from cochlear or tympanic disease. Also called dysacusia: dysacusia. —dysacusic adj.

dysaesthesia n. see dysesthesia.

dysarthria n. a MOTOR SPEECH DISORDER characterized by difficulty speaking coherently because of impairment in the central or peripheral nervous system. There are four main types usually described: dyskinetic, spastic, peripheral, and mixed. Dyskinetic dysarthria includes hypokinetic dysarthria, in which the rate and rhythm of speech are affected, and hyperkinetic dysarthria, in which articulation is poor due to problems controlling the rate and range of movement in ongoing speech. In spastic dysarthria, respiration is poor, intonation patterns are restricted, and spasticity in the vocal folds causes hoarseness. Peripheral dysarthria involves continual breathiness with audible inspiration, distortion of consonants, and often a need to speak in short phrases. Mixed dysarthria includes symptoms of more than one of the other types of dysarthria and results from tumors, degenerative diseases, trauma, or other conditions that cause multiple neurological impairments. It is important to distinguish dysarthria from ANARTHRIA, which is the complete inability to speak. —dysarthric adj.

dysautonomia n. see AUTONOMIC DYSFUNCTION.

dysbasia n. distorted or difficult walking due to either neurological disease or psychological disorder.

dyslexia n. 1. difficulty in thinking, maintaining attention, or maintaining a train of thought. 2. lack of willpower or weakness of volition.

dyscalculia n. an impaired ability to perform simple arithmetic operations that results from a congenital deficit. It is a developmental condition, whereas ACALCULIA is acquired.

dyschiria (dyschiria) n. disordered perception of one side of the body versus the other. Types include ACHIRIA, ALLOCHIRIA, and SYNCHIRIA.

dyschromatopsia n. a congenital or acquired defect in the discrimination of colors.

dysconjugate gaze a condition in which the motion of the two eyes is uncoordinated.

dyscontrol n. an impaired ability to direct or regulate volition, emotion, behavior, or cognition, or some other area, which often entails inability to resist impulses and leads to abnormal behaviors without significant provocation.

dysdiadochokinesis n. loss of ability to perform rapid alternating movements (e.g., repeatedly slapping one’s palm and then the back of one’s hand against the knee). Also called dysdiadochokinesia.

dyseidetic dyslexia a type of dyslexia that is marked by difficulty in recognizing whole words and thus by an over-reliance on sounding out words each time they are encountered. It is supposedly due to deficits in VISUAL MEMORY and VISUAL DISCRIMINATION. There is, however, no reliable empirical evidence for this form of dyslexia. See also DYSPHONETIC DYSLEXIA. [proposed in 1973 by U.S. psychologist Elena Boder (1907–1995)]

dysesthesia (disesthesia: dysesthesia) n. abnormalities of any sense but particularly that of touch.

dysexecutive syndrome (DES) a collection of symptoms that involve impaired executive control of actions (see EXECUTIVE DYSFUNCTION), caused by damage to the frontal lobes of the brain. Individuals can perform routine tasks but cannot deal with new tasks or situations. They have difficulty in initiating and switching actions; for example, they cannot prevent an inappropriate but highly automated action from occurring or change their actions to appropriate ones. A questionnaire called the Dysexecutive Questionnaire (DEX) can be used to assess the severity of the impairment.

dysfluency n. any disturbance in the normal flow or pattern of speech, marked by repetitions, prolongations, and hesitations. See also stuttering.

dysfunction n. any impairment, disturbance, or deficiency in behavior or operation. —dysfunctional adj.

dysfunctional family a family in which relationships or communication are impaired and members are unable to attain closeness and self-expression. Members of a dysfunctional family often develop symptomatic behaviors, and often one individual in the family presents as the IDENTIFIED PATIENT.

dysfunctions associated with sleep, sleep stages, or partial arousals one of four basic types of SLEEP DISORDERS, differentiated from the other types by the presence of physiological activations at inappropriate times during sleep rather than by abnormalities in the mechanisms involved in the timing of sleep and wakefulness. This type of sleep disorder includes NIGHTMARE DISORDER, SLEEP TERROR DISORDER, and SLEEPWALKING DISORDER; in DSM–IV–TR and DSM–5, these are classified as PARASOMNIAS.

dysgenic adj. describing a factor or influence that may be detrimental to heredity. Compare EUGENIC.

dysgeusia n. abnormalities of the sense of taste. These gustatory distortions may occur during pregnancy, prior to an epileptic seizure, or as a symptom of psychosis or an eating disorder. See also HYPOGEUSIA.

dysgnosia n. a mild form of ANOSIA.

dysgrammatism n. see AGRAMMATISM.

dysgraphia n. see AGRAPIA. —dysgraphic adj.

dyskinesia n. any involuntary (unintended) movement, such as a tic or spasm. The term also is used more precisely to denote distorted or impaired voluntary movement. Also called dyskinesia. —dyskinetic adj.
dyskinetic dysarthria see DYSARTHRIA.

**dyslexia** n. a neurologically based learning disability manifested as severe difficulties in reading, spelling, and writing words and sometimes in arithmetic. Dyslexia is characterized by impairment in the ability to process sounds, that is, to make connections between written letters and their sounds; written work is often characterized by REVERSAL ERRORS. It can be either acquired (in which case it is often referred to as ALEXIA) or developmental (see DEVELOPMENTAL DYSLEXIA), is independent of intellectual ability; and is unrelated to disorders of speech and vision that may also be present. It is not the result of lack of motivation, sensory impairment, inadequate instructional or environmental opportunities, emotional disturbances, or other such factors. Since the 1960s, information-processing and other psychological accounts of acquired dyslexia have prompted investigators to subdivide it into two general classes: (a) **VISUAL WORD-FORM DYSLEXIA**, which is characterized by difficulty in the visual analysis of written words; and (b) **CENTRAL DYSLEXIA**, which is characterized by difficulty in later stages of the reading process (i.e., pronunciation and comprehension). Various types and subtypes of dyslexia, both acquired and developmental, have also been proposed, but there is no universally accepted system of classification. See also READING DISABILITY; READING DISORDER. —**dyslexic** adj.

**dyslogia** n. see ALOGIA.

**dysmenorrhea** n. difficult or painful menstruation. The cause may be an obstruction in the cervix or vagina that traps menstrual blood, or the condition may be secondary with Alzheimer’s disease and temporal lobe epilepsy. Dysmenorrhea may be caused by cramplike pains in the lower abdomen, headache, irritability, depression, and fatigue. —**dysmenorrheic** adj.

**dysmetria** n. an impaired ability to control the distance, speed, or power of one’s body movements. It is a key sign of cerebellar damage.

**dysmetropsia** n. impairment in the ability to judge the size or shape of objects, although the objects may be recognized for what they are.

**dysnesia** n. an impairment of memory, which may occur as a discrete episode or persist as a chronic condition and may be caused by any of a number of problems, such as delirium, acute or chronic brain disorders, or brain injury. Also called **dysnestic syndrome**. —**dysnestic** adj.

**dysmorphism** n. an abnormality in the shape or structure of some part of the body.

**dysmorphophobia** n. a former name for BODY DYSMORPHIC DISORDER.

**dysnomia** n. a SEMANTIC MEMORY deficit that impairs word retrieval and object naming, as seen in individuals with Alzheimer’s disease and temporal lobe epilepsy.

**dysorexia** n. any distortion of normal appetite or disturbance in normal eating behavior. See also EATING DISORDER.

**dysorthographia** n. an impairment in the ability to spell.

**dysosmia** n. any disorder or disability in the sense of smell. See ANOSMIA; HYPEROSMIA; HYPOSOSMIA; PAROSMIA; PHANTOSMIA.

**dysostosis** n. the defective development of the skeleton of an individual, either because of hereditary factors or because of improper care following birth. The genetic causes are usually expressed in faulty development of the bones of the face and skull. Examples of dysostosis include Crouzon’s syndrome and Treacher Collins syndrome.

**dyspareunia** n. PAINFUL SEXUAL INTERCOURSE, particularly in women. If there are no medical causes for the pain, the diagnosis is FUNCTIONAL DYSPAREUNIA.

**dyspepsia** n. abdominal pain or discomfort that may be caused by ulcers; gastroesophageal reflux (i.e., acid reflux, acid indigestion, or heartburn); gallstones; and, rarely, stomach or pancreatic cancer, although in a majority of cases the cause is unknown. **Functional dyspepsia** (formerly called **nonulcer dyspepsia**) describes the condition when other medical illnesses have been excluded; it may be experienced, for example, after eating too much or too quickly or eating during stressful situations. See also GASTRODUODENAL ULCERATION.

**dysphagia** n. an impaired ability to swallow. It may be due to damage to the cranial nerves or to muscle problems.

**dysphagia spastica** a somatic or, more often, psychological symptom in which the act of swallowing is painful or difficult because of throat-muscle spasms. In psychological cases, it is a symptom of SOMATIZATION DISORDER.

**dysphasia** n. see APHASIA. —**dysphasic** adj.

**dysphemia** n. a disorder of phonation, articulation, or hearing associated with emotional or mental disturbance and, frequently, a predisposition to a neurological disorder. —**dysphemic** adj.

**dysphonetic dyslexia** a type of dyslexia that is marked by an inability to sound out the individual letters and syllables of words (see PHONES) and is supposedly due to difficulty with sound–symbol correspondences. There is, however, no reliable empirical evidence for this form of dyslexia. See also DYSLEXIC DYSLEXIA. [proposed in 1973 by U.S. psychologist Elena Boder (1907–1995)]

**dysphonia** n. any dysfunction in the production of sounds, especially speech sounds (see PHONATION; VOCALIZATION), which may affect pitch, intensity, or resonance. See also SPASTIC PHONOSIS; VOICE DISORDER.

**dysphoria** n. a mood characterized by generalized discontent and agitation. —**dysphoric** adj.

**dysphrasia** n. an older, less common name for dysphasia. See APHASIA.

**dysplastic type** the disproportioned type of an individual who, according to Kretschmer typology, presents a combination of traits but frequently tends toward the introverted, exclusive temperament. See also CONSTITUTIONAL TYPE.

**dyspnea** n. shortness of breath or difficulty in breathing. When not accounted for by high altitude, exertion, or any identifiable physiological cause, the condition is referred to as functional dyspnea.

**dyspnesia** n. in biofeedback and relaxation training, a state of habitual tension that generates hypertension, migraine headaches, bruxism (teeth grinding), or related disorders.

**dyspraxia** n. an impaired ability to perform skilled, coordinated movements that is neurologically based and not due to any muscular or sensory defect. See ACQUIRED
Dyspraxia; Developmental Dyspraxia. See also Apraxia.

Dyspraxic adj.

Dysprosody (dysprosodia) n. See Aprosody.

Dysregulation n. any excessive or otherwise poorly managed mechanism or response. For example, emotional dysregulation is an extreme or inappropriate emotional response to a situation (e.g., temper outbursts, deliberate self-harm); it may be associated with bipolar disorders, borderline personality disorder, autism spectrum disorder, psychological trauma, or brain injury.

Dyspraxia n. difficulty in receiving or sending nonverbal cues. More specifically, people with dyspraxia have trouble interpreting (decoding) or producing (encoding) interpersonal information in the form of facial, postural, gestural, and paralinguistic expressions. For example, a person with dyspraxia might fail to recognize the wide eyes of someone who is fearful. This nonverbal processing deficit is associated with a variety of social difficulties, including problems forming and maintaining friendships, conflict with others, and isolation or rejection. Innate or acquired damage to the amygdala or other limbic system structures is the most common contributing factor. See also Emory Dyspraxia Index. [term coined in 1992 by U.S. clinical psychologists Stephen Nowicki Jr. (1941– ) and Marshall Duke (1942– )]

Dysregulation in DSM–IV–TR. a mood disorder characterized by symptoms that are less severe but more enduring than those in major depressive disorder. It is identified as persistent depressive disorder in DSM–5. Also called dysthymia.

Dyspnea n. abnormal labor or childbirth.

dystonia n. impairment of normal muscle tone, causing prolonged muscle contraction that results in abnormal posture, twisting, or repetitive movements. See also Atonia. —dystonic adj.

Dystopia n. see Utopia. —dystopian adj.

Dystrophobia myotonica see Myotonic muscular dystrophy.

Dystrophin n. a protein that is needed for normal muscle function. Dystrophin is deficient or lacking in some forms of muscular dystrophy.

Dystrophy n. 1. any degenerative disorder arising from faulty or defective nutrition. 2. any disorder involving atrophy (wasting) and weakening of the muscles. See muscular dystrophy.

Dysuria n. difficult or painful urination. A frequent cause is a bacterial infection that produces irritation or inflammation of the urethra or the neck of the bladder.

DZ twins abbreviation for dizygotic twins.
E symbol for EXPECTED VALUE.

EA abbreviation for EDUCATIONAL AGE.

EAHCA abbreviation for EDUCATION FOR ALL HANDICAPPED CHILDREN ACT.

EAP 1. abbreviation for EMPLOYEE ASSISTANCE PROGRAM. 2. abbreviation for EQUINE-ASSISTED PSYCHOTHERAPY.

ear n. 1. the organ of hearing and balance. In humans and other mammals, the ear is divided into external, middle, and inner sections. The pinna of the external ear collects sounds that are then funneled through the external auditory meatus to the tympanic membrane. The sounds are vibrations of air molecules that cause the tympanic membrane to vibrate, which in turn vibrates the ossicles, three tiny bones in the middle ear. The motion of the last of these bones produces pressure waves in the fluid-filled cochlea of the inner ear. The motion of the fluid in the cochlea is converted by specialized receptors called hair cells into neural signals that are sent to the brain by the auditory nerve. 2. the projecting part of the external ear. See AUDITORY SYSTEM.

ear canal see EXTERNAL AUDITORY MEATUS.

cardrum n. see TYPANIC MEMBRANE.

Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) surveillance or search for indications or early manifestations of a disease or disorder, regularly carried out at specific intervals. In the United States, an EPSDT program of preventive health care services (e.g., for vision, hearing, and dental problems) and mental health and behavioral screenings (e.g., for substance abuse) is provided for children and young adults insured through Medicaid.

early bilingualism bilingualism attained early in life, either through the simultaneous acquisition of two languages at home or through early exposure to a second language before the completion of first-language acquisition at around age 5. This is often contrasted with late bilingualism, which refers to second-language acquisition after age 5 (or, in some definitions, after the onset of puberty). Early bilingualism is more likely to result in a native-like command of phonology and grammar than is late bilingualism.

early experience experience acquired in the first 5 years of life, which is believed to have a significant influence on a child’s subsequent cognitive, social, and emotional development. Whereas theorists in the first half of the 20th century believed that early experience permanently determined a child’s development, subsequent research has indicated that later experience can modify the effects of early experience.

early immersion see TOTAL IMMERSION.

early infantile autism see AUTISM.

early intervention a collection of specialized services provided to children from birth to 3 years of age with identified conditions placing them at risk of developmental disability or with evident signs of developmental delay. Services are designed to minimize the impact of the infant’s or toddler’s condition, and in addition to stimulatory, social, and therapeutic programs, they may include family training, screening, assessment, and health care.

early memory adult recollection of childhood events, which typically goes back only to the age of 3 or so, even though the capacity to learn is present at birth. The absence of earlier childhood memories, referred to as CHILDHOOD AMNESIA, has been noted since the time of Sigmund Freud. Explanations include neural immaturity, absence of language or adult schemas to organize event memory, and different coding dimensions in infancy.

early-morning awakening insomnia see TERMINAL INSOMNIA.

early-onset Alzheimer’s disease see ALZHEIMER’S DISEASE.

early-selection theory any theory of attention proposing that selection of stimuli for processing occurs prior to stimulus identification. According to early-selection theory, unattended stimuli receive only a slight degree of processing that does not encompass meaning, whereas attended stimuli proceed through a significant degree of deep, meaningful analysis. Compare LATE-SELECTION THEORY.

Early Years Cognitive Battery see DIFFERENTIAL ABILITY SCALES.

Early Years of Marriage Project (EYM Project) an ongoing longitudinal study of marriage in Black and White American couples. Started in 1986 by U.S. psychologists Joseph Veroff (1929–2007) and Elizabeth Douvan (1926–2002) and sociologist Shirley Hatchett at the University of Michigan, the EYM Project has followed a sample of 373 couples for more than 25 years. It is unique among longitudinal studies of marriage in comparing Black and White couples and has provided important insights into the understanding of the predictors of relationship satisfaction and divorce. Also called Early Years of Marriage Study. See also PAIR PROJECT.

ear ossicles see OSSICLES.

earwax n. see CERUMEN.

ease-of-learning judgment an individual’s prediction of how easy it will be to acquire and retain certain items of information, given before any attempt is made to do so. In tests of learning and memory, participants’ pretest ease-of-learning judgments tend to be only weakly correlated with their performance on the test. Like FEELING OF KNOWING, ease-of-learning judgments are an important aspect of METACOGNITION. Compare RETROSPECTIVE CONFIDENCE JUDGMENT.

Easterbrook hypothesis the hypothesis that the range of cues attended to is inversely related to the degree of arousal; that is, in a state of increased arousal, attention narrows and fewer environmental stimuli are focused on. The hypothesis was proposed as an explanation of YERKES–
DODSON LAW, which describes the relationship between arousal and performance. [proposed in 1959 by J. A. East-erbrook, 20th-century Canadian psychologist]

eating aid an ASSISTIVE TECHNOLOGY device that can be used by people with disabilities to feed themselves independently. Eating aids include metal or plastic devices for holding sandwiches; nonslip place mats, bowls, and dishes with suction cups attached to the bottom; handles that can swivel, are angled, or have extensions; and combination eating devices, such as knife–fork or fork–spoon combinations.

eating compulsion an irresistible impulse leading to abnormal eating behavior. This is a primary symptom of many eating disorders, such as BULIMIA NERVOSA and FOOD ADDICTIONS. See also COMPULSIVE EATING.

eating disorder any disorder characterized primarily by a pathological disturbance of attitudes and behaviors related to food, including ANOREXIA NERVOSA, BULIMIA NER-VOISA, and BINGE-EATING DISORDER. Other eating-related disorders include PICA and RUMINATION, which are usually diagnosed in infancy or early childhood.

Eating Disorders Awareness and Prevention, Inc. see NATIONAL EATING DISORDERS ASSOCIATION.

Ebbinghaus curve see FORGETTING CURVE. [Hermann Ebbinghaus]

Ebbinghaus illusion a size CONTRAST ILLUSION in which a concentric ring of large circles makes a mediumsized circle in the center of the ring look small, whereas the same circle in the center of a ring of smaller circles looks large. Also called Titchener circles; Titchener illusion. [introduced in the 1890s by Hermann Ebbinghaus but sometimes incorrectly attributed to Edward Bradford Titchener]

Ebonics n. see BLACK ENGLISH, [a blend of the words ebony and phonics, coined by U.S. psychologist Robert Lee Williams II (1930— ) at a 1973 conference of Black scholars, “Cognitive and Language Development of the Black Child”]

EBP abbreviation for EVIDENCE-BASED PRACTICE.

EBV abbreviation for EPSTEIN–BARR VIRUS.

ECA Survey abbreviation for EPIDEMIOLOGIC CATCHMENT AREA SURVEY.

cCB abbreviation for ENDOGENOUS CANNABINOID.

eccentric projection the phenomenon of experiencing a stimulus as being in the external world (as in vision and hearing), rather than at the receptor stimulated (as in touch).

eccyosis n. see ECTOPIC PREGNANCY.

ECF abbreviation for extended care facility. See EXTENDED CARE.

ECG abbreviation for ELECTROCARDIOGRAM.

echinacea n. an herbal agent derived from any of nine related plant species native to the United States and southern Canada, with Echinacea purpurea being the most commonly used and perhaps the most potent. Echinacea traditionally has been used in the belief that it stimulates the immune system and prevents or treats colds. Some studies have shown, however, that taking echinacea has no significant effects on preventing colds or reducing their severity or duration. Although it is generally considered safe and there are no known reports of toxicity, some people may experience hypersensitivity reactions to echinacea, such as rashes, increased asthma, and ANAPHYLAXIS. More common side effects include headache, dizziness, nausea, and constipation. People with autoimmune disorders (see AUTOIMMUNITY), leukemia, multiple sclerosis, tuberculosis, and HIV infection should not take echinacea. Concurrent use with immunosuppressant agents should be avoided, and, as echinacea is believed to be metabolized by the CY-TOCHROME P450 3A4 enzyme, it accordingly has numerous potential interactions with psychotropic drugs metabolized via the same enzyme (e.g., clonidine, nefazodone, St. John’s wort).

echo n. a reflected sound wave that is distinct from that directly transmitted from the source.

echocardiography n. the production of a graphic record or image (echocardiogram) of the internal structures and beating of an individual’s heart with an ultrasound device that uses sonarlike reflections. Echocardiography enables the visualization and measurement of all the chambers and valves of the heart as well as the pumping efficiency of the organ.

Écho des pensées an AUDITORY HALLUCINATION in which an individual hears his or her own thoughts repeated in spoken form. Also called thought echoing.

echoencephalography n. a method of mapping brain anatomy for diagnostic purposes by using ultrasonic waves. The waves are transmitted through the skull using an instrument called an echoencephalograph, and echoes of the waves from intracranial structures are recorded to produce a visual image called an echoencephalogram. The method, though still in use, is now considered outdated and has been largely superseded by such methods as TRANSCRANIAL DOPPLER ULTRASONOGRAPHY.

echographia n. pathological writing that involves copying words and phrases without understanding them.

echoic memory the retention of auditory information for a brief period (2–3 seconds) after the end of the stimulus. Also called auditory sensory memory.

echolalia n. mechanical repetition of words and phrases uttered by another individual. It is often a symptom of a neurological or developmental disorder, particularly cata-tonic schizophrenia or autism. Also called echophasia.

echolocation n. the ability to judge the direction and distance of objects or obstacles from reflected echoes made by acoustic signals, such as footsteps, the tapping of a cane, or traffic noises. People with visual impairment can learn to develop this ability to find their way and avoid obstacles. Among nonhuman animals, both bats and marine mammals (e.g., dolphins) can locate objects by emitting high-pitched sounds that are reflected from surfaces of the physical environment and prey objects. High-pitched sounds provide better spatial resolution of an object than sounds of lower pitch but require more energy to travel the same distance. Thus, a bat can locate a mosquito but only at a short range. See also ULTRASONIC COMMUNICATION.

echophasia n. see ECHOLALIA.

echopraxia n. mechanical repetition of another person’s movements or gestures. It is often a symptom of a neurological disorder, particularly catatonic schizophrenia.

echovirus n. enteric cytopathic human ORPHAN VIRUS: any of more than 30 types of viruses of the genus Enteroviruses. Infection is asymptomatic in 90% of cases; in others, infec-
tion may cause a range of conditions, from mild fever and respiratory symptoms to severe, sometimes fatal conditions such as meningitis and encephalitis. Infection occurs most often during the summer and fall in temperate climates and year-round in tropical climates. When first discovered, the viruses were not a part of any known family of infectious agents (hence their labeling as “orphan”).

**eclampsia** n. convulsions that occur in pregnant women and are not associated with epilepsy or other cerebral disorders. They are preceded by eclamptic seizures, which can occur before, during, or after delivery of the child, are usually followed by unconsciousness or coma of varying lengths. —eclamptic adj.

**eclectic behaviorism** an approach to behavior therapy that does not adhere to one theoretical model but applies, as needed, any of several techniques, including classical conditioning, modeling, and operant conditioning, self-control mechanisms, and cognitive restructuring.

**eclectic counseling** any Counseling theory or practice that incorporates and combines doctrines, findings, and techniques selected from diverse theoretical systems.

**eclecticism** n. a theoretical or practical approach that blends, or attempts to blend, diverse conceptual formulations or techniques into an integrated approach. —eclectic adj.

**eclectic psychotherapy** any psychotherapy that is based on a combination of theories or approaches or uses concepts and techniques from a number of different sources, including the integrated professional experiences of the therapist. With the more formalized prescriptive eclectic psychotherapy, the clinician attempts to customize psychological treatments and the therapeutic relationship to the specific needs of individual clients. This is done by drawing on effective methods from across theoretical cums and by matching those methods to particular cases on the basis of empirically supported guidelines.

**eclima** n. increased appetite or insatiable hunger, often associated with bulimia nervosa. Also called eclimia. See also hyperorexia; hyperphagia.

**ECM** abbreviation for external chemical messenger.

**ecobehavioral assessment** an observational research method used in applied behavior analysis to measure moment-to-moment effects of multiple environmental events on an individual’s specific behaviors. These events include the behavior of others, task demands, time of day, and situational changes.

**ECochG** abbreviation for electrocorticography.

**ecofeminism** n. a position that combines feminism with a commitment to environmentalism and environmental activism. It emphasizes a concomitance between the exploitation of nature and the exploitation of women, suggesting that there is a set of social, political, and philosophical attitudes that give rise to and maintain both. —ecofeminist n.

**ECG** abbreviation for electrocardiography.

**ecological assessment** the gathering of observations in various environments to examine whether individuals or entities behave differently depending on the surroundings. For example, a teacher at a child-development center may investigate whether children demonstrate more or less problem behavior in various settings at the center. Findings from the ecological assessment may offer ideas on how to intervene to improve the overall behavior of the children in multiple settings.

**ecological fallacy** a mistaken conclusion drawn about individuals based on findings from groups to which they belong. For example, if a university administrator found that the correlation between faculty salary and number of publications at the departmental level was strong and positive (e.g., r = .60), it would be an ecological fallacy to assume that for any particular faculty member the correlation would be the same.

**ecological momentary assessment** (EMA) the process of examining the behavior of individuals at random, multiple time points to get a clearer picture of how they behave in various real-world settings. For example, a researcher may conduct an EMA on individuals who are trying to quit smoking by contacting them randomly throughout a week to inquire about urges to smoke, mood, other people who are interacting with them, and other relevant circumstances that may be occurring at these times.

**ecological niche** 1. the function or position of an organism or a population within a physical and biological environment. 2. the particular area within a habitat occupied by an organism or a population.

**ecological perception** an organism’s detection of the affinities and invariances within its natural, real-world environment (i.e., its ecology as opposed to a laboratory setting), as mediated and guided by the organism’s immersion in and movement through that environment. James J. Gibson proposed that ecological perception is holistic (the organism and environment are a single inseparable system), that environmental properties are perceived as meaningful entities, and that perceptual patterns may be direct rather than concepts that require interpretation by higher brain centers from visual or other cues. See direct perception.

**ecological perspective** a concept of community psychology in which a community (or any other social entity) is viewed in terms of the interrelations among people, roles, organizations, local events, resources, and problems. It accounts for complex reciprocal interactions of individuals and their environment. The premise of the ecological perspective is that intervention should contribute to the development of the entire community.

**ecological psychology** 1. the analysis of behavior settings with the aim of predicting patterns of behavior that occur within certain settings. The focus is on the role of the physical and social elements of the setting in producing the behavior. According to behavior-setting theory, the behavior that will occur in a particular setting is largely prescribed by the roles that exist in that setting and the actions of those in such roles, irrespective of the personalities, age, gender, and other characteristics of the individuals present. In a place of worship, for example, one or more individuals have the role of leaders (the clergy), whereas a larger number of participants function as an audience (the congregation). Other factors that shape behavior are the size of the setting, the number of roles required to maintain it, its permeability (i.e., openness to outside influence or nonmembers), and the explicitness of rules and regulations relating to expected behavior there. 2. a less common name for the theoretical orientation embodied by...
James J. Gibson’s concepts of ecological perception and direct perception.

**ecological study** 1. research into the mutual relations between organisms and their environments. See ecology. 2. in psychology, research that evaluates the influence of environmental factors on individual behavior and mental health. See human ecology; social ecology; urban ecology. 3. any study in which the statistical analyses are conducted at the population level rather than the individual level. See epidemiology.

**ecological systems theory** an evolving body of theory and research concerned with the processes and conditions that govern the course of human development in the actual environments in which human beings live. Originally focused on the environment as a context for child development (in terms of nested systems ranging from micro- to macro-), the theory is now known as the bioecological model, denoting a broader conception of human development as a process that is affected, across the lifespan and across successive generations, by both environmental context and individual biopsychological characteristics. See also chronosystem; ecosystemic approach; exosystem; macrosystem; mesosystem. [originally conceptualized by Urie Bronfenbrenner]

**ecological validity** 1. the degree to which results obtained from research or experimentation are representative of conditions in the wider world. For example, psychological research carried out exclusively among university students might have a low ecological validity when applied to the population as a whole. Ecological validity may be threatened by experimenter bias, oversimplification of a real-world situation, or naive sampling strategies that produce an unrepresentative selection of participants. See also validity. [defined by Martin T. Orne on the basis of work by Egon Brunswik] 2. in perception, the degree to which a proximal stimulus (i.e., the stimulus as it impinges on the receptor) covaries with the distal stimulus (i.e., the actual stimulus in the physical environment). [originated by Egon Brunswik]

**ecology** n. the study of relationships between organisms and their physical and social environments. Behavioral ecology is a subfield that examines how the behavior of nonhuman animals is affected by physical and social factors.  

**economia** n. a morbid preoccupation with and pathological attitude toward members of one’s family, characterized by irritability and domineering behavior. It is often a factor in domestic violence and the cycle of violence. Also called okomania.

**economic model** in psychoanalytic theory, the view that the psyche can be explained in terms of the amounts and distributions of psychic energy associated with particular mental states and processes. Compare dynamic model; topographic model.

**Econo’mo’s disease** see encephalitis lethargica. [Constantin von Economo (1876–1931), Austrian neurologist]

**economy** n. 1. any system of rules and regulations by which something is managed; for example, a token economy is one in which a behavioral system is managed according to the disbursement of tokens as rewards. 2. management of resources in order to maximize efficiency or returns (material or psychological) and to avoid waste.

**economy of effort** the tendency of an organism to act efficiently and minimize the expenditure of energy, such as by avoiding any unnecessary movements.

**ecology principle** see law of parsimony.

**ecopathology** n. the identification of people as abnormal by other members of their community. Behavior considered normal in some communities (i.e., conforming to the attitudes and beliefs of community members) may be regarded as eccentric or even psychotic in other communities.

**ecopsychology** n. 1. a field that promotes a less egocentric mode of thinking in favor of a more ecocentric one. By encouraging humans to rethink their position in the natural world, some psychologists believe they can influence people to be more responsible stewards of nature. 2. an occasional synonym of environmental psychology.

**ecosystem** n. a self-contained unit comprising a community of individuals of different species and the environment they inhabit. There is an interdependent balance of predators, prey, food resources, and substrates such that a change in any one component is often followed by compensatory changes in the other components.

**ecosystemic approach** an approach to therapy that emphasizes the interaction between the individual or family and larger social contexts, such as schools, workplaces, and social agencies. The approach emphasizes interrelatedness and interdependency and derives from diverse fields, including psychology, sociology, anthropology, economics, and political science. Family therapy in particular has made use of this approach in designing interventions for complex families and systems. See also ecological systems theory. [developed in psychology by Urie Bronfenbrenner]

**ecphory** n. 1. the activation of a memory, which involves the retrieval of a memory by a cue. A retrieval cue that matches information stored in memory results in access to that memory. Cues or conditions that were present when the memory was formed are stored with the memory; therefore, those same conditions need to be reinstated at retrieval to provoke ecphory. 2. the process in which a memory, emotion, or the like is revived in the mind by a stimulus. Also called ecphoria. [defined by German biologist Richard Semon (1859–1918)]  

**ECT** abbreviation for electroconvulsive therapy. See electroconvulsive therapy.

**ecstasy** n. a feeling of intense pleasure and elation, including that experienced in some mystical states, during orgasm, with aesthetic reveries, and in drug-induced states. Such extreme euphoria also may occur in the context of a hypomanic episode or a manic episode.  

**Ecstasy** n. the popular name for MDMA.

**ecstatic trance** an altered state of consciousness characterized by joy and happiness. It is often associated with various religious practices, such as intense meditation or certain emotional styles of worship. See also mysticism; voodoo.

**ECT** 1. abbreviation for electroconvulsive therapy. 2. abbreviation for elementary cognitive task.

**ECT-induced amnesia** amnesia that is a by-product of electroconvulsive therapy (ECT). Although ECT is effective in the relief of severe depression, memory deficits often
ecto-

arise, especially when the current is applied to both sides of the brain. Memory can be severely compromised in the hours or days following treatment, but new learning typically returns to normal by 6 months after treatment. Some impairment in the retrieval of events that occurred close to the time of treatment may remain.

**ecto-** combining form outer or outside.

**ectoderm n.** the outermost of the primary GERM LAYERS of a developing embryo. Structures derived from ectoderm include skin and nails, hair, glands, mucous membranes, the nervous system, and external sense organs (e.g., ears, eyes). —ectodermal adj.

**ectohormone n.** see PHEROMONE.

**ectomorph n.** a constitutional type (SOMATOTYPE) in **Sheldon’s Constitutional Theory of Personality** characterized by a thin, long, fragile physique, which—according to this theory—is highly correlated with CEREBRITIONA. Also called **ectomorphic body type.** —ectomorphic adj. —ectomorphy n.

**ectomy** combining form surgical removal of a part of the body (e.g., lobectomy). See also -TOMY.

**ectopia n.** displacement or abnormal positioning of part of the body. For example, neurons are seen in unusual positions in the cerebral cortex of people with dyslexia. —ectopic adj.

**ectopic pregnancy** a pregnancy that develops outside the uterus, most commonly in a fallopian tube (a TUBAL PREGNANCY). Also called **ecysis; extraterine pregnancy; paracysis.**

**ectopic testis** a testis that descends improperly from the abdominal cavity and becomes lodged outside the scrotum, such as beneath the outer tissue layers of the thigh or in the perineum.

**ectoplasm n.** 1. the relatively more dense cytoplasm found at the periphery of a cell. Compare **endoplasm.** 2. in **SPIRITUALISM,** a viscous substance said to emanate from a medium’s body during a seance. Also called **teleplasm.** See also **MATURATIONAL.** —ectoplasmic adj.

**ectotherm n.** an animal whose body temperature is largely regulated by the environment, which is the source of most of its heat. Examples include snakes and bees. Such animals, formerly called poikilotherms, are popularly described as cold-blooded. Compare **endotherm.** —ectothermic adj.

**EDI** abbreviation for **EMORY DYSSEMIA INDEX.**

**Edinger–Westphal nucleus** a collection of small nerve cells in the midbrain. It is part of the PARASYMPATHETIC NERVOUS SYSTEM pathway to the ciliary muscle and the pupillary sphincter of the eye, which play a role in visual accommodation. [Ludwig **Edinger** (1855–1918), German neuroanatomist; Karl Friedrich Otto **Westphal** (1833–1890), German neurologist]

**EDR** abbreviation for **electrodermal response.** See **GALVANIC SKIN RESPONSE.**

**edrophonium n.** an anticholinesterase (see **CHOLINERGIC DRUG**) characterized by a rapid onset and short duration of action. It is the drug of choice in the diagnosis of myasthenia gravis, and it may also be used in surgical anesthesia to reverse the effects of neuromuscular blocking agents. U.S. trade names: **Enlon; Reversol.**

**educable adj.** having the potential for academic learning. —educability n.

**educable mentally retarded (EMR)** in **SPECIAL EDUCATION,** a rarely used term for a category of people with mild or high-moderate mental retardation (IQ 50 to 70 or 80) who are capable of achieving approximately a fifth-grade academic level.

**education n.** 1. the process of teaching or acquiring knowledge, skills, and values. 2. a field of advanced teacher preparation that involves the practice of methods for teaching and learning. —educational adj.

**educational acceleration** educational progress at a rate faster than usual through a variety of measures, such as strengthening or compacting the curriculum, accelerating instruction in particular subject areas, or grade skipping. These measures are designed to provide gifted students with work more ideally suited to their abilities. Grade acceleration is thought by some to represent a potential disadvantage if the student’s social and emotional development is lagging behind his or her intellectual development. Careful assessment of intellectual ability, educational achievement, and social, emotional, and physical development is essential prior to acceleration of one or more grades. Also called **scholastic acceleration.**

**educational attainment level** 1. the status of learning that has been achieved by a student or group of students. 2. the set of standards for acquired knowledge that a student must master before being considered for the next educational step, level, or grade. 3. the highest level of schooling completed. Research has linked higher educational attainment levels to greater income level, better health, and other positive outcomes.
educational counseling the COUNSELING specialty concerned with providing advice and assistance to students in the development of their educational plans, choice of appropriate courses, and choice of college or technical school. Counseling may also be applied to improve study skills or provide assistance with school-related problems that interfere with performance (e.g., learning disabilities). Educational counseling is closely associated with VOCATIONAL COUNSELING because of the relationship between educational training and occupational choice. Also called educational guidance; student counseling. See also COUNSELING PSYCHOLOGY.

educational diagnosis 1. the process of analytically examining a learning problem, which may involve identification of cognitive, perceptual, emotional, and other factors that influence academic performance or school adjustment. 2. the conclusion reached as a result of the analytical examination of a learning problem.

educational guidance see EDUCATIONAL COUNSELING.

educational linguistics a broad field of study concerned with language in education, particularly the use of linguistic theory in developing instructional methods and educational policy.

educational measurement the development and application of tests to measure student abilities.

educational neuroscience see NEUROEDUCATION.

educational pacing 1. the rate or speed of the learning process. 2. the control and monitoring of student work speed by a teacher, supervisor, or discussion leader. 3. the rate at which a whole class of students moves through a specific curriculum. This is determined by multiple factors, such as number of students in the class, student ability and interest, teacher philosophy, and teacher competence.

educational placement the act of matching students with the appropriate educational program or environment for their age, abilities, and needs. Standardized tests, classroom test data, interviews, and past student performance may all be taken into account in arriving at this decision.

educational program a curriculum or course of training that upon completion often leads to an academic degree, certification, or license. ACCREDITATION may be given by a supervisory organization of the minimum standards that must exist within the institution offering the educational program.

educational psychology a branch of psychology dealing with the application of psychological principles and theories to a broad spectrum of teaching, training, and learning issues in educational settings. Educational psychology also addresses psychological problems that can arise in educational systems. Educational psychologists often hold applied as well as academic positions, spending their time in a variety of teaching, research, and applied pursuits.

educational quotient (EQ) a ratio of EDUCATIONAL AGE to CHRONOLOGICAL AGE times 100.

educational retardation 1. slowness or delay of student progress in acquiring knowledge due to a physical, emotional, intellectual, or mental disability. 2. a slowness or delay that is specific to a certain subject or educational setting.

educational sport psychology a specialty focused on the use of psychological methods to improve performance in sport. Educational sport psychologists assist participants in sport to optimize PERFORMANCE ENHANCEMENT through, for example, use of IMAGERY and ATTENTIONAL FOCUS. Education and training may also be informed by SPORT SCIENCE, physical education, or KINESIOLOGY. Compare CLINICAL SPORT PSYCHOLOGY.

Educational Testing Service (ETS) a nonprofit organization, founded in 1947, whose mission is to help advance quality and equity in education by providing fair and valid assessments, research, and related services. The SCHOLASTIC ASSESSMENT TEST and GRADUATE RECORD EXAMINATIONS are well-known tests developed by ETS.

educational tests see DIAGNOSTIC EDUCATIONAL TESTS.

educational therapy individualized treatment interventions for people with learning disabilities or emotional or behavioral problems that significantly interfere with learning. Educational therapy integrates educational techniques and therapeutic practices to promote academic achievement and the attainment of basic skills while building self-esteem and confidence, fostering independence, and aiding personal development. It is usually conducted by a professionally trained educational therapist.

Education for All Handicapped Children Act (EAHCA; EHA) an act passed by the U.S. Congress in 1975 guaranteeing all children equal access to education in the LEAST RESTRICTIVE ENVIRONMENT, which led to the promotion of programs for admitting children with disabilities into the general population of students. This act has since been replaced by the INDIVIDUALS WITH DISABILITIES EDUCATION ACT.

eduction n. the comprehension of relations, or the comprehension of correlates, or both, in an analogy. Eduction of relations involves understanding the relationship between the first two terms of an analogy, whereas eduction of correlates involves the application of this understanding to the third term in the analogy to find the solution. For example, in the analogy “tall : short :: ?”, eduction of relations would be used to infer the relation between tall and short, and eduction of correlates would be used to apply the relation to produce light as a solution. [Defined in the early 20th century by Charles Spearman]

Edwards Personal Preference Schedule (EPPS) a personality inventory for college students and adults in which the strength of 15 “manifest needs” is assessed on a forced-choice basis. The needs are achievement, order, deference, autonomy, exhibition, affection, succorance, sympathy, change, endurance, heterosexuality, aggression, intrapersonal, abusement, and affiliation. [Developed in the 1950s by Allen L. Edwards (1914–1994), U.S. psychologist, based on the needs described in the personality theory of Henry Alexander Murray]

Edwards Social Desirability Scale a 39-item inventory derived from the MINNESOTA MULTIPHASIC PERSONALITY INVENTORY and used to measure whether respondents are truthful in self-reports or are misrepresenting themselves in a way likely to be seen as positive by others. [Developed in the 1950s by Allen L. Edwards]

Edwards syndrome see TRISOMY 18. [John Hilton Edwards (1928–2007), British geneticist]

EEG abbreviation for ELECTROENCEPHALOGRAPHY or electroencephalogram.
EEG biofeedback

**EEG biofeedback** see NEUROFEEDBACK.

**EEG measures of intelligence** measures of intelligence believed to be extractable from electroencephalographic assessments of sites in the brain. Although some investigators found correlations between EEG measures of intelligence and psychometric test scores, other investigators often failed to replicate their findings. These measures have largely been superseded by more precise ERP MEASURES OF INTELLIGENCE.

**EEOC** abbreviation for EQUAL EMPLOYMENT OPPORTUNITY COMMISSION.

**EFA** abbreviation for EXPLORATORY FACTOR ANALYSIS.

**effect** n. 1. an event or state that is brought about as the result of another (its CAUSE). 2. in ANALYSIS OF VARIANCE, a statistically significant relationship between variables, such that one variable is held to be an outcome of another (or some combination of others). See MAIN EFFECT; INTERACTION EFFECT. 3. short for EFFECT SIZE.

**effectance** n. the state of having a causal effect on objects and events in the environment; the word is commonly used in the term **effectance motivation**, coined by Robert W. WHITE in 1959.

**effect coding** in REGRESSION ANALYSIS, a procedure in which values of 1 or −1 are assigned to represent the categories of a DICHOTOMOUS VARIABLE (or 1, 0, and −1 for a trichotomous variable). The results obtained for the group indicated by values of 1 are then interpreted relative to the larger group comprising all participants. For example, a researcher could assign values of 1 to individuals in an EXPERIMENTAL GROUP and values of −1 to those in a CONTROL GROUP. He or she could conclude that there is a treatment effect if the experimental group has a mean different from the grand mean across all of the individuals. Compare CONTRAST CODING; DUMMY VARIABLE CODING.

**effective dose** (ED) the minimum amount of a drug that is required to produce a specified effect. It is usually expressed in terms of median effective dose, or **effective dose 50** (ED50), the dose at which 50% of the nonhuman animal test population has a positive response. In psychotherapy, this criterion is also used to express the number of sessions that are needed for 50% of patients to show a clinically significant change. See also THERAPEUTIC RATIO.

**effectiveness evaluation** the assessment of the degree of success of a program in achieving its goals. The process requires the determination of EVALUATION OBJECTIVES, methods, and CRITERIA OF EVALUATION and the presentation of findings. See also IMPACT ANALYSIS; PROGRAM OUTCOME.

**effectiveness research** reviewing past studies or conducting new studies to evaluate how well current and new treatments work, with the aim of improving the care and treatment of patients. The term is often used synonymously with CLINICAL UTILITY RESEARCH, although some have suggested clinical utility research is a broader term that encompasses studies of additional health-related access to care. Compare EFFICACY RESEARCH.

**effective stimulus** see FUNCTIONAL STIMULUS.

**effect law** see LAW OF EFFECT.

**effector** n. 1. an organ, such as a muscle or a gland, that responds to neural stimulation by producing a particular physical response or initiating a specific physiological event. 2. a motor nerve ending that triggers activity in tissue cells, such as causing a muscle to contract or a gland to secrete. 3. in motor control, the part of the body that interacts with the environment during an action (e.g., the hand during a reaching movement).

**effect size** any of various measures of the magnitude or meaningfulness of a relationship between two variables. For example, COHEN’S D shows the number of STANDARD DEVIATION units between two means. Often, effect sizes are interpreted as indicating the practical significance of a research finding. Additionally, in META-ANALYSES, they allow for the computation of summary statistics that apply to all the studies considered as a whole. See also STATISTICAL SIGNIFICANCE.

**effect-size correlation** (symbol: $r_{	ext{cor, raw}}$) an index of the association between an INDEPENDENT VARIABLE and scores on the DEPENDENT VARIABLE without removing any other sources of variation in the data. An effect-size correlation has values from −1 to +1, with absolute values of .1, .3, and .5 representing small, medium, and large relationships, respectively.

**effect variable** see DEPENDENT VARIABLE.

**effeminacy** n. female behavior or appearance in a male, which is regarded as not fitting the male GENDER ROLE expectations of society. —effeminate adj.

**efference copy** see COROLLARY DISCHARGE.

**efferent** adj. conducting or conveying away from a central point. Compare AFFERENT.

**efferent motor aphasia** a form of expressive APHASIA marked by difficulty in articulating sound and speech sequences, resulting from lesions in the lower part of the left PREMOTOR AREA of the brain.

**efferent nerve fiber** a nerve fiber that carries impulses from the central nervous system to the periphery. Compare AFFERENT NERVE FIBER.

**efferent neuron** a neuron, such as a MOTOR NEURON, whose axon carries impulses away from the central nervous system toward an EFFECTOR.

**efferent pathway** a NEURAL PATHWAY that carries impulses away from a particular region of the central nervous system toward an EFFECTOR. Examples are MOTOR PATHWAYS. Compare AFFERENT PATHWAY.

**Effexor** n. a trade name for VENLAFAXINE.

**efficacy** n. 1. competence in behavioral performance, especially with reference to a person’s perception of his or her performance capabilities, or perceived SELF-EFFICACY. 2. in pharmacology, see DOSE–RESPONSE RELATIONSHIP.

**efficacy research** an empirical study, such as a RANDOMIZED CLINICAL TRIAL, that examines whether a specific treatment or approach works when compared to outcomes in a PLACEBO CONTROL GROUP. Efficacy research is sometimes contrasted with EFFECTIVENESS RESEARCH, which uses NATURALISTIC OBSERVATION to assess whether an approach or treatment is working.

**efficiency** n. 1. a measure of the ability of an organization, work unit, or individual employee to produce the maximum output with a minimum investment of time, effort, and other inputs. Given the same level of output, efficiency increases as the time, effort, and other inputs taken to produce that level decrease. Also called INDUSTRIAL EFFICIENCY; ORGANIZATIONAL EFFICIENCY. See also ORGANIZATIONAL EFFECTIVENESS. 2. in statistics, the degree to which
an estimator uses all the information in a sample to estimate a particular parameter. It is a measure of the optimality of an estimator when comparing various statistical procedures or experimental designs. —efficient adj.

efficient cause in the doctrine of the four causes stated by Aristotle, the agent that initiates a causal process by bringing together the material cause (matter), the formal cause (form), and the final cause (purpose) of a particular effect. One of Aristotle’s examples of an efficient cause was a skilled craftsman who creates an artifact; another was a father who begets a child. More generally, the term is used to mean that which produces a given effect by a causal process.

effluvium n. a supposed flow of physical particles too subtle to be perceived by ordinary sensory mechanisms that is sometimes cited as an explanation for various paranormal and spiritualistic phenomena (Latin, “flowing out”). In the 18th century, the term was widely used to explain such phenomena as magnetism and electricity and later became associated with the idea of animal magnetism. In spiritualism and parapsychology, it is often linked with the notion that people and things have an invisible aura. See also Reichenbach phenomenon.

effort after meaning the persistent effort to put unfamiliar ideas into more familiar terms in an attempt to comprehend ambiguous or unfamiliar material. See repeated reproduction. [defined by Frederic C. Bartlett]

effortfulness n. exertion that demands attentional and other cognitive resources: a feature of many psychological tasks that can be judged reliably by participants. Effortful tasks compete against each other under dual-task conditions (see dual-task competition; dual-task performance), indicating that effortfulness correlates with demands on mental resources. Novel skills often begin in an effortful way but become more automatic with practice (see automaticity). Because the sense of effort lacks conscious sensory qualities, it can be considered an experience of fringe consciousness. Functional magnetic resonance imaging (fMRI) studies show major blood oxygenation level-dependent (BOLD) correlates of mental effort in the anterior cingulate cortex and dorsolateral prefrontal cortex, with a wider spread of cortical BOLD activity occurring with increased effort. —effortful adj.

effortful processing mental activity that requires deliberation and control and involves a sense of effort, or overcoming resistance. Compare automaticity. See also mental effort.

effort justification a phenomenon whereby people come to evaluate a particular task or activity more favorably when it involves something that is difficult or unpleasant. The effect is most likely to occur when there are no obvious reasons for performing the task. Because expending effort to perform a useless or unenjoyable task, or experiencing unpleasant consequences in doing so, is cognitively inconsistent (see cognitive dissonance), people are assumed to shift their evaluations of the task in a positive direction to restore consistency. See also cognitive dissonance theory; dissonance reduction.

effortless attention attention that is active, focused, and task-directed but that involves little or no subjective experience of exertion. It is associated with absorbing activities, such as reading a good book, and with tasks in which there is a balance of challenges with skills, as when a skilled athlete plays sports or a skilled musician plays a musical instrument. High levels of arousal, control, and relaxation are involved, and there is often a strong sense of flow or momentum. See also postvoluntary attention. [described in 2010 by U.S. philosopher and cognitive scientist Brian Bruya (1966–)].

effort syndrome the former name for an anxiety reaction now classified as panic disorder: The symptoms are those of a panic attack. This syndrome has been given many names, including cardiac neurosis, hyperkinetic heart syndrome, irritable heart, soldier’s heart, Da Costa’s syndrome, neurocirculatory asthenia, and hyperventilation syndrome.

EFP abbreviation for equine-facilitated psychotherapy. See equine-assisted psychotherapy.

EFPPA abbreviation for European Federation of Professional Psychologists’ Associations.

EFT 1. abbreviation for embedded figures test. 2. abbreviation for emotion-focused therapy.

egersis n. intense or extreme wakefulness.

egg cell see ovum.

ego n. 1. the self, particularly the conscious sense of self (Latin, “I”). In its popular and quasi-technical sense, ego refers to all the psychological phenomena and processes that are related to the self and that comprise the individual’s attitudes, values, and concerns. 2. in psychoanalytic theory, the component of the personality that deals with the external world and its practical demands. More specifically, the ego enables the individual to perceive, reason, solve problems, test reality, and adjust the instinctual impulses of the id to the demands of the superego. See also antilibidinal ego; body ego.

ego-alien adj. see ego-dystonic.

ego analysis psychoanalytic techniques directed toward discovering the strengths and weaknesses of the ego and uncovering its defenses against unacceptable impulses. See also ego strength; ego weakness.

ego anxiety in psychoanalytic theory, anxiety caused by the conflicting demands of the ego, id, and superego. Thus, ego anxiety refers to internal rather than external demands. Compare id anxiety; superego anxiety. See also signal anxiety.

ego boundary 1. the concept that individuals are able to distinguish between self and not-self. Someone who is said to lack clear ego boundaries blurs the distinction between himself or herself and others by identifying with them too easily and too much. 2. in psychoanalysis, the boundary between the ego and the id (the internal boundary) or between the ego and external reality (the external boundary).

ego-boundary loss a condition in which the person lacks a clear sense of where his or her own body, mind, and influence end and where these characteristics in other animate and inanimate objects begin.

ego-centered network in social network analysis, the subset of connections linking the focal individual or node to others in the group being studied. Also called egocentric network. Compare group network.

egocentric predicament a problematic condition arising from the assumption that each person’s experience is essentially private. The problem is commonly expressed in terms of one or more of the following propositions: (a) It
ego formation see EGO DEVELOPMENT.

ego functions in psychoanalytic theory, the various activities of the ego, including perception of the external world, self-awareness, problem solving, control of motor functions, adaptation to reality, memory, reconciliation of conflicting impulses and ideas, and regulation of affect. The ego is frequently described as the executive agency of the personality, working in the interest of the REALITY PRINCIPLE. See also SECONDARY PROCESS.

ego-ideal n. in psychoanalytic theory, the part of the EGO that is the repository of positive identifications with parental goals and values that the individual genuinely admires and wishes to emulate, such as integrity and loyalty, and that acts as a model of how he or she wishes to be. As new identifications are incorporated in later life, the ego-ideal may develop and change. In his later theorizing, Sigmund Freud incorporated the ego-ideal into the concept of the SUPEREGO. Also called self-ideal.

ego involvement in psychoanalytic theory, the process of organizing the various aspects of the personality, such as drives, attitudes, and aims, into a balanced whole. It is considered a strong indicator of psychological health and resiliency.

egoist adj. egoistic adj.

egoistic helping a form of HELPING behavior in which the goal of the helper is to increase his or her positive feelings or to receive some other benefit. For example, someone may make a large donation to an institution with the expressed interest of having a building named in his or her honor.

egoistic relative deprivation see RELATIVE DEPRIVATION.

egoistic suicide one of four types of suicide proposed in 1897 by Émile Durkheim, involving the perception that
one has failed to live up to the values and norms of society. Consequently, the individual withdraws from social groups and feels alienated from others. Thus lacking the social integration Durkheim viewed as essential to a healthy, meaningful life, the person becomes overwhelmed by independence and ultimately takes his or her own life. See also ALTRUSTIC SUICIDE; ANOMIC SUICIDE; FATALISTIC SUICIDE.

egotism n. extreme, pathological preoccupation with oneself, often characterized by an exaggerated sense of one’s abilities and worth. This includes the tendency to be totally self-centered, callous with regard to the needs of others, and interested only in the gratification of one’s own impulses and desires. See also EGOPATHY. —egotistic adj.

ego orientation a motivational focus on winning a game or achieving superior status in a social comparison. Ego orientation is a component of ACHIEVEMENT GOAL THEOR.

egopathy n. hostile attitudes and actions stemming from an exaggerated sense of self-importance, often manifested by a compulsion to deprecate others. See also EGOANIA.

ego psychology in psychoanalysis, an approach that emphasizes the functions of the ego in controlling impulses, planning, and dealing with the external environment. Ego psychology differs from CLASSICAL PSYCHOANALYSIS in proposing that the ego contains a CONFLICT-FREE SPHERE of functioning and that it has its own store of energy with which to pursue goals that are independent of instinctual wishes. In addition, ego psychology theories extend beyond classical psychoanalytic drive theory by combining a biological and psychological view of the individual’s development with a recognition of the complex influences of sociocultural dimensions on individual functioning. The scope of psychoanalysis is thereby broadened from the study of unconscious events and psychopathology to exploration of adaptive processes within the matrix of interpersonal, familial, and sociocultural forces. Compare ID PSYCHOLOGY.

ego resiliency a personality characteristic consisting of the ability to vary, in an adaptive manner, the degree to which one inhibits or expresses emotional impulses, depending on social demands.

ego resistance see REPRESSION RESISTANCE.

ego-splitting n. 1. in psychoanalytic theory, the ego’s development of opposed but coexisting attitudes toward a phenomenon, whether in the normal, neurotic, or psychotic person. In the normal context, ego-splitting can be seen in the critical attitude of the self toward the self in neuroses, contrary attitudes toward particular behaviors are fundamental; and in psychoses, ego-splitting may produce an “observing” part of the individual that sees and understands eidetic imagery (called eidetikers) continue to see a visual scene and are able to report on its details even though they know the stimulus is no longer there. This type of imagery is more common in children than in adults.

ego stress any situation, external or internal, that challenges the individual and produces stress (tension, anxiety, etc.) requiring adaptation by the ego. Ego stress is sometimes expressed as such defensive reactions as DISSOCELATION, SOMATIZATION, or panic.

ego structure in psychoanalytic theory, the organization of the ego.

ego-syntonic adj. compatible with the ego or conscious SELF-CONCEPT. Thoughts, wishes, impulses, and behavior are said to be ego-syntonic when they form no threat to the ego and can be acted upon without interference from the SUPEREGO. Compare EGO-DISTONIC. [first described in 1914 by Sigmund Freud]

egotheism n. identification of oneself with a deity. See also JEOVAH COMPLEX; MESSIAH COMPLEX.

egotism n. excessive conceit or a preoccupation with one’s own importance. See also EGOSM. —egotistic adj.

ego transcendence an ALTERED STATE OF CONSCIOUSNESS marked by the conviction that one is beyond concern with the self and thus able to perceive reality with greater objectivity.

ego weakness in psychoanalytic theory, the inability of the ego to control impulses and tolerate frustration, disappointment, or stress. The individual with a weak ego is thus one who suffers from anxiety and conflicts, makes excessive use of DEFENSE MECHANISMS or uses immature defense mechanisms, and is likely to develop neurotic symptoms. Compare EGO STRENGTH.

EHA abbreviation for EDUCATION FOR ALL HANDICAPPED CHILDREN ACT.

EHR abbreviation for ELECTRONIC HEALTH RECORD.

eidetic image a clear, specific, high-quality mental image of a visual scene that is retained for a period (seconds to minutes) after the event. Individuals who experience eidetic imagery (called eidetikers) continue to see a visual scene and are able to report on its details even though they know the stimulus is no longer there. This type of imagery is more common in children than in adults.

eigenvalue (symbol: λ) n. a numerical index, commonly used in FACTOR ANALYSIS and PRINCIPAL COMPONENTS ANALYSIS, that indicates the portion of the total variance among several correlated variables that is accounted for by a more basic, underlying variable or construct. An eigenvalue may be computed as the sum of the squared FACTOR LOADINGS for all the variables. Eigenvalues are of central importance in linear algebra (i.e., matrix algebra).

eigenvector n. in linear algebra, any vector within a p-dimensional space that is associated with a given TRANSFORMATION and is left invariant (except for stretching or shrinking) by that transformation. Eigenvectors are important in MULTIVARIATE statistics: their values are applied to variables to form a LINEAR combination that synthesizes much of the variance in a set of variables.

Eigenwelt n. in the thought of German philosopher Martin Heidegger (1889–1976), that aspect of DASEIN (being-in-the-world) that is constituted by a person’s relationship...
to the self. The term was introduced into the vocabulary of psychology chiefly through the work of Swiss existential psychologist Ludwig Binswanger (1881–1966). Compare MITWELT; UMWELT. [German, literally: “own world”]

eighth cranial nerve see AUDITORY NERVE; VESTIBULO-COCHLEAR NERVE.

80:20 rule see PARETO PRINCIPLE.

Einstellung n. an expectation or readiness associated with particular stimuli. It may foster a degree of mental inflexibility by instilling a tendency to respond to a situation in a certain way. For example, a person who successfully solves a series of problems using one formula may apply that same formula to a new problem solvable by a simpler method. The contemporary term for this concept is MENTAL SET. [German, “attitude”]

either–or fallacy a type of informal fallacy or persuasive technique in which an argument is constructed so as to imply the necessity of choosing one of only two alternatives. This ignores the possibility that (a) the alternatives may not be mutually exclusive and (b) there may be other equally viable alternatives. For example, the argument that the cause of behavior is either nature or nurture ignores the possibility that both might play a causal role or that human agency might also be part of the explanation.

either–or thinking a less common name for dichotomous thinking.

ejaculation n. the automatic expulsion of semen and seminal fluid through the penis resulting from involuntary and voluntary contractions of various muscle groups, normally associated with orgasm. See also premature ejaculation; retrograde ejaculation. —ejaculatory adj.

ejaculatory duct a duct on either side of the prostate gland, formed by union of the vas deferens and the efferent duct of the seminal vesicle. The ejaculatory ducts converge in the prostate gland and empty into the urethra at a point below the urinary bladder.

Ekbom’s syndrome a sense of uneasiness, twitching, or restlessness that occurs in the legs when at rest (i.e., sitting or lying) or after retiring for the night. The cause is unknown, but it has been associated with a deficiency of iron, vitamin B₁₂, or folic acid; nerve damage associated with rheumatoid arthritis, kidney failure, or diabetes; and the use of such drugs as lithium, anticonvulsants, antidepressants, and beta blockers. Also called restless-legs syndrome; tachyathetosis; Wittmaack–Ekbom syndrome. [Karl-Axel Ekbom (1907–1977), Swedish physician]

EKG abbreviation for ELECTROCARDIOGRAM.

elaborated code a linguistic register typically used in formal situations (e.g., academic discourse), characterized by a wide vocabulary, complex constructions, and unpredictable collocations of word and idea. This contrasts with the restricted code used in much informal conversation, which is characterized by a narrow vocabulary, simple constructions, and predictable ritualized forms, with much reliance on context and nonverbal communication to convey meaning.

elaboration n. 1. the process of interpreting or embellishing information to be remembered or of relating it to other material already known and in memory. The levels-of-processing model of memory holds that the level of elaboration applied to information as it is processed affects both the length of time that it can be retained in memory and the ease with which it can be retrieved. See activation–elaboration; see also chunking; deep processing; recoding. 2. the process of scrutinizing and thinking about the central merits of attitude-relevant information. This process includes generating inferences about the information, assessing its validity, and considering the implications of evaluative responses to the information. See also central route to persuasion; elaboration-likelihood model; peripheral route to persuasion. —elaborate vb.

elaboration-likelihood model (ELM) a theory of persuasion postulating that attitude change occurs on a continuum of elaboration and thus, under certain conditions, may be a result of relatively extensive or relatively little scrutiny of attitude-relevant information. The theory postulates that ATTITUDE STRENGTH depends on the amount of elaboration on which the attitude is based and proposes five possible mechanisms by which a variable may influence the persuasion process (i.e., serving as an argument, biasing factor, determinant of elaboration, peripheral cue, or self-validation factor). [first proposed by U.S. psychologists Richard E. Petty (1951– ) and John T. Cacioppo (1951– )]

elaborative rehearsal an encoding strategy to facilitate the formation of memory by linking new information to what one already knows. For instance, when trying to remember that someone is named George, one might think of five other things one knows about people named George. See depth-of-processing hypothesis; elaboration.

élan vital in the thought of French philosopher Henri Bergson (1859–1941), a vital force or energy that animates living organisms, including humans, and propels life toward some end through the process of evolution. Also called life force. See vitalism. [French, literally: “vital impetus”]

elation n. a state of heightened joy, exaggerated optimism, and restlessness. In extreme or prolonged forms, it is a symptom of a number of disorders; in particular, it may be drug induced or a symptom of acute mania, but it is also found in general paresis, schizophrenia, and psychosis with brain tumor. —elated adj.

Elavil n. a trade name for AMITRIPTYLINE.

ELBW abbreviation for extremely LOW BIRTH WEIGHT.

Eldepryl n. a trade name for SELEGBINE.

elder abuse harm to an adult aged 65 or older caused by another individual. The harm can be physical (violence), sexual (nonconsensual sex), psychological (causing emotional distress), material (improper use of belongings or finances), or neglect (failure to provide needed care).

elder care the provision of health-related services, supportive personal care, supervision, and social services to an older adult requiring assistance with daily living because of physical disabilities, cognitive impairments, or other conditions. Elder care may be home based or community based (via assisted living, residential care, or a skilled nursing facility).

elder neglect the failure of a caregiver to provide needed care to an older adult. Extreme neglect in the form of abandonment can occur when the caregiver deserts the older adult in need. See elder abuse.

elderspeak n. adjustments to speech patterns, such as speaking more slowly or more loudly, shortening sen-
electroconvulsive therapy

has also been used in humans to promote recall and as therapy.

electrical synapse a type of connection in which neurons are not separated by a cleft but instead are joined by a GAP JUNCTION so that the nerve impulse is transmitted across without first being translated into a chemical message.

electrical transcranial stimulation (ETS) see ELECTROSLEEP THERAPY.

electric ophthalma see OPHTHALMIA.

electric potential see POTENTIAL.

electric sense the ability of some species to generate and sense electric fields within their environment. Specialized muscle cells can be coupled to generate a significant electric field, and specialized neural receptors or other organs can detect changes in electric fields. Sea lampreys and eels generate an electric current that is used to stun and disable their prey, but these animals do not appear to sense electric fields. Dogfish sharks hide in the sand and use specialized receptors called Lorenzini ampullae to detect electric currents from prey. Several families of fish found in the tropics both generate and detect electric signals, adjusting signal production to avoid jamming with nearby fish and to change discharge rates to communicate aggression or reproductive status.

electric shock method see ELECTROCONVULSIVE THERAPY; ELECTROTHERAPY.

electric sink a device or region that collects or dissipates electrical energy: the opposite of an electric source.

electrocardiogram (ECG: EKG) n. a wavely tracing, either printed or displayed on a monitor, that represents the electrical impulses of the conduction system of the heart muscle as it passes through a typical cycle of contraction and relaxation. The electrical currents are detected by electrodes attached to specific sites on the patient’s chest, legs, and arms and recorded by an instrument, the electrocardiograph. In the procedure, which is called electrocardiography, the wave patterns of the electrocardiogram reveal the condition of the heart chambers and valves to provide an indication of possible cardiac problems.

electrocardiographic effect a change in the electrical activity of the heart as recorded by an electrocardiogram, especially a change associated with administration of a drug. Prolongation of segments of the cardiac cycle, particularly the T-Q interval (the period of ventricular contraction), may be observed with excess doses of numerous antipsychotics and tricyclic antidepressants. A malignant form of electrocardiographic change is an arrhythmia known as torsades de points (French, literally: “twisting of the points”), so called because of its characteristic outline on an electrocardiograph tracing. Torsades de points syndrome may result from drug interactions increasing the serum concentration of certain drugs or from an abnormal reaction to single drugs (e.g., pimozide) in susceptible individuals.

electrophysiology see ELECTROPHYSIOLOGIC AUDIOMETRY.

electrocochleography (ECoGh) n. see ELECTROPHYSIOLOGIC AUDIOMETRY.

electroconvulsive therapy (ECT) a controversial treatment in which a seizure is induced by passing a controlled, low-dose electric current (an electroconvulsive shock: ECS) through one or both temples. The patient is
prepared by administration of an anesthetic and injection of a muscle relaxant. An electric current is then applied for a fraction of a second and immediately produces a two-stage seizure (tonic and clonic). ECT may be bilateral or unilateral (usually of the right hemisphere). It is most often used to treat patients with severe endogenous depression who fail to respond to antidepressant drugs. Benefits are temporary, and the mechanisms of therapeutic action are unknown. Also called electroconvulsive shock therapy (EST); electroshock therapy (EST). See also BRIEF STIMULUS THERAPY; ECT-INDUCED AMNESIA. [introduced in 1938 by Italian psychiatrists Ugo Cerletti (1877–1963) and Lucio Bini (1908–1964)]

**electrocorticography** (ECoG) n. a method of studying the electrical activity of the brain using electrodes placed directly on the cerebral cortex, rather than on the scalp as in **ENCEPHALOGRAPHY**. The resulting record of brain-wave patterns is called an **electrocorticogram**.

electrode n. an instrument with a positive-pole cathode and a negative-pole anode used to stimulate biological tissues electrically or record electrical activity in these tissues. Also called **bipolar electrode**. See also **MICROELECTRODE**.

electrode placement the positioning of electrodes on the scalp or in neurons to record changes of electric potential caused by neural activity. In nonhuman animal research studies and some human studies, needlelike **MICROELECTRODES** are placed in specific brain cells.

electrodermal changes changes in the skin that alter its electrical conductivity. See **GALVANIC SKIN RESPONSE; SKIN CONDUCTANCE**.

electrodermal response (EDR) see **GALVANIC SKIN RESPONSE**.

electrodiagnosis n. the application of an electric current to nerves and muscles for diagnostic purposes. See **ENCEPHALOGRAPHY; ELECTROGRAPHY**.

electroencephalographic audiometry the measurement of hearing sensitivity with the use of **ENCEPHALOGRAPHY**. Gross measures are obtained from changes in brain-wave patterns when above-threshold sound stimuli are introduced.

**electroencephalography** (EEG) n. a method of studying brain waves using an instrument (**ENCEPHALOGRAPHY**) that amplifies and records the electrical activity of the brain through electrodes placed at various points on the scalp. The resulting record (**ENCEPHALOGRAM**) of the brain-wave patterns is frequently used in studying sleep, monitoring the depth of anesthesia, diagnosing epilepsy and other brain disorders or dysfunction, and studying normal brain function. Also called **cognitive electrophysiology**. See also **ELECTRICAL ACTIVITY OF THE BRAIN**.

electrolyte imbalance abnormal levels of one or more electrolytes, the ions of chemicals that play a vital role in fluid balance, acid–base balance, and other functions of body cells. Electrolytes that may be affected include sodium, which is needed for water regulation and normal nerve and muscle function; potassium, which is necessary for acid–base balance; and calcium, which is essential for normal blood and muscle functions.

electromagnetic spectrum the range of wavelengths of electromagnetic radiation from gamma rays (very short waves) to radio waves (very long waves). The human eye is sensitive to only a narrow range of wavelengths of approximately 400 to 700 nm. See **SPECTRUM**.

electromyography (EMG) n. the recording (via an instrument called an **ELECTROMYOGRAPH**) of the electrical activity of muscles through electrodes placed in or on different muscle groups. This procedure is used in the diagnosis of neuromuscular diseases, such as myasthenia gravis or amyotrophic lateral sclerosis. A record of the electrical potentials is called an **ELECTROMYOGRAM** (EMG).

electronic nose a device that is capable of sensing gases, especially odors. Electronic noses are used commercially to detect malodorous foodstuffs, for example, and scientifically in modeling the olfactory system.

electroolfactography (EOG) n. a neurological test that measures movements of the eye muscles, used to confirm the presence of **NYSTAGMUS**. A graphical recording of eye movements is generated and is used to evaluate dizziness, vertigo, and the function of the **AUDITORY NERVE** and the **SEMICIRCULAR CANALS**.

electrooculography (EOG) n. the process of recording the electric potential that exists between the front and back of the eye as fixation moves between two points. The graphic representation of the difference in this potential is called an **ELECTROOCULOSKINFELD** (EOG).

electroolfactography (EOG) n. the process of recording the response of olfactory nerve endings to various stimulating **ODORANTS**. It can be used to diagnose olfactory disorders, such as **ANOSMIA**, after injury or disease affecting the olfactory receptors. The recording itself is called an **ELECTROOLFACTOSKINFELD** (EOG).

electrophysiologic audiometry a large class of procedures for measuring auditory function that use electrical responses evoked by sound stimulation. Included in this class of procedures are averaged **ENCEPHALOGRAPHIC AUDIOMETRY** and **ELECTROCOCHLEOGRAPHY** (ECochG), which measures electrical activity in the inner ear. Responses include the **BRAINSTEM AUDITORY EVOKED RESPONSE**.
**electrophysiology** *n.* the study of the electrical properties and processes of tissues. This includes such specialized subfields as electrocardiography, **electroencephalography**, **electromyography**, **electrooculography**, and **electroretinography**. —electrophysiologic or electrophysiological *adj.*

**electrolythmosgraphy** *n.* a test or testing procedure based on the measurement of blood volume or volume changes in organs, organ systems, or circulation.

**electroretinography** *n.* a recording (via an instrument called an **electroretinograph**) of the electrical activity of the retina during visual stimulation using electrodes placed on the anesthetized surface of the eye. Different segments of the recorded waveform (called an **electroretinogram** [ERG]) correspond to activity in the different cells and layers of the retina.

**electroshock therapy** (EST) see ELECTROCONVULSIVE THERAPY.

**electro sleep therapy** a former treatment for depression, chronic anxiety, and insomnia by inducing a state of relaxation or sleep through low-voltage **electrical transcranial stimulation** (ETS; or **cranial electrical stimulation. CES**), a technique developed in the Soviet Union in the 1940s.

**electrostimulation** *n.* an anodal, or a negative-reinforcement, technique involving administration of an electric shock. See also AVERSION THERAPY.

**electrostimulation of the brain (ESB)** electrical stimulation of a specific area of the brain to determine the functions served by that area.

**electrostimulator** *n.* an instrument that delivers controlled electrical stimulation to a specific area of the body.

**electrotactile aid** see TACTILE SENSORY AID.

**electrotherapy** *n.* any therapeutic measure that involves the application of an electric current to the body.

**electrotonic conduction** the passive flow of a change in electric potential along a nerve or muscle membrane. It occurs in response to stimulation that is inadequate to trigger an actively propagated **action potential** (i.e., sub-threshold stimulation) but instead generates **depolarization** in a small area of membrane. This localized depolarization travels to neighboring areas via the drifting fluid within the cell, rapidly attenuating as it spreads.

**electrotonus** *n.* the change in the excitability, conductivity, or electrical status of a nerve or muscle following application of an electric current.

**elegant solution** a solution to a question or a problem that achieves the maximally satisfactory effect with minimal effort, materials, or steps. In terms of theories or models of behavior, an elegant solution would be one that satisfies the requirements of the **law of parsimony**. See also OCCAM’S RAZOR.

**element** *n.* 1. a subunit or constituent part of something, often with the connotation that it cannot be reduced further. 2. a member of a set, class, or group. For example, in the set of all PhD-conferring American universities, any one of those American universities that confer the PhD is an element of the set. See also SET THEORY. 3. one of the 118 officially identified chemical substances, of which 92 occur naturally, that cannot be reduced to simpler fragments by chemical means alone.

**elementarism** *n.* 1. in scientific theory, the procedure of explaining a complex phenomenon by reducing it to simple, elemental units. 2. the belief that such a procedure is appropriate to a science dealing with psychological phenomena, which are explained by reduction to simple elements, such as basic sensations or elementary reflexes. Both psychological **structuralism** and **behaviorism** have been described as elementarist approaches. Also called **elementalism; elementism**. See also ATOMISM; MOLECULAR. —elementarist *adj.*

**elementary cognitive task** (ECT) a simple laboratory test designed to measure participants’ response times as they perform very easy tasks and make what are presumed by the researchers to be simple decisions. Examples of elementary cognitive tasks include selecting the “odd man out” among three or more alternatives, identifying whether a single presented number (or letter) was or was not part of a previously presented set, and indicating whether or not a statement agrees with a pictorial representation. The low-level, or basic, processes measured by elementary cognitive tasks are believed to be closely related to physiological functioning and thus primarily under the influence of endogenous, inherited factors.

**element-level compatibility effect** see STIMULUS–RESPONSE COMPATIBILITY.

**Elephant Man’s disease** a disease named after a 19th-century patient, Joseph Carey Merrick, who was known as “the Elephant Man”; although **neurofibromatosis Type 1** was formerly suggested as the likely cause, **proteus syndrome** is now thought to be a more probable cause.

**elevated maze** a maze consisting of paths formed by elevated, flat runways without side walls, placed far enough apart that an individual within it cannot jump across the gaps. An incorrect choice within the maze leads to a cul-de-sac, signified by the end of an arm and open space. It is one of two primary types of maze, the other being an **alley maze**.

**elevated mood** a heightened mood characterized by feelings of euphoria, elation, and well-being.

**elevated plus maze** an apparatus used as a test of anxiety in laboratory rats and mice. It is a cross-shaped maze that is raised from the ground and has two enclosed arms and two open arms. Because of a natural fear of heights, rodents typically spend more time in the enclosed arms than in the open arms. However, if injected with anxiolytic (antianxiety) drugs, rodents will increase the amount of time they spend in the open arms.

**elevator phobia** a persistent and irrational fear of elevators, which may represent fear of heights (**acrophobia**), fear of being enclosed (**claustrophobia**), or fear of having panic symptoms (e.g., as occurs with **agoraphobia**).

**eleventh cranial nerve** see ACCESSORY NERVE.

**elicitation** *n.* the reliable production of a particular response by a stimulus. Salivation following food in the mouth is an example of elicitation. —elicit vb.

**elicited behavior** see RESPONDENT BEHAVIOR.

**elimination by aspects** a theory of decision making holding that a choice is reached through a series of eliminations. At each stage, the decision maker selects an attribute or aspect perceived to be important and eliminates alternatives lacking that attribute. The next most important attribute is then selected, and the process continues.
elimination disorder

until only one alternative is left. [introduced in 1972 by Amos Tversky]

elimination disorder any disorder related to defecation or urination, usually occurring in children (or individuals of equivalent mental age), that is not due to the use of substances or a general medical condition. See ENCOPRESIS; ENURESIS.

elimination drive the urge to expel feces or urine from the body. Psychological factors have considerable effects on these drives; for example, tension and fright may precipitate involuntary voiding of both the bladder and bowel. See DEFECATION REFLEX; ENCOPRESIS; ENURESIS; MICTURITION REFLEX.

eliminativism n. the view that mental states, such as beliefs, feelings, and intentions, are not necessary to a scientific account of human behavior. These are regarded as the stuff of folk psychology, informal and intuitive concepts by which human beings offer accounts of their behaviors. According to the eliminativist view, when truly scientific psychology progresses far enough to replace folk psychology, the explanatory language of mental states will probably be replaced by a language of biological states. Also called eliminative materialism. See also IDENTITY THEORY; REDUCTIONISM. Compare CONSCIOUS MENTALISM; MENTALISM. —eliminativist adj.

elision n. in speech, the omission of certain sounds in particular phonological environments, as when an unstressed vowel occurs at the beginning or end of a word (e.g., How d’you do).

elite athlete most often, an athlete who competes at a national, international, or professional level, although the term is sometimes used colloquially to refer to accomplished athletes in nonprofessional contexts.

elite bilingualism a type of BILINGUALISM attained through formal study of the second language, which involves literacy in that language and is considered a sign of social status and education. Also called elective bilingualism. Compare FOLK BILINGUALISM. [First described by U.S. sociolinguist Joshua A. Fishman (1926–)].

ellipsis n. 1. a linguistic structure in which a word or words normally needed for reasons of grammar or logic are omitted. This may be done for the sake of brevity, emphasis, or both, as, for example, in the reply Gone to the question Where is she? See also DELETION. 2. in psychoanalysis, a form of PARAPRAXIS involving the omission of significant ideas in free association or dreams. Efforts are made to recover these ideas during analysis. —elliptical adj.

Ellis–van Creveld syndrome an autosomal recessive disorder (see RECESSIVE ALLELE) marked by polydactyly (extra fingers or toes); poorly formed hair, teeth, and nails; and DWARFISM. Associated abnormalities may include genital anomalies and heart defects. A high incidence of the disorder is seen among the Old Order Amish of Pennsylvania. Also called chondroectodermal dysplasia. [Richard White Bernard Ellis (1902–1966), British physician; Simon van Creveld (1894–1971), Dutch pediatrician]

EMA abbreviation for ECOLOGICAL MOMENTARY ASSESSMENT.

ejaculate vb.
e
embalming fluid 1. slang for liquid PCP or a liquid containing PCP. See FRY. 2. the mixture of formaldehyde and other chemicals used to preserve dead bodies. This mixture may be a drug of abuse, although the actual frequency of such abuse is unknown, and many investigators believe that the substance called “embalming fluid” by drug dealers or users is nearly always PCP.

embarrassment n. a SELF-CONSCIOUS EMOTION in which a person feels awkward or flustered in other people’s company or because of the attention of others, as, for example, when being observed engaging in actions that are subject to mild disapproval from others. It often has an element of self-deprecating humor and is typically characterized by nervous laughter, a shy smile, or blushing. See also SELF-CONSCIOUSNESS. —embarrassed adj.

embedded figure a type of AMBIGUOUS FIGURE in which one or more images blend into a larger pattern and so are not immediately obvious. With repeated viewing, the embedded figure usually becomes obvious more rapidly.

Embedded Figures Test (EFT) a test that consists of finding and tracing a simple form embedded within a complex figure, in some cases further complicated by an irregularly colored background. The test, for use with individuals aged 10 years and over, was designed to evaluate cognitive style, particularly FIELD DEPENDENCE and FIELD INDEPENDENCE: Those demonstrating high performance on the test are defined as field-independent people, who tend to follow active, participant approaches to learning, whereas those who have difficulties in performing the test are defined as field-dependent people, who often use spectator approaches and are also more open and responsive to other people’s behavior. The EFT is also employed in neuropsychological contexts, as poor performance on the test may indicate a lesion or injury in the cerebral cortex. Also called Hidden Figures Test. [originally developed in 1950 by U.S. psychologist Herman A. Witkin (1916–1979)]

embeddedness of an attitude the extent to which an attitude is linked to or associated with other cognitive structures in memory. Such structures could include other
attitudes, values, and beliefs. See also ATTITUDE SYSTEM; BELIEF SYSTEM; INTERATTITUDINAL CONSISTENCY.

**embedded sentence** in TRANSFORMATIONAL GENERATIVE GRAMMAR, a subordinate CLAUSE in a COMPLEX SENTENCE. According to this analysis, the complex sentence The dog chased the squirrel that stole the peanut has a DEEP STRUCTURE consisting of two sentences, The dog chased the squirrel and The squirrel stole the peanut. In its SURFACE STRUCTURE, the second sentence is embedded within the first.

**emblem** n. a bodily movement that substitutes for a spoken word or phrase and that can be readily comprehended by most individuals in a culture. Examples are shaking the head back and forth to signify no and nodding the head up and down to indicate yes. See also NONVERBAL COMMUNICATION. —emblematic adj.

**embodied cognition** the thesis that the human mind is largely determined by the structures of the human body (morphology, sensory and motor systems) and its interactions with the physical environment. This concept emerged from work in late 20th-century linguistics, philosophy, and cognitive psychology. Also called embodiment.

**embolic stroke** a STROKE caused by a blood clot, cholesterol, fibrin, or other material breaking away from the wall of an artery or the heart and traveling up the arterial tree to lodge suddenly in a smaller cerebral artery (see CEREBRAL EMBOLISM). Embolic strokes account for approximately 30% of all strokes and are abrupt in onset.

**embolism** n. the interruption of blood flow due to blockage of a vessel by an embolus, material formed elsewhere and carried by the bloodstream to the site of obstruction. The embolus may be a blood clot, air bubble, fat globule, or other substance, such as a clump of bacteria or tissue cells. An embolus usually occurs at a point where a blood vessel branches or narrows. The symptoms are those associated with a disruption of the normal flow of fresh blood to a part of an organ and include pain, numbness, and loss of body warmth in the affected area. An embolus in a coronary artery may cause a fatal heart attack; in the brain, the result is an EMBOLIC STROKE.

**embolus** n. see EMBOLISM; THROMBUS.

**embryo** n. an animal in the stages of development between CLEAVAGE of the fertilized egg and birth or hatching. In human prenatal development, the embryo comprises the products of conception during the first 8 weeks of pregnancy; thereafter, it is called a FETUS. See EMBRYONIC STAGE.

—embryonic adj.

**embryology** n. the branch of biology that studies the formation, early growth, and development of organisms. —embryological or embryologic adj. —embryologist n.

**embryonic stage** in human prenatal development, the roughly 6-week period in which the three-layered embryo (GASTRULA) develops. The embryonic stage follows the 2-week GERMINAL STAGE and precedes the FETAL STAGE, which begins in the 3rd month of pregnancy. The term is, however, sometimes used to refer to the full first 8 weeks of pregnancy.

**embryonic stem cell** see STEM CELL.

**embryo transfer** the process in which an ovum fertilized in vitro is transferred to the uterus of the woman from whom it was originally removed or to the uterus of another woman.

**EmC** abbreviation for EXTREME CAPSULE.

**EMDR** abbreviation for EYE-MOVEMENT DESENSITIZATION AND REPROCESSING.

**emergence** n. 1. in philosophy of mind, the notion that conscious experience is the result of, but cannot be reduced to, brain processes. 2. the idea that higher order phenomena may be derived from lower order constituents but are not predictable from them. See EPGENETIC THEORY.

**emergency call system** a portable device that summons immediate assistance for an individual who, due to illness or an impairment, may not be able to reach a telephone in an emergency. The device, which may be worn (e.g., on the wrist, around the neck) or carried, is generally a noisemaker, a one-way alerting device (e.g., an alarm), or an intercom that may be used to contact a neighbor, family member, or 24-hour monitoring station staffed by trained personnel. Often used by people in their homes, emergency call systems are also used in hospitals, long-term care institutions, and ASSISTED LIVING facilities.

**emergency intervention** immediate action undertaken to minimize or eliminate the harm caused by a sudden and (usually) unforeseen occurrence. For example, emergency intervention for a rape victim may involve conducting a clinical interview within 24 to 78 hours after the rape in order to evaluate the person’s status, reduce his or her potential for experiencing adverse mental health consequences, and develop a plan for long-term recovery. Although many people use this term interchangeably with CRISIS INTERVENTION, others limit it to situations involving suicidal behavior, violent behavior, or interpersonal victimization.

**emergency psychotherapy** psychological treatment of individuals who have undergone a traumatic experience (e.g., a road accident) and are in a state of acute anxiety, panic, or shock or are suicidal. Therapists may call on a very broad range of techniques depending on the immediate needs of the client. See also CRISIS INTERVENTION.

**emergency reaction** see FIGHT-OR-FLIGHT RESPONSE.

**emergency services** in health care, services provided to an individual in response to perceived need for immediate medical or psychological treatment.

**emergency syndrome** see FIGHT-OR-FLIGHT RESPONSE.

**emergent evolution** the theory that new species and biological adaptations evolve from ancestral sources but cannot be reduced to them.

**emergent feature** an entity produced by the interaction of small or simple elements (e.g., short line segments) in the visual system, such an entity (e.g., a polygon) being more salient to human perception than are the elements themselves. In ergonomics, OBJECT DISPLAYS are usually designed to make use of emergent features; the display configurations yield an overall image (e.g., a rectangle or pentagon) that can be perceived holistically by the operator of a machine system and therefore rapidly analyzed to assess the state of the system. When a component of the system is not in the appropriate or normal state, the image will be distorted, alerting the operator to potential problems.

**emergentism** n. the view that complex phenomena and processes have EMERGENT PROPERTIES that arise from interactions of the more basic processes that underlie them but cannot be deduced or explained from the nature and logic of these processes. Compare REDUCTIONISM.
emergent leader in the social psychology of groups, an individual who becomes the leader of an initially leaderless group gradually and implicitly, as the members allow that individual to assume the responsibilities of the leadership role, rather than by appointment or election. See also LEADERSHIP EMERGENCE.

emergent literacy the skills, knowledge, and attitudes that are presumed to be developmental precursors to conventional forms of reading and writing. Emergent literacy begins before the child receives formal instruction in reading and writing and occurs in circumstances that support these developments, as when, for example, the child is being read to.

emergent-norm theory an explanation of COLLECTIVE BEHAVIOR suggesting that the uniformity in action often observed in CROWDS, CULTS, and other aggregations is caused by members’ conformity to unique SOCIAL NORMS that develop spontaneously in those groups. See UNIVERSALITY. [introduced in 1957 by U.S. sociologists Ralph H. Turner (1916– ) and Lewis M. Killian (1919–2010)]

emergent property a characteristic of a complex system that is not predictable from an analysis of its components and that thus often arises unexpectedly. For example, it has frequently been claimed that conscious experience is not predictable by analysis of the neurophysiological and biochemical complexity of the brain.

emerging adulthood a developmental stage that is neither adolescence nor young adulthood but is theoretically and empirically distinct from them both, spanning the late teens through the twenties, with a focus on ages 18 to 25. Emerging adulthood is distinguished by relative independence from social roles and from normative expectations. Having left the dependency of childhood and adolescence, and having not yet taken on the responsibilities that are normative in adulthood, emerging adults engage in identity exploration, a process of trying out various life possibilities (e.g., in love, work, and worldviews) and gradually moving toward making enduring decisions. During this period, individuals have the highest rates of residential instability (change) of any age group and see themselves neither as adolescents nor entirely as adults. [proposed in 2000 by U.S. developmental psychologist Jeffrey Jensen Arnett]

emic therapy the use of drugs that produce aversive states when combined with problem behaviors or stimuli. Side effects of the drugs used and other issues with regard to this form of treatment limit its application. See AVERSIVE THERAPY.

EMG abbreviation for ELECTROMYOGRAPHY.

emic adj. 1. denoting an approach to the study of human cultures that interprets behaviors and practices in terms of the system of meanings created by and operative within a particular cultural context. Such an approach would generally be of the kind associated with ETHNOGRAPHY rather than ETHNOLOGY. Compare ETIC. [introduced by U.S. linguist Kenneth Pike (1912–2000); first used in anthropology by U.S. cultural anthropologist Marvin Harris (1927–2001)] 2. in linguistics, see EMIC–ETIC DISTINCTION.

emic–etic distinction 1. a distinction between two fundamentally different approaches to language analysis, one characteristic of PHONEMICS and the other of PHONETICS. An emic analysis puts primacy on the characterization of a particular language through close attention to those features that have a meaningful structural significance within it. By contrast, an etic analysis concentrates on universal features of language, particularly the acoustic properties of speech sounds and the physiological processes involved in making them. To illustrate the point, an emic analysis of English speech sounds would show interest in the difference between the sounds /r/ and /l/ because this is used to make meaningful distinctions (e.g., it differentiates the words rash and lash); an etic analysis of Japanese, however, would disregard this difference in sounds, as it is not a meaningful contrast in that language. An etic analysis would show the same interest in this feature in both languages. See also MINIMAL PAIR. 2. the distinction between EMIC and ETIC approaches in anthropology and related disciplines.

emitted behavior a natural response to a circumstance; that is, behavior that is not influenced by, or dependent on, any external stimuli. Compare RESPONDENT BEHAVIOR.

Emmert’s law the principle that the perceived size of an afterimage is proportional to the distance of the surface on which it is projected: The larger the afterimage, the further away it is. See SIZE CONSTANCY. [Emil Emmert (1844–1913). German physiologist]

emmertopia n. the state of the eye’s normal optical system, in which distant objects are sharply focused on the retina by the curvature of the cornea and the lens. This normal optical system is said to be emmetropic. Compare HYPEROPIA; MYOPIA.

Emory Dysxia Index (EDI) a screening instrument to detect the presence of a processing deficit in which a person has difficulty recognizing and responding appropriately to nonverbal cues (see Dysxia). It consists of numerous statements grouped into seven categories: gaze and eye contact, space and touch, paralanguage, facial expression, objects/fashion, social norms, and nonverbal receptivity. A teacher, counselor, colleague, peer, or other third party uses a likert SCALE ranging from 1 (never) to 5 (very often) to rate how often the person demonstrates the behavior described in each statement. The index is available in a 42-item version for children (EDI–C) and an 85-item version for adults (EDI–A). [originally developed in 1994 by Elizabeth B. Love and clinical psychologists Stephen No-wicki Jr. (1941– ) and Marshall Duke (1942– ) at Emory University]

emotion n. a complex reaction pattern, involving experiential, behavioral, and physiological elements, by which an individual attempts to deal with a personally significant matter or event. The specific quality of the emotion (e.g., FEAR, SHAME) is determined by the specific significance of the event. For example, if the significance involves threat, fear is likely to be generated; if the significance involves disapproval from another, shame is likely to be generated. Emotion typically involves FEELING but differs from feeling in having an overt or implicit engagement with the world. —emotional adj.

emotional abuse nonphysical abuse: a pattern of behavior in which one person deliberately and repeatedly subjects another to nonphysical acts that are detrimental to behavioral and affective functioning and overall mental well-being. Researchers have yet to formulate a universally agreed upon definition of the concept, but they have identified a variety of forms that emotional abuse may take, including verbal abuse: intimidation and terrorization;
humiliation and degradation: exploitation; harassment; rejection and withholding of affection; isolation; and excessive control. Also called psychological abuse.

emotional adjustment the condition or process of personal acceptance of and adaptation to one’s circumstances, which may require modification of attitudes and the expression of emotions that are appropriate to a given situation.

emotional blocking the inhibition of thought, speech, or other responses due to extreme emotion, often associated with extreme fear. See also blocking.

emotional charge strong emotion, such as anger, conceived as being bottled up under pressure and ready to explode. The concept also involves the idea that emotions are negatively or positively charged.

emotional cognition the ability to recognize and interpret the emotions of others, notably from such cues as facial expression and voice tone, and to interpret one’s own feelings correctly. Impairment of emotional cognition is associated with a range of psychological conditions, notably Asperger’s Disorder.

emotional conflict a state of disharmony between incompatible intense emotions, such as love and hate or the desire for success and fear of failure, that causes distress to the individual.

emotional contagion the rapid spread of an emotion from one or a few individuals to others. For example, fear of catching a disease can spread rapidly within a community. See also behavioral contagion; mass contagion; social contagion.

emotional content themes or characteristics of feelings that tend to elicit strong emotions, especially as they are portrayed in various forms of communication (reading material, motion pictures, etc.) or as they are manifested in specific situations.

emotional dependence reliance on others for emotional support, comfort, and nurturance.

emotional deprivation lack of adequate interpersonal attachments that provide affirmation, love, affection, and interest, especially on the part of the primary caregiver during a child’s developmental years.

emotional deterioration an emotional state characterized by carelessness toward oneself, indifference to one's surroundings (including other people), and inappropriate emotional reactions.

emotional development a gradual increase in the capacity to experience, express, and interpret the full range of emotions and in the ability to cope with them appropriately. For example, infants begin to smile and frown around 8 weeks of age and to laugh around 3 or 4 months, and older children begin to learn that hitting others is not an acceptable way of dealing with anger. Expressions of delight, fear, anger, and disgust are evident by 6 months of age, and fear of strangers from 8 months. Expressions of affection and jealousy are seen between 1 and 2 years of age, and expressions of rage in the form of temper tantrums appear a year or so later. Cortical control, imitation of others, hormonal influences, home atmosphere, and conditioning play major roles in emotional development. Also called affective development.

emotional disorder 1. any psychological disorder characterized primarily by maladjustive emotional reactions that are inappropriate or disproportionate to their cause. Also called emotional illness. See also anxiety disorder; mood disorder. 2. loosely, any mental disorder.

emotional disposition a tendency to have a particular type or class of affective experience (e.g., positive affect or negative affect).

emotional dissemblance lack of correspondence between an individual’s internal affective state and its outward expression. There are two broad categories of emotional dissemblance: culturally acceptable display rules and nonverbal or verbal deception.

emotional disturbance a fear-, anxiety-, or other emotionally based condition that results in maladaptive behavior—ranging from withdrawal and isolation to acting out and aggression—and adversely affects an individual’s academic and social functioning. Children with a long-standing condition that meets specified criteria, such as the inability to form satisfactory relationships with peers and teachers, are considered to have a serious emotional disturbance (SED) that constitutes a disability under the Individuals with Disabilities Education Act.

emotional divorce a marital relationship in which the partners live separate lives, with an absence of normal interaction between them.

emotional dysregulation see dysregulation.

emotional engineering see Kansei engineering.

emotional expression 1. an outward manifestation of an intrapsychic state. For example, a high-pitched voice is a sign of arousal; blushing is a sign of embarrassment, and so on. See also affect display. 2. an emotional response in which the individual attempts to influence his or her relation to the world through the intermediacy of others, rather than directly. For example, a sad face and slumped posture elicit nurturing from others. Expressions differ from action tendencies, which influence the world directly, and from feelings, which are intrapsychic experiences of the significance of a transaction.

emotional flooding an influx of great and uncontrollable emotion that may be overwhelming to the person who experiences it.

emotional illness see emotional disorder.

emotional immaturity 1. a tendency to express emotions without restraint or disproportionately to the situation. Compare emotional maturity. 2. a lay term for maladjustment.

emotional incest a form of child sexual abuse consisting of nonphysical sexualized interactions between a parent figure and a child. Emotional incest may involve the caregiver commenting on the child’s sexual attractiveness, drawing attention to the caregiver’s own arousal to the child or the size or shape of the child’s secondary sexual characteristics (e.g., breasts, pubic hair), or implying that the child is sexually active (e.g., calling the child a slut). Also called covert incest.

emotional inoculation the imagining or cognitive rehearsal of an anxiety-producing experience. Rehearsal lowers anxiety by allowing the individual to anticipate reactions and plan responses.

emotional insight 1. an awareness of one’s own emotional reactions or those of others. 2. in psychotherapy, the client’s awareness of the emotional forces, such as internal
emotional instability

conflicts or traumatic experiences, that underlie his or her symptoms. This form of insight is considered a prerequisite to change in many therapeutic approaches.

emotional instability a tendency to exhibit unpredictable and rapid changes in emotions. See labile affect. Compare EMOTIONAL STABILITY.

emotional insulation a defense mechanism characterized by seeming indifference and detachment in response to frustrating situations or disappointing events. The extreme of emotional insulation is found in states of complete apathy and catatonic stupor; in lesser forms, it appears as emotional isolation.

emotional intelligence a type of intelligence that involves the ability to process emotional information and use it in reasoning and other cognitive activities, proposed by U.S. psychologists Peter Salovey (1958— ) and John D. Mayer (1953— ). According to Mayer and Salovey’s 1997 model, it comprises four abilities: to perceive and appraise emotions accurately; to access and evoke emotions when they facilitate cognition; to comprehend emotional language and make use of emotional information; and to regulate one’s own and others’ emotions to promote growth and well-being. Their ideas were popularized in a best-selling book by U.S. psychologist and science journalist Daniel J. Goleman (1946— ), who also altered the definition to include many personality variables.

emotional intelligence quotient an index of emotional intelligence. Popular writers and the media sometimes abbreviate the term to EQ (for emotional quotient, nominally similar to IQ).

emotional isolation see emotional insulation.

emotionality n. the degree to which an individual experiences and expresses emotions, irrespective of the quality of the emotional experience.

emotionally based persuasion see affectively based persuasion.

emotional maturity a high and appropriate level of emotional control and expression. Compare emotional immaturity. See Affective Maturity.

emotional memory memory for events that evoke an emotional response. Emotional memories can be either implicit (nonconscious) or explicit (conscious). In laboratory studies with nonhuman animals, implicit emotional memory is demonstrated through such phenomena as conditioned fear (see avoidance conditioning) and freezing; behavior; additional paradigms exist to study implicit emotional memory in humans. Explicit emotional memory is manifest when individuals reexperience the original emotions engendered by an event (e.g., terror when describing an accident, joy when describing a close family member’s wedding). Functional neuroanatomy suggests that the encoding process for implicit emotional memories centers around the amygdala in the subcortical portions of the limbic system, and adrenergic and dopaminergic mechanisms in particular. Indeed, a person whose amygdala is damaged may calmly recall the details of a traumatic event without showing any residual fear in relation to that event. In contrast, encoding of explicit emotional memories involves the cortical regions of the limbic system, such as the hippocampus. Emotional memory is distinct from the more general phenomenon of enhanced storage and retrieval of emotional stimuli, which for example is seen when experimental participants recall aversive nouns from a word list better than they recall neutral items. Also called affective memory.

emotional processing theory a theory proposing a hypothetical sequence of fear-reducing changes that is evoked by emotional engagement with the memory of a significant event, particularly a trauma. The theory is based on the concept of a fear structure, a type of mental framework for reacting to threat that includes information about a feared stimulus (e.g., a snake), about physiological and behavioral responses (e.g., rapid heartbeat, sweating), and about the meaning of the stimulus and response elements (e.g., the snake is poisonous and will bite me and I am afraid of it). Although most fear structures accurately represent legitimate threats, others become distorted: Individuals do not reflect sufficiently upon the event initially and thus do not successfully evoke and cope with the associated emotions, so that harmless stimuli become seen as dangerous and act to trigger excessive physiological reactions, deliberate avoidance of memories of the event, emotional withdrawal, and other maladaptive behaviors.

The existence of such erroneous fear structures originally was proposed in response to the difficulties of traditional learning theories in explaining intrusion symptoms and fear in posttraumatic stress disorder. According to this conceptualization, which has since been expanded to other anxiety disorders, treatment (i.e., prolonged exposure therapy) should be designed to provide information that is incompatible with the pathological elements of a specific fear structure. Thus, the repetitive exposure to the event memory in a safe environment in which the threat is not realized gradually decreases emotional responding until the fear structure changes to accommodate this new, more accurate information (e.g., If I am not anxious, the situation cannot be so bad). [proposed in 1986 by U.S. psychologists Edna B. Foa (1937— ) and Michael J. Kozak (1952—)]

equal emotional quotient see emotional intelligence quotient.

emotional reeducation psychotherapy focused on modifying the client’s attitudes, feelings, and reactions by helping him or her gain insight into emotional conflicts and self-defeating behavior arising from affective disturbance or disorder. Typical objectives are an increase in self-confidence, sociability, and self-reliance. The methods used include group discussions, personal counseling, relationship therapy, and self-exploration.

emotional release the catharsis or sudden outpouring of emotions that have been pent up or suppressed.

emotional response an emotional reaction, such as happiness, fear, or sadness, to a given stimulus.

emotional security the feeling of safety, confidence, and freedom from apprehension. In the approach of Karen D. Horn, the need for emotional security is the underlying determinant of personality and behavior; in the approach of Harry Stack Sullivan, it is itself determined primarily by interpersonal relations. See also security operations.

emotional stability predictability and consistency in emotional reactions, with absence of rapid mood changes. Compare EMOTIONAL INSTABILITY.

emotional stress the feeling of psychological strain and uneasiness produced by situations of danger, threat, and loss of personal security or by internal conflicts, frustra-
tions, loss of self-esteem, and grief. Also called emotional tension.

emotional stupor a form of stupor marked by depression or intense anxiety and accompanied by mutism.

emotional support the verbal and nonverbal processes by which one communicates care and concern for another, offering reassurance, empathy, comfort, and acceptance. It may be a major factor contributing to the effectiveness of self-help groups, within which members both provide and receive emotional support, and to ATTACHMENT, in which the caregiver provides emotional support to the child.

emotional tension see EMOTIONAL STRESS.

emotional unconscious that aspect of the nonconscious mind that consists of unreportable emotional or motivational states. It is suggested that such states may influence thought and action without the individual becoming consciously aware of them. The emotional unconscious is comparable to, but distinct from, the COGNITIVE UNCONSCIOUS, which consists of implicit percepts, memories, and thoughts. The extent to which an individual can be said to have emotions without being conscious of them, however, is controversial. [proposed by U.S. cognitive psychologist John F. Kihlstrom (1948–)]

emotional valence the value associated with a stimulus as expressed on a continuum from pleasant to unpleasant or from attractive to aversive. In FACTOR ANALYSIS and MULTIDIMENSIONAL SCALING studies, emotional valence is one of two axes (or dimensions) on which an emotion can be located, the other axis being arousal (expressed as a continuum from high to low). For example, happiness is typically characterized by pleasant valence and relatively high arousal, whereas sadness or depression is typically characterized by unpleasant valence and relatively low arousal.

emotion-focused coping a stress-management strategy in which a person focuses on regulating his or her negative emotional reactions to a stressor. Rather than taking actions to change the stressor itself, the individual tries to control feelings using a variety of cognitive and behavioral tools, including mediation and other relaxation techniques, prayer, positive REFRAMING, wishful thinking and other AVOIDANCE techniques, self-blame, seeking SOCIAL SUPPORT (or conversely engaging in SOCIAL WITHDRAWAL), and talking with others (including mental health care professionals). It has been proposed that emotion-focused coping is used primarily when a person appraises the situation or intense anxiety and accompanied by mutism. emotion-focused therapy (EFT) an integrative INDIVIDUAL THERAPY that focuses on emotion as the key determinant of personality development and of psychotherapeutic change. In sessions, the therapist helps the client to become aware of, accept, make sense of, and regulate emotions as a way of resolving problems and promoting growth. Techniques are drawn from CLIENT-CENTRED THERAPY, GESTALT THERAPY, and COGNITIVE BEHAVIOR THERAPY. A principal proponent of this approach is South African-born Canadian psychologist Leslie S. Greenberg (1945–).

cognitive therapy the ability of an individual to modulate an emotion or set of emotions. Explicit emotion regulation requires conscious monitoring, using techniques such as learning to construe situations differently in order to manage them better, changing the target of an emotion (e.g., anger) in a way likely to produce a more positive outcome, and recognizing how different behaviors can be used in the service of a given emotional state. Implicit emotion regulation operates without deliberate monitoring; it modulates the intensity or duration of an emotional response without the need for awareness. Emotion regulation typically increases across the lifespan. Also called emotional regulation. See also PROCESS MODEL OF EMOTION REGULATION.

emotive adj. related to or arousing emotion.

e motive imagery in behavior therapy and cognitive behavior therapy, a procedure in which the client imagines emotion-arousing scenes while relaxing in a comfortable, protective setting. See RECIPROCAL INHIBITION.

emotive technique any of various therapeutic techniques designed to encourage clients to express their thoughts and feelings in an intense and animated manner so as to make these more obvious and available for discussion in therapy. Emotive techniques are used, for example, in RATIONAL EMOTIVE BEHAVIOR THERAPY to dispute irrational beliefs in order to move from intellectual to emotional insight.

empathic failure 1. a lack of understanding of another person’s feelings, perceptions, and thoughts. In SELF PSYCHOLOGY, a parent or caregiver’s repeated empathic failure toward a child is thought to be a potential source of later psychopathology, such as NARCISSISTIC PERSONALITY DISORDER and BORDERLINE PERSONALITY DISORDER. 2. in psychoanalysis, a situation in which a patient feels misunderstood by the therapist or analyst. Compare ATTUNEMENT; MISATTUNEMENT. [first described in 1966 by Austrian-born U.S. psychoanalyst Heinz Kohut (1913–1981)]

empathy n. understanding a person from his or her frame of reference rather than one’s own, or vicariously experiencing that person’s feelings, perceptions, and thoughts. Empathy does not, of itself, entail motivation to be of assistance, although it may turn into SYMPATHY or personal distress, which may result in action. In psychotherapy, therapist empathy for the client can be a path to comprehension of the client’s cognitions, affects, motivations, or behaviors. See also PERSPECTIVE TAKING. —empathic or empathetic adj. —empathize vb.

empathy-altruism hypothesis a theory that explains helping behaviors as resulting from feelings of empathy and compassion toward others, which arouse an altruistic motivation directed toward the ultimate goal of improving another person’s welfare. [proposed in 1991 by U.S. social psychologist C. Daniel Batson (1943–)]
empathy training

empathy training 1. a systematic procedure to increase empathetic feeling and communications in an individual. 2. training to enable convicted abusers to envision their victims’ feelings and become sensitive to the pain they have caused, with the aim of decreasing the likelihood that they will commit similar crimes in the future.

empirical adj. 1. derived from or denoting experimentation or systematic observations as the basis for conclusion or determination, as opposed to speculative, theoretical, or exclusively reason-based approaches. Many forms of research attempt to gain empirical evidence in favor of a hypothesis by manipulating an independent variable and assessing the effect on an outcome or dependent variable. 2. based on experience.

empirical construct see construct.

empirical-criterion keying a method for developing personality inventories in which the items (presumed to measure one or more traits) are created and then administered to a criterion group of people known to possess a certain characteristic (e.g., antisocial behavior, significant anxiety, exaggerated concern about physical health) and to a control group of people without the characteristic. Only those items that demonstrate an ability to distinguish between the two groups are chosen for inclusion in the final inventory.

deductive reasoning

empirical grounding the practice or procedure of anchoring theoretical terms to scientifically measurable or observable events. The extent to which this is possible for a particular theory is a measure of the value of that theory. See operational definition.

empirical knowledge 1. in philosophy, knowledge gained from experience rather than from innate ideas or deductive reasoning. 2. in the sciences, knowledge gained from experiment and observation rather than from theory. See empiricism.

empirically keyed test an assessment in which answers are scored in such a way as to establish differences in responses among groups already known to differ. For example, on a test measuring problem solving, the correct alternative among the response choices would be the one preferred by members of a criterion group who were administered the test previously. See also empirical-criterion keying.

empirical method any procedure for conducting an investigation that relies upon experimentation and systematic observation rather than theoretical speculation. The term is sometimes used as a vague synonym for scientific method.

empirical psychology an approach to the study and explanation of psychological phenomena that emphasizes objective observation (see observational study) and the experimental method as the source of information about the phenomena under consideration. Compare rational psychology. See also experimental psychology.

empirical-rational strategy in social psychology, the idea that societal and institutional change can be brought about if the public receives enough convincing factual evidence. The concept holds that reason alone can motivate people to change their attitudes. See also normative-reeducative strategy; power-coercive strategy.

empirical self the self that is known by the self, rather than the self as knower. In the psychology of William James, the empirical self is held to consist of the material self (everything material that can be seen as belonging to the self), the social self (the self as perceived by others), and the spiritual self (the self that is closest to one’s core subjective experience of oneself). The empirical self (or “me”) is contrasted with the nominative self (or “I”).

empirical test the test of a hypothesis by means of experiments or other systematic observations.

empirical validity the degree to which the accuracy of a test, model, or other construct can be demonstrated through experimentation and systematic observation (i.e., the accumulation of supporting research evidence) rather than theory alone.

empiricism n. 1. an approach to epistemology holding that all knowledge of matters of fact either arises from experience or requires experience for its validation. In particular, empiricism denies the possibility of innate ideas, arguing that the mind at birth is like a blank sheet of paper (see tabula rasa). During the 17th and 18th centuries, empiricism was developed as a systematic approach to philosophy in the work of John Locke, George Berkeley, and David Hume. These thinkers also developed theories of associationism to explain how even the most complex mental concepts can be derived from simple sense experiences. Although there is a strong emphasis on empiricism in psychology, this can take different forms. Some approaches to psychology hold that sensory experience is the origin of all knowledge and thus, ultimately, of personality, character, beliefs, emotions, and behavior. Behaviorism is the purest example of empiricism in this sense. Advocates of other theoretical approaches to psychology, such as phenomenology, argue that the definition of experience as only sensory experience is too narrow; this enables them to reject the position that all knowledge arises from the senses while also claiming to adhere to a type of empiricism. 2. the view that experimentation is the most important, if not the only, foundation of scientific knowledge and the means by which individuals evaluate truth claims or the adequacy of theories and models. 3. in philosophy, the position that all linguistic expressions that are not tautologous must be empirically verifiable if they are to be deemed valid or meaningful. This principle was essential to the philosophy of logical positivism. See also positivism. —empiricist adj. n.

empiric-risk figure in genetic counseling, a percentage representing the risk for common disorders, such as schizophrenia and depression, when there is evidence of genetic factors of unknown mechanism. The figure is based upon reports of frequency of occurrence in large series of families (in addition to the approximately 3% risk of birth defects, including intellectual disability, present for every couple having a child).

employee appraisal see employee evaluation.

employee assistance program (EAP) a designated formal function within an organization for helping individual employees with personal problems that affect their job performance (e.g., substance abuse, family difficulties, emotional problems). EAP services include screening, assessment, and referral of employees to community resources, as well as direct clinical treatment by psychologists or other mental health professionals.

employee comparison technique any method of employee evaluation in which the performance of one employee is compared with that of others, rather than considered in absolute terms. Examples include the ranking
empower vb.

empowerment evaluation see participatory evaluation.

empty-chair technique a technique originating in gestalt therapy in which the client conducts an emotional dialogue with some aspect of himself or herself or some significant person (e.g., a parent), who is imagined to be sitting in an empty chair during the session. The client then exchanges chairs and takes the role of that aspect or of that other person. This technique is now sometimes also referred to as the two-chair technique.

empty nest the family home after the children have reached maturity and left, often creating an emotional void (empty nest syndrome) in the lives of the parents (empty nesters).

empty set in set theory, a collection of entities with no elements or members. Also called null set.

empty speech fluent speech that lacks information or meaningful content.

empty word see function word.

empyreumatic adj. in the zwaaemakever smell system, denoting an odor quality that is smelled in roasted coffee and creosote.

EMR abbreviation for educable mentally retarded.

EMSAM n. a trade name for transdermal selegiline.

emulation n. the ability to comprehend the goal of a model and engage in similar behavior to achieve that goal, without necessarily replicating the specific actions of the model. Emulation facilitates social learning.

enabling n. 1. a process whereby someone (i.e., the enabler) contributes to continued maladaptive or pathological behavior (e.g., child abuse, substance abuse) in another person. The enabler is typically an intimate partner or good friend who passively permits or unwittingly encourages this behavior in the other person: often, the enabler is aware of the destructiveness of the person’s behavior but feels powerless to prevent it. 2. the process of encouraging or allowing individuals to meet their own needs and achieve desired ends. A therapist attempts to enable clients to believe in themselves, have the confidence to act on their desires, and affirm their ability to achieve. See also empowerment.

enaction n. the process of putting something into action. The word is preferred to terms like execution, which have computing or machine-based connotations. Enaction thus involves guidance and support; it does not imply complete automation. Much of the literature on process modeling states that models should be enactable.

enactive representation representation of objects and events through action and movement, which is characteristic of infants and small children. That is, the child understands things in terms of how they can be manipulated, used, or acted upon. The process underlying this emergent understanding is called the enactive mode (or enactive stage). Compare iconic representation; symbolic representation. [proposed by Jerome Seymour Bruner]
enactment  n. 1. the acting out of an important life event rather than expressing it in words. See PSYCHODRAMA. 2. in some forms of PSYCHOANALYTIC PSYCHOTHERAPY, the patient’s reliving of past relationships in the TRANSFERENCE relationship with the therapist and, conversely, the therapist’s move away from active neutrality to unwittingly intertwine personal issues into symbolic interactions with the patient (a COUNTERTRANSFERENCE phenomenon). Attunement to the relational patterns that emerge in this therapeutic relationship offers the therapist an opportunity to help the patient acknowledge and work through similar patterns in the patient’s relationships with others. See also RELATIONAL PSYCHOANALYSIS; SELF PSYCHOLOGY. 3. in some forms of COUPLES THERAPY, a technique in which the therapist recreates areas of conflict between partners in order to facilitate understanding moments. 4. see STRUCTURAL FAMILY THERAPY.

enantiomorphy  n. 1. the conception of Greek philosopher Heraclitus (c. 535–c. 475 BCE) that all things eventually turn into, or are replaced by, their opposite. 2. ally, human–ape interactions, such as direct teaching, the

encephalocoele  n. a congenital hernia (see HERNIATION) of the brain, which protrudes through a cleft in the skull.

encephalomalacia  n. softening of the brain, usually due to tissue deterioration resulting from an inadequate blood supply to the area.

encephalomyelitis  n. inflammation of the brain and spinal cord. As with ENCEPHALITIS, it is most often caused by viral infection.

encephalon  n. see BRAIN.

encephalopathy  n. any of various diffuse disorders or diseases of the brain that alter brain function or structure and are characterized primarily by altered mental states, especially confusion.

encephalophy  n. a condition in which one associates colors with numbers, letters, smells, or other dimensions.

encoding  n. 1. the conversion of a sensory input into a form capable of being processed and deposited in memory. Encoding is the first stage of memory processing, followed by RETENTION and then RETRIEVAL. 2. in communications, the conversion of messages or data into codes or signals capable of being carried by a communication channel.

encoding specificity  the principle that RETRIEVAL of memory is optimal when the retrieval conditions (such as context or cues) duplicate the conditions that were present when the memory was formed. [proposed in 1983 by Endel Tulving]

encoding strategy  a mental or behavioral strategy that one may use to ensure learning or remembering, such as ELABORATIVE REHEARSAL, mental imagery, or a MNEMONIC.

encoding variability theory  see SPACING EFFECT.

encopresis  n. repeated defecation in inappropriate places (clothing, floor, etc.) that occurs after the age of 4 and is not due to a substance (e.g., a laxative) or to a general medical condition. Encopresis may or may not be accompanied by constipation and is often associated with poor toilet training and stressful situations. Compare FECAL INCONTINENCE.

encounter  n. a direct confrontatio or other involvement of one individual with another or between several people. See also INTERACTION.

encounter group  a group of individuals in which constructive insight, sensitivity to others, and personal growth are promoted through direct interactions on an emotional and social level. The leader functions as a catalyst and facilitator rather than as a therapist and focuses on here-and-now feelings and interaction rather than on theory or individual motivation.

encounter movement  a trend toward the formation of small groups in which various techniques, such as CONFRONTATION, GAMES, and REENACTMENT, are used to stimulate awareness, personality growth, and productive interactions. The movement gained popularity in the 1960s but diminished at the end of the 20th century.

enculturation  n. 1. the processes, beginning in early childhood, by which particular cultural values, ideas, beliefs, and behavioral patterns are instilled in the members of a society. Compare ACCULTURATION. See also CULTURAL HERITAGE; SOCIAL TRANSMISSION. 2. in anthropology, the rearing of great apes in an environment that includes frequent contact with humans and their artifacts and, usually, human–ape interactions, such as direct teaching, the
use of language, and joint attention. Some investigators have suggested that enucleated great apes may show aspects of social cognitive development that are more like those of children than of mother- or nursery-reared apes. —enculturate vb.

endarterectomy n. a surgical procedure in which an atherosclerotic plaque is removed from an artery, most commonly the carotid artery at the level of bifurcation in the neck. By removing the plaque, the bore of the artery is enlarged, allowing a greater flow of blood to the brain and thus decreasing the risk of stroke.

dentral tendency bias the tendency for individuals to avoid the extreme choices on a scale and instead select a choice in the middle of the scale, closer to neutral. Such an approach results in a narrower range of responses that most likely will not be an accurate representation of the variable being measured. For example, a supervisor assessing employees would show end-aversion bias if his or her ratings generally were around 4 on a 7-point scale. Also called central-tendency bias.

end brush the finely branched terminal of an axon. Also called telodendron.

endemic adj. occurring in a specific region or population, particularly with reference to a disease or disorder. Compare epidemic; pandemic.

end feet the terminal processes of an axon or an astrocyte.

endo-(end-) combining form inside or internal.

endocannabinoid n. see endogenous cannabinoid.

endocarditis n. inflammation of the endocardium, the inner lining of the heart, and often the heart valves. It is typically caused by bacterial or fungal infections. Primary diagnostic symptoms include fever, new or changing heart murmurs, and pinpoint hemorrhages (particularly in the extremities and conjunctiva of the eye).

endocast n. a cast of the cranial cavity of a skull. It is especially useful for studying the size and form of brains of fossils of extinct species.

endocochlear potential see endolymphatic potential.

endocrine adj. describing or relating to a type of chemical signaling in which a chemical messenger is released by a cell and is carried (e.g., via the bloodstream) to a distant target cell on which it exerts its effect. Compare autocrine; paracrine.

endocrine disruptor a natural or synthetic chemical that blocks, stimulates, mimics, or otherwise affects hormones in the endocrine system (e.g., sex hormones, thyroid hormones). Natural endocrine disruptors may include, for example, phytosterogens (i.e., estrogens produced by some plants). Examples of synthetic endocrine disruptors are industrial chemicals (e.g., polychlorinated biphenyls [PCBs]), plastics such as bisphenol A, plasticizers such as phthalate; pesticides (e.g., dichlorodiphenyltrichloroethane [DDT]), and pharmaceutical agents such as diethylstilbestrol. Effects of exposure to endocrine disruptors may include infertility, birth defects, and cancer.

endocrine gland any ductless gland that secretes hormones directly into the bloodstream to act on distant targets. Such glands include the pituitary gland, adrenal gland, thyroid gland, gonads (testis and ovary), and islets of Langerhans. Together, they comprise the endocrine system. Compare exocrine gland.

diocrinology n. the study of the morphology, physiology, biochemistry, and pathology of the endocrine glands. See also Neuroendocrinology; Psychoneuroendocrinology. —endocrinological adj. —endocrinologist n.

dendrimer n. the innermost of the three primary germ layers of a developing embryo. It gives rise to the gastrointestinal and respiratory tracts and some glands. —endodermal adj.

end of life the variable period during which dying individuals and their families, friends, and caregivers face issues related to the imminent prospect of death. The end-of-life concept is a way of considering the total context of an approaching death, rather than medical factors only. End-of-life issues include decisions relating to the nature of terminal care (hospice or traditional), whether to resuscitate, the distribution of property and assets (funeral and memorial arrangements, and leave taking and possible reconciliations with family and friends. See also advance directive; informed consent.

endogamy n. the custom or practice of marrying within one’s kinship network, caste, or other religious or social group. Compare exogamy. —endogamous adj.

endogenous adj. originating within the body as a result of normal biochemical or physiological processes (e.g., endogenous opioids) or of predisposing biological or genetic influences (e.g., endogenous depression). Compare exogenous. —endogenously adv.

endogenous attention see voluntary attention.

endogenous cannabinoid (eCB) any of several cannabis-like substances produced within the bodies of vertebrates. The primary endogenous cannabinoids are anandamide (arachidonoylthanolamide [AEA]) and 2-arachidonoylglycerol (2-AG), small fatty molecules that are synthesized from arachidonic acid only when needed and then rapidly degraded by the enzymes fatty acid amide hydrolase (FAAH) and monoacylglycerol lipase (MAGL). Although widely distributed throughout the body, endogenous cannabinoids are concentrated particularly within the central nervous system, where they function as neuromodulators, regulating communication between neurons by influencing the release of gamma-amino- butyric acid, glutamate, and other neurotransmitters at synapses. Together, the endogenous cannabinoids, their respective synthetic and degradative enzymes, and the different types of cannabinoid receptors to which they bind comprise the endogenous cannabinoid system.

In addition to regulating synaptic transmission, this system plays an important role in an array of other processes, including those related to immune function, pain perception, learning and memory, energy expenditure and metabolism, appetite control, nausea and vomiting, mood, responses to stress, facilitation of motor behavior, and the motivational and rewarding aspects of numerous behaviors and stimuli (including several recreational drugs). The endogenous cannabinoid system also has neuroprotective properties and performs additional functions within the circulatory, digestive, and respiratory systems. Alterations of this system may be involved in the pathophysiology of a variety of disorders, including multiple sclerosis, glaucoma, chronic pain, substance abuse and dependence, anxiety, bipolar disorder, depression, schizophrenia, eating disorders, and obesity. Indeed, growing research evidence
endogenous cue

suggests that manipulation of the endocannabinoid system could be a therapeutic target for these and other neurological and psychiatric conditions. Also called endocannabinoid. See also CANNABINOID.

endogenous cue a CUE, such as a centered arrow, that instructs a participant in a task to direct attention to a particular location but does not automatically draw attention to that location. It initiates a voluntary movement of attention. Compare EXOGENOUS CUE.

endogenous depression depression that occurs in the absence of an obvious psychological stressor and in which a biological or genetic cause is implied. Compare REACTIVE DEPRESSION.

endogenous opioid a substance produced in the body that has the analgesic and euphoric effects of morphine. Three families of endogenous opioids are well known: the enkephalins, endorphins, and dynorphins. All are NEUROPEPTIDES that bind to OPIOID RECEPTORS in the central nervous system; they are mostly inhibitory, acting like opiates to block pain. They bind relatively nonspecifically to opioid receptors, although enkephalins bind preferentially to the delta opioid receptors and dynorphins to kappa opioid receptors. Three other endogenous opioid peptides have been identified: nociceptin/orphanin FQ (N/OFQ) and endorphins 1 and 2. Also called opioid neurotransmitter.

endogenous oscillator a NEURAL CIRCUIT that generates regularly repeating sequences of neural activity or behavior. In the context of chronobiology, it refers to the BIOLOGICAL CLOCK. See also CIRCADIAN OSCILLATOR.

endogenous research research that is based on information inherent in a specific area or system, without taking into account outside, independent information.

endogenous rhythm see BIOLOGICAL RHYTHM.

endogenous smile a spontaneous or reflexive smile that is observed when an infant, early in life, is in a state of REM SLEEP. Characterized by a simple turning up of the corners of the mouth, such smiles are seen from birth and are not elicited by social stimulation. Compare SOCIAL SMILE.

endogenous thyrotoxicosis see THYROTOXICOSIS.

endogenous variable a DEPENDENT VARIABLE whose values are determined, caused, or explained by factors within the model or system under study. Compare EXOGENOUS VARIABLE.

endolymph n. the fluid contained in the membranous labyrinth of the inner ear, that is, within the SCALA MEDIA, SEMICIRCULAR CANALS, SACCULE, and UTRICLE. —endolymphatic adj.

endolymphatic potential a DC electric potential of approximately 80 mV measurable with electrodes inserted into the endolymph in the scala media. Also called endocochlear potential.

endometrium n. the layer of cells lining the uterus. It varies in thickness during the MENSTRUAL CYCLE, reaching a peak of cellular proliferation approximately 1 week after ovulation, in preparation for implantation of a fertilized ovum, and sloughing off as menstrual flow 2 weeks after ovulation if the ovum is not fertilized. —endometrial adj.

endomorph n. a constitutional type (SOMATOTYPE) in SHeldon’s CONSTITUTIONAL THEORY OF PERSONALITY characterized by a soft, round physique, which—according to this theory—is highly correlated with VISCEROTONIA. Also called endomorphic body type. —endomorphic adj. —endomorphy n.

dendomorphin n. see ENDOGENOUS OPIOID.

endomusia n. literally, inner music (Greek): the reproduction of a tune or piece of music in the mind.

endophasia n. literally, inner speech (Greek): the reproduction of spoken language in the mind. See also COVERT SPEECH.

endophenotype n. a type of BIOLOGICAL MARKER that is simpler to detect than genetic sequences and that may be useful in researching vulnerability to a wide range of psychological and neurological disorders. Endophenotypes may be a useful link between genetic sequences and their external emotional, cognitive, or behavioral manifestations. [coined in the 1970s by U.S. behavioral geneticist and clinical psychologist Irving I. Gottesman (1930–) and British psychiatrist James Shields (d. 1978)]

endoplasm n. the relatively less dense CYTOPLASM that fills the bulk of a cell, away from the periphery and excluding the nucleus. Compare ECTOPLASM. —endoplasmic adj.

endoplasmic reticulum (ER) a network of membranous tubules and sacs extending from the nucleus to the outer membrane of a typical animal or plant cell. It is responsible for the processing and modification of proteins and lipids, both for distribution within the cell and for secretion.

endopsychic adj. pertaining to nonconscious material or intrapsychic processes (i.e., processes occurring within the mind). Compare EXOPSYCHIC.

endopsychic structure in psychoanalysis, the internal structure of the mind or psyche. In Sigmund Freud’s formulation, the mind is divided into three components: the ID, EGO, and SUPEREGO. See STRUCTURAL MODEL.

endoradiosonde n. a miniature instrument consisting of recording devices and a radio transmitter that is implanted in or fed to a nonhuman animal in order to study internal reactions or behaviors.

end organ the structure associated with a motor or sensory nerve ending, such as a muscle END PLATE or a sensory receptor. The latter may be encapsulated end organs, which are enclosed in a membranous sheath and usually located in peripheral tissue, such as the skin. Kinds of encapsulated end organs include MEISSNER’S CORPUSCLES (sensitive to touch) and PACINIAN CORPUSCLES (sensitive to pressure).

endorphin n. any of a class of NEUROPEPTIDES, found mainly in the pituitary gland, that function as ENDOGENOUS OPIOIDS. The best known is BETA-ENDOPHRIN; the others are alpha-endorphin and gamma-endorphin. The production of endorphins during intense physical activity is one explanation for the RUNNER’S HIGH or EXERCISE HIGH, as well as for an athlete’s ability to feel little or no pain during a competition.

endosomatic current an electrical current produced by a living organism.

endotherm n. an animal whose body temperature is regulated chiefly by internal metabolic processes. The only true endotherms are mammals and birds. Such animals, formerly called homeotherms, are popularly described as warm-blooded. Compare ECTOTHERM. —endothermic adj. —endothermy n.
endowment effect the tendency of people to place a higher value on items once they own them or once these have been associated with the self in some other way. For example, an individual selling goods often prices them above what he or she would be willing to pay to acquire those same goods (i.e., selling prices exceed buying prices). The endowment effect is characterized by increased positive emotions toward the object. [coined in 1980 by U.S. economist Richard Thaler (1945– )]

end-plate potential the terminal stage of a motor neuron within a neuromuscular junction. The depolarization that is induced in this muscular region when stimulated by a neurotransmitter released from the adjacent motor neuron terminus is called the end-plate potential (EPP). A very small variation in this potential due to the random release of tiny amounts of a neurotransmitter at an axon terminal is called a miniature end-plate potential. Also called motor end plate.

end plate a specialized region of a muscle-cell membrane that faces the terminus of a motor neuron within a neuromuscular junction.

end plate a specialized region of a muscle-cell membrane that faces the terminus of a motor neuron within a neuromuscular junction. The depolarization that is induced in this muscular region when stimulated by a neurotransmitter released from the adjacent motor neuron terminus is called the end-plate potential (EPP). A very small variation in this potential due to the random release of tiny amounts of a neurotransmitter at an axon terminal is called a miniature end-plate potential. Also called motor end plate.

end spurt the increased productivity or gain in performance frequently noted near the end of a task, series of trials, or day’s work. It is also commonly observed in athletic endeavors, such as long-distance running. Compare initial spurt.

end-stage renal disease the terminal stage of chronic kidney failure, requiring the individual with the disease to undergo hemodialysis, peritoneal dialysis, or kidney transplant to survive. The psychological effects of living with the condition and its treatment can include depression arising from a sense of lost or limited personal control due to dependence on a dialysis machine, to dialysis-related diet restrictions, and the like. Body-image problems caused by transplantation can develop as well.

end-stopped cell a neuron in any visual area of the cerebral cortex that is maximally responsive to a line of a certain length or to a corner of a larger stimulus. Such neurons have a reduced or absent response when the line or corner is extended beyond a certain point. End stopping is a characteristic of hypercomplex cells in striate cortex.

endurance activity a physical activity that depends on aerobic capacity, that is, the ability to produce energy for muscles by using oxygen for long periods of time. Sport performances that are endurance activities include marathons, runs over 10,000 m, and triathlons. Also called aerobic activity. See aerobic exercise; anaerobic exercise.

enema n. the injection of a liquid into the rectum via the anus or the liquid itself. Enemas are used to empty the bowel, to introduce radiopaque contrast media into the bowel for radiography, and to administer certain drugs in the bowel. This condition is often associated with eating disorders in which enemas are routinely used for purging. See also enema addiction; laxative addiction.

engendering psychology the project of developing an approach to psychological issues that is sensitive to questions of gender. See feminist psychology; woman-centered psychology. [introduced by U.S. psychologist Florence L. Denmark (1932– )]

engineering anthropometry measurement of the static and dynamic features of the human body, including dimensions, movements, and center of gravity, and the application of these data to the design and evaluation of equipment for human use.

engineering controls the avoidance of hazards through redesign of machinery or equipment (e.g., by using guards, ventilation systems, and radiation shields) and the replacement or removal of unsafe systems or practices. Engineering controls are considered the first resort in the creation of a safe working environment, followed by administrative controls and the use of personal protective equipment. See also hazard-control protocol.

engineering model 1. a belief or hypothesis that living organisms, including humans, can be viewed mechanistically, that is, as machines. 2. in evaluation research, a simple comparison of treatment gains for different groups, some of which have been exposed to the treatment program of interest. Compare medical model.

engineering psychology a subfield of human factors psychology concerned with identifying the psychological principles that govern human interaction with environments, systems, and products and applying these principles to issues of engineering and design. Engineering psychologists may consult with architects and designers of various industrial and consumer products (e.g., airplanes, automobiles, home appliances, electronics and software applications) while specializing in such areas as ergonomics, human–computer interaction, or usability engineering. Engineering psychology is often used synonymously with human factors engineering. See also equipment design; human engineering; tool design; workspace design.

English as a second language (ESL) education in English for students who are not native English speakers, associated with agitation, anxiety, insomnia, and arrhythmias. Caffeinated alcoholic beverages are also considered to be energy drinks. In 2010, in response to concerns about the safety of these beverages, the U.S. Food and Drug Administration labeled caffeine an “unsafe food additive” to alcohol and effectively banned its use in alcoholic beverages.

energy-flow system any system in which the component organisms or entities convert energy into forms that can be used by the other organisms or entities, such that there is a constant energy flow through the entire system. An ecosystem is perhaps the clearest example of an energy-flow system. In psychology, Sigmund Freud’s early models of the psyche were essentially energy-flow models, in which libido was employed by the instincts to bring thoughts to consciousness while simultaneously employed by other parts of the psyche to keep them out of consciousness. More recently, a field known as energy psychology has emerged, which attempts to treat trauma and emotional problems by intervening in the energy flow of the body.

enervate vb. 1. to weaken or deprive of energy. 2. to surgically remove a nerve or a part of a nerve. —enervation n.

engagement theory the subjective perception of a goal’s value or attainability corresponds to the level of energy expended to reach that goal. [proposed by Jack W. Brehm and colleagues]

energy drink any of a group of widely available liquids that may contain large quantities of caffeine as well as sugar, taurine, ginseng, ginkgo biloba, B vitamins, antioxidants, and artificial sweeteners that are used to increase energy, alertness, and endurance. Overuse has been
**engram**

most often with an emphasis on language proficiency. When English language proficiency is achieved, the use of English can be applied to the broader curriculum. It was formerly known as **English as a foreign language**.

**engram n.** the hypothetical MEMORY TRACE that is stored in the brain. The nature of the engram, in terms of the exact physiological changes that occur to encode a memory, is as yet unknown. The term was introduced by German biologist Richard Semon (1859–1918) in the early 1900s and was popularized by Karl S. Lashley in his 1950 paper “In Search of the Engram.” Also called mnemonic trace: neurogram.

**enlargement n.** 1. the use of genetic technology to produce superior offspring. 2. more generally, any improvement in the nature or value of an entity.

**enjoyment n.** a perception of great pleasure and happiness brought on by success in or simple satisfaction with an activity.

**enkephalin n.** see ENDOGENOUS OPIOID.

Enlon n. a trade name for edrophonium.

**enmeshment n.** a condition in which two or more people, typically family members, are involved in each other’s activities and personal relationships to an excessive degree, thus limiting or precluding healthy interaction and compromising individual autonomy and identity.

**enrichment n.** 1. enhancement or improvement by the addition or augmentation of some desirable property, quality, or component. For example, the INSTRUMENTAL ENRICHMENT program was originally designed to help pupils with intellectual disability improve their metacognitive and cognitive skills; JOB ENRICHMENT policies are designed to enhance QUALITY OF WORKLIFE and thus employees’ interest in and attitude toward work tasks; and MARRIAGE ENRICHMENT GROUPS are intended to enhance the interpersonal relationships of married couples. 2. the provision of opportunities to increase levels of behavioral or intellectual activity in an otherwise unstimulating (i.e., impoverished) environment. For example, the provision of play materials and opportunities for social contacts has been shown to enhance the development of young children. In laboratory studies of animal behavior, the addition of physical features or task requirements to an environment elicits a more natural behavioral repertoire from the animals. Devices, such as puzzle boxes and complex feeders, are used to reduce boredom and STEREOTYPY. Enriched environments have been shown to induce greater brain neuronal growth and complexity in rats than do standard caging environments. Also called environmental enrichment.

**enrichment program** 1. an educational program designed to supplement the academic curriculum and facilitate the intellectual stimulation of children at risk of educational difficulties or failure, particularly those from culturally or economically disadvantaged homes. Activities, such as arts and music instruction, theater, and science experiments, are typically provided through special preschool or kindergarten classes and intended to facilitate the acquisition of oral, written, motor, and interpersonal skills. 2. an educational program designed to provide gifted children with an expanded curriculum. Enrichment programs most often focus on expanding the horizons of learning by means of auxiliary instruction rather than by providing accelerated instruction in the regular curriculum.

**entelechy n.** in philosophy and metaphysics, actuality or realization as opposed to potentiality. ARISTOTLE used the word to refer to the soul (psyche), seen as that form within the material being by virtue of which it achieves the actuality of its nature (see ACTUAL). Later philosophers employed the term in a similar vein. Gottfried Wilhelm Leibniz referred to MONADS as being entelechy; or having entelechy, defined as the power to perfect their given nature (see NISUS). In certain vitalist philosophy, entelechy refers to the vital force within an organism that allows for life, development, and self-fulfillment (see ELAN VITAL; VITALISM).

**enteric virus infection** a disease produced by one of the polio, Cocksackie, or echoviruses (called enteroviruses), which are members of the picornavirus family. Such infections include poliomyelitis, aseptic meningitis, herpangina, and myocarditis. The viruses have been classed as enteric because they multiply in the human gastrointestinal tract. Also called enteroviral infection.

**enterogastrone n.** a hormone secreted by the small intestine that inhibits the secretion of gastric juice by the stomach. It is released when the stomach contents pass into the small intestine.

**enthusiasm n.** a feeling of excitement or passion for an activity, cause, or object. —enthusiastic adj.

**entitativity n.** the extent to which a group or collective is considered by others to be a real entity having unity, coherence, and internal organization rather than a set of independent individuals. In general, groups whose members share a common fate, are similar to one another, and are located close together are more likely to be considered a group rather than a mere aggregation. [first described by Donald Campbell]

**entitlement n.** 1. rights or benefits legally bestowed on a person or group, for example, by legislation or contract. 2. unreasonable claims to special consideration, especially as a disturbance of self-concept in NARCISSISTIC PERSONALITY DISORDER.

**entitlement program** a program of the U.S. government that provides financial assistance and welfare benefits to individuals who meet requirements set by law (e.g., people with mental or phylial disabilities). Entitlement programs are administered through MEDICARE, MEDICAID, SOCIAL SECURITY disability insurance, and similar funding sources.

**entity theory** see IMPLICIT SELF THEORY.

**entoptic adj.** originating within the eyeball itself. The term is used particularly to denote visual sensations caused by stimulation within the eye (entoptic phenomena), the classic example of which is seeing faint dark specks moving through the visual field when gazing at a clear, blue sky. These are shadows caused by blood cells moving through the vasculature on the surface of the retina.

**entorhinal cortex** a region of cerebral cortex in the
ventromedial portion of the temporal lobe. It has reciprocal connections with the hippocampal formation and various other cortical and subcortical structures and is an integral component of the medial temporal lobe memory system. It is also involved in spatial navigation. Lesions in this area are used to study neural plasticity and working memory; they are also seen in temporal lobe epilepsy and the early stages of Alzheimer’s disease.

entainment n. the process of activating or providing a timing cue for a biological rhythm. For example, the production of gonadal hormones in seasonally breeding animals can be a result of entrainment to increasing day length. The timing of circadian rhythms can be due to entrainment to either sunrise or sunset. See Brainwave entrainment.

entrapment n. 1. a process in which one makes increasing commitments to a failing course of action or an unattainable goal in order to justify the amount of time and effort already invested, feeling helpless to do otherwise. An example is provided by a company that proceeds with the design and construction of a new building for its employees after economic and other changes significantly reduce profits. 2. disengagement from the function of a task or organization that make the new space not only financially burdensome but also no longer necessary. See also escalating commitment. 2. a pathological condition in which swelling of surrounding tissue places excessive pressure on a nerve. Fibers located on the surface of the nerve usually bear the brunt of the compression, whereas interior fibers tend to be less affected. Repeated or long-term entrapment can cause nerve damage and muscle weakness. 3. a law enforcement agent’s provocation or inducement of an individual to necessarily have engaged in the activity otherwise. If entrapment is proved, it can serve as a defense in a criminal prosecution.

entrepreneurship n. the assumption of all the risks of the creation, organization, and management of a business venture for the reward of future profits. Social entrepreneurship is the use of an entrepreneurial approach with similar assumed risks to create, organize, and manage a venture whose profits are used primarily to promote a positive return to society by effecting social change.

entropy n. 1. a thermodynamic quantity providing a measure of the unavailability of the energy of a closed system to do work. 2. in statistics, an indication of the degree of disorder, disequilibrium, or change of a closed system. It is also used to study neural plasticity and working memory; it is also seen in temporal lobe epilepsy and the early stages of Alzheimer’s disease. 3. a thermodynamic quantity providing a measure of the unavailability of the energy of a closed system to do work.

environmental assessment the evaluation of situational and environmental variables that influence behavior, based on the theory that disordered functioning may be rooted partly in the social system, or particular social context, rather than wholly in the individual and his or her personal characteristics. In an organizational context, for example, measures of manager support and availability of resources to accomplish a job would likely be used in the environmental assessment of employee job satisfaction.

environmental attribution see situational attribution.

environmental approach a therapeutic approach in which efforts are directed either toward reducing external pressures (e.g., employment or financial problems) that contribute to emotional difficulties or toward modifying aspects of the individual’s living or working space to improve functioning.

environmental attitudes the beliefs and values of individuals or societies with respect to nature, ecology, or environmental issues. Research in this area examines how such factors as age, gender, and politics relate to people’s environmental attitudes, the influence of environmental attitudes on attitudes, and the role of attitudes in pro-environmental behavior.
environmental cognition information processing in real-world settings, often with regard to memory for geographic location and way finding. See COGNITIVE MAP; LANDMARK.

environmental constraint any circumstance of a person’s situation or environment that discourages the development of skills, independence, social competence, or adaptive behavior or inhibits the display of skills previously acquired. For example, living in a COMMUNITY RESIDENCE where staff prepare all the meals would act as an environmental constraint for someone who has learned how to make sandwiches, because it would provide no opportunity to display this ability.

environmental control device an ASSISTIVE TECHNOLOGY device with the capacity to regulate or manipulate aspects of a person’s physical surroundings. Examples include devices that turn on lights, open doors, and operate appliances. Also called electronic aid to daily living; environmental control unit. See also CONTROL DEVICE; FEEDBACK DEVICE; SWITCH DEVICE; TARGET DEVICE.

environmental deprivation an absence of environmental conditions that stimulate intellectual and behavioral development, such as educational, recreational, and social opportunities. Environmental deprivation is often associated with social isolation and may be so severe that it causes PSEUDORETARDATION.

environmental design the creative planning of living and working areas to enhance their HABITABILITY. Environmental design may also be applied to the enhancement of recreational areas. Habitability factors range from simple shelter needs to complex and sophisticated environmental aesthetics and conformance factors, such as the use of specific colors of paint or levels of illumination for the optimum performance of tasks.

environmental determinism the view that psychological and behavioral characteristics are largely or completely the result of environmental conditions. Biological factors are considered to be of minor importance, exerting little if any influence. Compare BIOLOGICAL DETERMINISM; GENETIC DETERMINISM. See also DETERMINISM; NATURE–NURTURE.

environmental education the development of principles and materials to raise awareness and change behaviors with respect to environmental problems. See ENVIRONMENTAL ATTITUDES; PROECOLOGICAL BEHAVIOR; SOCIAL TRAP.

environmental enrichment see ENRICHMENT.

environmental field in GESTALT PSYCHOLOGY, the entire context in which an event takes place and with which the components of the event interact.

environmental hazards environmental factors that pose some danger to an organism or community, such as exposed electrical wiring in a home or workplace and nuclear reactors or lead smelters in a community. Exposure to environmental hazards is linked to both psychological and physiological stress.

environmentalism n. 1. the concept that the environment and learning are the chief determinants of behavior and thus are the major cause of interpersonal variations in ability and adjustment; accordingly, behavior is largely modifiable. Compare HEREDITARIANISM. See also NATURE–NURTURE. 2. a social movement and position that emphasizes the ecological relationship between humans and the natural environment and strives to protect the environment as an essential resource. —environmentalist n.

environmental justice fair and impartial treatment with respect to the distribution of environmental hazards in the general population, such that no single group is exposed disproportionately to suboptimal environmental conditions at home, work, or school.

environmental load theory the theory that human beings have a limited ability to handle environmental stimuli. The limit is determined by the amount of information inputs that can be processed by the central nervous system. When the environmental load exceeds the individual’s capacity for processing, the central nervous system reacts by ignoring some of the inputs. See also COGNITIVE OVERLOAD; INFORMATION OVERLOAD; SENSORY OVERLOAD; STIMULUS OVERLOAD.

environmental manipulation improving the well-being of people by changing their living conditions, such as by placing an abused or delinquent child in a foster home or by transferring an adult patient from a mental hospital to an ADULT HOME or a HALFWAY HOUSE.

environmental modifications changes in the home environment (e.g., installing ramps, grab bars) to accommodate an individual’s disabilities and enable him or her to live more independently.

environmental noise see DIFFERENTIATION THEORY; NOISE.

environmental press–competence model a model of stress and adaptation in which adaptive functioning in the environment depends on the interaction between stimuli in a person’s physical and social environment that place demands on that individual (environmental press) and the individual’s competence in meeting these demands, which is shaped by such personal characteristics as physical health and cognitive and perceptual abilities. See also PERSON–ENVIRONMENT INTERACTION. [proposed in 1973 by U.S. geropsychologists M. Powell Lawton (1923–2001) and Lu-cille D. Nahemow (1933–2000)]

environmental psychology a multidisciplinary field that investigates the effects of the physical environment on human behavior and welfare. Influences studied may include environmental stressors (e.g., noise, crowding, air pollution, temperature); design variables (e.g., lighting); the design of technology (see ERGONOMICS); and larger, more ambient qualities of the physical environment, such as floorplan layouts, the size and location of buildings, and proximity to nature.

environmental psychophysics the application of psychophysical methods to problems in real-world environments, such as investigating the magnitude of odor created by a processing plant.

environmental sounds agnosia see AUDITORY AGNOSIA.

environmental stress any kind of STRESS caused by factors in one’s physical and social surroundings.

environmental stress theory the concept that autonomic and cognitive factors combine to form an individual’s appraisal of stressors in the environment as threatening or nonthreatening. Stressors perceived as threatening may lead to stress reactions involving physiological, emotional, and behavioral elements, which in turn may elicit strategies designed to cope with and potentially adapt to the threat.
environmental therapy therapy that addresses the client’s interaction with his or her physical or social surroundings (or both) in an effort to promote greater cognitive, affective, and behavioral health. See milieu therapy; therapeutic community.

envy 1. n. A negative emotion of discontent and resentment generated by desire for the possessions, attributes, qualities, or achievements of another (the target of the envy). Unlike jealousy, with which it shares certain similarities and with which it is often confused, envy need involve only two individuals—the envious person and the person envied—whereas jealousy always involves a three-some. See also primal envy. 2. vb. To feel such discontent or resentment. —envious adj.

enzyme n. A protein that acts as a biological catalyst, accelerating the rate of a biochemical reaction without itself becoming permanently altered. Many enzymes require other organic molecules (coenzymes) or inorganic ions (cofactors) to function normally. Most enzymes are named according to the type of reaction they catalyze; for example, glucosidases convert glucoses to glucose; acetylcholinesterase (see Cholinesterase) splits and inactivates molecules of the neurotransmitter acetylcholine.

enzyme induction the ability of drugs or other substances to increase the activity of enzymes, especially hepatic (liver) enzymes, that are responsible for the metabolism of those drugs or other substances. The Cytochrome P450 hepatic enzymes, which are responsible for the metabolism of numerous psychotropic compounds, are susceptible to induction. Barbiturates, alcohol, benzodiazepines, some anticonvulsants, and steroids may induce hepatic enzymes, usually resulting in a decrease in activity of the drug or other substances metabolized via the same enzyme system. Substances contained in cigarette smoke, charbroiled meat, and environmental pollutants are also capable of enzyme induction.

enzyme inhibition the ability of drugs or other substances to impair or arrest the ability of enzymes, especially liver (hepatic) enzymes, to metabolize those drugs or other substances. The Cytochrome P450 enzymes that are responsible for the metabolism of numerous psychotropic drugs are susceptible to inhibition by psychotropics or other substances. Many of the SSRIs (selective serotonin reuptake inhibitors) inhibit the activity of enzymes for which they are substrates, leading to increased concentrations of the SSRIs or other drugs that are metabolized by the same enzyme. Enzyme inhibition can be competitive, when a drug partially inhibits an enzyme by competing for the same binding site as the substrate (the compound on which the enzyme acts), or irreversible, when a drug binds so completely to an enzyme that it fundamentally alters the enzyme and even partial metabolism of other substances cannot take place.

EOG 1. abbreviation for electrooculography or electrooculogram. 2. abbreviation for electrooculactography or electrooculactogram.

eonism n. The adoption by a male of a female role, or vice versa, as in transvestism. Eonism is named for Charles Eon de Beaumont, a French political adventurer who died in 1810 after posting as a woman for many years.

EP abbreviation for evoked potential.

epena n. A hallucinogenic snuff prepared from the bark of South American trees of the genus Virola and used in Colombia, Brazil, and Venezuela. The bark is scraped from the trees and boiled to extract a red resin that is dried, ground, and mixed with wood ash. The active agents, which include dimethyltryptamine (see DMT), produce effects that are comparable to those of LSD. Also called nyawana; parica; yakee.

ependyma n. The membrane lining the brain ventricles and the central canal of the spinal cord. —ependymal adj.

ependymal cell a type of nonneuronal central nervous system cell (glia) that comprises the ependyma and helps circulate cerebrospinal fluid.

ependymoma see glioma.

ephelophobia n. Sexual attraction to and arousal by adolescent children, usually early adolescents who are just going through puberty.

ephedra n. A bushy shrub (Ephedra sinica), known to Chinese herbalists as ma huang, that is indigenous to arid regions of the world, particularly Mongolia and northern China. The leaves contain significant amounts of the alkaloid stimulants ephedrine and pseudoephedrine and are traditionally made into a beverage. Both ephedrine and pseudoephedrine are strong sympathomimetic agents and therefore increase blood pressure, alertness, and anxiety, as well as causing peripheral symptoms of sympathetic activity (e.g., tremor, sweating). These agents also relax smooth muscle; hence, the plant and its active components have often been used as a remedy for asthma or other respiratory complaints. In addition, ephedra has been combined into many dietary supplements that are reputed to aid weight loss, increase energy, and enhance athletic performance. There is, however, little evidence of ephedra’s effectiveness for these uses except for modest, short-term weight loss without any clear health benefit. It is toxic and potentially fatal, particularly in high doses or when combined with other stimulants, such as caffeine; reported adverse events include headaches, insomnia, rapid or irregular heartbeat, nerve damage, muscle injury, psychosis, memory loss, heart attack, stroke, seizure, and death. In 2004, the U.S. Food and Drug Administration banned the sale of products containing ephedra, the first U.S. government ban of a dietary supplement.

ephemeral adj. Fleeting, transient, or short-lived. The term literally means “lasting only one day.” —ephemera n.

EPI abbreviation for eyenck personality inventory.

epi- prefix. Upon, above, or over. 2. Close or near. 3. After or in addition to.

epicritic adj. Denoting or relating to cutaneous nerve fibers involved in minute sensori-discomfort sensations, particularly those involving very small or near-threshold variations in temperature and touch sensations. Compare protopathic.

epidemic adj. Generally prevalent; affecting a significant number of people, particularly with reference to a disease or disorder not ordinarily present in a specific population or present at a much higher rate than is typical. Compare endemic; pandemic.

epidemic catalepsy a situation in which catalepsy occurs in a number of individuals at the same time as a result of identification or imitation.

epidemic hysteria see collective hysteria.
Epidemiologic Catchment Area Survey

Epidemiologic Catchment Area Survey (ECA Survey) a telephone survey of mental disorders carried out in two waves from 1980 to 1985 using DSM–III and the Diagnostic Interview Schedule (DIS). More than 20,000 people were surveyed in households, group homes, and long-term care institutions across the United States to obtain information on the prevalence and incidence of mental disorders, the use of services for mental health problems, and the extent to which those with mental disorders were underserved.

epidemiology n. the study of the incidence and distribution of specific diseases and disorders. The epidemiologist also seeks to establish relationships to such factors as heredity, environment, nutrition, or age at onset. Results of epidemiological studies are intended to find clues and associations rather than necessarily to show causal relationships. See also incidence; prevalence; risk ratio.—epidemiologic or epidemiological adj.

epidermis n. 1. the outer, protective, nonvascular layer of the skin of vertebrates. 2. the outer layer of cells of various invertebrates. 3. the outermost layer of cells covering the leaves and young parts of plants.

epididymis n. (pl. epididymides) an elongated tube running along the top and back of the testis that stores spermatogenous received from seminiferous tubules within the testis. It empties into the vas deferens.—epidymidal adj.

epidural hematoma an accumulation of blood (see hematoma) in the space above the dura mater caused by rupture of a blood vessel (see extradural hemorrhage), typically due to trauma.

epidural hemorrhage see extradural hemorrhage.

epigastric reflex a spinal reflex that draws in the upper central region of the abdominal wall, elicited by a quick stroke with a pin from the nipple downward.

epigenesis n. 1. the theory, now accepted, that prenatal development is a gradual, complex, and cumulative process involving successive differentiation of morphological structures from fertilized ovum to embryo to fetus. Compare preformism. 2. the theory that characteristics of an organism, both physical and behavioral, are due to interaction between genetic and environmental influences rather than from one or the other. See also nature–nurture. 3. in genetics, the occurrence of a heritable change in gene function that is not the result of a change in the base sequence of the organism’s DNA. See also epigenetics. In the theory of Erik ERIKSON, the emergence of different goals at each stage of ego and social development. See Erikson’s eight stages of psychosocial development.—epigenetic adj.

epigenetic landscape a visual metaphor that depicts development as a hill with valleys of various depths and steepness, to convey the idea that some aspects of development are directed along certain general pathways and likely to occur under most circumstances but that the exact sequence of paths varies across individuals and can be altered by sudden environmental or genetic change. [proposed by British biologist Conrad Hall Waddington (1905–1975)].

epigenetics n. the study of heritable chemical modifications to DNA that alter gene activity without changing nucleotide sequence. Such modifications instead typically involve the attachment of additional material to the DNA molecule itself (DNA methylation) or the structural alteration of its associated proteins (chromatin remodeling), which disrupt the normal development and functioning of cells by influencing gene activation, deactivation, transcription, and so forth. Epigenetic mechanisms have been proposed as the means by which environmental and psychosocial factors such as toxins and early childhood experiences interact with physiology: They affect neural function through changes in gene expression that lead to individual differences in cognition and behavior (e.g., learning, memory, aggression, affect). Research also suggests that some epigenetic changes of an individual can be passed down to more than one generation of descendants. Additionally, epigenetic abnormalities have been linked to the etiology of many diseases and mental disorders, including autoimmune disturbances, cancer, heart disease, anxiety, autism, depression, intellectual disability, schizophrenia, and substance abuse.

epigenetic theory the concept that mind and consciousness develop when living organisms reached a high level of complexity. See emergence.

epilepsy n. a group of chronic brain disorders associated with disturbances in the electrical discharges of brain cells and characterized by recurrent seizures, with or without clouding or loss of consciousness. Symptomatic epilepsy is due to known conditions, such as brain inflammation, brain tumor, vascular disturbances, structural abnormality, brain injury, or degenerative disease; idiopathic epilepsy is of unknown origin or is due to nontarget specific brain defects. Types of seizures vary depending on the nature of the abnormal electrical discharge and the area of the brain affected (see absence seizure; generalized seizure; partial seizure; tonic–clonic seizure). Epilepsy was formerly known as falling sickness. Also called seizure disorder. See also status epilepticus; temporal lobe epilepsy. —epileptic adj.

epilepsy surgery neurosurgery to remove a part of the brain, often the anterior temporal lobe, that is the focus for intractable uncontrollable epileptic seizures. The goal of the surgery is to reduce or eliminate seizures.

epileptic cry a momentary cry produced by sudden contraction of the chest and laryngeal muscles during the tonic phase of a tonic–clonic seizure. Also called initial cry.

epileptic furor see furor.

epileptiform adj. resembling epilepsy. Also called epileptoid.

epileptiform seizure an episode that resembles an epileptic seizure. See also nonepileptic seizure.

epileptogenic adj. describing any factor or agent that causes or potentially may induce epileptic seizures. The goal of the surgery is to reduce or eliminate seizures.

epileptogenic focus a discrete area of the brain in which originate the electrical discharges that give rise to seizure activity.

epileptogenic lesion an area of tissue damage in the brain that results in epileptic seizures. Epilepsy may result from various brain lesions—for example, head injury, laceration, tumor, or hemorrhage—arising either immediately after the injury or, in some cases, months or years later.

epimenorrhagia n. see menorrhagia.

epinephrine n. a catecholamine neurotransmitter and adrenal hormone that is the end product of the metabolism
of the dietary amino acid tyrosine. It is synthesized primarily in the adrenal medulla by methylation of norepinephrine, which itself is formed from dopamine by the action of the enzyme dopamine β-hydroxylase. As a hormone, it is secreted in large amounts when an individual is stimulated by fear, anxiety, or a similar stress-related reaction. As a neurotransmitter, it is the primary stimulant of both α-ADRENERGIC RECEPTORS and β-ADRENERGIC RECEPTORS. Thus, it increases the heart rate and force of heart contractions, relaxes bronchial and intestinal smooth muscle, and produces varying effects on blood pressure as it acts both as a vasodilator and vasoconstrictor. Also called adrenaline.

epiphany n. a sudden perception of the essential nature of oneself, others, or reality.

epiphenomenalism n. the position that bodily (physical) events produce mental events, such as thoughts and feelings, but that mental events do not have causal power to produce bodily (physical) events. Thus, causality between the mental and the physical proceeds in one direction only. A more radical form of the same position would add that mental events lack causal efficacy to produce anything, including other mental events. The term was coined in 1902 by James Ward, but the concept itself predates his usage. For example, British philosopher Shadworth H. Hodgson (1832–1912) and British biologist Thomas Henry Huxley (1825–1895) wrote about it some 30 years earlier, with Huxley in 1874 famously likening mental events (e.g., consciousness) to the steam whistle of a locomotive; They are by-products of the locomotive but cannot affect the locomotive itself. Huxley’s term for the concept was conscious automatism. See also MIND–BODY PROBLEM, REDUCTIONISM.

epiphenomenon n. (pl. epiphenomena) a mere by-product of a process that has no effect on the process itself. The term is used most frequently to refer to mental events considered as products of brain processes. Thus, though mental events are real in some sense, they are not real in the same way that biological states and events are real, and not necessary to the explanation of mental events themselves. Epiphenomena are conceived of as having no causal power. See EPIPPHEMENALISM. —epiphenomenal adj.

epiphthora n. excessive secretion of tears, which is most commonly due to an organic condition causing an insufficient drainage of tears but may be associated with emotional stress, such as chronic anxiety or fear.

episode n. a noteworthy isolated event or series of events. An episode of an illness is an isolated occurrence, which may be repeated.

episodic amnesia a loss of memory only for certain significant events. Episodic amnesia may involve a transient ability to recall an event followed by periods of inability to access the memory.

episodic buffer a fourth component added to the 1974 tripartite model of WORKING MEMORY proposed by British cognitive psychologists Alan D. Baddeley (1934– ) and Graham J. Hitch (1946– ). Introduced in 2000 as a further subsidiary of the CENTRAL EXECUTIVE, the episodic buffer is a temporary multimodal store that combines information from the PHONOSOMATIC LOOP and VISUOSPATIAL SKETCHPAD subsystems of working memory with information about time and order to form and maintain an integrated, detailed representation of a given stimulus or event that can then be deposited into long-term memory as necessary. It is “episodic” in the sense that it holds integrated episodes or scenes and a “buffer” in the sense of providing a limited capacity interface between systems using different representational codes. In addressing certain shortcomings of the original working memory model—particularly the failure to explain the process of CHUNKING and the dilemma of linking the two distinct representational formats of the loop and sketchpad—the episodic buffer provides a means to allow multiple sources of information to be considered simultaneously, thus creating a model of the environment that may be manipulated to solve problems and plan future behavior.

episodic disorder any disorder characterized by the appearance of symptoms in discrete, often brief, periods or episodes.

episodic memory the ability to remember personally experienced events with a particular time and place. As defined in 1972 by Endel TULVING, episodic memory supplements SEMANTIC MEMORY as a form of DECLARATIVE MEMORY. Although Tulving’s original description of episodic memory required recollecting the three ‘Ws’ of an event—what, where, and when—it has since been revised to include a sense of self-awareness and a subjective conscious experience as well (termed AUTOONTOIC consciousness). In other words, in addition to recalling the facts of a past event, an individual has to engage in “mental time travel” and remember that he or she was the one who lived the event. The hippocampus plays a key role in episodic memory formation and retrieval. Atrophy of this area and structures in the associated HIPPOCAMPAL FORMATION is a hallmark feature of Alzheimer’s disease, although episodic memory also declines considerably with normal aging. See also AUTOBIOGRAPHICAL MEMORY.

epistemic adj. of or relating to knowledge or to EPistemology. The epistemic drive, created by the desire for knowledge, is often considered a fundamental drive. See NEED FOR COGNITION.

epistemic value the extent to which a theory, model, or cognitive process (e.g., a sense perception or memory) is capable of providing accurate knowledge; also, any specific attribute of a theory or process that is considered to be a sign of its ability to convey such knowledge. For example, falsifiability and empirical grounding are important epistemic values in science; consistency and clarity might be considered epistemic values in relation to memory.

epistemology n. the branch of philosophy concerned with the nature, origin, and limitations of knowledge. It is also concerned with the justification of truth claims. Mainly owing to the work of René DESCARTES, epistemology has been the dominant question in philosophy since the 17th century (see CARTESIANISM; CARTESIAN SELF; MODERNISM). In psychology, interest in epistemology arises from two principal sources. First, as the study of the behavior of human beings, psychology has long had interest in the processes of knowledge acquisition and learning of all sorts. Second, as a science, psychology has an interest in the justification of its knowledge claims. In connection with this concern, most work on epistemology in psychology has concentrated on the scientific method and on the justification of scientifically derived knowledge claims. In general, the guiding epistemology of psychology has been EPIERMISM, although some approaches to the subject, such as psychosynthesis, the developmental psychology of Jean PIAGET, and the humanistic psychology of Carl ROGERS, are
heavily influenced by RATIONALISM. —epistemological adj.

epistemophilia n. the love of knowledge; the impulse to investigate and inquire. See also CURIOSITY.

epithelium n. any tumor that originates in cells of the epithelium. Skin cancer may begin as an epithelioma.

epithalamus n. a portion of the DIENCEPHALON that is immediately above and behind the THALAMUS. It includes the PINEAL GLAND and the posterior COMMISSURE.

epithelioma n. a portion of the DIENCEPHALON that is immediately above and behind the THALAMUS. It includes the PINEAL GLAND and the posterior COMMISSURE. —epithelial adj.

EPP abbreviation for END-PLATE potential.

EPQ abbreviation for Eysenck Personality Questionnaire. See EYSENCK PERSONALITY INVENTORY.

EPS abbreviation for EXTRAPYRAMIDAL SYMPTOMS or syndrome.

EPSDT abbreviation for EARLY AND PERIODIC SCREENING, DIAGNOSIS, AND TREATMENT.

epsilon movement the perception of motion occurring when a white line on a black background is changed to a black line on a white background. Also called epsilon motion.

EPSP abbreviation for EXCITATORY POSTSYNAPTIC POTENTIAL.

Epstein–Barr virus (EBV) a herpes virus that infects most people, at various ages. Infection during childhood is asymptomatic or produces mild symptoms; in adolescence or young adulthood, EBV leads to infectious mononucleosis in up to half of cases. EBV has been associated with certain cancers (e.g., Burkitt’s lymphoma), but its exact role in these diseases is not known. [Michael Anthony Epstein (1921– ) and Yvonne M. Barr (1932– ), British pathologists]

EQ 1. abbreviation for EDUCATIONAL QUOTIENT. 2. see EMOTIONAL INTELLIGENCE QUOTIENT.

equal-and-unequal-cases method see METHOD OF EQUAL AND UNEQUAL CASES.

equal-appearing-intervals method see METHOD OF EQUAL-APPEARING INTERVALS.

Equal Employment Opportunity Commission (EEOC) a U.S. federal agency, created by the 1964 Civil Rights Act, that is responsible for enforcing the laws and regulations prohibiting discrimination by an employer against job applicants or current employees on the basis of race, sex, age, disability, ethnicity, religion, and national origin. See EQUAL OPPORTUNITY. See also AFFIRMATIVE ACTION; UNIFORM GUIDELINES FOR EMPLOYEE SELECTION PROCEDURES.

equality law see LAW OF EQUALITY.

equality of variance see HOMOGENEITY OF VARIANCE.

equality stage see DISTRIBUTIVE JUSTICE.

equal loudness contour the function relating DECIBELS sound-pressure level (dBA SPL) to frequency for PURE TONES that have a loudness equal to that of a 1 kHz tone at a fixed level. For example, a 100 Hz tone presented at 70 dB SPL is as loud as a 1 kHz tone presented at 60 dB SPL. This is a point on the equal loudness contour for a 60-phon reference. This function has been incorporated in audio circuitry as “loudness compensation,” primarily in an attempt to correct for the decreased loudness of low frequencies when listening at low levels. See LOUDBNESS.

equal opportunity under U.S. federal law, the principle that all individuals should have the opportunity to find employment and to succeed in their jobs regardless of race, age, color, religion, sex, disability, and national origin. The principle of equal opportunity also applies to education, health care, and social and other services, and in some states and municipalities, it has been extended to include sexual orientation. See also AFFIRMATIVE ACTION; AGE DISCRIMINATION IN EMPLOYMENT ACT; AMERICANS WITH DISABILITIES ACT; FOUR-FIFTHS RULE; REVERSE DISCRIMINATION; UNIFORM GUIDELINES FOR EMPLOYEE SELECTION PROCEDURES.

equal rights amendment (ERA) a proposed amendment to the U.S. Constitution that would guarantee equal rights under the law for both sexes. First proposed in 1923, it was approved by Congress in 1972 but failed to achieve ratification in 1982.

equal sense-difference method see METHOD OF EQUAL-APPEARING INTERVALS.

equal weighting see WEIGHTING.

equated score the score distribution from Measure B transformed to match the distribution of Measure A in one or more features. See TRANSFORMATION.

equation n. a formal, usually brief, statement showing that two expressions are the same or equal. In mathematics or statistics, an equation is often a statement with y on the left of an equal sign and an expression for delineating or modeling y on the right side. For example, a commonly used equation for a straight line is $y = mx + b$, where m stands for the slope of the line, x stands for different values along the X-AXIS, and b stands for the point where the line crosses the Y-AXIS.

equilibration n. in PIAGETIAN THEORY, the process by which an individual uses assimilation and accommodation to restore or maintain a psychological equilibrium, that is, a cognitive state devoid of conflicting SCHEMAS.

equilibrium model of group development in general, any conceptual analysis that assumes that the processes contributing to GROUP DEVELOPMENT fluctuate around, but regularly return to, a resting point where opposing forces are balanced or held in check. For example, U.S. social psychologist Robert Freed Bales (1916–2004) suggested that groups vary over time in the extent to which they stress the accomplishment of group tasks relative to the improvement of interpersonal relationships among group members.

equilibrium-point model a model of limb control in which the target of a movement is specified as an equilibrium point between the AGONIST and ANTAGONIST muscle groups acting on the limb. Variants of this model are called...
the mass-spring model and the lambda (λ) model. See also IMPULSE-TIMING MODEL.

equilibrium potential the state in which the tendency of ions (electrically charged particles) to flow across a cell membrane from regions of high concentration is exactly balanced by the opposing potential difference (electric charge) across the membrane.

equine-assisted psychotherapy (EAP) a form of ANIMAL-ASSISTED THERAPY in which a licensed mental health professional, in conjunction with an equine specialist, uses handling, grooming, and other activities with specially trained horses as part of psychological treatment for those with emotional and behavioral problems. Despite its unusual approach, the method is grounded in traditional therapeutic forms, notably COGNITIVE BEHAVIOR THERAPY, EXPERIMENTAL PSYCHOTHERAPY, and GESTALT THERAPY. The goal is to help clients, through attentive interactions with horses, to achieve self-esteem, self-awareness, confidence, trust, and empathy; to gain a sense of responsibility; and to develop better communication, teamwork, leadership, and social skills. The few empirical studies on the efficacy and long-term effects of EAP have been equivocal. Nonetheless, the technique has been applied to both children and adults, individually and in groups, and to a variety of conditions, including behavioral problems, relationship issues, grief, anxiety, anger, depression, posttraumatic stress disorder, attention-deficit/hyperactivity disorder, substance dependence, adjustment disorders, and eating disorders. EAP differs from HIPPPERTHERAPY, which involves mounted exercises to help people with physical and developmental disabilities improve their balance and motor functions. Also called equine-facilitated psychotherapy (EFP).

equipercenil method a procedure for showing how two measures are similar, such that a shared value of x on the two measurements implies that the probability of a person drawn at random having a score greater than x is the same for both measures.

equipment automation the extent to which equipment can operate without human intervention. For example, progress from manual feeds to fully automated feeds reflects an increasing degree of equipment automation.

equipment design an area of HUMAN ENGINEERING concerned with the design of work tools, home appliances, and machines of all kinds, including their displays and controls. One particularly important application is the design of transport systems, such as roads, road signs, and the vehicles that use them. The major goal is to see that the equipment is designed with HUMAN FACTORS in mind, such as safety, fatigue, convenience, comfort, and efficiency. See TOOL DESIGN; WORKSPACE DESIGN. See also ENGINEERING PSYCHOLOGY: ERGONOMICS.

equivalence n. a relationship between two or more items, scales, variables, or stimuli that permits one to replace another.

equivalence class a stimulus group whose members exhibit reflexivity, symmetry, and transitivity in the context of CONDITIONAL DISCRIMINATIONS. In other words, the members demonstrate STIMULUS EQUIVALENCE and hence may substitute for one another.

equivalence paradox the situation in which two different procedures produce very similar outcomes, despite having different initial assumptions or features. For example, two very different psychotherapy procedures may nonetheless produce very similar, positive outcomes, possibly due to the therapeutic relationship instead of the specific treatments. In statistics, the term refers to the fact that PRINCIPAL COMPONENTS ANALYSIS and FACTOR ANALYSIS often produce a similar pattern of dimensions and loadings, although they each have a different premise.

equivalency test an assessment of one’s educational level regardless of whether one has completed a specific course of study. For example, by taking the appropriate equivalency test, one may obtain a high school diploma without completing high school state requirements.

equivalent form see ALTERNATE-FORM.

equivalent-forms reliability see ALTERNATE-FORMS RELIABILITY.

equivalents method see METHOD OF ADJUSTMENT.

equivalent stimulus see STIMULUS EQUIVALENCE.

equivocal death analysis see PSYCHOLOGICAL AUTOPSY.

equivocal sign see SOFT SIGN.

ER 1. abbreviation for ENGNEOPLASMIC RETICULUM. 2. abbreviation for evoked response (see EVOKE POTENTIAL).

ERA abbreviation for EQUAL RIGHTS AMENDMENT.

erect adj. 1. upright or vertical. See PILOEROSION; POSTURE. 2. tumescent, as an erect penis (see TUMESCENCE).

erectile dysfunction the lack or loss of ability to achieve an erection. It may be primary, in which a man has never been able to achieve erection sufficient for sexual intercourse; or secondary, in which a man is no longer capable of producing or maintaining an erection or can have one only in some situations (e.g., during masturbation) or with some partners. Causes of erectile dysfunction may be psychological or physical, including the effects of medicat-
eremophilia

tions or drug abuse. If a man normally experiences a nocturnal erection or is able to induce an erection by masturbation, but cannot achieve or maintain an erection during sexual intercourse, the dysfunction is assumed to be due largely or solely to psychological factors. See MALE ERECTILE DISORDER.

eremophilia n. a pathological desire to be alone.

erethism n. 1. an abnormally high degree of sensitivity to sensory stimulation in some or all parts of the body. It is associated with a number of conditions and is a major symptom of mercury poisoning. See also MAD HATTER’S DISEASE. 2. any abnormally high degree of sensitivity, excitability, or irritability in response to stimulation, such as emotional erethism.

ERF abbreviation for EVENT-RELATED MAGNETIC FIELD.

erg n. 1. a term used by Raymond B. Cattell, in preference to drive or instinct, to denote a type of innate DYNAMIC TRAIT that directs an individual toward a goal and provides the motivational energy to obtain it. Examples include curiosity; self-assertion, gregariousness, protectiveness, and hunger. 2. in physics, a unit of work or energy.

ERG abbreviation for electoretinogram. See ELECTRORETINOGRAPHY.

gerasiology n. see PSYCHOBIOLOGY.

ergative a. in English and some other languages, a verb that can be used either transitively or intransitively with the same noun to describe the same action. An example is close in or closed the door or the door closed: The direct object of the transitive verb (here door) becomes the subject of the intransitive verb. Such constructions are of great interest in CASE GRAMMAR and GENERATIVE GRAMMAR.

ergic trait a dynamic trait that motivates an individual to achieve an objective.

ergodicity n. a principle stating that the average value of a variable over a set of individuals in a defined space or time, such as a SAMPLE, will be the same as the average across a long TIME SERIES of points for a single individual. For example, if ergodicity held for a measure of satisfaction in an organization, the average satisfaction score of all employees in the organization would be the same as the average satisfaction score across a one-year period for one employee. In reality, ergodicity does not always hold, thus giving rise to different streams of NOMOTHETIC and IDIOTYPIC research, which focus on the group or the individual, respectively.

ergograph n. a device used to record the work capacity or fatigue of a muscle or muscle group. The output of an ergograph is called an endogram, indicating the amount of work done or the physical exertion of the muscles.

ergomania n. see WORKAHOLISM.

ergometry n. the measurement of physical work performed by the muscles under various task demands. —ergometric adj.

ergonomics n. the discipline that applies a knowledge of human abilities and limitations drawn from physiology, biomechanics, anthropometry, and other areas to the design of systems, equipment, and processes for safe and efficient performance. A practitioner in the field is sometimes called an ergonomist. Specialty areas include COGNITIVE ERGONOMICS, COMMUNICATION ERGONOMICS, CULTURAL ERGONOMICS, INDUSTRIAL ERGONOMICS, MACROERGONOMICS, and OCCUPATIONAL ERGONOMICS. This term is often used synonymously with HUMAN FACTORS. See also HUMAN SYSTEMS INTEGRATION. —ergonomic adj.

ergonomic traps components of a design that contribute to the probability of accidents and human error. Designs that are not intuitive or that violate normal human tendencies in terms of behavior and mental processing contain ergonomic traps. For example, clothes irons with the power cable on the right side present an ergonomic trap to someone who is left-handed. See BEHAVIOR-BASED SAFETY.

ergonovine n. see ERGOT DERIVATIVE.

ergot alkaloid any of a group of pharmacologically active substances derived from the parasitic fungus Claviceps purpurea, which grows naturally on rye and other grains. Although highly toxic, ergot alkaloids have been used for centuries by midwives to induce abortion or labor. A number have been isolated, including lysergic acid, and the compounds are sometimes utilized as adrenergic blocking agents (see ERGOT DERIVATIVE). Epidemics of ergot poisoning (ergotism) were widespread in Europe until relatively modern times; symptoms included peripheral vasoconstriction (occasionally to the point of gangrene) and changes in mental functioning, including visual hallucinations. Because of the pharmacological relationship between ergot and LSD (lysergic acid diethylamide), the hallucinogenic effects are similar to those of LSD.

ergotamine n. an alkaloid drug (an ERGOT DERIVATIVE) used in the treatment of vascular headaches, including migraines. The exact nature of its therapeutic action is unknown, but ergotamine is believed to constrict the dilated cranial blood vessels responsible for headache symptoms. U.S. trade name (among others): Cafergot.

ergot derivative any of a group of ADRENERGIC BLOCKING AGENTS with selective inhibitory activity, derived from ERGOT ALKALOIDS. Ergot derivatives act on the central nervous system in a complex manner and, in various forms and doses, can both stimulate and depress higher brain centers. A circulatory effect is vasoconstriction. Some of these agents, including ERGOTAMINE, are used in the control of migraine headaches, sometimes combined with other drugs (e.g., caffeine). The derivative ergonovine is used as an OXYTOCIC.

ergotherapy n. treatment of disease by muscular exercise. This term is used in Europe; it is not common in the United States.

ergotropic adj. related to or concerning a capacity or propensity for expenditure of energy; that is, for activity, effort, or work. Compare TROPHOTROPIC.

ERG theory abbreviation for EXISTENCE, RELATEDNESS, AND GROWTH THEORY.

Erhard Seminar Training (est. EST) a controversial group therapy technique and personal development training system introduced in 1971. It purports to be consciousness expanding, borrowing from business-world motivation techniques and various theories of psychology. It was renamed LANDMARK FORUM in 1985. [Werner Erhard (born John Paul Rosenberg: 1935— ), U.S. consultant and lecturer]

Erichsen’s disease a disorder characterized by back pain and other spinal symptoms that was first identified in 1866 (at a time when railroad transportation was becoming increasingly popular) and was believed to be a re-
result of railroad accidents. As the state of medicine advanced, it was realized that these symptoms were not of organic origin but may have indicated either MALINGERING or a psychogenic disorder that may have been a precursor to posttraumatic stress disorder. Also called RAILWAY SPINE. [John Eric Eriksen (1818–1896), British surgeon]

Ericksonian psychotherapy a form of psychotherapy in which the therapist works with the client to create, through hypnosis (specifically through indirect suggestion) and metaphors, real-life experiences intended to activate previously dormant, intrapsychic resources. Also called ERIKSSONIAN HYPONOTHERAPY. [Milton H. Erickson]

Eriksen flankers task see FLANKER TASK. [Charles W. Eriksen (1923— ), U.S. psychologist]

Erikson's eight stages of psychosocial development the theory proposed by Erik Erikson that ego identity is gradually achieved by facing goals and challenges during each stage of development across the lifespan. The stages are (a) infancy: BASIC TRUST VERSUS MISTRUST; (b) toddler: AUTONOMY VERSUS SHAAME AND DOUBT; (c) preschool age: INITIATIVE VERSUS GUILT; (d) school age: INDUSTRY VERSUS INFERIORITY; (e) adolescence: IDENTITY VERSUS IDENTITY CONFUSION; (f) young adulthood: INTIMACY VERSUS ISOLATION; (g) middle age: GENERATIVITY VERSUS STAGNATION; and (h) older adulthood: INTEGRITY VERSUS DESPAIR.

ERISA Acronym for EMPLOYEE RETIREMENT INCOME SECURITY ACT.

erogenous zone an area or part of the body sensitive to stimulation that is a source of erotic or sexual feeling or pleasure. Among the primary zones are the genitals, buttocks and anus, the breasts (especially the nipples), and the mouth.

Eros n. the god of love in Greek mythology (equivalent to the Roman Cupid), whose name was chosen by Sigmund Freud to designate a theoretical set of strivings oriented toward sexuality, development, and increased life activity (see LIFE INSTINCT). In Freud's DUAL INSTINCT THEORY, Eros is seen as involved in a dialectic process with THANATOS, the striving toward reduced psychical tension and life activity (see DEATH INSTINCT). See also LIBIDO.

erosion n. the deterioration or corrosion of a physical setting from climate effects and from use by organisms, including human beings. For example, the degree of erosion evident in footpaths or trails in a woodland may be taken as an indication of their degree of use. Compare ACCRETION.

erótica pl. n. literature, illustrations, motion pictures, or other artistic material likely to arouse an emotional response through an aesthetic treatment of sexuality and sexual love. The term is sometimes used interchangeably with PORNOGRAPHY. However, the distinction is often made that eroticia, unlike most pornography, does not involve violence, coercion, or exploitative sexuality, instead depicting sexuality in a positive manner. [from erotic (Greek erotikos, derived from eros: “love”)]

erotic asphyxiation sexual pleasure associated with restriction of breathing during sexual activity. See ASPHYXIOPHILIA; AUTOEROATIC ASPHYXIA.

erotic delusion the false perception or belief that one is loved by or has had a sexual affair with a public figure or other individual. Also called EROTO MANIA: EROTOMANIC DELUSION. See CLÉRAMBAULT'S SYNDROME: DELUSIONAL DISORDER; EROTIC PARANOIA; SIMENON'S SYNDROME.

erotic feminism a type of FEMINISM that emphasizes female sexuality and its expression as a means of opposing the exploitation of women and escaping male domination. This contrasts with some other tendencies in mainstream feminism, which can appear wary or even dismissive in their approach to erotic expression.

erotic instinct 1. in psychoanalytic theory, the sex drive or LIBIDO. 2. EROS, or the LIFE INSTINCT.

eroticism n. 1. the quality of being sexually arousing or pleasurable or the condition of being sexually aroused. 2. a preoccupation with or susceptibility to sexual excitement. 3. the use of sexually arousing themes, images, or suggestions in entertainment or the arts. 4. in psychoanalytic theory, the pleasurable sensations associated not only with stimulation of the genitals but also with nongenital parts of the body, such as the mouth or anus (see ANAL EROTICISM; ORAL EROTICISM). Also called eros, see also AUTOERO TICISM; EROTIZATION. —erotic adj.

eroticization n. see EROTIZATION.

erotic love a type of love, identified in certain classification systems, that is characterized by strong sexual arousal. See also LIMERENCE; PASSIONATE LOVE.

erotic paranoia a disorder in which the individual experiences EROTIC DELUSIONS. Also called EROTOMANIC-TYPE DELUSIONAL DISORDER. See DELUSIONAL DISORDER. See also CLÉRAMBAULT’S SYNDROME; SIMENON’S SYNDROME.

erotic plasticity the degree to which sexual desire and sexual behavior are shaped by social, cultural, and situational factors. See BEHAVIORAL PLASTICITY.

erotic pyromania see PYROLAGNIA.

erotic type see LIBIDINAL TYPES.

erotism n. see EROTICISM.

erotization n. the investment of bodily organs and functions with sexual pleasure and gratification. Common examples are the eroticization of certain areas of the body, such as the oral or anal ERogenous_zones; organs such as the skin; functions such as sucking, defecation, or urination; and olfactory sensations associated with sex. Theoretically, almost any interest or activity can be eroticized by the individual; for example, activities such as dancing and eating are not infrequently seen as erotic or as having erotic components. Also called eroticization; libidinization; sexualization. —eritize vb.

erotogenesis n. in classical psychoanalytic theory, the origination of erotic impulses from sources that may include the anal, oral, and genital zones. See EROTIZATION.

erotogenic adj. denoting or relating to any stimulus that evokes or excites sexual feelings or responses.

erotogenic masochism see PRIMARY MASOCHISM.

erotographomania n. an obsession with erotic writing that is accompanied by a pathological compulsion to write about sexual matters or draw sexual images, typically expressed through anonymous love letters or graffiti.

erotalia n. speech that contains sexual obscenities, particularly as used to enhance gratification during sexual intercourse.

erotolalia
erotomania

n. 1. compulsive, insatiable sexual activity. 2. see EROTIC DELUSION. —erotomaniac adj.

erotomaniac delusion see EROTIC DELUSION.

erotophonophilia n. see LUST MURDER.

ERP 1. abbreviation for EVENT-RELATED POTENTIAL. 2. abbreviation for EXPOSURE AND RESPONSE PREVENTION.

ERP measure of attitudes a physiological measure of attitudes based on electrocortical activity. The procedure makes use of the phenomenon that one component of EVENT-RELATED POTENTIALS (ERPs), the late positive potential (or P300), varies as a function of categorization of stimuli. This component is large when a target stimulus is judged to be inconsistent with the context in which it is encountered and small when it is judged to be consistent with the context. To assess attitudes, the target attitude object is evaluated as part of a series of objects that are either positive or negative in nature. If a large late positive potential is produced when the attitude object is evaluated in the negative context and a small positive potential is produced when it is evaluated in the positive context, this indicates a positive attitude. The reverse pattern indicates a negative attitude. [originally developed by U.S. psychologists John T. Cacioppo (1951- ), Stephen L. Crites Jr. (1967- ), and their associates]

ERP measures of intelligence measures of intelligence elicited by observing EVENT-RELATED POTENTIALS (ERPs) in the brain in response to various kinds of stimuli. These measures show reliable correlations with traditional measures of intelligence, with the level of the correlation depending on the particular potential being measured. For example, P300, a positive potential observed roughly 300 ms after presentation of a stimulus, tends to be related to effectiveness in coping with novelty and appears to be related to intelligence.

error n. 1. a deviation from true or accurate information (e.g., a wrong response, a mistaken belief). 2. in experimentation, any change in a DEPENDENT VARIABLE not attributable to the manipulation of an INDEPENDENT VARIABLE. 3. in statistics, a deviation of an observed score from a true score, where the true score is often defined by the mean of the particular group or condition in which the score being assessed for error occurs, or from the score predicted by a model. Errors generally are categorized as SYSTEMATIC ERROR or RANDOM ERROR. See also RESIDUAL.

error analysis 1. the study of HUMAN FACTORS and engineering-design factors that may result in production or operation errors. See also ACCIDENT ANALYSIS; FAILURE MODES AND EFFECTS ANALYSIS; FAULT TREE ANALYSIS; JOB-SAFETY ANALYSIS. 2. a systematic analysis of the language corpus obtained from second-language learners to identify ways in which the linguistic forms systematically deviate from target-language norms and to make inferences about the learner’s state of second-language development. See FOSILIZATION; INTERLANGUAGE; LANGUAGE TRANSFER.

error-choice technique an INDIRECT ATTITUDE MEASURE that consists of a series of objective-knowledge multiple-choice questions about an ATTITUDE OBJECT. These questions are constructed so that people are unlikely to know the true answers, but with response options that imply positive or negative evaluations of the attitude object. For example, an error-choice measure of attitudes toward capital punishment might include questions about the percentage of people falsely convicted for capital crimes and the percentage difference in the number of violent crimes in states with and without capital punishment. The procedure is based on the assumption that participants will use their attitudes as a basis for guessing; that is, they will tend to select answers that support their attitudes. Attitudes are assessed by computing the number of positive response options selected relative to the number of negative response options selected. Also called INFORMATION-ERROR TECHNIQUE.

errorless learning a method that prevents the production of incorrect answers during the learning period. Specifically, learning occurs across several sessions but memory is not tested until the last session. It is thought to be more efficient than standard trial-and-error learning because it eliminates INTERFERENCE.

error method see METHOD OF ADJUSTMENT.

error of anticipation in the METHOD OF LIMITS, an error in which the participant responds target present before it is actually detected, based on the knowledge that the stimuli are being presented in an ascending order.

error of commission a category of HUMAN ERROR in which an operator performs an incorrect or additional action, such as pressing a control button twice, leading to inappropriate or duplicate performance of a function. Compare ERROR OF OMISSION.

error of habitation in the METHOD OF LIMITS, a tendency to continue with the previous response (either target present or target absent) beyond the point at which a transition in judgments should occur.

error of omission a category of HUMAN ERROR in which an operator fails to perform a necessary step or action, such as failing to press a control button, leading to the failure of a function. Compare ERROR OF COMMISSION.

error of refraction see REFRACTIVE ERROR.

error rate the frequency with which errors are made. Examples include the proportion of an experimenter’s data recordings that are wrong or the number of TYPE I ERRORS that occur during SIGNIFICANCE TESTING.

error score in CLASSICAL TEST THEORY, the difference between a person’s observed measurement or score and his or her expected measurement or score. Also called RESIDUAL SCORE.

error sum of squares the difference between a score and the mean score, multiplied by this same difference. It is part of the denominator of the F RATIO in an ANALYSIS OF VARIANCE and represents the amount of variation in the DEPENDENT VARIABLE that cannot be explained by the INDEPENDENT VARIABLES. Also called RESIDUAL SUM OF SQUARES: SUM OF SQUARED ERRORS (SSE). Compare REGRESSION SUM OF SQUARES.

error term the element of a statistical equation that indicates the amount of change in the DEPENDENT VARIABLE that is unexplained by change in the INDEPENDENT VARIABLES. Also called DISTURBANCE TERM; RESIDUAL TERM.

error variance the element of variability in a score that is produced by extraneous factors, such as measurement imprecision, and is not attributable to the INDEPENDENT VARIABLE or other controlled experimental manipulations. Error variance usually indicates how much random fluctuation is expected within scores and often forms part of the denominator of test statistics, such as the F RATIO in an
ANALYSIS OF VARIANCE. Also called residual error; residual variance: unexplained variance.

erythema multiforme major a skin condition due to hypersensitivity to certain infections and medications. Previously thought to be a form of STEVENS-JOHNSON SYNDROME, it is now generally considered to be a distinct condition.

erythro- (eryth-) combining form red.
erthropoietin n. a protein produced by the kidneys and liver that stimulates the production of red blood cells (erythrocytes) in the bone marrow and maintains erythrocytes in the circulation at an optimal level.
erthropsia n. see CHROMATOPSIA.

Esalen Institute an alternative educational center in California, founded in 1962, where enhancement of well-being is approached through a number of meditative and New Age therapies. Therapists and members of the general public participate in seminars, workshops, experiential programs, and other events that are designed to promote self-exploration and enhance relationships with others.

ESB abbreviation for ELECTROSTIMULATION OF THE BRAIN.
escalating aggression increasing intensity or severity of hostile or destructive behavior, often to the point of violence. This process is often associated with assaultive behavior, DOMESTIC VIOLENCE, and the CYCLE OF VIOLENCE.
escalating commitment continued commitment and increased allocation of resources to a failing course of action, often in the hope of recouping past losses associated with that course of action. It is often associated with expenditures and decision making in the development of new products, when a company increases the allocation of resources to a failing product, regardless of the low probability of its success, in an attempt to recover some of its initial investment.
escape behavior any response designed to move away from or eliminate an already present aversive stimulus. Escape behavior may be mental (through fantasy or daydreams) or behavioral (physical withdrawal from a noxious stimulus or a conditioned response, as when an animal taps a lever in order to terminate a shock). See also AVOIDANCE. Compare AVOIDANCE BEHAVIOR.
escape conditioning the process by which a subject acquires a response that results in the termination of an aversive stimulus. For example, if a monkey learns that pulling a string eliminates a loud noise, escape conditioning has occurred. Also called escape learning: escape training. See also AVOIDANCE CONDITIONING.
escape from freedom a false solution to an individual’s problems of loneliness and isolation, in which he or she seeks refuge in social conformity. See also IDENTITY NEED, [defined by Erich Fromm]
escape from reality a defensive reaction involving the use of fantasy as a means of avoiding conflicts and problems of daily living. See also FLIGHT FROM REALITY.
escape into illness see FLIGHT INTO ILLNESS.
escape mechanism see DEFENSE MECHANISM.
escape titration a procedure in which an animal, presented with an aversive stimulus that increases in intensity over time, can give a response to decrease the stimulus intensity by some fixed (usually small) amount. By responding, therefore, the subject can control the intensity of the stimulus at virtually any level within the range set by the experimenter. Also called fractional escape.
escapism n. the tendency to escape from the real world to the delight or security of a fantasy world. Escapism may reflect a periodic, normal, and common impulse, as might be seen in harmless DAYDREAMS, or it may be evidence of or accompany symptoms of neurosis or more serious mental pathology.—escapist adj.
eskalith n. a trade name for LITHIUM.

ESL abbreviation for ENGLISH AS A SECOND LANGUAGE.

ESM abbreviation for EXPERIENCE-SAMPLING METHOD.
esophageal speech a type of phonation, not involving the larynx, in which the air supply originates in the narrow upper portion of the esophagus, with the pharyngo-esophageal segment (the sphincterlike muscle at the junction of the LARYNGOPHARYNX and the esophagus) acting as a neoglottis (vibratory apparatus). Compare BUCAL SPEECH.
esphoria n. an inward deviation of one eye that is due to a muscular imbalance and that interferes with binocular vision. Esphoria is a form of HETEROPHORIA. See also PHORIA.
esotropia n. see CROSS-EYE; TROPIA.
espanto n. see SUSTO.

ESP cards see ZENER CARDS.

ESP forced-choice test in parapsychology experiments, a technique in which a participant’s “calls,” or guesses, are restricted to a predetermined set of TARGETS, as with ZENER CARDS. The main advantages of this procedure are that the success or failure of the participants’ calls should be (a) unambiguous and (b) statistically measurable, enabling them to be compared with chance expectations.

ESP free-response test in parapsychology experiments, a technique in which a participant’s “calls,” or guesses, are restricted to a predetermined set of TARGETS. The calls are then correlated to possible targets by a process of PREFERENTIAL MATCHING.
esprit de corps a feeling of unity, commitment, purpose, and COLLECTIVE EFFICACY shared by most or all of the members of a cohesive group or organization. Unlike GROUP MORALE, which can be low when members are dissatisfied or indifferent, esprit de corps implies confidence and enthusiasm for the group. See also GROUP COHESION; GROUP SOLIDARITY.

ESS abbreviation for EVOLUTIONARILY STABLE STRATEGY.

ESSB abbreviation for ELECTROSELF-STIMULATION OF THE BRAIN. See INTRACRANIAL STIMULATION.

essence n. in philosophy, the presumed ontological reality at the core of something that makes it what it is and not something else. There have been various philosophical attempts to define the difference between what something necessarily is and what it merely coincidentally is (see ACCIDENTAL PROPERTY; ESSENTIAL PROPERTY). In psychology, the concept of essence is relevant to discussions of personhood, including questions of human agency and of the SELF. It is thus important for personality theories. The view...
essential amino acid

that human beings have certain important essential characteristics is known as ESSENTIALISM. —essential adj.

essential amino acid see AMINO ACID.

essential fatty acid see FATTY ACID.

essential hypertension high blood pressure (see HYPERTENSION) that is not secondary to another disease and for which no obvious cause can be found. It accounts for at least 85% of all cases of hypertension; risk factors include obesity, cigarette smoking, genetic factors, and psychological influences (e.g., aggressive personality, stressful environment).

essentialism n. in philosophy, the position that things (or some things) have ESSENCES; that is, they have certain necessary properties without which they could not be the things they are. In MARXISM, POSTMODERNISM, POSTSTRUCTURALISM, and certain feminist perspectives, essentialism is the rejected position that human beings have an essential nature that transcends such factors as social class, gender, and ethnicity. See also UNIVERSALISM.

essential property a characteristic of an idea or entity that is essential to its nature or existence. For example, being female is an essential property of mothers, whereas being tired is an ACCIDENTAL PROPERTY.

essential tremor trembling of the hands, head, or voice that appears to be hereditary. It is the most common type of movement disorder and is thought to be a benign condition, although its etiology and neurological substrates remain unclear. Also called familial tremor.

est n. abbreviation for ERHARD SEMINAR TRAINING.

EST 1. abbreviation for electroshock therapy or electroconvulsive shock therapy. See ELECTROCONVULSIVE THERAPY. 2. abbreviation for ERHARD SEMINAR TRAINING.

establishing operation any event or procedure that changes the efficacy of a stimulus as a reinforcer or punisher. For example, in an operant-conditioning study where food is used to positively reinforce behavior, the establishing operation may be food deprivation, which sets up food as a rewarding and reinforcing stimulus.

esteem need any desire for achievement, reputation, or prestige that is necessary for a sense of personal value and SELF-ESTEEM. Comprising the fourth level of MASLOW’S MOTIVATIONAL HIERARCHY, esteem needs are dependent upon the admiration and approval of others.

Estes–Skinner procedure another name for CONDITIONED SUPPRESSION. [after William K. Estes and B. F. Skinner, who developed the technique in 1941]

esthesiometry (aesthesiometry) n. the measurement of sensitivity to touch. Classically, two different versions of an instrument called an esthesiometer (or aesthesiometer) have been used. One is the Frey esthesiometer (named after the German physiologist Maximilian von Frey [1852–1932]), which consists of bristles of different lengths and thicknesses (called von Frey hairs) that are applied to determine the minimum pressure intensity required to produce a sensation. The other is a compaslike device to determine the smallest separation distance at which two points of stimulation on the skin are perceived as one. More sophisticated techniques have now been developed, such as those involving electrodes.

estimate 1. n. a best guess of the value of a parameter of a DISTRIBUTION on the basis of a set of empirical observations. 2. vb. to assign a value to a parameter in this way.

estimating function a mathematical equation used to approximate values and properties (e.g., bias, consistency, efficiency) for a specific parameter (e.g., regression coefficient) by using information from the sample data and the parameter of interest. This approach is particularly suitable when a LIKELIHOOD FUNCTION is not easily known.

estimation n. in statistics, the process of approximating a population PARAMETER from sample data while allowing for some degree of uncertainty by giving a range of values within which the parameter will most likely fall. Estimation usually requires a large random sample, from which one can calculate POINT ESTIMATE values, such as the mean and STANDARD DEVIATION, in the larger population of interest. The process of estimation also involves building a CONFIDENCE INTERVAL around the obtained sample value, plus and minus some MARGIN OF ERROR.

estimator n. a quantity calculated from the values in a sample according to some rule and used to give an approximation of the value in a population. For example, the sample mean or average is an estimator for the population mean; the value of the sample mean is the estimate.

estimators pl. n. the mental processes involved in judging quantity, as in the ability to recognize that a given set contains six elements rather than five or seven. Compare OPERATORS. [defined in this sense by U.S. statistician Andrew Gelman]

estradiol n. a naturally occurring steroid hormone that is the most potent of the ESTRATOGENS. It is secreted mainly by the ovary but also by the placenta and testes.

estrangement n. 1. a state of increased distance or separation from oneself or others. See ALIENATION. 2. a significant decrease or discontinuation of contact with individuals with whom one formerly had close relationships, such as a spouse or family member, due to apathy or antagonism. —estranged adj.

estrogen n. any of a class of STEROID HORMONES that are produced mainly by the ovaries and act as the principal female SEX HORMONES, inducing estrus in female mammals and secondary female sexual characteristics in humans. The estrogens occurring naturally in humans are ESTRADIOL, ESTRONE, and ESTRIOL, secreted by the ovarian follicle, corpus luteum, placenta, testes, and adrenal cortex. Estrogens are also produced by certain plants; these PHYTOESTROGENS may be used in the manufacture of synthetic steroid hormones. Estrogens are used therapeutically in ESTROGEN REPLACEMENT THERAPY and oral contraceptives and to treat certain menstrual disorders and some types of breast and prostate cancers.

estrogen antagonist see ANTIESTROGEN.

estrogen replacement therapy the administration of natural or synthetic estrogens, such as estradiol or ethinyl estradiol, for the relief of symptoms associated with menopause, surgical removal of the ovaries, or failure of the ovaries to develop. Although estrogen replacement therapy was once an extremely common therapy in menopausal women, studies have questioned its material long-term benefits, and its use has fallen off considerably in recent years. See HORMONE REPLACEMENT THERAPY.
estrone n. an ESTROGEN produced by ovarian follicles and other tissues. It is used therapeutically in the treatment of menopausal symptoms, estrogen-deficiency disorders, and certain cases of vaginitis.

estrous cycle the cyclical sequence of reproductive activity shown by female mammals except humans and other primates; see MENSTRUAL CYCLE. Animals that experience one estrous cycle per year are called monestrous; those that have multiple estrous cycles annually are polyestrous. See also DIESTRUS; ESTRUS; PROESTRUS.

estrus n. the stage in the ESTRUS CYCLE when a female animal is receptive to the male and willing to mate. Also called heat.—estrus adj.

eszopiclone n. a nonbenzodiazepine HYPNOTIC used for the short-term treatment of insomnia. Like the related drug ZALEPTON, it is relatively selective for a specific subunit on the GABA_A RECEPTOR complex. Side effects include excessive sedation or confusion, dry mouth, and a bitter taste.

ethchlorvynol n. an alcohol derivative introduced in the 1950s as a nonbarbiturate sedative. Ethchlorvynol is an effective, rapidly acting hypnotic, but because of its toxicity in overdose, as well as its ability to induce enzymes involved in drug metabolism (see ENZYME INDUCTION) and its association with blood disorders, it has become clinically obsolete. It is at times a substance of abuse. U.S. trade name: Lunesta.

e \((\text{symbol: } \eta)\) n. 1. in STRUCTURAL EQUATION MODELING, denoting a LATENT VARIABLE, 2. see CORRELATION RATIO.

eeta squared (symbol: \(\eta^2\)) a measure of the amount of variance in a DEPENDENT VARIABLE that can be explained by one or more INDEPENDENT VARIABLES, as calculated in a variety of statistical procedures. In an ANALYSIS OF VARIANCE, for example, eta squared is calculated as the SUM OF SQUARES for the treatment (i.e., sum of squared differences between a group mean and the GRAND MEAN) divided by the TOTAL SUM OF SQUARES. Eta squared is often used as an EFFECT SIZE measure.

ethanol n. a substance formed naturally or synthetically by the fermentation of glucose and found in beverages such as beers, wines, and distilled liquors. It is the most frequently used and abused CNS DEPRESSANT in many cultures. When consumed, it primarily affects the central nervous system, mood, and cognitive functions. In small doses, it can produce feelings of warmth, well-being, and confidence. As more is consumed, there is a gradual loss of self-control, and speech and control of limbs become difficult; at high consumption levels, nausea and vomiting, loss of consciousness, and even fatal respiratory arrest may occur. Ethanol has been mistakenly identified as a stimulant, since its stimulating effect derives from an associated loss of cortical inhibition. Also called ethyl alcohol. See also ALCOHOL.

ethchlorvynol n. an ALCOHOL DERIVATIVE introduced in the 1950s as a nonbarbiturate sedative. Ethchlorvynol is an effective, rapidly acting hypnotic, but because of its toxicity in overdose, as well as its ability to induce enzymes involved in drug metabolism (see ENZYME INDUCTION) and its association with blood disorders, it has become clinically obsolete. It is at times a substance of abuse. U.S. trade name: Placidyl.

ether n. a drug introduced into medicine as a general anesthetic in the mid-1800s. The effects of ether include a progressive series of physical and psychological reactions, beginning with a feeling of suffocation, bodily warmth, visual and auditory aberrations, and a feeling of stiffness and inability to move the limbs. A second stage may be marked by some resistance to the sense of suffocation of the anesthetic, but the muscles relax, blood pressure and pulse increase, and pupils dilate. In the third stage, pulse and blood pressure return to normal, pupils contract, and reflexes are absent. If additional ether is administered beyond the third stage, there is danger of paralysis of the medullary centers, followed by shock and death. In clinical practice, ether has been replaced by safer anesthetics.

e-therapy n. an Internet-based form of DISTANCE THERAPY used to expand access to clinical services typically offered face-to-face. This therapy can be conducted via webcam, in real-time messaging, in chat rooms, and in e-mail messages. Also called ONLINE THERAPY.

etheral adj. 1. in the ZWAARDEMAKER SMELL SYSTEM, denoting an odor quality that is smelled in fruits and wines. 2. denoting one of the seven classes of odorants in the STEROCHEMICAL SMELL THEORY.

ethical code see CODE OF ETHICS.

ethical conflict see BOUNDARY ISSUES; CONFLICT OF INTEREST.

ethical consumerism the purchase and consumption of goods and services in accordance with one’s social or moral beliefs. For example, an environmentally conscious consumer will prefer GREEN BRANDS and is often willing to pay a premium for them.

ethical determinism the position, stated definitively by Greek philosopher PLATO, that one who knows the good will (necessarily) do the good. It is implied that a sense of obligation is the defining feature of knowledge of the good, and that this sense will be strong enough to compel, rather than merely suggest, action. This position assumes the essential rationality of human beings. Later modifications of the position have argued that a person will necessarily act in accordance with what he or she perceives to be good, whether or not it really is good, or that a person will act consistently with what he or she perceives to be good, where what is good is what is in that person’s self-interest (see EUDENISM). Also called MORAL DETERMINISM.

ethical dilemma a situation in which two moral principles conflict with one another. Fictional or hypothetical dilemmas of this kind are often used to assess the moral beliefs or moral reasoning skills of individuals. Also called moral dilemma. See HEINZ DILEMMA.

ethical imperative a principle or practice taken to be ethically required of one. The binding character of the principle or behavior may result from a perceived logical or rational necessity, as in the CATEGORICAL IMPERATIVE defined by Immanuel KANT, or it may seem to arise from some set of empirical facts; for example, energy conservation may seem to be an ethical imperative given that one accepts the evidence of global warming.

ethical judgment 1. a moral decision made by an individual, especially a difficult one made in the context of a real or hypothetical ETHICAL DILEMMA. Such judgments often reveal the beliefs that an individual applies in discriminating between right and wrong and the attitudes that comprise his or her basic moral orientation. 2, the faculty of making moral distinctions. Also called MORAL JUDGMENT.

ethical nihilism see MORAL NIHILISM.

ethical principle orientation see POSTCONVENTIONAL LEVEL.

ethics n. 1. the branch of philosophy that investigates both the content of moral judgments (i.e., what is right and what is wrong) and their nature (i.e., whether such
ethics of animal research

judgments should be considered objective or subjective. The study of the first type of question is sometimes termed normative ethics and that of the second metaethics. Also called moral philosophy. 2. the principles of morally right conduct accepted by a person or a group or considered appropriate to a specific field. In psychological research, for example, proper ethics requires that participants be treated fairly and without harm and that investigators report results and findings honestly. See code of ethics; professional ethics; research ethics. —ethi-cal adj.

**ethics of animal research** the complex set of issues relating to the ethics of manipulating nonhuman animals experimentally, holding them in captivity, and using them for the purpose of research. Some argue that any animal research is unethical because animals cannot give informed consent. Others see value in animal research if the animals are well cared for and treated humanely. See animal care and use; institutional animal care and use committee.

**ethinamate** n. see alcohol derivative.

**ethnocephaly** n. a birth defect involving the olfactory system and often marked by a rudimentary proboscis-shaped nose, which may have imperforate nostrils. The condition is sometimes associated with CIBOCEPHALY and tends to occur as part of trisomy 13.

**ethmoid fossa** see fossa.

**ethnic** adj. denoting or referring to a group of people having a shared social, cultural, linguistic, and sometimes religious background.

**ethnic bias** 1. discrimination against individuals based on their ethnic group, often resulting in inequities in such areas as education, employment, health care, and housing. 2. in testing and measurement, contamination or defici-ency in an instrument that differentially affects the scores of those from different ethnic groups. Ideally, researchers strive to create culture-fair tests.

**ethnic cleansing** the methodical removal, detention, or genocide of an ethnic group or groups to produce an ethnically homogeneous territory or society.

**ethnic drift** 1. the process by which people belonging to an ethnic minority tend to lose, alter, or redefine their sense of ethnic identity over time, generally as a result of assimilation with the dominant culture, intermarriage, or loss of contact with their culture of origin. See also cultural drift. 2. the tendency for people of the same ethnicity to gather in or be assigned to the same formal or informal groups, as a result of voluntary association or the policies of others. At work, for example, people of the same ethnicity are often assigned to the same work team or supervisor.

**ethnic group** any major social group that possesses a common identity based on history, culture, language, and often religion.

**ethnic identity** an individual’s sense of being a person who is defined, in part, by membership in a specific ethnic group. This sense is usually considered to be a complex construct involving shared social, cultural, linguistic, religious, and often racial factors but identical with none of them.

**ethnicity** n. a social categorization based on an individual’s membership in or identification with a particular cultural or ethnic group.

**ethnic psychology** a branch of psychology that studies how the culture, language, and related phenomena of different ethnic groups within a nation or region affect the attitudes, experiences, and behaviors of group members. Influenced by sociology, the field focuses on the unique sociocultural attributes of those of different races and ethnicities within each society, particularly as related to social class distinctions. Also called ethnopsychology; racial and ethnic minority psychology. See also cross-cultural psychology; multicultural psychology.

**ethnic research** the body of studies that investigates the backgrounds of people from different races and cultures.

**ethnic socialization** the transmission by parents, caregivers, or others of information, values, and perspectives about their ethnic group to the next generation, with the goal of instilling children with pride in their ethnic heritage and providing them with strategies for coping with ethnic discrimination and other barriers to success in mainstream society. This term is used in reference to research with a number of ethnic groups, including African Americans. See also racial socialization.

**ethnocentrism** n. 1. the practice of regarding one’s own ethnic, racial, or social group as the center of all things. Just as egocentrism is a sense of self-superiority, so ethnocentrism is the parallel tendency to judge one’s group as superior to other groups. 2. the tendency, often unintentional, to base perceptions and understandings of other groups or cultures on one’s own. Also called ethnocentricity. See also ingroup bias; racism; sociocentrism.

**—ethnocentric** adj. [first described by U.S. sociologist William G. Sumner (1840–1910)]

**ethnographic approach** a strategy frequently used by anthropologists for studying a community as a way of life. The method requires extensive residence in the community; fluency in the local languages, and active participation in community life to develop insight into its total culture.

**ethnography** n. the descriptive study of cultures or societies based on direct observation (see field research) and ideally some degree of participation. Compare ethnology. See also emic. —ethnographer n. —ethnographic adj.

**ethnolinguistics** n. the investigation of language within the context of human cultures or societies, paying attention to cultural influences and incorporating the principles of anthropology and ethnography. See also anthropological linguistics.

**ethnology** n. the comparative, analytical, or historical study of human cultures or societies. Compare ethnography. See also etic. —ethnological adj. —ethnologist n.

**ethnomethodology** n. the analysis of the underlying conventions and systems of meaning that people use to make sense of commonplace social interactions and experiences. —ethnomethodological adj. —ethnomethodologist n. [introduced by U.S. sociologist Harold Garfinkel (1917–2011)]

**ethnopsychology** n. see ETHNIC PSYCHOLOGY.

**ethnopsychopharmacology** n. the branch of pharmacology that studies ethnic and cultural variations in the
use of and response to psychoactive agents across divergent groups, as well as the mechanisms responsible for such differences. —ethnopsychopharmacological adj.

ethogram n. a detailed listing and description of the behavior patterns of a nonhuman animal in its natural habitat. The description is objective rather than interpretative. For example, a vocalization given in response to a predator would be described in terms of its acoustic properties rather than its apparent function of alarm call. An ethogram can be used to determine categories for a behavior record and is a prerequisite for observational research. See ETHOLOGY.

ethologically oriented universal see PSYCHOLOGICAL UNIVERSAL.

ethology n. the comparative study of the behavior of nonhuman animals, typically in their natural habitat but also involving experiments both in the field and in captivity. Ethology was developed by behavioral biologists in Europe and is often associated with connotations of innate or species-specific behavior patterns, in contrast with COMPARATIVE PSYCHOLOGY. The theory and methods from both areas are now closely interrelated, and ANIMAL BEHAVIOR is a more neutral and more broadly encompassing term. Increasingly, ethology is used to describe research involving observation and detailed descriptions of human behavior as well. —ethological adj. —ethologist n.

ethos n. the distinctive character or spirit of an individual, group, culture, nation, or period, as revealed particularly in its attitudes and values. See also ORTI GEIST; ZEITGEIST.

ethosuximide see SUCINIMIDE.

ethotoxin n. see HYDANTOIN.

ethyl alcohol see ETHANOL.

etic adj. 1. denoting an approach to the study of human cultures based on concepts or constructs that are held to be universal and applicable cross-culturally. Such an approach would generally be of the kind associated with ETHNOLOGY rather than ETHNOGRAPHY. The term is sometimes used critically of studies or perspectives that aspire to objectivity but succeed only in defining social behaviors in terms of the researcher’s own cultural values. Compare EMIC. [introduced by U.S. linguist Kenneth Pike (1912–2000); first used in anthropology by U.S. cultural anthropologist Marvin Harris (1927–2001)] 2. in linguistics, see EMIC–ETIC DISTINCTION.

etiology n. 1. the causes and progress of a disease or disorder. 2. the branch of medical and psychological science concerned with the systematic study of the causes of physical and mental disorders. —etiological adj.

Etrafon n. a trade name for a combination of the tricyclic antidepressant AMITRIPTYLINE and the antipsychotic PERPHENAZINE, used for the treatment of concurrent anxiety and depression. Its use has, however, declined because of its association with TARDIVE DISKINIESIA.

E trisomy see TRISOMY 18.

ETS 1. abbreviation for EDUCATIONAL TESTING SERVICE. 2. abbreviation for electrical transcranial stimulation. See ELECTRO-EFFECT THERAPY.

etymology n. the study of the origins and historical development of words and morphemes. —etymological adj.

eu- combining form well or good (e.g., EUPHORIA).

eudaimonic well-being the type of happiness or contentment that is achieved through SELF-ACTUALIZATION and having meaningful purpose in one’s life. Compare HEDONIC WELL-BEING.

eudemonia (eudaemonia) n. happiness considered as a criterion for what is moral and as a motivation for human action. Modern versions of eudemonia, such as those found in psychology, have most often emphasized its individualist and pleasure-seeking aspects; older theories, particularly that of ARISTOTLE, have given greater emphasis to the notion of one’s being drawn by nature toward a higher good or a “flourishing life” as the source of genuine happiness.

eudemonism (eudaemonism) n. 1. the position that happiness or EUDEMONIA is the ultimate ground of morality, so that what is good is what brings happiness. Debate then centers on whose happiness is achieved and whether certain means of achieving happiness are immoral. UTILITARIANISM is a eudemonism. 2. the position that humans will naturally act in ways that bring them happiness. Psychoanalytic, behavioralistic, and humanistic psychologies can all be seen as modern eudemonisms. Debate centers on whether humans are compelled to act so as to maximize their happiness, as HEDONISM would suggest, or whether the association between happiness and behavior is more subtle. Older versions of eudemonism suggested that the motives for human action included some altruistic impulses, so that the achievement of the happiness of others or a greater good could also be the cause or source of behaviors.

euergasia n. normal mental or psychobiological functioning. Also called orthergasia. [defined by Adolf MEYER]

eugenic adj. describing a factor or influence that is favorable to heredity. Compare DYSGENIC.

eugenics n. a social and political philosophy, based loosely on Charles DARWIN’s evolutionary theory and Francis GALTON’s research on hereditary genius, that seeks to eradicate genetic defects and improve the genetic makeup of populations through selective human breeding. Positive eugenics is directed toward promoting reproduction by individuals with ostensibly superior traits, whereas negative eugenics is directed toward preventing reproduction by individuals with traits that are considered to be undesirable. The eugenic position is groundless and scientifically naive, in that many conditions associated with disability or disorders, such as syndromes that increase risk of intellectual disability, are inherited recessively and occur unpredictably. Nevertheless, the philosophy gained popularity in the United Kingdom and United States, where eugenic policies, such as sterilization of people with intellectual disability, persisted into the latter half of the 20th century. Attitudes toward genetics in the 21st century are often influenced by individual and community concerns about prior eugenic abuses.

Euler diagram a pictorial image of how entities or situations intersect or overlap. Whereas a VENN DIAGRAM depicts all areas of intersection, an Euler diagram does not necessarily include all areas. For example, a researcher might create a Venn diagram in which a large circle represents a population, a circle inside that represents a sample or subset of the population, and overlapping circles inside the previous one indicate additional subsets. If the image were to leave out some of the inner circles, such as the ones representing different kinds of random samples, it
eumorphic adj. denoting a constitutional body type characterized by normal shape and structure and roughly equivalent to the normosplanchnic type.

eumuch n. a male who has been castrated before puberty and who therefore develops the secondary sex characteristics of a female, such as a higher voice. See also castration.

euphenics n. interventions that aim to improve the outcome of a genetic disease by altering the environment to minimize expression of the disease. For example, people with phenylketonuria can reduce or prevent its expression by eliminating major sources of phenylalanine (e.g., soft drinks sweetened with aspartame) from their diet.

euphoria n. extreme happiness and an elevated sense of well-being. An exaggerated degree of euphoria that does not reflect the reality of one’s situation is common in manic episodes and hypomanic episodes. —euphoric adj.

—euphoric —adj.
euphoriocentric n. a substance capable of inducing a strong subjective sense of well-being and happiness.
euphoriogenic n. a substance capable of inducing a strong subjective sense of well-being and happiness.
euphoriogenic adj. describing an event or medication that generates a state of euphoria.
eurekha task a problem-solving task designed to investigate the phenomenon of sudden insight into a problem’s solution. The route to solving the problem is usually not obvious and typically requires a mental leap beyond the sorts of solutions used for everyday problems. See also AHA EXPERIENCE: DISCONTINUITY HYPOTHESIS.

European Federation of Professional Psychologists’ Associations (EFPPA) a federation of national psychology associations founded in 1981 to provide a forum for European cooperation in a wide range of fields of academic training, psychological practice, and research.

European Federation of the Psychology of Sport and Physical Activity a European federation of national organizations in the area of SPORT AND EXERCISE PSYCHOLOGY. The organization is usually called FEPSAC, an acronym of its French name (Fédération Européenne de Psychologie des Sports et des Activités Corporelles).

eurychromic adj. see BODY-BUILD INDEX.
euryplastic adj. denoting a constitutional body type that is roughly equivalent to the pyknic type in kretschmer typology.
europathyology n. a social structure among nonhuman animals in which there is a marked division of labor, with only a few individuals that reproduce and many more nonreproductive individuals that guard the nest, gather food and nest materials, or help to care for the young. Neuropathyology is a common form of social structure in colonial species of bees and wasps (see SOCIAL INSECTS). The haplodiploid mode of inheritance helps to explain the adaptiveness of nonreproductive helpers caring for the young of the queen.
—neuroplastic adj.
eustachian tube a slender tube extending from the middle ear to the pharynx, with the primary function of equalizing air pressure on both sides of the tympanic membrane (eardrum). [Bartolomeo Eustachio (1524–1574), Italian anatomist]
eusthenic adj. denoting a constitutional body type that is equivalent to the asthenic type and close to the athletic type in kretschmer typology.
eustress n. the positive stress response, involving optimal levels of stimulation: a type of stress that results from challenging but attainable and enjoyable or worthwhile tasks (e.g., participating in an athletic event, giving a speech). It has a beneficial effect by generating a sense of fulfillment or achievement and facilitating growth, development, mastery, and high levels of performance. Compare DISTRESS. [first described by Hungarian-born Canadian endocrinologist Hans Selye (1907–1982)]
euthanasia n. the act or process of terminating a life, usually to prevent further suffering in an incurably or terminally ill individual. Voluntary euthanasia requires the consent of a competent person who has established a valid advance directive or made his or her wishes otherwise clearly known. Euthanasia is distinguished from the much more widely accepted practice of forgoing invasive treatments, as permitted under natural-death laws throughout the United States. Traditionally, a distinction between passive euthanasia (withholding treatment) and active euthanasia (taking directly lethal action) has been made. In current practice, however, the term euthanasia typically is used to mean active euthanasia only. The practice of and debate over euthanasia in various forms have a long history going back to Ancient Greece (the term itself derives from the Greek: eu, “good, well,” and thanatos, “death”). Worldwide, legal and ethical questions persist to this day about the circumstances under which, in the absence of an advance directive, euthanasia can and cannot be pursued, as famously occurred, for example, in the case of Terri Schaivo, a Florida woman in a permanent vegetative state who died in 2005 after her life support was discontinued following a lengthy court battle. Ethical questions apply as well to the euthanasia of nonhuman animals, particularly concerning whether it is ethical to terminate the lives of healthy animals in shelters and zoos. See also assisted death. —euthanize vb.
euthymia n. a mood of well-being and tranquility. The term often is used to refer to a state in patients with a bipolar disorder that is neither manic nor depressive but in between, associated with adaptive behavior and enhanced functioning. —euthymic adj.
evaluability assessment a review that may be carried out before a program evaluation: The aim is to identify the evaluation objective, specific questions to be answered by program-evaluation data, and possible designs, measurements, and analyses to be used in the evaluation.
evaluation n. a careful examination or overall appraisal of something, particularly to determine its worth, value, or desirability. For example, the evaluation of a particular therapeutic technique refers to a determination of its success in achieving defined goals.
evaluation apprehension uneasiness or worry about being judged by others, especially worry experienced by participants in an experiment as a result of their desire to be evaluated favorably by the experimenter or by others observing their behavior. Participants with evaluation apprehension may inhibit reactions (e.g., the display of aggression) that they believe will lead the experimenter to regard them as psychologically unhealthy.
evaluation interview an interview conducted as part of an employee-evaluation program. An evaluation interview may be a routine or periodic discussion of the individ-
ual’s job performance (see PERFORMANCE REVIEW) or may arise from specific circumstances. In some cases, it may involve psychological incentives, such as suggesting that the employee develop a set of personal goals.

**evaluation objective** any of the purposes of an evaluation of a program. For example, the purpose of FORMATIVE EVALUATIONS is to consider implementation problems, program integrity, and program monitoring, whereas the purpose of SUMMATIVE EVALUATIONS is to focus on program impact, program effectiveness, and cost analysis.

**evaluation research** the use of scientific principles and methods to assess the effectiveness of social interventions and programs, including those related to mental health, education, and safety (e.g., crime prevention, automobile accident prevention). Evaluation research is thus a type of APPLIED RESEARCH. See also ASSESSMENT RESEARCH.

**evaluation utilization** an effort to act on the findings of an evaluation program. It involves managing disparate evaluation outcomes as well as generalizing solutions for the problems brought to light by the evaluation process.

**evaluative priming measure** an implicit attitude measure based on the phenomenon that the speed of evaluating some target attitude object is facilitated by a prime (i.e., the prior presentation of another attitude object) that is evaluatively consistent with the target and inhibited by a prime that is evaluatively inconsistent with the target. For example, if the name of a product is presented as a prime immediately prior to a target word likely to be negative to most people (e.g., cockroach), evaluation of the target should be faster if the attitude toward the product is negative and slower if the attitude toward the product is positive. A measure of attitudes toward the prime (i.e., the product) can be created by computing the relative difference in the speed of evaluating a negative target paired with the prime versus a positive target paired with the prime. Also called bona fide pipeline measure. See also DIRECT ATTITUDE MEASURE: EXPLICIT ATTITUDE MEASURE: INDIRECT ATTITUDE MEASURE. [originally developed by U.S. psychologist Russell H. Fazio (1952–)]

**evaluative ratings** scores reflecting individuals’ judgments of the aesthetic or other qualities of a group of objects. Evaluative ratings may be based on hedonic values, such as the relative pleasantness of a set of paintings, on the relative complexity of a series of patterns, or on other factors.

**evaluative reasoning** a form of critical thinking that involves appraisal of the effectiveness, validity, meaning, or relevance of any act, idea, feeling, technique, or object.

**evaluator** n. an individual whose role is to assess and provide advice about the progress of a therapy or sensitivity group, a project team, an institution, or an individual. See also EXTERNAL EVALUATOR; INTERNAL EVALUATOR.

**evaluator credibility** the extent to which the evaluator of a program is viewed by the STAKEHOLDERS as trustworthy, technically competent, and knowledgeable enough to execute an evaluation in a fair and responsible manner.

**evasion** n. 1. a form of PARALOGIA in which an idea that is logically next in a chain of thought is replaced by another idea closely but not accurately or appropriately related to it. 2. elusion or avoidance.

**evenly hovering attention** see FREE-FLOATING ATTENTION.

**event** n. 1. any occurrence or phenomenon that has a definite beginning and end and that involves or produces change. 2. in probability theory, any of the namable things that can be said to result from a single trial of an experiment of chance. For example, in the roll of a single die, the events could include (among others) any of the six individual numbers, any even number, and any odd number.

**event history analysis** see SURVIVAL ANALYSIS.

**event memory** memory for everyday events, which is a form of EPISODIC MEMORY.

**event-related magnetic field (ERP)** a change in the magnetic field of the brain, detected at the scalp through MAGNETORENCEPHALOGRAPHY, that is elicited by a cognitive event, such as determining whether a specific word was part of a recently presented list. ERFs allow more accurate localization of function than do EVENT-RELATED POTENTIALS because they are less influenced by the surrounding brain structures.

**event-related potential (ERP)** a specific pattern of electrical activity produced in the brain when a person is engaged in a cognitive act, such as discriminating one stimulus from another. There are a number of different ERP components, including the highly researched P3 COMPONENT (or P300), and different cognitive operations have been associated with the amplitude and latency of each. Because ERPs provide specific information about the precise timing and (given appropriate caveats) location of mental events, they can yield data about cognitive operations not readily derived from behavioral measures and also serve as an important bridge between psychological function and neural structures. Although the terms are sometimes used synonymously, ERPs are distinct from EVOKED POTENTIALS, which are associated with more elementary sensory stimulation.

**event sampling** a strategy commonly used in DIRECT OBSERVATION that involves noting and recording the occurrence of a carefully specified behavior whenever it is seen. For example, a researcher may record each episode of apnea that occurs within a 9-hour period overnight while a person sleeps.

**event space** a subset of the set of all possible outcomes in a situation (the SAMPLE SPACE). For example, the sample space of working days for a particular organization might comprise Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday for all employees, but the event space for working days might include only Monday through Friday for some employees.

**everyday creativity** the ability to think divergently and demonstrate flexibility and originality in one’s daily activities. Examples include redecorating a room at home or devising a novel solution to a business problem. Also called ordinary creativity. Compare EXCEPTIONAL CREATIVITY.

**everyday intelligence** the intellectual skills used in ordinary activities (e.g., price comparison shopping, using a map to travel unfamiliar streets). Everyday intelligence refers not to a psychometrically validated construct but to a loosely conceptualized kind of intelligence relevant to the problems people face on a daily basis.

**everyday racism** differential treatment of individuals on the basis of their racial group that occurs in common, routine social situations. For example, consider two college students who are pictured in the newspaper for participating as volunteers at an event to clean up a local neighbor-
Evidence-based Practice (EBP) is the integration of the best available scientific research from laboratory and field settings with clinical expertise so as to provide effective psychological services that are responsive to a patient’s cultural, preference, and characteristics (e.g., functional status, level of social support, strengths). In unifying researchers and practitioners, EBP ensures that the research on psychological assessment, case formulation, intervention strategies, therapeutic relationships and outcomes, and specific problems and patient populations is both clinically relevant and internally valid. Clinical decisions should be made in collaboration with the patient, based on relevant data, and with consideration for the probable costs, benefits, and available resources and options. The ultimate goal of EBP is to promote empirically supported principles that can be used to enhance public health.

Evil Eye a folk belief in the supernatural powers of a malevolent stare or hostile gaze, which is believed to cause adversity, illness, injury, or destruction to the recipient. The term is applied more specifically to a Culture-Bound Syndrome in Mediterranean countries and other regions (see MAL DE QO). See also WITCHCRAFT.

Evocation n. 1. castration or emasculation. 2. the delusion of a man that he has been turned into a woman.

Evocative therapy therapy based on the idea that behavior is aroused by underlying factors. Once the factors underlying a maladaptive or unwanted behavior have been identified, dispositional and environmental changes can be made to affect those factors and therefore alter the behavior. [originated by Jerome D. Frank]

Evoked potential (EP) a specific pattern of electrical activity produced in a particular part of the nervous system, especially the brain, in response to external stimulation, such as a flash of light or a brief tone. Different modalities and types of stimuli produce different types of sensory potentials, and these are labeled according to their electrical polarity (positive- or negative-going) and timing (by serial order or in milliseconds). Although the terms are sometimes used synonymously, EPs are distinct from event-related potentials, which are associated with higher level cognitive processes. Also called evoked response (ER).

Evolution n. 1. the process of gradual change in the appearance of populations of organisms that takes place over generations. Such changes are widely held to account for the present diversity of living organisms originating from relatively few ancestors since the emergence of life on earth. See EVOLUTIONARY THEORY. See also CONVERGENT EVOLUTION; DIVERGENT EVOLUTION. 2. any other process of gradual change. —evolutionary adj.

Evolutionarily stable strategy (ESS) a state of equilibrium between two different adaptive strategies that allows both strategies to be maintained within a population. For example, shy animals are less likely than bold animals to behave in a way that attracts predators, but bold animals are more likely to find new food resources or secure additional mates. Within a population, therefore, there will be an optimal balance of costs and benefits for both shy and bold animals so that members of both types can survive. The evolutionarily stable strategy is a mechanism that accounts for the maintenance of diversity within a population.

Evolutionary aesthetics the concept that art evolves due to intrinsic forces rather than changing to reflect extra-artistic forces.

Evolutionary developmental psychology the application of the basic principles of Darwinian evolution, particularly NATURAL SELECTION, to explain human development. Evolutionary developmental psychology involves the study of the genetic and environmental mechanisms that underlie the universal development of social and cognitive competencies and the evolved epigenetic processes (GENE-ENVIRONMENT INTERACTIONS) that adopt these competencies to local conditions. It assumes that not only are behaviors and cognitions that characterize adults the product of selection pressures operating over the course of evolution, but so also are characteristics of children’s behaviors and minds. [proposed in 2002 by U.S. developmental psychologists David Bjorklund (1949—) and Anthony D. Pellegrini (1949—)]

Evolutionary epistemology any of a number of approaches to EPistemology that seek to explain the origins and development of human knowledge in terms of biological, chiefly Darwinian, evolution. One form suggests that ideas and explanations evolve in a way analogous to the evolution of organisms; that is, they survive as they show themselves to be “fit,” or useful. Another form suggests that there is a literal biological origin of ideas and that certain ideas, such as the rules of logic, have enhanced the survival of those in whom they evolved: Thus, the ideas themselves tend to survive and take on importance.

Evolutionary psychology an approach to psychological inquiry that views human cognition and behavior in a broadly Darwinian context of adaptation to evolving physical and social environments and new intellectual challenges. It differs from SOCIOBIOLOGY mainly in its emphasis on the effects of NATURAL SELECTION on information processing and the structure of the human mind.

Evolutionary theory any theory to account for the evolution of organisms over successive generations. One early and influential example was the theory of evolution by use or disuse (see LAMARCKISM). Nowadays, the most widely accepted is an updated version of Charles Darwin’s theory of evolution through NATURAL SELECTION, called neo-Darwinism (see DARWINISM). Theories concerning specific aspects of evolution include COEVOLUTION, EXAPTATION, NEOTENY, PUNCTUATED EQUILIBRIUM, and recapitulation theory. Opposed to all theories of evolution is the doctrine of CREATIONISM. The application of evolutionary principles permeates different subdisciplines within psychology, including clinical science, cognitive psychology, and neuroscience. For example, the influence of evolutionary theories can be seen in studies conducted to determine whether particular clinical disorders (e.g., depression, anxiety) are in fact psychological adaptations or in assertions that emotions evolved to serve primary functions (particularly to motivate and communicate) that would enhance survival.

Evolution of consciousness the process by which consciousness arose and developed as a biological adaptation in animals. In mammals, conscious wakefulness, attentional orienting, sensory perception, immediate memory, and so forth are associated with the evolution of the THALAMOCORTICAL SYSTEM of the mammalian brain over
more than 200 million years. Close functional parallels may exist in birds, some cephalopods, and reptiles such as salamanders and crocodilia.

**evolution of intelligence** the process by which intelligence has developed from earlier and generally simpler species to later and generally more complex species. There are many theories of how intelligence has evolved, but most emphasize some kind of Darwinian natural-selection process, in which evolution favored skills that were more useful over the eons for adaptation to environments than skills that were less useful.

**evolution of the brain** the concept that the brains of complex animals have evolved over many millions of years from a network of simple NERVE FIBERS connecting various body areas, as in primitive multicellular animals. At a more advanced stage, a neural axis developed to connect and integrate peripheral neurons and to house cell bodies; this axis became a spinal cord. Still later, collections of neurons with control functions developed at the head end of the spinal cord, as in the brains of higher vertebrates, birds, fish, and reptiles. From those concentrations of brain tissue evolved the FOREBRAIN, with its highly convoluted CEREBRAL CORTEX, of mammals, especially prominent in whales, great apes, and Homo sapiens. See also CEPHALIZATION; ENCEPHALIZATION.

**evolved mechanism** a subsystem of the brain (or mind) that is a product of natural selection and is generally seen as having evolved as a result of its success in solving a problem related to survival or reproduction during the evolution of a species. For example, the elements of the brain’s visual system that enable organisms to perceive objects in three-dimensional space (despite the fact that vision is a product of the brain’s visual system that enable organisms to perceive objects in three-dimensional space) would be seen as an evolved mechanism that solved the problem of determining the distance between oneself and objects in the environment.

**ex-** prefix see EXO-.

**exacerbation** n. an increase in the severity of a disease or disorder or of its symptoms.

**exact replication** see REPLICATION.

**exact test** any statistical test in which the probability of finding a result as extreme or more extreme than the one obtained, given the NULL HYPOTHESIS, can be calculated precisely rather than approximated. The FISHER EXACT TEST is an example.

**exaggeration** n. the act of embellishing or overstating a quality or characteristic of a person, thing, or situation. It is often a defensive reaction in which the individual justifies questionable attitudes or behavior through overstatement, such as dramatizing the oppressive acts of a parent as a means of justifying rebellious behavior.

**exaltation** n. an extreme state of EUPHORIA and PSYCHOMOTOR AGITATION, accompanied by a lack of restraint. It occurs in some MANIC EPISODES.

**examination** n. a test, observation, or other means of investigation carried out on a patient to evaluate physical or mental health or detect the presence or absence of signs or symptoms of diseases, disorders, or conditions. See also MENTAL EXAMINATION; NEUROLOGICAL EVALUATION; PSYCHOLOGICAL EXAMINATION.

**exaptation** n. a trait that, having evolved to serve one function, is later used for another. For example, feathers may have evolved as cooling or insulating mechanisms and later aided in flying. Also called **spandrel**. [proposed by U.S. paleontologist Stephen Jay Gould (1941–2002)]

**exceptional child** a child who is substantially above or below the average in some significant respect. Often applied to a child who shows marked deviations in intelligence, the term may also be used to indicate the presence of a special talent or an unusual emotional or social difficulty. See also GIFTEDNESS; SLOW LEARNER.

**exceptional creativity** the capability of individuals to make unique and important contributions to society through their work and the products of their work. Exceptional creativity, as measured by creative output, seems to peak at different points in the adult lifespan depending on the field of activity. Also called **creative genius**. Compare EVERYDAY CREATIVITY.

**exchangeability** n. the ability to be used in different circumstances or situations. For example, in measurement and statistics, items that are equally appropriate on different versions of a test and methods or parameters that work well under different conditions show exchangeability.

**exchange relationship** see COMMUNAL RELATIONSHIP.

**exchange theory** see SOCIAL EXCHANGE THEORY.

**excitability** n. 1. the tendency of some individuals to be readily aroused to emotional responses. 2. in neurophysiology, the capacity of neurons and some muscle cells to respond electrically to external stimulation with a sudden, transient increase in their ionic permeability and a change in the electric potential across their cell membrane. —excitable adj.

**excitant** n. an agent capable of eliciting a response.

**excitation** n. the electrical activity elicited in a neuron or muscle cell in response to an external stimulus, specifically the propagation of an ACTION POTENTIAL.

**excitation pattern** a spatial pattern of responses to sound in the auditory system. It usually refers to the ENVELOPE of the displacement pattern on the BASILAR MEMBRANE or its representation in the auditory nerve. See TONOTOPIC ORGANIZATION; TUNING CURVE.

**excitation-transfer theory** the theory that emotional responses can be intensified by AROUSAL from other stimuli not directly related to the stimulus that originally provoked the response. According to this theory, when a person becomes aroused physiologically, there is a subsequent period of time when the person will experience a state of residual arousal yet be unaware of it. If additional stimuli are encountered during this time, the individual may mistakenly ascribe his or her residual response from the previous stimuli to those successive stimuli. [originally proposed in 1971 by U.S. psychologist Dolf Zillmann (1935– )]

**excitatory conditioning** direct CLASSICAL CONDITIONING in which a conditioned stimulus acts as a signal that a particular unconditioned stimulus will follow. Compare INHIBITORY CONDITIONING.

**excitatory field** an area of the brain surrounding and sharing the response of an excited sensory area.

**excitatory gradient (excitation gradient)** see GENERALIZATION GRADIENT.

**excitatory–inhibitory processes** 1. processes in which the transmission of neuronal signals is activated or inhibited by the effects of neurotransmitters on the post-
Excitatory neurotransmitter

1. synaptic membrane. 2. antagonistic functions of the nervous system defined by Ivan PAVLOV. 3. the stimulation of the cortex and the subsequent facilitation of learning, memory, and action (excitatory processes) versus central nervous system processes that inhibit or interfere with perceptual, cognitive, and motor activities (inhibitory processes). Individuals with a predominance of inhibitory over excitatory processes are theorized to be predisposed to a higher degree of EXTRAVERSION, whereas individuals with a predominance of excitatory over inhibitory processes are theorized to be predisposed to a higher degree of INTROVERSION. Introverted–extraverted behaviors are said to serve the function of modulating these excitation and inhibitory processes: That is, individuals who build up excitatory processes slowly and inhibitory processes quickly need to have an extraverted fashion to provide “excitement,” whereas introverts are already excited so they do not need to behave in an extraverted way to increase this excitability but tend instead to shy away from excitatory stimuli. [proposed by Hans EYSENCK]

**Excitatory neurotransmitter** see NEURONTRANSMITTER.

**Excitatory postsynaptic potential (EPSP)** a brief decrease in the difference in electrical charge across the membrane of a neuron that is caused by the transmission of a signal from a neighboring neuron across the synapse (specialized junction) separating them. EPSPs increase the probability that the postsynaptic neuron will initiate an ACTION POTENTIAL and hence fire a nerve impulse. Compare INHIBITORY POSTSYNAPTIC POTENTIAL.

**Excitatory synapse** a specialized type of junction at which activity from one neuron (in the form of an ACTION POTENTIAL) facilitates activity in an adjacent neuron by initiating an EXCITATORY POSTSYNAPTIC POTENTIAL. Compare INHIBITORY SYNAPSE.

**Excitatory threshold** the stimulus intensity that is just sufficient to trigger a NERVE IMPULSE.

**Excrement n.** see FECES.

**Excoriation (skin-picking) disorder** in DSM–5, a new diagnosis characterized by recurrent picking at one’s own skin, leading to lesions and causing significant distress or impairment.

**Exculpatory evidence** evidence supporting a defendant’s claim of innocence.

**Executive n.** a theoretical superordinate mechanism in some models of cognition—particularly those in cognitive science, cognitive neuropsychology, and artificial intelligence—that organizes, initiates, monitors, and otherwise controls information-processing activities and other mental operations. A similar concept specific to working memory is that of the CENTRAL EXECUTIVE

**Executive area** a region of the brain hypothesized to account for higher order brain functions, such as thinking and reasoning (see EXECUTIVE FUNCTIONS). The FRONTAL LOBE is commonly referred to as an executive area.

**Executive attention** see SELECTIVE ATTENTION.

**Executive coaching** one-on-one, customized counseling and feedback provided to managers in an organization to develop their interpersonal and other managerial skills and enhance their ability to achieve short- and long-term organizational goals. Executive coaching is provided by external consultants or similar professional coaches, rather than by managers, peers, or human resources personnel within the organization. See MANAGEMENT DEVELOPMENT.

**Executive control structure** a theoretical mental system governing the use of different cognitive strategies: an internal blueprint. Particularly relevant to problem solving, executive control structures contain representations of situations, their objectives, and the various procedures available for obtaining them. They are one of two mechanisms proposed by Canadian developmental psychologist Robbie Case (1944–2000) as guiding learning and thinking processes in children, the other being the CENTRAL CONCEPTUAL STRUCTURE.

**Executive dysfunction** impairment in the ability to think abstractly; plan; solve problems; synthesize information; or start, continue, and stop complex behavior. It is related especially to disorders of the frontal lobe or associated subcortical pathways.

**Executive functions** higher level cognitive processes of planning, decision making, problem solving, action sequencing, task assignment and organization, effortful and persistent goal pursuit, inhibition of competing impulses, flexibility in goal selection, and goal-conflict resolution. These often involve the use of language, judgment, abstraction and concept formation, and logic and reasoning. They are frequently associated with neural networks that include the frontal lobe, particularly the prefrontal cortex. Deficits in executive functioning are seen in various disorders, including Alzheimer’s disease and schizophrenia. In the latter, for example, selection and maintenance of goals may be impaired, as may the ability to exclude distractions. Also called central processes: higher order processes. See also SUPERVISORY ATTENTIONAL SYSTEM.

**Executive leadership** the processes by which those occupying the highest level positions of power and authority in an organization structure, direct, coordinate, and motivate others toward achieving certain goals.

**Executive organ** the body organ that plays the major role in responding to a stimulus. For example, when the stimulus instigates touching an object, the hand becomes the executive organ. Other organs often play subsidiary roles; for example, the eye that helps direct the hand serves as an auxiliary organ.
executive self the subjective agent to which regulation and implementation of voluntary actions is ordinarily attributed. The concept of an executive self has acquired considerable scientific plausibility, being associated with well-studied functions of the prefrontal cortex and other brain structures. Self-descriptions are vulnerable to a variety of attribution errors, however (see illusion of agency).

executive stage see Schae's Stages of Cognitive Development.

executive stress strain experienced by management personnel who are responsible for major decisions, the effectiveness of subordinates, and the success of the company as a competitive organization. See Burnout; Occupational Stress.

Exelon n. a trade name for Rivastigmine.

exemplar theory the hypothesis that categorization depends on specific remembered instances of the category, as opposed to an abstract prototype or a feature-based rule that delineates category membership. Exemplar theory has also been applied to questions of attention, skill acquisition, and social decision making, among other issues. Exemplar theories of prejudice, for example, suggest that stereotypes are not just abstractions about the typical characteristics of members of a particular group but instead are based on the perceiver's memories of specific individual group members. Also called instance theory.

exemplary damages see punitive damages.

exemplification n. a strategy for self-presentation that involves inducing other people to regard one as a highly moral, virtuous person whose actions are consistent with positive, shared values.

exercise n. a form of physical activity that is planned, repetitive in nature, and designed to enhance or maintain physical condition. Physical exercise may also be used as an adjunct to mental health therapy. See also exercise psychology; time-out theory.

exercise addiction the condition of being dependent on or excessively devoted to physical exercise. Stopping exercise will cause the addicted person to experience withdrawal symptoms. Also called exercise dependence. See negative exercise addiction; positive exercise addiction.

exercise adherence a combination of attending to an exercise program and achieving the set intensity and duration of exercise in the program. Also called exercise compliance.

exercise–behavior model an adaptation of the health–belief model that identifies the relationships of the following to likelihood of exercising: (a) personal predispositions, (b) sociodemographic variables, (c) perceived cost and benefits of exercising, and (d) perceived self-efficacy and locus of control. [proposed in 1984 by health education specialists Melody Powers Noland (1952– ) and Robert H. Feldman]

exercise high a feeling of euphoria during or immediately after physical exercise. See endorphin; runner's high.

exercise obsession see negative exercise addiction.

exercise play play that involves gross, vigorous movement in various directions, such as running or jumping. It usually begins around 2 years of age and peaks between 5 and 6 years. Exercise play is a form of locomotor play and may or may not be social.

exercise psychology a combination of exercise science and psychology used to study the psychological circumstances and consequences of involvement in exercise. See also sport and exercise psychology.

exercise therapy the prevention or treatment of disorders and chronic disease through regular, repetitive physical activity that enhances fitness and mobility. This type of therapy is designed to improve the functional capacity of body structures and has been demonstrated to have beneficial effects for many conditions, such as the alleviation of symptoms of depression and multiple sclerosis and the reduction in risk of developing cardiovascular disease and osteoporosis. More generally, there is widespread research evidence for a positive relationship between regular exercise and several indices of mental health and physical well-being.

exhaustion n. a state of extreme fatigue.

exhaustion death see lethal catatonia.

exhaustion delirium delirium occurring under conditions of extreme fatigue resulting from prolonged and intense overexertion, particularly when coupled with other forms of stress, such as prolonged insomnia, starvation, excessive heat or cold, or exposure to toxins. It is typically associated with the extreme physical effort required of those who engage in endurance sports or of others facing extreme environmental conditions, as well as with debilitating diseases.

exhaustion stage see general adaptation syndrome.

exhaustive adj. complete or all encompassing. For example, a set of 13 hearts, 13 spades, 13 diamonds, 13 clubs, and two jokers forms an exhaustive set of all possible playing cards that could be drawn.

exhaustive search any search process in which every item of a set is checked before a decision is made about the presence or absence of a target item. This may be a search for particular items in memory, a visual search, or any problem-solving exercise that involves choosing the best path to a solution from a number of alternative paths. Compare self-terminating search; heuristic search.

exhibitionism n. 1. the disposition or tendency to draw attention to oneself, particularly through conspicuous behavior. See also attention-getting. 2. a paraphilia in which the genitals are exposed to an unsuspecting stranger as a means of achieving sexual excitement, but without any attempt at further sexual activity with the stranger. —exhibitionist n.

existence n. 1. being: the quality by virtue of which something is, and which distinguishes it from what is not. 2. in existentialism, the concrete lived experience of human beings rooted in a concrete world, as opposed to a more abstract concept of a human being, such as an essence. —existential adj.

existence, relatedness, and growth theory (ERG theory) a variation of Maslow's motivational hierarchy as applied in industrial and organizational psychology. The model recognizes three main categories of work motivation: existence needs, relating to the physical needs of the individual (food, clothing, shelter); relatedness needs,
existential analysis

involving interpersonal relations with others on and off the job; and growth needs, in the form of personal development and improvement. [proposed in 1969 by U.S. organizational psychologist Clayton P. Alderfer (1940–)]

existential analysis a type of psychoanalysis, or a phase in existential psychotherapy, that places an emphasis on conscious perception and experience over unconscious motivation and drive in the search for meaning. The therapist typically takes an active, often confrontational, role by posing difficult questions and noting maladaptive decision making. The approach to “being” is future- or growth-oriented, and the goal is to develop and encourage highly conscious decision making on the part of the client. Also called existential psychoanalysis.

existential anxiety 1. In existentialism, the angst associated with one’s freedom as a human being to make choices; with one’s responsibility for the consequences of those choices; and with the sense that one’s existence is devoid of absolute meaning and purpose given that such choices occur in the absence of rational certainty or structure. See nothingness. 2. A general sense of anguish or despair associated with an individual’s recognition of the inevitability of death.

existential crisis 1. In existentialism, a crucial stage or turning point at which an individual is faced with finding meaning and purpose in life and taking responsibility for his or her choices. See existential neurosis; existential vacuum. 2. More generally, any psychological or moral crisis that causes an individual to ask fundamental questions about human existence.

existential dread a profound, deep-seated psychic or spiritual condition of insecurity and despair in relation to the human condition and the meaning of life. See also angst.

existential–humanistic therapy a form of psychotherapy that focuses on the entire person rather than solely on behavior, cognition, or underlying motivations. Emphasis is placed on the client’s subjective experiences, free will, and ability to decide the course of his or her own life. Also called humanistic–existential therapy.

existential intelligence a kind of intelligence proposed as a “candidate” intelligence in the multiple-intelligences theory. It is involved in understanding larger fundamental questions of existence and the role and place of humans in the universe. At present, there are no developed measures of existential intelligence.

existentialism n. A philosophical and literary movement that emerged in Europe in the period between the two World Wars and became the dominant trend in Continental thought during the 1940s and 1950s. Existentialism is notoriously difficult to sum up in a single definition—partly because many who might be identified with the movement reject the label, and partly because the movement is itself often a rejection of systematization and classification. The origins of existentialism have been traced to a range of thinkers, including French philosopher and mathematician Blaise Pascal (1623–1662), Danish philosopher Soren Kierkegaard (1813–1855), German philosopher Friedrich Nietzsche, and Russian novelist Fyodor Dostoevsky (1821–1881). However, the first fully developed philosophy of existentialism is usually taken to be the existential phenomenology elaborated by German philosopher Martin Heidegger (1889–1976) in the 1910s and 1920s. Heidegger’s concept of dasein was a key influence on the work of the French philosopher and author Jean-Paul Sartre (1905–1980), who is usually seen as the existentialist thinker par excellence. In the immediate postwar years, Sartre popularized both the term existentialism and most of the ideas now associated with it.

Existentialism represents a turning away from systematic philosophy, with its emphasis on metaphysical abstractions and principles of rational certainty, and toward an emphasis on the concrete existence of a human being “thrown” into a world that is merely “given” and contingent. Such a being encounters the world as a subjective consciousness, “condemned” to create its own meanings and values in an “absurd” and purposeless universe. The human being must perform this task without benefit of a fixed essence or inherent nature, and in the absence of any possibility of rational certainty. However, by accepting the burden of this responsibility, and refusing the “bad faith” of religion and other spurious rationalizations, he or she can achieve authenticity. Various forms of existential psychology have taken up the task of providing explanations, understandings of human behavior, and therapies based on existentialist assumptions about human existence. They have emphasized such constructs as alienation, authenticity, and freedom, as well as the difficulties associated with finding meaning and overcoming anxiety. [existential adj. —existentialist n. adj.]

existential judgment in philosophy, a judgment having to do with the existence, origin, or nature of a thing (i.e., its factual status), as contrasted with a judgment of the meaning, value, or importance of a thing.

existential living the capacity to live fully in the present and respond freely and flexibly to new experience without fear. Existential living is considered to be a central feature of the fully functioning person. [defined in psychology by Carl Rogers]

existential neurosis a pathological condition characterized by feelings of despair and anxiety that arise from living inauthentically, that is, from failing to take responsibility for one’s own life and to make choices and find meaning in living. See authenticity; existential crisis; existential vacuum.

existential phenomenology a philosophical development from the phenomenology of German thinker Edmund Husserl (1859–1938) that can be seen most clearly in the work of German philosopher Martin Heidegger (1889–1976) and French philosopher Maurice Merleau-Ponty (1908–1961). Phenomenology originally sought to achieve immediate and direct apprehension of phenomena at the most fundamental level, the level of that which manifests itself to pure consciousness. Heidegger’s contribution was to turn the phenomenological method toward the existential, or lived experience, rather than toward mere objects of consciousness. Thus, existential phenomenology seeks to get at the meaning of lived experience through the careful and systematic analysis of lived experience itself. In its fundamental project and subject matter, Heidegger’s work of the 1910s and 1920s anticipated the French existentialism of the postwar era. See being-in-the-world; dasein.

existential psychoanalysis see existential analysis.

existential psychology a general approach to psychological theory and practice that derives from existentialism. It emphasizes the subjective meaning of human experience, the uniqueness of the individual, and personal
responsibility reflected in choice. Such an approach was pioneered by Swiss existential psychologist Ludwig Binswanger (1881–1966). See BEING-IN-THE-WORLD; WORLD DESIGN. See also HUMANISTIC PSYCHOLOGY.

**existential psychotherapy** a form of psychotherapy that deals with the HERE AND NOW of the client's total situation rather than with his or her past or underlying dynamics. It emphasizes the exploration and development of meaning in life, focuses on emotional experiences and decision making, and stresses a person's responsibility for his or her own existence. See also LOGOTHERAPY.

**existential vacuum** the inability to find or create meaning in life, leading to feelings of emptiness, alienation, futility, and aimlessness. Most existentialists have considered meaningless to be the quintessential symptom or ailment of the modern age. See EXISTENTIAL CRISIS; EXISTENTIAL NEUROSIS. See also LOGOTHERAPY. [introduced by Viktor E. Frankl]

**exit interview** 1. a meeting between a student and a school counselor before the student leaves to begin high school, college, technical school, a vocational program, or a job. Future plans (e.g., future course of study) and the student's degree of preparation are discussed. 2. an employee's final meeting with a supervisor or personnel staff primarily to discuss the reasons for the employee's resignation or termination of employment. Information from such interviews can be used to reduce TURNOVER of and improve JOB SATISFACTION for remaining staff.

**ex-** (ex-) prefix outside or external.

**exocrine gland** any gland that secretes a product onto the outer body surface or into body cavities through a duct. Examples are the tear-producing lacrimal (or lachrymal) gland and the SALIVARY GLAND. Compare ENDOCRINE GLAND.

**exogamy** n. the custom or practice of marrying outside one's KINSHIP NETWORK or other religious or social group. Compare ENDOGAMY. —exogamous adj.

**exogenous** adj. originating outside the body, referring, for example, to drugs (exogenous chemicals) or to phenomena, conditions, or disorders resulting from the influence of external factors. Compare ENDOGENOUS. —exogenously adv.

**exogenous attention** see INVOLUNTARY ATTENTION.

**exogenous cue** a CUE, usually the onset of a stimulus in the peripheral visual field, that draws attention automatically to the location of the stimulus. It initiates involuntary movement of attention. Compare ENDOGENOUS CUE.

**exogenous depression** see REACTIVE DEPRESSION.

**exogenous variable** an INDEPENDENT VARIABLE whose value is determined by factors outside the model or system under study. Compare ENDOGENOUS VARIABLE.

**exon** n. a sequence of DNA within a gene that encodes a part or all of the gene's product or function. Exons are separated by noncoding sequences (see INTRON).

**exophoria** n. deviation of one eye in an outward direction. See also PHORIA.

**exophthalmos** n. abnormal protrusion of the eyeball, a condition commonly associated with hyperthyroidism. Exophthalmos combined with a goiter, a swelling in the neck due to an enlarged thyroid gland (exophthalmic goiter), is a prominent feature of GRAVES’ DISEASE. Exophthalmos may also be the result of a tumor or infection involving the eye. It is often characterized by the appearance of a fixed stare. —exophthalmic adj.

**exopsychic** adj. characterizing mental activity that purportedly produces effects outside the individual. Compare ENDOPSYCHIC.

**exorcism** n. the act or practice in which supposed evil spirits are expelled from a person believed to be possessed, or a place thought to be haunted, by means of certain rites, ceremonies, prayers, and incantations. It was once widely believed that such spirits were the major cause of mental disease and other disorders and that exorcism was therefore a suitable form of treatment. The Roman Catholic Church still performs ritual exorcisms in certain very restricted circumstances. See also INHABITANCE. —exorcise vb. —exorcist n.

**exosomatic method** a technique used in psychogalvanic-response studies in which skin resistance to a small electric current from an external source is measured. See GALVANIC SKIN RESPONSE.

**exosystem** n. in ECOCLOGICAL SYSTEMS THEORY, those societal structures that function largely independently of the individual but nevertheless affect the immediate context within which he or she develops. They include the government, the legal system, and the media. Compare CHRONOSYSTEM; MACROSYSTEM; MESOSYSTEM. [introduced by Urie BRONFENBRENNER]

**exotropia** n. the permanent outward deviation of one eye. Also called divergent strabismus; walleye. See also STRABISMUS; TROPIA.

**exp** abbreviation for EXPONENTIAL FUNCTION.

**expanded consciousness** a sense that one’s mind has been opened to a new or larger kind of awareness, associated particularly with mystical experiences, meditation, or hallucinogenic drug use. See also ALTERED STATE OF CONSCIOUSNESS.

**expansion** n. a description of a mathematical or statistical function via a series of sums.

**expansive delusion** a less common name for a DELUSION OF GRANDURE.

**expansive mood** a mood that reflects feelings of GRANDBORITY.

**expansiveness** n. a personality trait manifested by loquaciousness, overfriendliness, hyperactivity, and lack of restraint.

**ex-patient club** a group that provides individuals discharged from a psychiatric hospital with social and recreational experience, promotes their rehabilitation and readjustment to posthospital life, and maintains their mental health improvement through group support and, in some cases, group therapy. Ex-patient clubs may be organized by former patients or by the discharging hospital as part of its aftercare program. See also MENTAL HEALTH SUPPORT ORGANIZATION.

**expectancy** n. 1. the internal state resulting from experience with predictable relationships between stimuli or between responses and stimuli. This basic meaning becomes slightly more specific in some fields. For example, in cognitive psychology, it refers to an attitude or MENTAL SET that determines the way in which a person approaches a situation, and in motivation theory, it refers to an individ-
expectancy effect

ual’s belief that his or her actions can produce a particular outcome (e.g., attainment of a goal). 2. see EXPERIATION. —expectant adj.

expectancy effect the effect of one person’s expectation about the behavior of another person on the actual behavior of that other person (interpersonal expectancy effect), or the effect of a person’s expectation about his or her own behavior on that person’s actual subsequent behavior (intrapersonal expectancy effect). See also EXPERIMENTER EXPECTANCY EFFECT.

expectancy theory 1. a theory that cognitive learning involves acquired expectations and a tendency to react to certain objects (as signs of other objects previously associated with them). PURPOSEFUL BEHAVIORISM is a specific form of expectancy theory. 2. see VALENCE–INSTRUMENTALITY–EXPECTANCY THEORY.

expectancy-value model the concept that motivation for an outcome depends on the significance of that outcome and the probability of achieving it.

expectancy wave see CONTINGENT NEGATIVE VARIATION.

expectation n. 1. a state of tense, emotional anticipation. 2. In probability and statistics, the long-term average of a RANDOM VARIABLE. For example, the expectation is that the mean for a specific random variable obtained with an extremely large sample will equal the mean of the population of interest. Also called expectancy. See EXPECTED VALUE.

expectation-states theory a sociological explanation of status differentiation in groups proposing that group members allocate status not only to those who possess qualities suggesting competence at a task (SPECIFIC-STATUS CHARACTERISTICS) but also to those who have qualities that the members (miswisely) think are indicators of competence and potential, such as sex, age, wealth, and ethnicity (DIFFUSE-STATUS CHARACTERISTICS). See also STATUS GENERALIZATION.

expected frequency a FREQUENCY predicted from a theoretical model. For example, a university administrator may want to examine the observed frequency of female and male students and compare it to the expected frequency for each gender to determine how similar the pattern is to that in the general population. Expected frequencies are chiefly used in the CHI-SQUARE TEST.

expected value the value of a random variable or one of its functions as derived by mathematical calculation rather than observation. It is symbolized by \( E(x) \), with \( x \) varying according to the specific item of interest that is being calculated. Usually, the expected value is a mean or weighted average.

experience n. 1. an event that is actually lived through, as opposed to one that is imagined or thought about. 2. the present contents of CONSCIOUSNESS. 3. a stimulus that has undergone expected species-typical experiences during the developmental period, a predetermined maturational process in which synapses are formed and maintained only when an organism has undergone expected species-typical experiences during a particular CRITICAL PERIOD. Such functions as vision will develop for all members of a species if given species-typical environmental stimulation (e.g., light).

experience-expectant process in brain development, a predetermined maturational process in which synapses are formed and maintained only when an organism has undergone expected species-typical experiences during a particular CRITICAL PERIOD. Such functions as vision will develop for all members of a species if given species-typical environmental stimulation (e.g., light).

experiencer n. in CASE GRAMMAR, the entity that experiences the effect of the action, state, or process described in a sentence, such as John in John saw Mary, The wind felt soft to John, and The walk invigorated John. Note that experiencer case is independent of the grammatical role of John in the sentence. The category, which overlaps with that of PATIENT, is usually reserved for ANIMATE NOUNS capable of sensory or emotional experience. See also AGENT; INSTRUMENTAL.

experience-sampling method (ESM) a procedure for assessing research participants’ thoughts and feelings at specific, predetermined points in time. For example, researchers conducting a weight reduction program may check in with participants at various times to assess their dietary intake of healthy food and any urges to eat unhealthy food. The experience-sampling method is believed to provide more reliable input on the inner state of participants than may be obtained via after-the-fact feedback.

experiential family therapy an intervention that emphasizes intuition, feelings, and underlying processes in treating families and deemphasizes theoretical frameworks. The work is often characterized by the use of the therapist’s own feelings and self-disclosures in interactions with clients. Notable experiential family therapists have included U.S. psychiatrists Carl A. Whitaker (1912–1995) and Virginia M. Satir (1916–1988).

experiential history the social, environmental, and behavioral components of an individual’s background from birth to death.

experiential knowledge understanding and expertise that emerge from life experience rather than from formal education or professional training. For example, members of SELF-HELP GROUPS draw upon experiential knowledge in supporting and helping each other.

experiential learning learning that occurs by actively performing and participating in an activity.

experiential psychotherapy a broad family of psychotherapies originating in the 1950s and 1960s and falling under the umbrella of existential–humanistic psychology. A core belief of the approach is that true client change occurs through direct, active “experiencing” of what the client is undergoing and feeling at any given point in therapy. Both on the surface and at a deeper level, Experiential therapists typically engage clients very directly with regard to accessing and expressing their inner feelings and experiencing both present and past life scenes, and they offer clients perspectives for integrating such experiences into realistic and healthy self-concepts. Experiential psychotherapy has its antecedents in the work of U.S. psychiatrists Carl A. Whitaker (1912–1995) and Thomas P. Malone (d. 2000). U.S. psychologist Carl Rogers. Austrian-born U.S. philosopher and psychologist Eugene T. Gendlin (1926- ), and others.
experimental subtheory n. a subtheory in the TRIARCHIC THEORY OF INTELLIGENCE specifying the kinds of experience to which the components of intelligence (specified in the COMPONENTIAL SUBTHEORY) are applied. According to the experiential subtheory, people are creatively intelligent to the extent that they can cope with relatively novel and automatize routine aspects of tasks so as to devote more resources to novel stimuli in their environment.

experiment n. a series of observations conducted under controlled conditions to study a relationship with the purpose of drawing causal inferences about that relationship. An experiment involves the manipulation of an INDEPENDENT VARIABLE, the measurement of a DEPENDENT VARIABLE, and the exposure of various participants to one or more of the conditions being studied. RANDOM SELECTION of participants and their RANDOM ASSIGNMENT to conditions also are necessary in experiments. —experimental adj.

experimental aesthetics the use of techniques of experimental psychology in the study of responses to natural objects or art forms and their components. Studies in experimental aesthetics may also involve the use of Gestalt and other concepts in analyzing emotional effects and preferences for colors and patterns.

experimental analysis of behavior an approach to experimental psychology that explores the relationships between particular experiences and changes in behavior, emphasizing the behavior of individuals rather than group averages. It is concerned especially with describing how contingencies of reinforcement control the rate of an instrumental response.

experimental attrition see ATTRITION.

experimental condition a level of the INDEPENDENT VARIABLE that is manipulated by the researcher in order to assess the effect on a DEPENDENT VARIABLE. Participants in an experimental condition receive some form of TREATMENT or experience whereas those in a CONTROL CONDITION do not. For example, patients in an experimental condition may receive a new drug, whereas those in a control condition may receive a pill that looks like the new drug but is only a placebo containing some inert substance.

experimental control see CONTROL.

experimental design an outline or plan of the procedures to be followed in scientific experimentation in order to reach valid conclusions, with consideration of such factors as participant selection, variable manipulation, data collection and analysis, and minimization of external influences.

experimental epilepsy induction of repeated episodes of abnormal neural activity (seizures) in a nonhuman animal through electrical or chemical brain stimulation or through repeated sensory stimulation.

experimental ethics see RESEARCH ETHICS.

experimental group a group of participants in a research study who are exposed to a particular manipulation of the INDEPENDENT VARIABLE (i.e., a particular treatment level). The responses of the experimental group are compared to the responses of a CONTROL GROUP, other experimental groups, or both.

experimental hypothesis a premise that describes what a researcher in a scientific study hopes to demonstrate if certain conditions are met, such as RANDOM SELECTION of participants, RANDOM ASSIGNMENT to EXPERIMENTAL GROUPS or CONTROL GROUPS, and manipulation of an INDEPENDENT VARIABLE.

experimental manipulation in an experiment, the manipulation of one or more INDEPENDENT VARIABLES in order to investigate their effect on a DEPENDENT VARIABLE. An example would be the assignment of a specific treatment or PLACEBO to participants in a research study in order to control possible CONFOUNDs and assess the effect of the treatment.

experimental method a system of scientific investigation, usually based on a design to be carried out under controlled conditions, that is intended to test a hypothesis and establish a causal relationship between independent and dependent variables.

experimental neuropsychology the use of empirical methods to study the physiological structures and processes of the nervous system and their relationships to cognition and behavior. For example, an EXPERIMENTAL NEUROPSYCHOLOGIST might examine how different probes affect REMEMBERING memory performance in individuals with and without schizophrenia in order to identify which memory processes are most vulnerable to disruption in schizophrenia and to determine how people with the disorder can best remember. Experimental neuropsychology encompasses both healthy functioning and impairment in a variety of areas and relies on numerous techniques, such as laboratory research, NEUROPSYCHOLOGICAL TESTS, BRAIN IMAGING, ELECTROENCEPHALOGRAPHY, and qualitative analysis.

experimental neurosis a pathological condition induced in a nonhuman animal during conditioning experiments requiring discriminations between nearly indistinguishable stimuli or involving punishment for necessary activities (e.g., eating). Experimental neurosis may be characterized by a range of behavioral abnormalities, including agitation, irritability, aggression, regressive behavior, escape and avoidance, and disturbances in physiological activity such as pulse, heart, and respiration rates. For example, in one experiment a dog learned to salivate in the presence of a circle, which had been paired with food, but not in the presence of an ellipse, which had not been paired with food. Faced with a difficult discrimination, the dog became agitated, barked violently, and attacked the apparatus, and all simple discriminations that had been learned were lost.

experimental philosophy 1. in the late 17th and 18th centuries, a name for the new discipline of experimental science then emerging. Use of the term often went with an optimism about the ability of experimental science to answer the questions that had been posed but unsolved by “natural philosophy.” The systematic work of Isaac NEWTON is often given as a defining example of experimental philosophy. 2. a late 20th-century movement holding that modern experimental science, particularly neuroscience, will ultimately uncover the biological foundations of thought and thereby provide a material answer to the questions of EPISTEMOLOGY. In other words, experimental philosophy holds that answers to philosophical questions regarding the mind and its activities can, and likely will, be reduced to questions of how the brain functions. See REDUCTIONISM.

experimental psychology the scientific study of behavior, motives, or cognition in a laboratory or other controlled setting in order to predict, explain, or influence...
behavior or other psychological phenomena. Experimental psychology aims at establishing quantified relationships and explanatory theory through the analysis of responses under various controlled conditions and the synthesis of adequate theoretical accounts from the results of these observations. See also empirical psychology.

**Experimental realism** the extent to which a controlled study is meaningful and engaging to participants, eliciting responses that are spontaneous and natural. See also mundane realism.

**Experimental research** research utilizing randomized assignment of participants to conditions and systematic manipulation of variables with the objective of drawing causal inference. It is generally conducted within a laboratory or other controlled environment, which in reducing the potential influence of extraneous factors increases internal validity but decreases external validity. Compare correlational research; field research; quasi-experimental research.

**Experimental treatment** 1. in research, the conditions applied to one or more groups that are expected to cause change in some outcome or dependent variable. 2. an intervention or regimen that has shown some promise as a cure or ameliorative for a disease or condition but is still being evaluated for efficacy, safety, and acceptability.

**Experimental unit** the unit to which an experimental manipulation is applied. For example, if an intervention is applied to a classroom of students, the classroom (not the individual students) is the experimental unit. In quasi-experimental research and other nonexperimental contexts, the term unit of analysis is used instead.

**Experimental variable** an independent variable that is manipulated by the researcher to determine its relationship to or influence upon some outcome or dependent variable.

**Experimenter bias** any systematic errors in the research process or the interpretation of its results that are attributable to a researcher’s behavior, preconceived beliefs, expectancies, or desires about results. For example, a researcher may inadvertently cue participants to behave or respond in a particular way. See experimenter effect.

**Experimenter drift** a gradual and nonconscious change in the way a researcher conducts or interprets a controlled study, leading to systematic error in the results.

**Experimenter effect** any influence a researcher may have on the results of his or her research, derived from either interaction with participants or unintentional errors of observation, measurement, analysis, or interpretation. In the former, the experimenter’s personal characteristics (e.g., age, sex, race), attitudes, and expectations directly affect the behavior of participants. In the latter, the experimenter’s procedural errors (often arising from his or her expectations about results) have no effect on participant responses but indirectly distort the research findings.

**Experimenter expectancy effect** a type of experimenter effect in which a researcher’s expectations about the findings of his or her research are inadvertently conveyed to participants and influence their responses. This distortion of results arises from participants’ reactions to subtle cues (demand characteristics) unintentionally given by the researcher—for example, through body movements, gestures, or facial expressions—and may threaten the ecological validity of the research. The term is often used synonymously with Rosenthal effect.

**Experiment-wise alpha level** the significance level (i.e., the acceptable risk of making a type I error) that is established by a researcher for a set of multiple comparisons and statistical tests. It is often set at the conventional level of .05; by setting the alpha for individual tests (the testwise alpha level) at a lower rate (e.g., .01), it can be ensured that the whole set of tests does not produce error greater than the desired experiment-wise level.

**Experiment-wise error rate** in a test involving multiple comparisons, the probability of making at least one type I error over an entire research study. The experiment-wise error rate differs from the testwise error rate, which is the probability of making a type I error when performing a specific test or comparison.

**Expert authority** see authority.

**Expert fallacy** see false authority.

**Expertise** n. a high level of domain-specific knowledge and skills accumulated with age or experience.

**Expert–novice differences** the ways in which the performance of those skilled in a particular domain will typically differ from that of those who have no experience in that domain.

**Expert performance** the perception of small differences between two stimuli. For example, distinguishing between identical twins might require expert performance.

**Expert power** a capacity to influence others that is based on the assumption that the influencer is highly skilled.

**Expert system** a program, often mimicking expert problem-solving performance, that uses the explicit representation of human knowledge, usually in the form of “if then” rules. The expert system often employs a certainty-factor algebra to support reasoning in uncertain situations in which there are missing or vague data or unclear alternatives. Expert systems are used in such fields as medical diagnosis and financial prediction. Also called knowledge-based system (KBS).

**Expert testimony** evidence given in court by an expert witness. Unlike other testimony, this evidence may include the witness’s opinions about certain facts to help the trier of fact to make a decision. See opinion testimony; ultimate opinion testimony.

**Expert witness** an individual who is qualified to testify on scientific, technical, or professional matters and provide an opinion concerning the evidence or facts presented in a court of law. Eligibility to testify as an expert witness is based on the person’s special skills or knowledge as judged by the court. In U.S. federal courts, eligibility criteria are established by the Federal Rules of Evidence 702–706; see Daubert test. Mental health professionals often serve as expert witnesses in such cases as those involving insanity pleas and child custody.

**Expiatory punishment** a punishment in which the wrongdoer is made to suffer in proportion to the severity of the wrongdoing, but not necessarily in a way that reflects the nature of the transgression. Compare reciprocal punishment.

**Explained variance** the proportion of the variance in a dependent variable that can be determined or explained.
by one or more other variables. In ANALYSIS OF VARIANCE procedures, the explained variance usually is given by ETA SQUARED or OMEGA SQUARED, whereas in prediction methods, such as MULTIPLE REGRESSION, it usually is given by the COEFFICIENT OF MULTIPLE DETERMINATION. Explained variance also is applied in procedures such as PRINCIPAL COMPONENTS ANALYSIS or FACTOR ANALYSIS to describe the proportion of the variance in a measure that can be understood or predicted from a component or FACTOR. Compare ERROR VARIANCE.

explanation n. an account that provides a meaning for some phenomenon or event in terms of causal conditions, a set of beliefs or assumptions, or a metaphor that relates it to something already understood. See SCIENTIFIC EXPLANATION. —explanatory adj.

explanatory research a study conducted to assess why a particular finding occurred. For example, one might conduct explanatory research to determine why individuals who have been abused as children tend to be at higher risk for negative outcomes as adults. Compare PREDICTIVE RESEARCH.

explanatory style an individual’s unique way of describing and explaining some phenomenon, event, or personal history.

explanatory variable see INDEPENDENT VARIABLE.

explant n. a small piece of tissue that is isolated from the body and grown in an artificial medium, often for experimental purposes.

explicit attitude a relatively enduring and general evaluative response of which a person is consciously aware. Compare IMPLICIT ATTITUDE.

explicit attitude measure any procedure for evaluating attitudes in which a person is consciously aware of the fact that his or her attitude toward something or someone is being assessed. Measures of this type are generally DIRECT ATTITUDE MEASURES. Compare IMPLICIT ATTITUDE MEASURE.

explicit behavior see OVERT BEHAVIOR.

explicit emotion regulation see EMOTION REGULATION.

explicit memory long-term memory that can be consciously recalled: general knowledge or information about personal experiences that an individual retrieves in response to a specific need or request to do so. This term, proposed in 1985 by Canadian psychologist Peter Graf and U.S. psychologist Daniel L. Schacter (1952– ), is used interchangeably with DECLARATIVE MEMORY but typically with a performance-based orientation—that is, a person is aware that he or she possesses certain knowledge and specifically retrieves it to complete a task overtly eliciting that knowledge (e.g., a multiple-choice exam). Compare IMPLICIT MEMORY.

explicit memory test a memory test that elicits conscious memories of previously experienced events. Such tests (e.g., FREE RECALL, RECOGNITION METHOD) include explicit instructions to participants to recall earlier events. Also called direct memory test. Compare IMPLICIT MEMORY TEST. See also CONCEPTUAL TEST; PERCEPTUAL TEST.

explicit prejudice a negative attitude against a specific social group that is consciously held, even if not expressed publicly. The person is thus aware of and can report on this type of prejudice, typically via questionnaires that require participants to indicate whether they agree or disagree with the statements presented. Compare IMPLICIT PREJUDICE.

explicit process a COGNITIVE PROCESS that can be described accurately and that is available to introspection. Compare IMPLICIT PROCESS.

exploitative orientation in the existential psychoanalysis of Erich FROMM, a character pattern marked by the use of stealth, deceit, power, or violence to obtain what the individual wants. The character type is plagiaristic rather than spontaneously or resourcefully creative. Also called exploitative character. Compare HOARDING ORIENTATION; MARKETING ORIENTATION.

exploratory behavior the movements made by human beings or other animals in orienting to new environments. Exploratory behavior occurs even when there is no obvious biological reward associated with it. A lack of such behavior in a new environment is often used as a measure of fearfulness or emotionality. See also DIVERSE EXPLORATION; INSPECTIVE EXPLORATION.

exploratory data analysis (EDA) the analysis of data to generate new research questions or insights rather than to address specific preplanned research questions. Compare CONFIRMATORY DATA ANALYSIS.

exploratory drive the motivation that compels an organism to examine its environment. The exploratory drive may be secondary to other drives, such as fear or hunger leading to exploration. Alternatively, EXPLORATORY BEHAVIOR may be a separate and independent drive. Also called exploration drive. See also CURIOSITY.

exploratory factor analysis (EFA) a method for finding a small set of underlying dimensions from a large set of related measures. The observed data are freely explored in order to discover the underlying (latent) variables that explain the interrelationships among a larger set of observable (manifest) variables. For example, exploratory factor analysis has been conducted to assess whether there are one, two, or more dimensions underlying items used to assess intelligence. The analysis does not yield a unique solution: Although points are fixed in a multidimensional space of underlying factors, the axes according to which one should interpret the factors are not fixed and are infinite in number. These axes may be either ORTHOGONAL (producing uncorrelated factors) or OBLIQUE (producing correlated factors). Compare CONFIRMATORY FACTOR ANALYSIS.

exploratory procedure 1. a surgical procedure used to diagnose disease when less invasive methods are inconclusive. 2. a method used by people for feeling the surfaces of objects. People tend to modify their use of touch to optimize the acquisition of information. Thus, they may push on a surface to judge its hardness or stroke it with the index finger to perceive texture. [described in 1987 by Canadian psychologist Susan J. Lederman and U.S. psychologist Robert L. Klitzky (1947– )]

exploratory research a study that is conducted when not much is known about a particular phenomenon. In exploratory research, one typically seeks to identify multiple possible links between variables. In contrast, in CONFIRMATORY RESEARCH, one tests whether a specific prediction holds under specific circumstances.

explosive disorder see INTERMITTENT EXPLOSIVE DISORDER; ISOLATED EXPLOSIVE DISORDER.

explosive personality a personality with a pattern of
frequent outbursts of uncontrolled anger and hostility out of proportion to any provocation. See INTERRUMPTED EXPLOSIVE DISORDER.

exponent n. a number shown as a superscript of another number to indicate how many times the base number is to be multiplied by itself. For example, the base number 2 with an exponent of 3 (i.e., $2^3$) denotes the number formed by multiplying 2 by itself three times (i.e., $2 \times 2 \times 2 = 8$).

exponential curve a graph of a rapidly growing function in which the increase is proportional to the size of an x variable and the slope is equal to the value of the y variable.

exponential distribution a theoretical arrangement of survival times, used in parametric SURVIVAL ANALYSIS when the hazard rate is thought to be constant over time. It is a specific type of GAMMA DISTRIBUTION.

exponential function (exp) a mathematical expression of the type $y = e^x$, where $e$ is a constant. A particular type has the form $y = e^x$, where $e$ is a fundamental mathematical constant that is the base of natural logarithms (with the value 2.718...). Often, functions of this type (e.g., $e^{ax}$) are written as $\exp(x + a)$.

ex post facto design research that examines past occurrences in order to understand a current state. Although this type of design involves both a DEPENDENT VARIABLE and an INDEPENDENT VARIABLE, the investigator cannot manipulate the latter. For example, a researcher who is interested in determining the effectiveness of a particular television advertisement on consumer behavior may recruit a group of participants who saw the advertisement and a group of participants who did not, yet the researcher has no control over which specific people actually viewed the advertisement. Also called ex post facto study. [from Latin ex post facto, “after the event”]

ex post facto evaluation see SUMMATIVE EVALUATION.

exposure and response prevention (ERP, EX/RP) an intensive form of BEHAVIOR THERAPY for OBSESSIVE-COMPULSIVE DISORDER, involving exposure to situations or cues that trigger recurrent, intrusive, and distressing thoughts (obsessions) or provoke repetitive behaviors (compulsions), followed by abstinence from the compulsive behavior. Typically, exposures are conducted in a graduated fashion, with moderately distressing situations confronted before more upsetting ones. For example, for a person who fears contact with dirt and germs and repeatedly washes throughout the day, ERP might involve the therapist asking the client first to touch doorknobs and then a well-traveled floor, then to sit on a public toilet seat, and so forth without engaging in compulsive cleaning behavior. An alternative method is flooding, in which therapy is started with the most feared situation. Regardless of the approach taken, the exposure exercises are performed multiple times until the client’s emotional responses no longer occur or are greatly diminished. Therapists conducting ERP do not, however, actually prevent clients from engaging in compulsive rituals. Instead, they encourage the client to remain in the fear-evoking situation until the urge to perform a ritual decreases noticeably. Empirically demonstrated to be highly effective, ERP is the most commonly used treatment for obsessive-compulsive disorder and has been extended to other conditions as well (e.g., phobias). Also called exposure and ritual prevention: response prevention.

exposure deafness loss of hearing due to prolonged exposure to loud sounds. The condition may be temporary or permanent, depending upon the loudness, length of exposure, and sound frequencies. See also AUDITORY FATIGUE.

exposure therapy a form of BEHAVIOR THERAPY that is effective in treating anxiety disorders. It involves systematic and repeated confrontation with a feared stimulus, either in vivo (live) or in the imagination, and may encompass any of a number of behavioral interventions, including DESENSITIZATION, FLOODING, IMPLOSIVE THERAPY, and extinction-based techniques. It works by (a) HABITUATION, in which repeated exposure reduces anxiety over time by a process of EXTINCTION; (b) disconfirming fearful predictions; and (c) increasing feelings of self-efficacy and mastery.

expressed emotion (EE) negative attitudes, in the form of criticism, hostility, and emotional overinvolvement, demonstrated by family members toward a person with a mental disorder. High levels of expressed emotion have been shown to be associated with poorer outcomes in mood, anxiety, and schizophrenic disorders and an increased likelihood of relapse. [first described in 1972 by British psychiatrists (George W. Brown (1930– )) James L. T. Birley, and John K. Wing]
extended care a service provided at a residential facility where 24-hour nursing care and rehabilitation therapy are available, usually following an acute hospitalization. A facility that provides such a service is known as an extended care facility (ECF). See also CONTINUING CARE UNIT; SKILLED NURSING FACILITY.

extended Cox regression model see COX REGRESSION ANALYSIS.

extended family 1. a family unit consisting of parents and children living in one household with other individuals united by kinship (e.g., grandparents, cousins). 2. in modern Western societies, the nuclear family together with various other relatives who live nearby and keep in regular touch. 3. most generally, any family members beyond the nuclear family (e.g., grandparents, cousins, aunts, uncles). Also called consanguineous family

extended-family therapy GROUP THERAPY involving not only the nuclear family but also other family members, such as aunts, uncles, grandparents, and cousins.

extended-release preparation see SLOW-RELEASE PREPARATION.

extended-stay review a review of a continuous hospital stay that has equaled or exceeded the period defined by a hospital or third-party UTILIZATION REVIEW. See also CONTINUOUS-STA Y REVIEW.

extended suicide MURDER-SUICIDE in which both the murder and the suicide reflect the suicidal process. The individual first kills those perceived as being a part of his or her identity or extended self and then commits suicide.

extension n. the straightening of a joint in a limb (e.g., the elbow joint) so that two parts of the limb (e.g., the forearm and upper arm) are drawn away from each other.

extensional meaning the meaning of a word or phrase as established by a list of the individual instances to which it applies. For example, the extensional meaning of the word "dog" is established by the list of individual dogs. Compare INTENSIONAL MEANING.

extension reflex any reflex action that causes a limb or part of a limb to move away from the body. Extension reflexes include the EXTENSOR THRUST, STRETCH REFLEXES, and CROSSED-EXTENSION REFLEXES. Compare FLEXION REFLEX.

extensor n. a muscle whose contraction extends a part of the body; for example, the triceps muscle group extends, or straightens, the arm. Compare FLEXOR.

extensor motor neuron a motor neuron whose fibers connect with extensor muscles that extend a part of the body by contracting.

extensor posturing see DECEREBRATE RIGIDITY.

extensor rigidity rigid contractions of extensor muscles. The kind of rigidity sometimes indicates the site of the motor neuron lesion associated with the disorder. Injury to the cerebellum produces increased tone of extensor muscles, called cerebellar rigidity. See also DECEREBRATE RIGIDITY.

extensor thrust a reflex extension of the leg caused by applying a stimulus to the sole of the foot. The reflex normally occurs each time a person takes a step in walking or running, signaling a need for body support and providing the thrust for taking the next step. See also STRETCH REFLEX.

exteriorization n. 1. the act of relating one's inner feelings and attitudes to external, objective reality. 2. the outward expression of one's private and personal ideas.

external aim see OBJECT OF INSTINCT.

external attribution see SITUATIONAL ATTRIBUTION.

external auditory meatus the canal that conducts sound through the external ear, from the pinna to the tympanic membrane (eardrum). Also called auditory canal: ear canal.

external boundary in psychoanalytic theory, the boundary between the EGO and external reality, as opposed to the INTERNAL BOUNDARY between the ego and ID.

external capsule a thin layer of myelinated nerve fibers separating the CLAUSRUM from the PUTAMIN. See also EXTREME CAPSULE; INTERNAL CAPSULE.

external chemical messenger (ECM) an ODORANT or other substance that is secreted or released by an organism and influences other organisms. PHEROMONES are examples.

external control see LOCUS OF CONTROL.

external ear the part of the ear consisting of the PINNA, the EXTERNAL AUDITORY MEATUS, and the outer surface of the eardrum (see TYPANIC MEMBRANE). Also called outer ear.

external evaluator an individual conducting a PROGRAM EVALUATION who is not a regular full-time employee of the program being evaluated. Such an evaluation is considered more objective and potentially less biased than one produced by an INTERNAL EVALUATOR. External agents are often preferred for SUMMATIVE EVALUATIONS, with possible highly visible consequences, to ensure the validity and credibility of the results.

external fertilization see FERTILIZATION.

external genitalia see GENITALIA.

external granular layer see CORTICAL LAYERS.

external inequity the situation in which employers compensate employees at levels that are unfair in relation to the levels of compensation they would receive from other comparable employers. Compare INEQUITABLE. See EQUITY THEORY.

externality effect the tendency of very young infants to direct their attention primarily to the outside of a figure and to spend little time inspecting internal features. The externality effect appears to diminish after the age of 1 month. [initially described in 1979 by I. W. R. Bushnell]

externalization n. 1. a DEFENSE MECHANISM in which one's thoughts, feelings, or perceptions are attributed to the external world and perceived as independent of oneself or one's own experiences. A common expression of this is PROJECTION. 2. the process of learning to distinguish between the self and the environment during childhood. 3. the process by which a drive, such as hunger, is aroused by external stimuli, such as food, rather than by internal stimuli.

externalizing–internalizing a broad classification of children's behaviors and disorders based on their reactions to stressors. Externalizing behaviors and disorders are characterized primarily by actions in the external world, such as acting out, antisocial behavior, hostility, and aggression. Internalizing behaviors and disorders are characterized primarily by processes within the self, such as...
external locus of control

anxiety, somatization, and depression. See also child behavior checklist. [proposed by U.S. psychologist Thomas M. Achenbach (1940– )]

external locus of control see locus of control.

external pyramidal layer see cortical layers.

external rectus see lateral rectus.

external reliability the extent to which a measure is consistent when assessed over time or across different individuals. External reliability calculated across time is referred to more specifically as retest reliability; external reliability calculated across individuals is referred to more specifically as Interrater reliability.

external respiration see respiration.

external validity the extent to which the results of research or testing can be generalized beyond the sample that generated them. For example, if research has been conducted only with male participants, it cannot be assumed that similar results will apply to female participants. The more specialized the sample, the less likely will it be that the results are highly generalizable to other individuals, situations, and time periods. Compare internal validity.

external world the world of real existing things external to and independent of human consciousness. The question of how one can have knowledge of such a world, or even be sure that such a world exists, has been fundamental to philosophy since the time of Rene Descartes. See absolute reality; objective reality. See also cartesian self; egocentric predication; solipsism.

exteroception n. sensitivity to stimuli that are outside the body, resulting from the response of specialized sensory cells called exteroceptors to objects and occurrences in the external environment. Exteroception includes the five senses of sight, smell, hearing, touch, and taste, and exteroceptors thus take a variety of forms (e.g., photoreceptors—retinal rods and cones—for sight; cutaneous receptors—Pacinian corpuscles, Meissner’s corpuscles, Merkel’s tactile disks—for touch). Compare interoception.

—exteroceptive adj.

exteroceptive stimulus a stimulus that arises in the external world and is sensed by an organism through any of the five senses of sight, smell, hearing, touch, and taste. Compare interoceptive stimulus; proprioceptive stimulus.

exteroceptor n. see exteroception.

extinction n. 1. in biology, the loss of a species or subspecies either completely or within a particular environment. For example, the passenger pigeon is globally extinct, and condors and whooping cranes were extinct in many places where previously they had been found but have been reintroduced after successful captive breeding. 2. see perceptual extinction. 3. in classical conditioning, (a) a procedure in which pairing of stimulus events is discontinued, either by presenting the conditioned stimulus alone or by presenting the conditioned stimulus and the unconditioned stimulus independently of one another; or (b) the result of this procedure, which is a gradual decline in the probability and magnitude of the conditioned response. 4. in operant conditioning, (a) a procedure in which reinforcement is discontinued, that is, the reinforcing stimulus is no longer presented; or (b) the result of this procedure, which is a decline in the rate of the formerly reinforced response. —extinguish vb.

extinction burst see burst.

extirpation n. see ablation.

extra- (extr-) prefix outside of or beyond (e.g., extrasensory perception).

extracellular space the fluid-filled space in an organism that lies outside the plasma membrane of cells.

extradural hemorrhage bleeding that occurs outside the dura mater, the outermost of the three protective membranes (meninges) that cover the brain. It usually involves a ruptured artery resulting from a severe head injury, such as a skull fracture. There may be a brief lucid period after the injury, then severe headaches, dizziness, confusion, loss of consciousness, and finally death if the hemorrhage is not controlled. Also called epidural hemorrhage.

extrafusal fiber any of the muscle fibers that lie outside muscle spindles and provide most of the force for muscle contraction. Compare intrafusal fiber.

extraneous variable a measure that is not under investigation in an experiment but may potentially affect the outcome or dependent variable and thus may influence results. Such potential influence often requires that an extraneous variable be controlled during research. See also confound.

extrapair mating in socially monogamous species, mating that occurs with individuals other than the mate. In many monogamous bird species, genetic evidence of paternity suggests extensive extrapair mating, with the result that many chicks are not sired by the male that cares for them. Extrapair mating might also occur at times when conception is not possible, either to test other potential mates or to strengthen social relationships with others. See also cuckoldry.

extrapolation n. the process of estimating or projecting unknown score values on the basis of the known scores obtained from a given sample. For example, a researcher might estimate how well students will do on an achievement test on the basis of their current performance, or estimate how well a similar group of students might perform on the same achievement test.

extrapsychic adj. pertaining to that which originates outside the mind or that which occurs between the mind and the environment. Compare intrapsychic.

extrapsychic conflict conflict arising between the individual and the environment, as contrasted with intrapsychic conflict.

extrapunitive adj. referring to the punishment of others: tending to direct anger, blame, or hostility away from the self toward the external factors, such as situations and other people, perceived to be the source of one’s frustrations. Compare intrapunitive.

extrapyramidal dyskinesia any of various distortions of voluntary movement (dyskinesias), such as tremors, spasms, tics, rigidity, or gait disturbances, associated with some lesion of the extrapyramidal tract. These dyskinesias can occur in neurological disorders or as a side effect of antipsychotic drugs, which produce such conditions as akathisia, acute dystonia, and tardive dyskinesia.

extrapyramidal symptoms (EPS) a group of adverse drug reactions attributable to dysfunction of the extrapyramidal tract, such as rigidity of the limbs, tremor, and
other Parkinson-like signs; dystonia (abnormal facial and body movements); and akathisia (restlessness). Extrapyramidal symptoms are among the most common side effects of the high-potency antipsychotics and have also been reported with use of other drugs (e.g., SSRIs). Also called extrapyramidal syndrome (EPS).

extrapyramidal tract a motor portion of the central nervous system that includes the basal ganglia and some closely related structures (e.g., the subthalamic nucleus) and descending pathways to the midbrain. It regulates muscle tone and body posture and coordinates opposing sets of skeletal muscles and movement of their associated skeletal parts. Also called extrapyramidal motor system; extrapyramidal system.

extrasensory perception (ESP) alleged awareness of external events by other means than the known sensory channels. It includes telepathy, clairvoyance, and precognition. Despite considerable research, the existence of any of these modalities remains highly controversial. Also called paranormal cognition. See parapsychology. [coined by German physician Gustav Pagenstecher (1855–1942) in his 1924 text, Ausserimlicher wahrnehmung (Extraromotional Perception); the English term was adopted in 1934 by Joseph B. Rhine].

extraspective perspective a methodological approach based on objective, empirical observation of actions and reactions, as contrasted with an introspective, first-person account of experience. The approach of behaviorism is based on an extraspective perspective.

extraspectral hue a hue composed of a mixture of wavelengths, and thus not falling along the visible spectrum (compare spectral color). Two examples are purple and white: Purple is a mixture of long and short wavelengths, whereas white is a mixture of all wavelengths. Also called nonspectral hue.

extrastriate cortex see prestriate cortex.

extrastriate visual area any of the visually responsive regions of cerebral cortex that are located outside the primary visual cortex (striate cortex), that is, in the prestriate cortex. Extrastriate visual areas include V2, V3, V4, and V5.

extraterrestrial kidnapping see alien abduction.

extraterine pregnancy see ectopic pregnancy.

extraversion (extroversion) n. one of the elements of the Big Five and five-factor personality models, characterized by an orientation of one’s interests and energies toward the outer world of people and things rather than the inner world of subjective experience. Extraversion is a broad personality trait and, like introversion, exists on a continuum of attitudes and behaviors. Extraverts are relatively outgoing, gregarious, sociable, and openly expressive. Extraversion is also one of the three personality dimensions in Eysenck’s dimensions. —extraversive adj. —extraverted adj. —extravert n.

extreme environments extreme living conditions (e.g., space habitats, polar regions, offshore oil platforms) as they affect human health and well-being. Salient issues in the analysis of extreme environments include privacy, crowding, social support, and levels of stimulation.

extremely low birth weight (ELBW) see low birth weight.

extremity of an attitude the extent to which a person’s evaluation of an attitude object deviates from neutrality. Extremity is related to attitude strength.

extrinsic eye muscles see eye muscles.

extrinsic motivation an external incentive to engage in a specific activity; especially motivation arising from the expectation of punishment or reward (e.g., completing a disliked chore in exchange for payment). Compare intrinsic motivation.

extrinsic reinforcement provision of a reward for performing an action, such as giving a child candy for reading. The reward itself is called an extrinsic reinforcer. Some evidence suggests that extrinsic reinforcement decreases later involvement in the action unless the reward is given only to induce interest. Compare intrinsic reinforcement.

extrinsic religion a religious orientation in which religiosity is largely a means to other ends, such as social morality or individual well-being, rather than an end in itself. Compare intrinsic religion. [introduced by Gordon W. Allport].

extrinsic reward a reward for behavior that is not a natural consequence of that behavior. For example, winning a trophy for finishing first in a race and receiving praise or money in the work setting are extrinsic rewards. Compare intrinsic reward.

extraversion see extraversion.

ex vivo referring to procedures taking place outside of a living organism. For example, during surgery an organ may be removed, treated ex vivo, and returned to the body. Ex vivo research uses living cells or tissue in a laboratory setting soon after their removal from the organism. These ex vivo cells or tissue are not necessarily cultured, as in in vitro experiments. Compare in vivo. [Latin, literally: “out of life”].

eye n. the organ of sight. The human eye is a layered, globular structure whose shape is maintained by fluid filling its interior. There are three layers: (a) the outer cornescleral coat, which includes the transparent cornea in front and continues as the fibrous sclera over the rest of the globe; (b) the middle layer, called the uveal tract, which includes the iris, the ciliary body, and the choroid layer; and (c) the innermost layer, the retina, which is sensitive to light. Retinal ganglion cells within the retina communicate with the central nervous system through the optic nerve, which leaves the retina at the optic disk. The eye has three chambers. The anterior chamber, between the cornea and the iris, and the posterior chamber, between the ciliary body, lens, and posterior aspect of the iris, are filled with a watery fluid, the aqueous humor. The anterior and posterior chambers are in continuity through the pupil. The third chamber, the vitreous body, is the large cavity between the lens and the retina filled with vitreous humor. See also eye muscles; visual system.

eye bank a repository for corneas or other parts of the
eye contact

human eye to be used for surgical transplantation in medically and immunologically appropriate recipients.

eye contact a direct look exchanged between two people who are interacting. Maintaining eye contact is considered essential to communication between therapist and client during face-to-face interviews. Social psychological studies of eye contact generally find that people look more at the other person when listening to that person than when they themselves are talking; that people tend to avoid eye contact when they are embarrassed; and that the more intimate the relationship, the greater the eye contact. Also called mutual gaze.

eye dominance a preference for using one eye rather than the other. Preference is often for the right eye and is caused mainly by the differential acuity of the two eyes.

eye–hand coordination the integration of visual information-processing skills and appropriate motor responses of the hands in grasping and exploring objects and performing specific tasks. By 6 months of age, most infants perform specific tasks. By 6 months of age, most infants get of an individual's visual fixations as he or she observes displays. See also EYE-MOVEMENT CAMERA.

eyesight sign a reaction of eyelid movement to the stimulus of stroking the eyelashes. It can be used as part of a diagnostic test for LOSS OF CONSCIOUSNESS due to a functional or psychogenic disorder. If the loss of consciousness is due to a neurological disease or injury, the reflex will not occur.

eyelid conditioning a procedure for studying CLASSICAL CONDITIONING in which the UNCONDITIONED STIMULUS (usually an electrical stimulus or a puff of air) elicits an eyelid reflex.

eye-movement camera a device that video-records eye movements to study rapid foveal fixations during perceptual, cognitive, or social information processing. See also EYE TRACKER.

eye-movement desensitization and reprocessing (EMDR) a treatment methodology used to reduce the emotional impact of trauma-based symptoms such as anxiety, nightmares, flashbacks, or intrusive thought processes. The client incorporates simultaneous visualization of the traumatic event while concentrating on the rapid lateral movements of a therapist’s finger. [developed in the late 1980s by U.S. psychologist Francine Shapiro]

eye movements movements of the eyes caused by contraction of the extrinsic eye muscles. These include movements that allow or maintain the fixation of stationary targets: SMOOTH-PIRUSUIT EYE MOVEMENTS; VERGECE movement; saccadic movements (see SACCACDE), and reflexive movements of the eyes, such as the OPTOKINETIC REFLEX and VESTIBULO-OCULAR REFLEX.

eye muscles 1. (extrinsic eye muscles) the muscles that move the eye within the eye socket. There are three pairs: (a) the SUPERIOR RECTUS and INFERIOR RECTUS, (b) the LATERAL RECTUS and MEDIAL RECTUS, and (c) the SUPERIOR OBlique and INFERIOR OBlique. 2. (intrinsic eye muscles) the muscles that move structures within the eye itself. They include the CILIARY MUSCLES, which alter the shape of the lens during ACCOMMODATION, and the muscles of the iris, which change the size of the pupil.

eye preference see DOMINANT EYE: EYE DOMINANCE.

eye-roll sign the tendency of the eyes to roll upward in their sockets during the onset of sleep: the eye roll can also occur when people close their eyes during hypnotic induction. It has been proposed that the degree of eye roll is an index of hypnotic suggestibility, though whether the eye roll is a correlate to or plays a causal role in suggestibility is unknown.

eye span see READING SPAN.

eye structure see EYE.

eye tracker a device that measures the successive targets of an individual’s visual fixations as he or she observes displays. See also EYE-MOVEMENT CAMERA.

eye–voice span in oral reading, the distance in terms of characters between the word being spoken and the word the eye is focused on. See also READING SPAN.

eyewitness memory an individual’s recollection of an event, often a crime or accident of some kind, that he or she personally saw or experienced. The reliability of eyewitness memory is a major issue in FORENSIC PSYCHOLOGY, given the existence of such phenomena as the MISINFORMATION EFFECT and WEAPON-FOCUS EFFECT.

eyewitness testimony evidence given under oath in a court of law by an individual who claims to have witnessed the facts under dispute.

EYM Project abbreviation for EARLY YEARS OF MARRIAGE PROJECT.

Eysenck Personality Inventory (EPI) a self-report personality test for use with adolescents and adults. It originally comprised 57 yes–no questions designed to measure two of EYSENCK’S DIMENSIONS—extraversion and neuroticism—and included a lie scale intended to detect response distortion. The EPI was revised and expanded following its initial publication in 1963 to become the Eysenck Personality Questionnaire (EPQ), the most recent version of which (the EPQ–R) includes 90 questions and measures the additional personality dimension of psychoticism. [Hans EYSENCK and British psychologist Sybil B. G. Eysenck]

Eysenck’s dimensions a system for classifying personality types in which individual differences are described according to three dimensions: PSYCHOTICISM, EXTRAVERSION, and NEUROTICISM (referred to as PEN). See also FACTOR THEORY OF PERSONALITY. [Hans Eysenck]
f in mathematics, symbol for FUNCTION.

f 1. in an ANALYSIS OF VARIANCE or an ANALYSIS OF COVARIANCE, an EFFECT SIZE index that represents the STANDARD DEVIATION of a set of group means divided by the average standard deviation of scores across the set of groups. Its value ranges from 0 to 1, with small, medium, and large effect size values suggested as .10, .25, and .40, respectively. 2. in a table or distribution, symbol for FREQUENCY. 3. in vision science, symbol for VERTICAL LENGTH.

F symbol for F RATIO.

F1 abbreviation for FIRST FILIAL GENERATION.

F2 abbreviation for second FILIAL GENERATION.

FA abbreviation for FACTOR ANALYSIS.

FAAH abbreviation for fatty acid amide hydrolase. See ENDOGENOUS CANNABINOID.

FABBS abbreviation for FEDERATION OF ASSOCIATIONS IN BRAIN AND BEHAVIORAL SCIENCES.

fabrication n. 1. the act of concocting or inventing a whole or part of a story, often with the intention to deceive. 2. a story concocted in this way.

fabulation n. random speech that includes the recounting of imaginary incidents by a person who believes these incidents are real. See also DELUSION. [first described by Adolf MEYER]

face-hand test a test of tactile extinction (see DOUBLE-SIMULTANEOUS TACTILE SENSATION) in which the examiner touches the individual’s face and the back of his or her hand at the same time.

face-ism n. the alleged tendency for advertisements and other visual media to represent men by their faces (symbolizing their intellectual nature) but women by their whole bodies (symbolizing their sensual nature). It is thus a form of SEXISM. —face-ist adj.

face perception neurocognitive processes involved in the recognition of individual faces and the interpretation of FACIAL EXPRESSION. Face perception is an early and highly developed human social skill. See also FACIAL ACTION CODING SYSTEM.

face recognition the identification of a specific face. A specialized face-recognition region in the temporal lobe has been demonstrated by brain imaging; injury to this region results in such deficits as PROSOPAGNOSIA, a failure to recognize previously familiar faces.

face saving an act in which one attempts to uphold one’s dignity, as by redressing a social blunder or compensating for a poor impression one has made. Face-saving behavior is an aspect of IMPRESSION MANAGEMENT. See also FACEWORK.

face-to-face group any group whose members are in personal contact and, as a result, are able to perceive each other’s needs and responses and carry on direct interaction. Examples include T-GROUPS and psychotherapy groups. Also called direct-contact group.

face-to-face interaction a direct encounter between two or more individuals, as opposed to one involving communication by writing, telephone, or some other medium or intercession by third parties.

face validity the apparent soundness of a test or measure. The face validity of an instrument is the extent to which the items or content of the test appear to be appropriate for measuring something, regardless of whether they actually are. A test with face validity, however, may lack EMPIRICAL VALIDITY.

facework n. 1. in social interactions, a set of strategic behaviors by which people attempt to maintain both their own dignity ("face") and that of the people with whom they are dealing. Facework strategies include politeness, deference, tact, avoidance of difficult subjects, and the use of half-truths and "white lies." The conventions governing facework differ widely between cultures. 2. formal face-to-face interactions between people engaged in business, politics, diplomacy, and other goal-directed activities. Such interactions may involve a certain amount of small talk and personal conversation as well as discussion of the official agenda.

Facial Action Coding System (FACS) a coding system for classifying facial expressions in terms of the movements of particular facial muscles, such as the orbicularis oculi (the muscle encircling each eye) and the zygomaticus major (the muscle pulling the corners of the lips upward). Elaborations of this system have been used in attempts to identify the emotional state of a person. True happiness, for example, is said to be indicated by contraction of the orbicularis oculi muscle, which is not under conscious control. Compare MAXIMALLY DISCRIMINATIVE FACIAL MOVEMENT CODING SYSTEM. See also DUCHENNE SMILE; FACIAL EXPRESSION. [first published in 1978 by U.S. psychologists Paul Ekman (1934— ) and Wallace V. Friesen (1933— )]

facial affect program a hypothetical set of central nervous system structures that accounts for the patterning of universal, basic facial expressions of emotion in humans. Such a program could provide the link between a specific emotion and a given pattern of facial muscular activity.

facial angle any of various angles that quantify facial protrusion, established by using a set of craniometric reference points, such as the juncture of the frontal and nasal bones, the foremost projection point of the chin, and the horizontal eye–ear plane.

facial disfigurement any distortion, malformation, or abnormality of facial features due to injury, disease, or congenital anomaly. Because of a common tendency to assign traits to individuals on the basis of their facial features, people with facial disfigurements are particularly vulnerable to social, psychological, and economic discrimination and unfavorable stress effects.

facial electromyography a technique for measuring the endogenous electrical activity of any muscle or muscle group in the face by the appropriate placement of electrodes (see ELECTROMYOGRAPHY). This procedure is usually carried out to detect subtle facial movements related to emotion or speech.
facial expression

facial expression a form of nonverbal signaling using the movement of facial muscles. An integral part of communication, facial expression also reflects an individual’s emotional state. Charles Darwin suggested that facial expressions are innate reactions that possess specific survival value; for example, a baby’s smile evokes nurturing responses in parents. Although controversial, this theory has been supported by cross-cultural research, which indicates that certain facial expressions are spontaneous and universally correlated with such primary emotions as surprise, fear, anger, sadness, and happiness. Display rules, however, can modify or even inhibit these expressions, as can physical conditions such as parkinsonism, which produces an expressionless, masklike countenance.

facial feedback hypothesis the hypothesis that sensory information provided to the brain from facial muscle movements is a major determinant of intrapsychic feeling states, such as fear, anger, joy, contempt, and so on. This idea was introduced by Charles Darwin and developed by Silvan S. Tomkins and Carroll E. Izard.

facial muscle any one of the numerous muscles in the human face that control not only functional movements (e.g., biting, chewing) but also a variety of facial expressions.

facial nerve the seventh cranial nerve, which innervates the facial musculature and some sensory receptors, including those of the external ear and the tongue. Also called cranial nerve VII. See greater superficial petrosal nerve.

-facient suffix making or causing.

faces n. facial characteristics, particularly those of an unusual nature or associated with a medical condition (e.g., Williams syndrome, parkinsonism). [Latin, “face”]

facilitated communication 1. communication that is made more effective or efficient (e.g., easier to understand, faster), often with the aid of a technological device or process. Examples include the captioning of TV broadcasts for the benefit of viewers with hearing loss (see closed-captioned television) and the use of speech synthesizers by people who are unable to talk. See also augmentative communication. 2. a controversial method of communication in which a person with a severe developmental disability (e.g., autism) is assisted by a facilitator in typing letters, words, phrases, or sentences on a keyboard. Facilitated communication involves a graduated manual prompting procedure, with the intent of supporting a person’s hand sufficiently to make it more feasible to strike the keys he or she wishes to strike, without influencing the key selection. The procedure is often claimed to produce unexpected literacy, revealed through age-normative or superior communication content, syntax, and fluency. Scientific research findings, however, indicate that the content of the communication is being determined by the facilitator via nonconscious movements. [developed in the 1970s by Australian educator Rosemary Crossley (1945– )]

facilitation n. 1. the strengthening or increased occurrence of a response resulting from environmental support for the response. See also social facilitation. 2. in neuroscience, the phenomenon in which the threshold for propagation of the action potential of a neuron is lowered because of repeated signals at a synapse or the summation of subthreshold impulses. 3. see occasion setting. —facilitate vb.

facilitative anxiety a level of anxiety that an individual (e.g., a musician, an athlete) perceives as assisting performance.

facilitator n. 1. a professionally trained or lay member of a group who fulfills some or all of the functions of a group leader. The facilitator encourages discussion among all group members, without necessarily entering into the discussion. 2. see facilitated communication.

FACM abbreviation for functional analytic causal model. FACS acronym for facial action coding system. fact finder see trier of fact.

factitious disorder in DSM–IV–TR, a disorder in which the patient intentionally produces or feigns physical or psychological symptoms solely so that he or she may assume the sick role. Physical symptoms may include pain, vomiting, blackouts, seizures, or infections (see münchausen syndrome). Psychological symptoms may include depression, suicidal thoughts following the (unconfirmed) death of a spouse, hallucinations, or delusions. DSM–5 defines the disorder similarly but divides it into two subtypes characterized by (a) the falsification of symptoms or induction of injury or disease imposed on oneself, and (b) the same deceptions or harm imposed on others (e.g., a dependent). The latter is a proxy disorder that is synonymous with münchausen syndrome by proxy. Compare malingerering. factitious disorder by proxy see münchausen syndrome by proxy.

fact memory memory for specific items of factual knowledge. Compare source memory.

factor n. 1. anything that contributes to a result or has a causal relationship to a phenomenon, event, or action. 2. an underlying influence that accounts in part for variations in individual behavior. 3. in analysis of variance and other statistical procedures, an independent variable. 4. in factor analysis, an underlying, unobservable latent variable thought (together with other factors) to be responsible for the interrelations among a set of variables. 5. in mathematics, a number that divides without remainder into another number.

factor analysis (FA) a broad family of mathematical procedures for reducing a set of interrelations among manifest variables to a smaller set of unobserved latent variables or factors. For example, a number of tests of mechanical ability might be intercorrelated to enable factor analysis to reduce them to a few factors, such as fine motor coordination, speed, and attention. See confirmatory factor analysis; exploratory factor analysis; principal components analysis.

factor-comparison method a method of evaluating jobs for the purpose of setting wage or salary levels in which positions are compared to certain benchmark jobs in terms of compensable job factors. The factors usually include mental requirements, skill requirements, physical requirements, responsibility, and working conditions. Compare classification method; hay method; job-component method; point method; ranking method. See job evaluation.

factorial analysis of covariance a statistical procedure to understand the effect on a dependent variable of two or more independent variables that are categorical in nature, plus one or more additional correlated variables
that are Quantitative in nature. For example, a researcher may use a factorial analysis of covariance to understand reading performance by examining the effect of phoneme training (i.e., yes vs. no) and gender (male vs. female), after taking into account the intelligence scores of the research participants.

Factorial analysis of variance a statistical procedure to understand the effect on a dependent variable that is Quantitative in nature of two or more independent variables that are Categorical in nature. For example, a health researcher may use a factorial analysis of variance to examine the effects of diet (e.g., high vs. low carbohydrates) and exercise (e.g., 3 hours per week vs. 1 hour per week) on weight.

Factorial design an experimental study in which two or more categorical variables are simultaneously manipulated or observed in order to study their joint influence (interaction effect) and separate influences (main effects) on a separate dependent variable. For example, a researcher could use a factorial design to investigate treatment type (e.g., new exercise procedure vs. traditional procedure) and age (<40 vs. >40). The primary advantages of factorial designs are that they allow for the evaluation of interrelationships and that they are more efficient than conducting multiple studies with one variable at a time. See also fractional factorial design: Two-by-two factorial design.

Factorial invariance the situation in which the pattern of factor loadings on a latent variable in a factor analysis remains identical from sample to sample. For example, if the same factor loading values were obtained for a measure of general intelligence whether a researcher tested men or women, the general intelligence test would be said to demonstrate factorial invariance by gender. In other contexts, factorial invariance is referred to more broadly as measurement invariance.

Factor loading in factor analysis, the correlation between a manifest variable and a latent variable (factor). The factor loading reflects the degree to which a manifest variable is said to be “made up of” the factor being examined.

Factor method any means by which latent variables (factors) are extracted or identified in factor analysis. Widely used factor methods include principal-components analysis, which seeks to find a set of linear combinations called components that help explain the correlations among variables; and principal-axis factor analysis, in which underlying dimensions or factors are sought to explain the correlations among variables after separating out communality and putting aside the error variance in a set of variables.

Factor of similarity see similarity.

Factor reflection changing the signs of a set of factor loadings from positive to negative, or vice versa. For example, researchers studying a newly revised scale to measure the positive emotion such as happiness might use factor reflection to change a negative sign on the factor loadings for positive items as well as to change a positive sign for sadness items. The resulting pattern of loadings thus shows positively focused items as having a positive sign and sadness-focused items as having a negative sign, such that the entire scale could accurately be said to measure the positive state of happiness.

Factor rotation in factor analysis, the repositioning of latent variables (factors) to a new, more interpretable configuration by a set of mathematically specifiable transformations. Factors initially are extracted to meet a mathematical criterion of maximal variance explanation, which often does not result in a scientifically meaningful representation of the data. Indeed, for any one factor solution that fits the data to a specific degree, there will exist an infinite number of equally good mathematical solutions. Thus, rotation is required to obtain a solution that is both mathematically viable and logically sound. See oblique rotation; orthogonal rotation.

Factor score an estimate of the quantitative value that an individual would have on a latent variable were it possible to measure this directly; the latent variable or factor is determined through factor analysis.

Factor theory in classical test theory, the supposition that a set of correlated variables can be reduced to a smaller set of underlying dimensions or factors. It follows that each person’s observed score can be represented by a factor loading times a factor plus error variance.

Factor theory of intelligence any of various theories postulating that intelligence consists of a number of latent variables (factors) that cannot be measured directly but whose existence is proposed on the basis of factor analysis; it is the individual’s ability in these factors that underpins his or her test scores. For example, a factor theory of intelligence might hold that underlying scores on the many different tests of intelligence are verbal and nonverbal factors.

Factor theory of personality an approach to the discovery and measurement of personality components through factor analysis. The components are identified primarily by a statistical study of the differences between people as revealed by tests covering various aspects of behavior. The factor-analytic method is central to such personality models as the Big Five personality model, Cattell’s personality trait theory, and Eysenck’s dimensions.

Fact retrieval the retrieval of a fact directly from long-term memory without using great mental effort.

Factual knowledge knowledge of specific factual items of information, without memory of when each fact was learned. Factual knowledge is technically referred to as semantic knowledge or generic knowledge.

Facultative polyandry see polyandry.

Faculty n. 1 generally, any intrinsic mental or physical power, such as reason, sight, or will. See also cognitive faculty. 2. the body of the teaching, research, and administrative staff of an educational institution.

Faculty psychology any approach to psychological issues based on the idea that mental processes can be divided into separate specialized abilities or powers, which can be developed by mental exercises in the same way that muscles can be strengthened by physical exercises. Faculty psychology was formulated in the 18th century by Scottish philosophers Thomas Reid (1710–1796) and Dugald Stewart (1753–1828), who held that will, judgment, perception, conception, memory, and so forth could be explained simply by referring to their active powers; for example, individuals remember because they possess the faculty of memory.
fad

fad n. an abrupt but short-lived change in the opinions, behaviors, or lifestyles of a large number of widely dispersed individuals. Preoccupations with new products, dances, television programs, and fashions can be considered fads when many people quickly embrace the trend but then lose interest just as rapidly. Fads often pertain to relatively trivial matters and thus disappear without leaving any lasting impact on society. Extremely irrational, expensive, or widespread fads are termed crazes.

fading n. in conditioning, the gradual changing of one stimulus to another, which is often used to transfer stimulus control. Stimuli can be faded out (gradually removed)—as in, for example, the gradual removal of extrinsic feedback so that an athlete becomes more dependent on sensory feedback while learning a skill—or faded in (gradually introduced).

FAE abbreviation for fetal alcohol effects (see FETAL ALCOHOL SYNDROME).

fail-safe adj. 1. describing or relating to a feature by which the failure of a component or subsystem of a machine or work system results in automatic shutdown or switch to a safer mode of operation. This fail-safe design reduces the chance that an operator will be exposed to hazards related to the malfunction or that machinery will be damaged. Fail-safe designs do not, however, reduce the likelihood of an accident or failure. See also EXCLUSION DESIGN; PREVENTION DESIGN. 2. more generally, having no or an extremely low probability of failure.

failure modes and effects analysis (FMEA) a method of qualitative safety or ACCIDENT ANALYSIS in which the components of a system are listed along with the possible safety consequences that may occur should each of them fail or should the system as a whole go into failure mode.

failure-to-inhibit hypothesis a theory of cognitive aging that attributes attention and memory problems in older adults to their increasing inability to select relevant information and suppress irrelevant information when performing a cognitive task. [developed by U.S.-born Canadian psychologist Lynn Ann Hasher (1944- ) and U.S. psychologist Rose T. Zacks (1941- )]

failure to thrive (FTT) significantly inadequate gain in weight and height by an infant. It reflects a degree of growth failure due to inadequate release of growth hormone and, despite an initial focus on parental neglect and emotional deprivation, is currently believed to have multifactorial etiology, including biological, nutritional, and environmental contributors. The condition is associated with poor long-term developmental, health, and socioemotional outcomes.

fainting n. see SYNCOPE.

faintness n. 1. absence of loudness, distinctness, or intensity, especially with reference to auditory stimuli. 2. a sudden sensation of dizziness and weakness. See SYNCOPE.

Fairbairnian theory the psychoanalytic concepts of British psychoanalyst W. Ronald D. Fairbairn (1889-1964), which form a part of OBJECT RELATIONS THEORY. Fairbairn saw personality structure developing in terms of object relationships rather than in terms of Sigmund Freud’s id, ego, and superego. Fairbairn proposed the existence of an ego at birth, which then splits apart during the paranoid-schizoid position to form the structures of personality. In response to frustrations and excitement experienced in the relationship with the mother, the infant’s ego is split into (a) the central ego, which corresponds to Freud’s concept of the ego; (b) the libidinal ego, which corresponds to the id; and (c) the antilibidinal ego, which corresponds to the superego.

fairness n. the equitable treatment of test takers in order to eliminate systematic variance in outcome scores among people with different racial or cultural experiences and other background influences. Fundamentally a sociocultural (rather than a technical) issue, fairness is a broad area encompassing quality management in test design, administration, and scoring; adequate coverage of relevant content; sufficient work to establish CONSTRUCT VALIDITY; equal learning opportunities and access to testing; and items measuring only the skill or ability under investigation without being unduly influenced by construct-irrelevant variance introduced through test-taker background factors. See also CULTURE-FAIR TEST.

faith n. unwavering loyalty, belief, and trust. See also RELIGIOUS FAITH. —faithful adj.

faithful participant a research participant who cooperates fully with the explicit and implicit wishes of the experimenter. Also called faithful subject.

faith healing 1. the treatment of physical or psychological illness by means of religious practices, such as prayer or “laying on of hands.” Adherents hold that this may be effective even when those being prayed for have no knowledge of the fact and no belief in the process themselves. Also called faith cure: religious healing: spiritual healing. 2. any form of unorthodox medical treatment whose efficacy is said to depend upon the patient’s faith in the healer or the healing process (see PLACEBO EFFECT). In such cases, any beneficial effects may be attributed to a psychosomatic process rather than a paranormal or supernatural one. See also MENTAL HEALING: PSYCHIC HEALING.

faking n. the practice of some participants in an evaluation or psychological test who either (a) “fake good” by choosing answers that create a favorable impression, as may occur, for example, when an individual is applying for a job or admission to an educational institution; or (b) “fake bad” by choosing answers that make them appear disturbed or incompetent, as may occur, for example, when an individual wishes to be exempted from military service or exonerated in a criminal trial. —fake vb.

fallacy n. 1. an error in reasoning or argument that leads to a conclusion that may appear valid but is actually invalid. A fallacy may be formal or informal. A formal fallacy involves a violation of a principle of formal logic. An informal fallacy leads to an invalid conclusion because it is misleading in its language or appears to apply to a situation when it does not really apply. See also EITHER-OR FALLACY: FALSE ANALOGY: FALSE AUTHORITY: FALSE CAUSE: HISTORICAL FALLACY. 2. more generally, any mistaken idea. —fallacious adj.

fallacy of personal validation see BARNUM EFFECT.

falling out a CULTURE-BOUND SYNDROME found in the United States and the Caribbean. Symptoms include sudden collapse, sometimes preceded by feelings of dizziness or “swimming” in the head. Although their eyes are usually open, patients claim to be unable to see them usually hear and understand what is occurring around them but feel powerless to move. The condition may be associated with CONVERSION DISORDER or DISASSOCIATIVE DISORDER. Also called blacking out.
falling sickness see EPILEPSY.

fallopian tube either of the slender fleshy tubes in mammals that convey ova (egg cells) from each ovary to the uterus and where fertilization may occur. [Gabriele Fallopius (1521–1562), Italian anatomist]
fallopian-tube pregnancy see TUBAL PREGNANCY.

false alarm in signal detection tasks, an incorrect observation by the participant that a signal is present in a trial when in fact it is absent. The false-alarm rate is the proportion of incorrect yes responses in such a task. See also SIGNAL DETECTION THEORY. Compare MISS.

false analogy a type of informal FALLACY or a persuasive technique in which the fact that two things are alike in one respect leads to the invalid conclusion that they must be alike in some other respect. For example, The brain is in some respects like a computer; Computers receive and store input in discrete bits; Therefore, ideas in the brain are formed from discrete bits of information. See ANALOGY.

false authority a type of informal FALLACY or a persuasive technique in which it is assumed that the opinions of a recognized expert in one area should be heeded in another area. For example, Mr. X should know how to deal with government deficits because he is a successful businessman. Also called expert fallacy.

false belief a mental proposition that is asserted with high confidence but lacks a basis in reality.

false-belief task a type of task used in THEORY OF MIND studies in which children must infer that another person does not possess knowledge that they possess. For example, children shown that a candy box contains pennies rather than candy are asked what someone else would expect to find in the box. Children of about 3 years or younger would say pennies, whereas older children would correctly reply candy.

false cause a type of informal FALLACY or a persuasive technique in which a temporal sequence of events is assumed to be a causal sequence of events. Thus, because B follows A, A is considered the cause of B. For example, Because Smith became angry after being frustrated, Smith’s frustration caused Smith’s anger. See also CAUSAL ORDERING; REVERSE CAUSALITY.

false-consensus effect the tendency to assume that one’s own opinions, beliefs, attributes, or behaviors are more widely shared than is actually the case. A robustly demonstrated phenomenon, the false-consensus effect is often attributed to a desire to view one’s thoughts and actions as appropriate, normal, and correct. Compare FALSE-UNIQUENESS EFFECT.

false dementia a condition that mimics the symptoms of dementia but is a normal response to certain environmental conditions, such as sensory deprivation, restricted movement, or institutionalization with prolonged administration of medication.

false detection the incorrect detection of a signal in the presence of NOISE. See also FALSE ALARM.

false memory a distorted recollection of an event or, most severely, recollection of an event that never actually happened. False memories are errors of commission, because details, facts, or events come to mind, often vividly, but the recollections fail to correspond to prior events. Even when people are highly confident that they are remembering “the truth” of the original situation, experi-
falsificationism

Karl Popper (1902–1994) argued that falsifiability is an essential characteristic of any genuinely scientific hypothesis. Also called disconfirmability, refutability. See RISKY PREDICTION. —falsifiable adj.

falsificationism n. the position that (a) the disproving, rather than proving, of hypotheses is the basic procedure of scientific investigation and the chief means by which scientific knowledge is advanced; and (b) falsifiability is the property that distinguishes scientific claims from truth claims of other kinds, such as those of metaphysics or political ideology. [introduced by Austrian-born British philosopher Karl Popper (1902–1994)] —falsificationist adj.

familial dysautonomia an autosomal recessive disorder (see RECESSIVE ALLELE) affecting nerve function throughout the body and characterized by insensitivity to pain, feeding difficulties, seizures, deficient tear production, excessive sweating, drooling, and blotchy skin. Mental impairment may be associated with the disorder, but most patients have normal intelligence. Also called Riley–Day syndrome.

familial factor an element or condition in a family that accounts for a certain disease, disorder, or trait. A familial factor may or may not be inherited.

familial Portuguese polyneuritic amyloidosis see ANDRADE’S SYNDROME.

familial tremor see ESSENTIAL TRIMOR.

familial Turner syndrome see ESSENTIAL TRIMOR.

familiar n. in folklore and DEMONOLOGY, a supernatural spirit that supposedly lives with somebody and acts as a servant, often taking the form of an animal (e.g., a witch’s cat).

familiarity n. a form of remembering in which a situation, event, place, person, or the like provokes a subjective feeling of recognition and is therefore believed to be in memory, although it is not specifically recalled.

familism n. a cultural value common in collectivist or traditional societies that emphasizes strong interpersonal relationships within the EXTENDED FAMILY, together with interdependence, collaboration, and the placing of group interests ahead of individual interests. —familistic adj.

family n. 1. a kinship unit consisting of a group of individuals united by blood or by marital, adoptive, or other intimate ties. Although the family is the fundamental social unit of most human societies, its form and structure vary widely. See BIOLOGICAL FAMILY; EXTENDED FAMILY; NUCLEAR FAMILY; PERMEABLE FAMILY; STEPFAMILY. 2. in BIOLOGICAL TAXONOMY, a main subdivision of an ORDER, consisting of a group of similar, related genera (see GENUS). 3. a collection of mathematically or statistically related entities. For example, a set of statistical tests conducted when there are more than two groups for an INDEPENDENT VARIABLE within a DESIGN OF EXPERIMENT constitutes a family of tests. See also FAMILY-WISE ALPHA LEVEL; FAMILY-WISE ERROR RATE. —familial adj.

Family and Medical Leave Act see FAMILY LEAVE.

family bed see BED-SHARING.

family constellation the total set of relationships within a particular family, as characterized by such factors as the number and birth order of members and their ages, roles, and patterns of interaction. The term is associated with Alfred ADLER.

family counseling counseling of parents or other family members by psychologists, social workers, licensed counselors, or other professionals, who provide information, emotional support, and practical guidance on problems faced in the family context, such as raising a child who is disabled, family planning, or substance abuse. See also GENETIC COUNSELING.

family dynamics see INFRAFAMILY DYNAMICS.

family group psychotherapy therapeutic methods that treat a family as a system rather than concentrating on individual family members. The various approaches may be psychodynamic, behavioral, systemic, or structural, but all regard the interpersonal dynamics within the family as more important than individual intrapsychic factors.

family interaction method a study technique for investigating family behavior by observing the interaction of its members in a controlled situation, such as a clinic or laboratory.

family intervention 1. a synonym for FAMILY THERAPY. 2. an intervention taught by a therapist to one family member (e.g., parent) who then delivers the intervention to another family member (e.g., child) in the home. It is frequently used as an early intervention for a variety of disorders, such as autism, attention-deficit/hyperactivity disorder, speech and language pathology, and disruptive behavior disorders. 3. see INTERVENTION.

family leave time off (paid or unpaid) from work to address family responsibilities, such as the birth or adoption of a child or the care of an immediate family member with a serious health condition. In the United States, the FAMILY AND MEDICAL LEAVE ACT of 1993 provides eligible full-time employees with up to 12 weeks of unpaid, job-protected leave per year. Globally, the majority of developed countries have legislated parental leave policies with varying periods of paid time off to care for children after birth.

family life cycle the series of stages that occur in the life history of any given family, with such stages typically including marriage (or coupling), raising children to independent young adulthood, and retirement.

family life education any initiative or effort intended to ameliorate widespread societal issues by fostering healthy relationships within families. The approach is preventive; it provides family members at risk of various problems (e.g., substance abuse, domestic violence, teenage pregnancy, school or career failure) with information and resources to encourage, for example, good communication, strong decision-making and problem-solving skills, positive self-esteem, and understanding of others’ differences and respect for their points of view. For example, a family life education program for stepfamilies might use behavior-modeling videos to demonstrate effective parenting practices, and a program for low-achieving students in families might use a job-shadowing exercise to aid in vocational planning. Professionals in the field, known as family life educators, are not licensed but may be certified from any of several organizations worldwide.

family mediation a structured process in which a neutral third party, typically an attorney or a mental health practitioner with training in negotiation, helps individuals or families to resolve conflicts and reach agreements in such areas as divorce and child custody.

family medicine the practice of treating a wide variety
of illnesses and disorders in individuals and family members of all ages. Physicians now specializing in this area (called family practice doctors) must first undergo special training and become certified or board-eligible in family medicine in order to practice; such requirements did not apply until the 1970s. Family physicians trained before family medicine became a certifiable specialty are usually called general practitioners or GPs (labels sometimes also used by osteopaths). Both types of family physician are considered primary care providers.

family mythology the shared stories, norms, and beliefs within a family system. The mythology can be used to deny trauma or pathology within the family or to ascribe meaning to events in ways that suggest their inevitability or importance.

family of origin the family in which an individual was raised, which may or may not be the individual’s biological family.

family pattern a characteristic quality of the relationship between the members of a particular family (e.g., between parents and children). Family patterns vary widely in emotional tone and in the attitudes of the members toward each other. Some families are warm, others cool; some are extremely close and symbiotic, in others the members keep each other at a distance; some are open to friends and relatives, others are not; in some, one or more children are accepted and loved, in others one or more children are distanced or otherwise rejected. Such patterns or elements of such patterns may range from nonconscious to fully realized. See also pathogenic family pattern.

family planning controlling the size of the family, especially through the use of birth-control measures for determining the number and spacing of children. See also population research.

family psychology a basic and applied specialty in psychology that focuses on interactions within the family and developmentally influential contexts (e.g., neighborhoods, schools). Research and clinical intervention in this specialty are taught in doctoral psychology programs, either within a specified family curriculum or more often within broader programs, such as clinical research and applied clinical and counseling programs.

family resemblance in studies of categorization, the idea that a set of instances may form a category or give rise to a concept even though there is no single attribute common to all the instances: It is sufficient that each instance have one or more attributes in common with one or more other instances. The members of the category that have the most attributes in common with other members are said to have the highest family resemblance. The category prototype will be based on those members with the highest family resemblance and the lowest resemblance to members of other categories. See also disjunctive concept.

family romance a common childhood fantasy in which a child imagines that he or she is the offspring not of his or her biological parents but of a noble or royal personage. Sigmund Freud saw this as rooted in the Oedipus complex. See foster-child fantasy.

family sculpting a technique in family therapy in which the therapist asks one or more members of the family to arrange the other members (and lastly themselves) in relation to one another in terms of posture, space, and attitude so as to portray the arranger’s perception of the family, either in general or with regard to a particular situation or conflict. This technique often reveals family dynamics visually in a way that may not be adequately captured in verbal descriptions by family members.

family study research conducted among siblings, parents, or children to assess evidence for genetic links for characteristics or outcomes, often related to health or disease. For example, a family study might be conducted to assess whether individuals from the same family who share a similar genetic structure also have similar responses to a health-promotion intervention such as diet, exercise, or medication. The extent to which performance on a given measure varies as a function of genetic similarity is used as an indication of the heritability of that measure.

family support services periodic services provided to families of a person with a disability or chronic illness for the purpose of enhancing their ability to care for the person or alleviating stress associated with family living. Examples include day and overnight respite care, caregiver training and education, behavioral consultation, transportation to appointments, and sibling services (e.g., counseling).

family systems theory a broad conceptual model that focuses on the relationships between and among interacting individuals in a family and combines core concepts from general systems theory, cybernetics, family development theory, object relations theory, and social learning theory. Underlying various family therapies, the theory stresses that therapists must see the whole family, rather than work only with individual members, to create constructive, systemic, and lasting changes in the family. Also called Bowen family systems theory, family systems model. [developed by U.S. psychiatrist Murray Bowen (1913–1990)].

family therapy a form of psychotherapy that focuses on the improvement of intrafamilial relationships and behavioral patterns of the family unit as a whole, as well as among individual members and groupings, or subsystems, within the family. Family therapy includes a large number of treatment forms with diverse conceptual principles, processes and structures, and clinical foci. Some family therapy approaches (e.g., object relations theory) reflect extensions of models of psychotherapy with individuals in the interpersonal realm, whereas others (e.g., structural family therapy) evolved in less traditional contexts. Most approaches emphasize contexts in which clinical problems arise. This accompanying systemic view potentially allows clinical attention to all levels of the organization of behavior, from the individual, to the family, and to the community. Family therapy models vary enormously in terms of length, past versus present orientation, techniques used, and treatment goals. See also conjoint therapy; couples therapy; family group psychotherapy; family systems theory.

family values moral and social values attributed to the traditional nuclear family. In some Christian contexts, for example, these typically include discipline, respect for authority, heterosexual identity, and sexual abstinence outside marriage. The term is now primarily associated with political or religious conservatism.

family-wise alpha level a set value of the probability of making a type I error when carrying out a set of hypothesis tests (e.g., when conducting multiple compari-
family-wise error rate

SONS within a data set). In many studies, family-wise alpha is kept at .05, such that there is only a 5% total chance of rejecting a NULL HYPOTHESIS when it should be retained over a set of tests.

family-wise error rate the probability of making a TYPE I ERROR when conducting MULTIPLE COMPARISONS among groups within a data set. Although similar to the FAMILY-WISE ALPHA LEVEL, which is a predetermined probability value to keep the amount of FALSE-POSITIVE errors at a manageable level, the family-wise error rate is assessed after a set of hypothesis tests have been conducted. Researchers often like to keep this value at .05. See also TEST-WISE ERROR RATE.

fan n. a trade name for ILOPERIDONE.

fanaticism n. excessive and often irrational zeal or devotion to a cause or set of beliefs. —fanatic adj., n.

fan effect the finding that as the number of relations between one concept and others increases, the time required to make a decision about one of those relations increases. For example, if John has one brother and Bill has six, it would take longer to verify that Joe is Bill’s brother than it would to verify that Ted is John’s brother.

fantasy n. 1. any of a range of mental experiences and processes marked by vivid imagery, intensity of emotion, and relaxation or absence of logic. Fantasizing is normal and common and often serves a healthy purpose of releasing tension, giving pleasure and amusement, or stimulating creativity. It can also be indicative of pathology, as in delusional thinking or significant disconnection from reality.

fast mapping the ability of young children to learn new words quickly on the basis of only one or two exposures to the words. See also QUINIAN BOOTSTRAPPING. [coined in 1978 by U.S. developmental psychologist Susan E. Carey (1942—) and Elsa Bartlett]

fast muscle fiber a type of muscle fiber found in SKELETAL MUSCLE that contracts rapidly but fatigues readily. Compare SLOW MUSCLE FIBER.

fat n. a mixture of lipids, mainly triglycerides, that is typically solid at room temperature. In mammals (including humans), it serves as the most concentrated store of food energy and is deposited primarily beneath the skin and around certain organs. In many animals, it also serves as a primary source of insulation. See ADIPOSE TISSUE; BROWN FAT; FAT METABOLISM.

fatal familial insomnia a genetic disorder caused by a mutation of the PRION protein in the brain. It affects the thalamus, causing progressive insomnia and eventually dementia; death occurs about 18 months after onset of symptoms.

fatalistic suicide one of four types of suicide proposed in 1897 by Émile DURKHEIM, involving excessive social regulations that restrict individuation. Feeling controlled by the values and norms of society, the person becomes hopeless and despair of ever escaping these oppressive external forces. Durkheim associated fatalistic suicide with preindustrial social orders, citing suicides of slaves and of older childless married women as examples, and believed it to be of little contemporary relevance. Indeed, fatalistic suicide often is omitted from modern discussions of Durkheim’s ty-
fat cell see adipocyte.
fate control the circumstance in which a person or group has absolute control over the fate or outcomes of another person or group. Fat control exists when the other’s behavior plays no role in determining what outcomes are to be received. This is in contrast to behavior control, in which the other’s behavior does affect outcomes and the other is induced to behave in the desired direction. Fate control can, under certain circumstances, induce learned helplessness. [introduced by Harold H. Kelley and John W. Thibaut in their Interdependence Theory]
fate neurosis in psychoanalytic theory, a compulsive, unconscious, and self-punitive need to arrange life experiences in such a way that failure and defeat are inevitable.
father figure see father surrogate.
father fixation in psychoanalytic theory, an abnormally strong emotional attachment to the father.
father-ideal n. in psychoanalytic theory, the father component of the ego-ideal, which is formed through identification with the parents.
father surrogate a substitute for a person’s biological father, who performs typical paternal functions and serves as an object of identification and attachment. Father surrogates may include such individuals as adoptive fathers, stepfathers, older brothers, teachers, and others. Also called father figure: surrogate father.
fatigability n. the susceptibility of an organ or an individual to fatigue, as compared with other organs or individuals.
fatigue n. 1. a state of tiredness and diminished functioning. Fatigue is typically a normal, transient response to exertion, stress, boredom, or inadequate sleep but also may be unusually prolonged and indicative of disorder (e.g., chronic fatigue syndrome, anemia, hypothyroidism). 2. reduced response of a receptor cell or sense organ resulting from excessive stimulation.
fatigue checklist a list of symptoms and causes of fatigue developed to assess a person’s ability to carry out a job or task safely. Fatigue checklists may survey lack of energy, poor endurance, difficulty concentrating, muscle weakness, moodiness, number of hours worked, difficulty of work, and so on. They have been developed for nurses, drivers of heavy vehicles, soldiers, and pilots, among others.
fatigue effect a decline in performance on a prolonged or demanding research task that is generally attributed to the participant becoming tired or bored with the task. The fatigue effect is an important consideration when administering a lengthy survey or test in which participants’ performance may worsen simply due to the challenges of an extended task.
fatigue studies research on factors that cause both mental and physical fatigue, such as job stress, caregiving, chronic illness, and ergonomic design.
fat metabolism all the biochemical processes involved in the breakdown, manufacture, or storage of fat in the body. Excess dietary carbohydrates (in the form of glucose) can be converted to fat (in the form of glyc erides) and stored in specialized adipose tissue at sites distributed around the body. Excess dietary fat is also stored in this way. Following a meal, uptake of glucose into fat cells (adipocytes) and manufacture of fat are promoted by the hormone insulin. Mobilization of fat occurs during fasting, exercise, and in response to stress and is triggered by the hormone epinephrine and by norepinephrine released by nerve endings of the sympathetic nervous system. Stored fat is mobilized by being broken down to its constituents—fatty acids and glycerol—which are released into the bloodstream to provide fuel for other tissues, especially liver and muscle. Here, the fatty acids are converted into the energy carrier ATP by means of beta oxidation. However, fatty acids cannot be converted (at least in appreciable amounts) into glucose, which is the fuel required by the brain.
fatty acid an organic acid with a long, usually unbranched hydrocarbon chain and an even number of carbon atoms. Fatty acids are the fundamental constituents of many important lipids, including triglycerides. Some fatty acids can be synthesized by the body, but others—the essential fatty acids, such as linoleic acid—must be obtained from the diet. See fat metabolism.
fatty acid amide hydrolase (FAAH) see Endogenous Cannabinoid.
fault tree analysis (FTA) a method of qualitative or quantitative safety or accident analysis in which logic symbols are used to analyze the possible factors contributing to an accident or hazardous system state. The accident or hazardous state forms the “root” of the tree, and the logic symbols representing the possible contributing factors form the “branches.”
FBA abbreviation for functional behavioral assessment.
FDA 1. abbreviation for functional data analysis. 2. abbreviation for U.S. food and drug administration.
F distribution a theoretical probability distribution widely used in the analysis of variance, multiple regression, and other statistical tests of hypotheses about population variances. It is the ratio of the variances of two independent random variables each divided by its degrees of freedom. In an analysis of variance, for example, the F distribution is used to test the hypothesis that the variance between groups is significantly greater than the variance within groups, thus demonstrating evidence of some differences among the means. See F-ratio; F-test.
fear n. a basic, intense emotion aroused by the detection of imminent threat, involving an immediate alarm reaction that mobilizes the organism by triggering a set of physiological changes. These include rapid heartbeat, redirection of blood flow away from the periphery toward the gut, tension of the muscles, and a general mobilization of the organism to take action (see fear response; flight-or-flight response). Fear differs from anxiety in that the former is considered an appropriate short-term response to a present, clearly identifiable threat, whereas the latter is a future-oriented, long-term response focused on a diffuse threat. Some theorists characterize this distinction more particularly, proposing that fear is experienced when avoiding or escaping an aversive stimuli and that anxiety is experienced when entering a potentially dangerous situation (e.g., an animal foraging in a field where there might be a predator). Whatever their precise differences in meaning, however, the terms are often used interchangeably in common parlance. See also fright.
fear appeal

fear appeal a persuasive message that is designed to alter attitudes by producing fear in the recipient. Such messages are most effective when they provide compelling arguments for the likelihood of negative outcomes if a certain advocated measure is not adopted, and when the arguments make a strong case that adopting the measure will eliminate the threat. See also AFFECTIVELY BASED PERSUASION.

fear drive the learned aversion to a situation or other stimulus that motivates escape from or avoidance of the stimulus.

feared self in analyses of self-concept, a mental representation of psychological attributes that one might possess in the future, in which thoughts about the acquisition of these attributes elicit a sense of anxiety or dread.

fearful attachment an adult attachment style characterized by a negative INTERNAL WORKING MODEL OF ATTACHMENT of oneself and of others. Individuals with fearful attachment doubt both their own and others’ competence and efficacy and are presumed not to seek help from others when distressed. Compare DISMISSIVE ATTACHMENT; PREOCCUPIED ATTACHMENT; SECURE ATTACHMENT.

fear-induced aggression a form of aggression in which an animal attacks after it has been severely threatened or cornered.

fear of commitment feelings of anxiety and uncertainty related to the decision to become bound to a course of action. Such feelings are commonly aroused by the decision to become emotionally or legally committed to a longstanding relationship with another person and often stem from problems with intimacy and attachment; in an extreme form, fear of commitment may lead to social maladjustment.

fear of darkness normal or pathological anxiety about darkness or night. Fear of darkness is associated with feelings of helplessness and a sense of unfamiliarity. The fear first occurs normally at about 3 years of age but may develop into a SPECIFIC PHOBIA in which darkness is associated with danger and threat.

fear of failure persistent and irrational anxiety about failing to measure up to the standards and goals set by oneself or others. This may include anxiety over academic standing, losing a job, sexual inadequacy, or loss of face and self-esteem. Fear of failure may be associated with PERFECTIONISM and is implicated in a number of psychological disorders, including eating disorders and some anxiety disorders.

fear of flying a persistent and irrational fear of traveling by airplane or other airborne vehicle, also called aviophobia (although this name is now seldom used). In DSM–IV–TR and DSM–5, fear of flying is classified as a SPECIFIC PHOBLA, situational type.

fear of rejection a persistent and irrational fear of being socially excluded or ostracized, which is often a feature of SOCIAL PHOBIA.

fear of strangers see STRANGER ANXIETY.

fear of success a fear of accomplishing one’s goals or succeeding in society, or a tendency to avoid doing so. Fear of success was originally thought to be experienced primarily by women, because striving for success was held to place a woman in conflict between a general need for achievement and social values that tell her not to achieve “too much.” It is now thought that men and women are equally likely to experience fear of success. Also called FEAR OF SUCCESS SYNDROME: HORNER EFFECT. See also JONAH COMPLEX. [first proposed in 1969 by U.S. psychologist Matina Horner (1939– )]

fear response a response to a threat in which the threatened organism attempts to guard vulnerable vital organs and to protect itself. In addition to these protective functions, the fear response is aimed at removing the person or animal from the threatening situation, by overt withdrawal, by coping behaviors (e.g., shutting the eyes to avoid seeing the fear stimulus), or by remaining motionless. Physiological responses vary depending on the situation and the proximity of the threat. See also FIGHT-OR-FLIGHT RESPONSE; FREEZING BEHAVIOR.

fear structure see EMOTIONAL PROCESSING THEORY.

Fear Survey Schedule (FSS) a questionnaire designed to measure fear, phobic behavior, and generalized anxiety. It is currently available in numerous versions, with the 72-item FSS–III being the most commonly used, particularly in SYSTEMATIC DESENSITIZATION. These items consist of fear- or anxiety-producing objects or situations, grouped into six classes (animal fears, social fears, etc.), to which participants respond on a scale from 0 (not at all) to 4 (very much) regarding their degree of discomfort. [originally published in 1964 by Joseph Wolpe and U.S. clinical psychologist Peter J. Lang (1930– )]

feasibility standards criteria used to judge the practical, feasible, and cost-effective nature of any enterprise or project. For example, the feasibility of an evaluation research study is determined on the basis of its pragmatic implementation, its political viability among various STAKEHOLDERS, and the cost of the resources necessary to carry out the research. See also ACCURACY STANDARDS; PROPRIETY STANDARDS; UTILITY STANDARDS.

feasibility test an investigation conducted prior to a study in order to establish properties of response measures and to determine the successfullness of the study’s design. It is used to establish the validity of response measures, to provide early information on the probable level of effects, or to try out new methodologies. See also EVALUABILITY ASSESSMENT; FEASIBILITY STANDARDS.

feature n. 1. an attribute of an object or event that plays an important role in distinguishing it from other objects or events and in the formation of category judgments. For example, a particular nose is a feature of one person’s face, wings are a feature of the category bird, particular lines and angles are features of a particular shape, line segments of various types are features of letters, and so on. 2. in phonemics, an attribute of a speech sound, such as whether it is VOICED or UNVOICED, that plays a critical role in distinguishing one PHONEME from another. See BINARY FEATURE; MINIMAL PAIR.

feature abstraction a hypothetical process by which people learn from their experience with exemplars of different categories to determine the features that might be used to define membership in these categories.

feature attention a form of SELECTIVE ATTENTION in which the unit of selection is a distinguishing feature or property of a target item (e.g., the red hair of the person one is looking for in a crowd). Numerous studies have confirmed that focusing on one such feature enhances the discriminability of the item being sought. See also FOCAL ATTENTION.
feature detection theory the theory that all complex stimuli can be broken down into individual parts (features), each of which is analyzed by a specific feature detector.

feature detector any of various hypothetical or actual mechanisms within the human information-processing system that respond selectively to specific distinguishing features. For example, the visual system has feature detectors for lines and angles of different orientations as well as for more complex stimuli, such as faces. Feature detectors are also thought to play an important role in speech perception, where their function would be to detect those binary features that distinguish one phoneme from another. Also called feature analyzer.

feature indicator any aspect of an object that provides visual cues to feature detectors in the visual cortex. Examples of feature indicators include boundaries between dark and light regions, straight or curved edges or surfaces, and connecting features (e.g., crossbars).

feature-integration theory (FIT) a two-stage theory of visual attention. In the first (preattentive) stage, basic features (e.g., color, contrast, location in space, shape) are processed automatically, independently, and in parallel. In the second (attentive) stage, other properties, including relations between features of an object, are processed serially, one object (or group) at a time, and are "bound" together to create a single object that is consciously perceived. Also called feature-integration hypothesis. See also textons. [proposed in 1980 by British psychologist Anne Marie Treisman (1935–)]

feature model a model of general knowledge or semantic memory suggesting that information can be described as sets of features (e.g., the features that define bird).

feature-negative discrimination a go/no-go discrimination procedure, based on a distinctive feature of one of two similar stimuli, in which the feature is part of the negative, or no-go, stimulus—that is, the stimulus associated with extinction.

feature-positive discrimination a go/no-go discrimination procedure, based on a distinctive feature of one of two similar stimuli, in which the feature is part of the positive, or go, stimulus—that is, the stimulus associated with reinforcement.

febrile delirium delirium associated with or caused by fever.

febrile seizure a seizure arising from a high fever. It is the most common type of seizure in childhood and 20% to 30% of them recur. Febrile seizures are a benign condition for most children, but experiments with nonhuman animals and neuroimaging studies in humans suggest some febrile seizures may damage the hippocampus.

fecal incontinence the involuntary passage of flatus and feces in inappropriate places (clothing, floor, etc.) resulting from loss of bowel control due to an injury or physiological condition. Also called bowel incontinence. Compare encopresis.

feces n. waste matter expelled from the bowels. In psychoanalytic theory, a child’s interest in feces is one of the earliest expressions of curiosity, and withholding feces is one of the earliest expressions of the drive for aggression and independence. Also called excrement: fecal matter. See also anal personality; anal stage sphincter control. —fecal adj.

Fechner's colors illusory sensations of color that arise when a disk with black and white sectors is spun about its axis. The appearance of these subjective colors is widely believed to be governed by local interactions in early and likely retinal, mechanisms. See also Benham’s top. [Gustav Theodor FECHNER]

Fechner's law a mathematical formula relating subjective experience to changes in physical stimulus intensity: Specifically, the sensation experienced is proportional to the logarithm of the stimulus magnitude. It is derived from Weber's law and expressed as \( \Psi = k \log S \), where \( \Psi \) is the sensation, \( k \) is a constant, and \( S \) is the physical intensity of the stimulus. Also called Weber–Fechner law. See also stEVENS law. [Gustav Theodor FECHNER]

Fechner's paradox the apparent increase in the brightness of a figure caused by closing one eye after viewing the figure with both eyes open. [Gustav Theodor FECHNER]

fecundity n. 1. in biology, a measure of the number of offspring produced by an individual organism over a given time. 2. in demography, the general capacity of a human population to have offspring. A below-average capacity is termed subfecundity. Compare birth rate. Fertility. —fecund adj.

Federation of Associations in Brain and Behavioral Sciences (FABBS) an association of scientific societies whose mission is to promote human potential and well-being by advancing the sciences of mind, brain, and behavior. It was founded in 1980 as the Federation of Behavioral, Psychological, and Cognitive Sciences, changing to its present name in 2009. The federation's efforts focus on legislative and regulatory advocacy, education, and the communication of information to the federal government, public, and the scientific community.

feeblemindedness n. an obsolete name for intellectual disability or learning disability.

feedback n. information about a process or interaction provided to the governing system or agent and used to make adjustments that eliminate problems or otherwise optimize functioning. It may be stabilizing negative feedback or amplifying positive feedback. The term’s origins in engineering and cybernetics lend it a distinct connotation of input–output models that is not as strictly applicable to the wide variety of usages found in psychology, such as biofeedback, information feedback, and social feedback. Compare feedforward.

feedback device a device that presents a visual, auditory, or tactile signal to communicate to the operator of an environmental control device the status of actions taken. See also control device; switch device; target device.

feedback evaluation see formative evaluation.

feedback loop in cybernetic theory, a self-regulatory model that determines whether the current operation of a system is acceptable and, if not, attempts to make the necessary changes. Its operation is summarized by the acronym TOTE (test-operate-test-exit). The two test phases compare the current reality against the goal or standard. The operate phase involves any processes or interventions designed to resolve unacceptable discrepancies between the reality and the standard. In the exit phase, the supervisory feedback loop is closed down because the circumstances have been brought into agreement with the standard. Also called TOTE model. See also negative feedback.
feedback system

Feedback System A circuit in which output information (e.g., biological, mechanical) is used to modulate the input to the same circuit. In a negative feedback system, the output is used to reduce the input; such systems play important roles in maintaining equilibrium of processes within organisms. See homeostasis; positive feedback.

Feeding and Eating Disorders of Infancy or Early Childhood In DSM–IV–TR, a category of disorders characterized by pathological feeding or eating behaviors that are usually first diagnosed in infancy, childhood, or adolescence. They include pica, rumination, and feeding disorder of infancy or early childhood.

Feeding behavior The behavior involved in taking nourishment. In humans, the development of feeding behavior includes (a) stimulation and coordination of the sucking and swallowing reflexes in early infancy, (b) adaptation to breast or bottle and to scheduled or self-demand feeding, (c) biting at about the 4th month, (d) anticipatory chewing movements, (e) actual chewing when the teeth are developed, and (f) transferring from finger feeding to the use of various utensils.

Feeding center A traditional name for the region of the lateral hypothalamus in the brain that, when stimulated, produces eating behavior. Also called hunger center.

Feeding disorder of infancy or early childhood In DSM–IV–TR, a disorder with an onset before the age of 6 (but typically within the 1st year following birth), characterized by persistent failure to eat adequately that results in significant failure to gain weight or significant loss of weight over a period of 1 month or more. The cause of the disorder is unknown.

Feeding problem A form of behavior disorder in children that is characterized by refusal to eat, persistent failure to eat adequate amounts or types of food, or failure to hold down the food ingested. It is not due to a gastrointestinal or other medical condition or lack of available food, and it is not an eating disorder. Also called feeding disturbance. Compare oral–motor feeding problem. See also rumination.

Fee-for-service adj. Denoting the traditional method of payment for health care services, in which physicians or other providers set their own fees for services, and patients or insurance companies pay all or a percentage of these charges. This is the system of reimbursement used by indemnity insurance plans. Compare pay-for-performance.

Feeling n. 1. A self-contained phenomenal experience. Feelings are subjective, evaluative, and independent of the sensations, thoughts, or images evoking them. They are inevitably evaluated as pleasant or unpleasant, but they can have more specific intrapsychic qualities, so that, for example, the affective tone of fear is experienced as different from that of anger. The core characteristic that differentiates feelings from cognitive, sensory, or perceptual intrapsychic experiences is the link of affect to appraisal. Feelings differ from emotions in being purely mental.

Feeling of knowing (FOK) A sense of conviction that one possesses certain information despite being unable to retrieve it from memory at a given time. FOKs meet the empirical definition of conscious events in that they are accurately reportable. However, they typically lack such qualities as visual images, inner speech, imagined actions, and the like. The classic case of an FOK is the tip-of-the-tongue phenomenon during word retrieval. See also fringe consciousness.

Feeling of reality The sense that the world is actual, which may be lost in mild dissociative conditions (e.g., derealization) and in more serious disorders (e.g., posttraumatic stress disorder, psychosis).

Feeling of unreality See depersonalization; derealization.

Feeling tone See affective tone.

Feeling type In Carl Jung’s analytic psychology, a functional type characterized by a dominance of feeling or affects. Feeling types evaluate their experiences and the world in terms of how these make them feel. The feeling type is one of Jung’s two rational types, the other being the thinking type. See also intuitive type; sensation type.

Feighner Criteria A set of formal diagnostic descriptions published in 1972 for 15 mental disorders. Developed to improve reliability in psychiatric diagnosis by standardizing the definition of specific disorders, the Feighner criteria were the first symptom-based diagnostic system to be used in psychiatric research and signaled a major shift away from the then-dominant psychoanalytic approach to mental illness. They became widely cited and used in research and played an influential role in the revival of biological thinking in U.S. psychiatry. See research diagnostic criteria. [developed by a team of researchers led by U.S. psychiatrist John P. Feighner (1937– at Washington University, St. Louis]

Felbamate n. An anticonvulsant drug, structurally related to meprobamate, that is thought to work by both enhancing the effects of the inhibitory neurotransmitter gamma-aminobutyric acid and inhibiting the effects of the excitatory amino acid glutamate (see NMDA receptor). Due to the increased incidence of aplastic anemia and hepatitis associated with this drug, it is less commonly used than other anticonvulsants; it is generally reserved for patients with severe epilepsy who respond inadequately to other treatments. U.S. trade name: felbatol.

Feldenkrais Method A system of body movements that are designed to enhance psychological functioning. The method is used by certified practitioners and may be interpreted in numerous ways, but it always involves a dynamic interaction between bodily movements and psychological awareness. [Moshe Feldenkrais (1904–1984), physicist and engineer]

Fellatio n. The use of the mouth in sexual stimulation of the penis. Also called fellation: oral coitus. See also genital activity. —fellate vb.

Felt need A consciously experienced need that may relate to a sense of deprivation or a discrepancy with an affective ideal.
felt sense in focusing therapy, vague bodily feelings that are thought to correspond to unresolved emotional conflicts, which tend to resolve when one simply pays attention to them. [defined by Austrian-born U.S. philosopher and psychologist Eugene T. Gendlin (1926— )]

female choice the selectivity displayed by females in choosing a mate. Because females often expend much more energy than males in the production and care of the young, females are thought to be more careful than males in choosing their mates. See also CRYPTIC FEMALE CHOICE; MATE SELECTION; MULTIPLE MATING.

female circumcision see FEMALE GENITAL MUTILATION.

female ejaculation expulsion of a lubricating fluid by the VESTIBULAR GLANDS of a woman during sexual stimulation and orgasm. The fluid may reach peak flow before orgasm, often increasing when stimulation is prolonged. Some researchers deny the existence of female ejaculation; however, it has been written about since the 4th century, and many women attest to having experienced it. See also GRAEPENBERG SPOT.

female–female competition see MALE–MALE COMPETITION.

female genitalia see GENITALIA.

female genital mutilation (FGM) any nontherapeutic procedure performed to modify or remove any part of the external genitalia in females, associated with cultural norms of femininity, chastity, and religious observance in certain countries, particularly in Africa. FGM takes one of four forms: excision of the clitoral hood only; excision of the entire clitoris (CLITORIDECTOMY) and often the labia minora; excision of the clitoris, labia minora, and most of the labia majora, with the sewing together of the remaining tissue to leave only a small vaginal opening (INFIBULATION); and any other injurious procedure, such as incising or burning of the clitoris, cutting of the vagina, and insertion of substances to cause vaginal bleeding. FGM may have numerous adverse consequences, such as severe pain, excessive bleeding, infection, reduced sexual sensitivity, less frequent orgasm, decreased enjoyment of sexual intercourse, and obstetrical complications. Also called clitoral circumcision; female circumcision; female genital cutting.

femaleness n. the quality of being female in the anatomical and physiological sense by virtue of possessing the female complement of a pair of X CHROMOSOMES. Compare FEMININITY.

female Oedipus complex see OEDIPUS COMPLEX.

female orgasmic disorder in DSM–IV–TR and DSM–5, a condition in which a woman recurrently or persistently has difficulty obtaining orgasm or is unable to reach orgasm at all following sexual stimulation and excitement, causing marked distress or interpersonal difficulty.

female sexual arousal disorder in DSM–IV–TR, a condition in which a woman recurrently or persistently is unable to attain or maintain adequate vaginal lubrication and swelling during sexual excitement, causing marked distress or interpersonal difficulty. It is a prevalent sexual problem for women and has a complex etiology involving a variety of physiological and psychological factors. It is identified as female sexual interest/arousal disorder in DSM–5.

female sexual dysfunction (FSD) any of various conditions experienced by women that involve sexual difficulties and associated distress significant enough to interfere with participation in sexual relationships. Although specific definitional criteria vary, female sexual dysfunction generally is categorized into four groups of symptoms: persistent absence of desire, inability to get or stay excited, difficulty achieving orgasm, and pain associated with stimulation or intercourse. Among the particular problems often included as FSD are DYSPAREUNIA, FEMALE ORGASMIC DISORDER, FEMALE SEXUAL AROUSAL DISORDER, VAGINISMUS, and sexual difficulties from underlying medical causes. Prevalence estimates also vary, but research suggests that more than 40% of women in the United States experience FSD.

female sperm spermatozoa that bear an X CHROMOSOME and therefore determine that an ovum they fertilize will become a female embryo.

femininity n. possession of social-role behaviors that are presumed to be characteristic of a girl or woman, as contrasted with FEMALINESS, which is genetically determined. —feminine adj.

femininity complex in psychoanalytic theory, a man’s envy of women’s procreative powers that has its roots in the young boy’s envy of the mother’s body. Some psychoanalysts see the femininity complex as the male counterpart to the female CASTRATION COMPLEX and PENIS ENVY. [first used in 1930 by German psychoanalyst Felix Boehm (1881–1958)]

femininity phase in the OBJECT RELATIONS Theory of Melanie Klein, a period during the early phases of the OEDIPUS COMPLEX in which both boys and girls are posited to adopt a feminine attitude toward the father and to desire a child by him. Klein saw this turning to the father as an object of desire and away from the mother as the child’s first object.

feminism n. any of a number of perspectives that take as their subject matter the problems and perspectives of women or the nature of biological and social phenomena related to gender. Feminism has evolved from a largely political movement in the 19th century, focused (in the United States) on women’s suffrage and political and economic opportunities, into broader and more comprehensive academic, philosophical, and social movements. Although some feminist perspectives continue to focus on issues of fairness and equal rights, other approaches emphasize what are taken to be inherent and systematic gender inequities in Western society (see PATRIARCHY). In psychology, feminism has focused attention on the nature and origin of gender differences in psychological processes. See WOMEN’S LIBERATION MOVEMENT. See also ECOFEMINISM; EROTIC FEMINISM; INDIVIDUALIST FEMINISM; LESBIAN FEMINISM; MARXIST FEMINISM; MATERIAL FEMINISM; RADICAL FEMINISM. —feminist adj., n.

feminist family therapy an intervention, informed by FEMINIST THERAPY, that is used by therapists to reorganize the family so that no one is entrapped in dysfunctional roles or patterns of interaction based on the politics of power, particularly with regard to patriarchal roles.

feminist psychology an approach to psychological issues that emphasizes the role of the female perspective in thought, action, and emotion in the life of the individual and in society. It is seen by its proponents as an attempt to counterbalance traditional male-oriented and male-dominated psychology, as well as a model for similar approaches.
for other less represented groups. See also ENGENDERING PSYCHOLOGY; WOMAN-CENTERED PSYCHOLOGY.

**feminist therapy** an eclectic approach to psychotherapy based conceptually in feminist political analyses and scholarship on the psychology of women and gender. In this orientation, the ways in which gender and gendered experiences inform people’s understanding of their lives and the development of the distress that serves as a catalyst for seeking therapy are central. Race, class, sexual orientation, age cohort, and ability, as they interact with gender, are explored. Feminist therapy attempts to create an egalitarian therapeutic relationship in which intentional efforts are made by the therapist to empower and define the client as an authority equal in value to the therapist. Feminist therapy can be indicated for both female and male clients.

**feminization** n. the process of acquiring FEMININITY, regardless of the sex of the individual. —feminize vb.

**feminization of poverty** the trend for a disproportionate number of the poorest people in Western societies to be women. This can be attributed to a range of factors, including the growing number of families that are headed by a single mother, often with no financial support from the father, and the continuing tendency for occupations with a largely female workforce to pay lower wages. See also UNDERCLASS.

**feminizing testes syndrome** see ANDROGEN-INSENSITIVITY SYNDROME.

**fenestration** n. 1. see BLOOD–BRAIN BARRIER. 2. the surgical creation of an opening, as in the procedure, now rarely used, in which an opening is formed in the bony wall of the middle ear and into the semicircular canal in order to improve hearing loss caused by OTOSCLEROSIS.

**fenfluramine** n. a sympathomimetic agent, structurally related to the AMPHETAMINES, that functions as a SEROTONIN AGONIST and was formerly used for management of obesity (see APPETITE SUPRESSANT). It was withdrawn from the U.S. market in 1997 due to the incidence of heart-valve abnormalities associated with its use.

**fentanyl** n. a highly potent OPioid ANALGESIC that is used for anesthesia during surgery; for the management of severe cancer pain in patients resistant to other opioids, and (as a lozenge or sucker) for the relief of severe anxiety in children prior to surgical procedures. Its toxicity is similar to that of other opioids, with respiratory and circulatory depression predominating. It is known as China white in illicit use. Analogos of fentanyl in current use include sufentanil, alfentanil (U.S. trade name: Alfenta), and remifentanil (U.S. trade name: Ultiva). U.S. trade names: Sublimaze (injectable form); Actiq, Fentora, and Oralet (oral forms); Duragesic (transdermal form, i.e., applied to the skin).

**FEPsac** see EUROPEAN FEDERATION OF THE PSYCHOLOGY OF SPORT AND PHYSICAL ACTIVITY.

**feral children** children who reportedly have been raised by wild animals and isolated from human contact and care and, consequently, from social norms and behavior. Famous examples include the Wild Boy of Aveyron and the Wolf Children of India.

**Fernald method** an approach to reading based on the idea that students learn best when material is presented to several different senses. These methods, which employ tracing, hearing, writing, and seeing, are often referred to as VAKT (visual, auditory, kinesthetic, tactile). The Fernald method teaches whole words. [Grace Fernald (1879–1950), U.S. psychologist]

**Ferry–Porter law** see PORTER’S LAW.

**fertility** n. 1. in biology, the potential of an individual to have offspring. Although most frequently applied to females, it may also refer to reproductive capacity in males. 2. in demography, the number of live children born to an individual or within a population. Compare BIRTH RATE; FECUNDITY.

**fertilization** n. the fusion of a sperm and an egg cell to produce a ZYGOTE. External fertilization occurs outside the female’s body, as in fish and amphibians. Mammals, birds, and reptiles have internal fertilization (i.e., within the body of the female). In humans, fertilization occurs in a FALLOPIAN TUBE.

**FES** abbreviation for FUNCTIONAL ELECTRIC STIMULATION.

**festinating gait** a gait disturbance often seen in individuals with Parkinson’s disease, marked by short, shuffling steps that begin slowly but increase in rapidity until the walk becomes a half run. The body leans stiffly forward to maintain balance, and there is an associated risk of falling. Also called festination; propulsive gait.

**fetal activity** the activity level of the fetus during intraterine development, such as kicking or other movements.

**fetal age** see GESTATIONAL AGE.

**fetal alcohol syndrome (FAS)** a group of adverse fetal and infant health effects associated with heavy maternal alcohol intake during pregnancy. It is characterized by low birth weight and retarded growth, craniofacial anomalies (e.g., microcephaly), neurobehavioral problems (e.g., hyperactivity), and cognitive abnormalities (e.g., language acquisition deficits); intellectual disability may be present. Children showing some but not all features of this syndrome are described as having fetal alcohol effects (FAE).

**fetal cephalometry** see CEPHALOMETRY.

**fetal distress** the condition of a fetus whose life or health is threatened, most commonly by an inadequate supply of oxygen via the placenta. Signs of fetal distress include abnormal heart rate, elevated blood acidity, and absence of movement. This term has been criticized as being imprecise and nonspecific; it is recommended that the specific symptoms be described, assessed, and treated. Also called nonreassuring fetal status.

**fetal hypoxia** a significant reduction in oxygen to the fetus, which is believed to be a risk factor for severe mental illness, such as schizophrenia.

**fetal infection** any disease that may affect a fetus as a result of an infectious agent transmitted from the mother via the placenta. Fetal infections are usually caused by viruses; other agents may include tuberculosis bacteria, the syphilis spirochete, or the toxoplasmosis protozoa. Rubella
is a common viral fetal infection, resulting in various congenital defects (see CONGENITAL RUBELLA SYNDROME).

**fetal–maternal exchange** the exchange of substances between mother and fetus, via the placenta, during gestation. The fetus is thereby supplied with nutrients and oxygen, and its waste products (e.g., carbon dioxide, urea) are eliminated. Substances of low molecular weight cross the placental barrier easily, but large molecules (e.g., proteins) do not; therefore, the fetus manufactures its own proteins from amino acids supplied by the mother. Some drugs (e.g., alcohol, opioids) as well as disease agents (e.g., the rubella virus) may cross the placental barrier and produce congenital defects.

**fetal monitoring** measurement of the physiological characteristics (e.g., heart rate) of a fetus. Fetal monitoring is used to assess the well-being of the fetus before and during childbirth.

**fetal presentation** the way the fetus is oriented during the birth process. Specifically whether or not the fetus is exiting the birth canal head first. If the fetus is oriented so that it will be delivered buttocks first, this is known as a breech birth (or breech presentation); breech births are associated with risks to mother and baby (see BIRTH INJURY).

**fetal programming** during prenatal development, a fetus’s physiological adaptation in utero to changing environmental conditions or stimuli (e.g., maternal stress, poor maternal nutrition, environmental toxins) and the long-term consequences of this adaptation on the child’s postnatal development into adulthood. It is believed that the effects of fetal programming may predispose individuals to later health and mental health disorders. See DUTCH HUNGER WINTER.

**fetal response** a response of a fetus to environmental conditions. For example, there is an increase in the fetal heart rate when the mother smokes, and some investigators believe that there is an increase in fetal activity when the mother is undergoing severe emotional stress. See PREGNATAL INFLUENCE.

**fetal stage** the final stage of human prenatal development, from the 8th or 9th week after fertilization to the time of birth. It is preceded by the EMBRYONIC STAGE.

**fetal tobacco syndrome (FTS)** a group of adverse fetal and infant health effects associated with maternal smoking during pregnancy. These include low birth weight, retarded growth, premature labor and preterm delivery, increased risk of sudden infant death syndrome, and neurological damage manifested as developmental delay, intellectual deficits, and behavioral problems.

**fetation** n. see PREGNANCY.

**feticide** n. destruction of the embryo or fetus in the uterus. See also ABORTION.

**fetish** n. 1. a material object (e.g., a shoe, an undergarment, an animal fur or hide) or nonsexual part of the body (e.g., a foot, lock of hair) that arouses sexual interest or excitement. 2. any object, idea, or behavior that is the focus of irrational devotion or excessive attention, such as punctuality or the pursuit of wealth. 3. in anthropology, an object, such as a talisman or amulet, that is believed to embody a supernatural spirit or exert magical force.

**fetishism** n. a type of PARAPHILIA in which inanimate objects—commonly undergarments, stockings, rubber items, shoes, or boots—are repeatedly or exclusively used in achieving sexual excitement. Objects designed for use in stimulating the genitals (e.g., vibrators) are not considered to be involved in fetishism. Fetishism occurs primarily among males and may compete or interfere with sexual contact with a partner. See also PARTIALISM. —fetishistic adj.

**fetoscopy** n. a procedure for observing the fetus in which a viewing instrument (fetoscope) is passed through a pregnant woman’s abdomen and into the amniotic sac.

**fetus** n. an animal EMBRYO in the later stages of development. In humans, the fetal period is from the end of the 8th week after fertilization until birth. —fetal adj.

**fetus at risk (FAR)** a fetus that has a significant chance of being born with a mental or physical disorder because of known influences from the parents or other family members (e.g., a mother with diabetes or hypertension). The risk of a mental disorder in a child born into a family with no history of mental disorder is relatively small, but the risk may be as much as 50% in certain cases, such as when the disorder is a SIX-LINKED recessive trait inherited from the mother’s side of the family and the parents are related.

**FFA** abbreviation for fusiform face area. See FUSIFORM GYRUS.

**FFDE** abbreviation for FITNESS FOR DUTY EVALUATION.

**FFFS** abbreviation for fight–flight–freeze system. See REINFORCEMENT SENSITIVITY THEORY.

**FFM** abbreviation for FIVE-FACTOR PERSONALITY MODEL.

**FFS** abbreviation for fight–flight system. See REINFORCEMENT SENSITIVITY THEORY.

**FGM** abbreviation for FEMALE GENITAL MUTILATION.

**FI** abbreviation for fixed interval. See FIXED-INTERVAL SCHEDULE.

**fiat** n. in IDEOMOTOR THEORY, the intuitive sense of allowing an action to execute when it is felt to be ready. [from Latin: “let it be done” or “let it happen”; originally defined by William James]

**fibril** n. any small anatomical fiber or threadlike structure.

**fibrillation** n. an involuntary contraction of muscle due to unprompted activation of muscle cells or fibers with damaged source nerves, especially the rapid, abnormal contraction of individual muscle fibers of the heart.

**fibromyalgia** n. a syndrome of uncertain origin that is characterized by widespread musculoskeletal pain and chronic fatigue. Pain may be triggered by pressure on numerous tender points on the body. Other commonly associated symptoms are muscle stiffness, headaches, sleep disturbance, and depression. Symptoms overlap with those of CHRONIC FATIGUE SYNDROME, and fibromyalgia often occurs simultaneously with other disorders, such as irritable bowel syndrome and migraine. The condition was formerly called fibromyositis–fibromyalgia syndrome. See also CHRONIC MYOFASCIAL PAIN.

**fiction** n. 1. in psychology, an unproven or imaginary concept that may be accepted by an individual as if it were true for pragmatic reasons. See ALIAS OR AS-IF HYPOTHESIS. 2. see GUIDING FICTION. —fictional adj.

**fictional finalism** in the psychoanalytic theory of Alfred Adler, the belief that human beings are more strongly
fidelity

motivated by the goals and ideals—realizable or unattainable—that they create for themselves and more influenced by future possibilities than by past events such as childhood experiences. This is in strong contrast to the emphasis of classical Freudian psychoanalytic theory. See also GUIDING FICTION; INDIVIDUAL PSYCHOLOGY.

fidelity n. 1. faithfulness to a person, group, belief, or the like. 2. the degree of accuracy of a measuring instrument or STATISTICAL MODEL. For example, a representation derived from STRUCTURAL EQUATION MODELING that depicts a pattern of relationships between health attitudes and behaviors could be said to have fidelity if it accurately explains the VARIATION and COVARIATION in the data. 3. the degree of accuracy of sound or visual reproduction in an electronic device (e.g., a sound system, television).

fidgetiness n. a state of increased motor activity, which is associated with anxiety, tics, chorea, or boredom.

fiduciary 1. adj. describing a relationship in which one person holds a position of trust in relation to another and is required to apply his or her skill and effort in the best interests of that other. A psychologist and client have a fiduciary relationship in that the psychologist is assumed to place the welfare and best interests of the client above all else. 2. n. a person who holds a position of trust in a fiduciary relationship.

field n. 1. a defined area or region of space, such as the VISUAL FIELD. 2. a complex of personal, physical, and social factors within which a psychological event takes place. See FIELD THEORY. 3. an area of human activity or knowledge or a division of such an area. 4. somewhere other than a laboratory, library, or academic setting in which experimental work is carried out or data collected. See FIELD EXPERIMENT.

field defect see VISUAL FIELD DEFECT.

field dependence a COGNITIVE STYLE in which the individual consistently relies more on external referents (environmental cues) than on internal referents (bodily sensation cues). The opposite tendency is FIELD INDEPENDENCE. Discovered during experiments conducted in the 1950s to understand the factors that determine perception of the upright in space, field dependence—dependence typically is measured using the ROD-AND-FRAME TEST or EMBEDDED FIGURES TEST.

field experiment a study that is conducted outside the laboratory in a “real-world” setting. Participants are exposed to one of two or more levels of an INDEPENDENT VARIABLE and observed for their reactions; they are likely to be unaware of the research. Such research often is conducted without RANDOM SELECTION or RANDOM ASSIGNMENT of participants to conditions and without deliberate experimental manipulation of the independent variable by the researcher. See FIELD RESEARCH; QUASI-EXPERIMENTAL RESEARCH.

field independence a COGNITIVE STYLE in which the individual consistently relies more on internal referents (bodily sensation cues) than on external referents (environmental cues). Field-independent people tend to be able to disregard deceptive environmental cues, particularly in tasks requiring the performance of simple actions or the identification of familiar elements in unfamiliar contexts. Compare FIELD DEPENDENCE.

field memory an autobiographical memory that one remembers from a first-person perspective; that is, one remembers the event as if viewing it with one’s own eyes. Also called first-person perspective memory. Compare OBSERVER MEMORY.

field notes notes on observations made in natural settings (i.e., the field) rather than in laboratories. Field notes comprise the data for subsequent analysis in FIELD EXPERIMENTS and FIELD RESEARCH.

field of consciousness the total awareness of an individual at a given time. See CONSCIOUSNESS.

field of regard the total space and all the objects within that space that can be seen at one time by the moving eye.

field research studies conducted outside the laboratory, in a “real-world” setting, which typically involve observing or interacting with participants in their typical environments over an extended period of time. Field research has the advantages of ECOLOGICAL VALIDITY and the opportunity to understand how and why behavior occurs in a natural social environment; it has the disadvantages of loss of environmental control and ability to do precise experimental manipulations. Thus, field research is often said to have more EXTERNAL VALIDITY and less INTERNAL VALIDITY than laboratory-based research. In studies of the behavior of nonhuman animals, field research stands in contrast to studies conducted on animals in CAPTIVITY. See also FIELD EXPERIMENT.

field survey an assessment that involves collecting information on specific individuals or entities, usually in their natural environment. For example, a field survey could be conducted on a sample of students from underrepresented groups to assess their attitudes, experience, and performance regarding quantitative methods, before providing an intervention to increase their quantitative reasoning. See also FIELD RESEARCH.

field theory 1. in psychology, a systematic approach describing behavior in terms of patterns of dynamic interrelationships between individuals and the psychological, social, and physical situation in which they exist. This situation is known as the field space or LIFE SPACE, and the dynamic interactions are conceived as forces with positive or negative VALENCEs. [proposed by Kurt LEWIN] 2. in physics, the theory that forces acting at a distance between bodies not in contact do so by means of a field of force that fills the space between them. See ACTION AT A DISTANCE.

field theory of personality a theory in which personality is understood in terms of dynamic interrelations among a field of intrapsychic forces. [devised by Kurt LEWIN]

field work 1. a less common name for FIELD RESEARCH. 2. in clinical practice education, a practicum in which the student supplements and applies classroom theory by taking responsibility for actual cases under the tutelage of experienced, qualified supervisors.

fifth cranial nerve see TRIGEMINAL NERVE.

fight-flight-freeze system (FFFS) see REINFORCEMENT SENSITIVITY THEORY.

fight-flight system (FFS) see REINFORCEMENT SENSITIVITY THEORY.

fighting n. direct physical aggression between two individuals. In nonhuman animals, much aggression can be communicated through THREAT DISPLAYS and SUBMISSIVE SIGNALS; fighting typically occurs only when signals alone do not resolve the encounter.
fight-or-flight response a pattern of physiological changes elicited by activity of the SYMPATHETIC NERVOUS SYSTEM in response to threatening or otherwise stressful situations that leads to mobilization of energy for physical activity (e.g., attacking or avoiding the offending stimulus), either directly or by inhibiting physiological activity that does not contribute to energy mobilization. Specific sympathetic responses involved in the response include increased heart rate, respiratory rate, and sweat gland activity; elevated blood pressure; decreased digestive activity; pupil dilation; and a routing of blood flow to skeletal muscles. In some theories, such changes are the basis of all human emotions. Also called emergency reaction; emergency syndrome. See also CANNON–BARD THEORY. [first described by Walter B. CANNON]

figural aftereffect a gestalt-type perceptual phenomenon in which the perceived location or shape properties of an object may be influenced by prolonged viewing of that or another object.

figural cohesion the tendency for parts of a figure to be perceived as a whole figure even if the parts are disjointed.

figural fluency test see DESIGN FLUENCY TEST.

figural synthesis the creation of a meaningful figure from the synthesis of selected portions of the incoming stimulus input. [proposed in 1967 by Ulric NEISSER]

figurative knowledge knowledge about static things, acquired by attending to and remembering specific factual information or perceptual details (e.g., vocabulary words, dates, colors, shapes). Compare OPERATIVE KNOWLEDGE. [first described by Jean PIAGET]

figurative language language in which meaning is extended by analogy, metaphor, or personification or emphasized by such devices as antithesis, alliteration, and so forth. Figurative language is most important in poetry and rhetoric but extends into almost all areas of language use.

figure n. a graph, drawing, or other depiction used to convey the essential findings from a research study. Common figures used in psychological research include BAR GRAPHS, which show the frequency of endorsement for several categories (e.g., the number of individuals who have various diseases), and VENN DIAGRAMS, which use overlapping circles to show how much shared variance there is between two or more variables.

figure-drawing test any test in which the participant draws a human figure, used as a measure of intellectual development or as a projective technique. See MACOVER DRAW-A-PERSON TEST.

figure-ground adj. relating to the principle that perceptions have two parts: a figure or object that stands out in good contour and an indistinct, homogeneous background.

figure-ground distortion the interference of an object’s background with the perception of the object itself, rendering the viewer unable to focus on the object.

file-drawer analysis a statistical procedure for addressing the FILE-DRWER PROBLEM by computing the number of unretrieved studies, averaging an EFFECT SIZE of .00, that would have to exist in file drawers before the overall results of a META-ANALYSIS would become nonsignificant at \( p > .05 \), that is, would exceed an acceptable probability level (.05) of occurring by chance. A small computed value indicates a weak finding that may just be due to chance. Conversely, a large value suggests that the finding is rather robust, as it would take a large number of nonsignificant findings to provide enough evidence to refute the results.

file-drawer problem the fact that a large proportion of all studies actually conducted are not available for review because they remain unpublished in “file drawers,” having failed to obtain positive results. Thus, the results of a meta-analysis may not yield reliable EFFECT SIZE estimates since only studies that have been published or otherwise are widely available to researchers can be included in the analysis. See FILE-DRWER ANALYSIS.

filial anxiety fear and apprehension in children caused by their relationships with their parents, often in anticipation of caregiving responsibility by adult children of older parents.

filial generation any of the successive generations of descent from an original parental generation. The immediate descendants of the initial parents are the first filial generation (denoted \( F_1 \)), their descendants are the second filial generation (denoted \( F_2 \)), and so on.

filial imprinting a process in which a young animal develops a strong bond with and learns to recognize its parent (see IMPRINTING).

filial maturity a mutual caring relationship between adult children and older parents, involving an understanding of each other’s needs, responsibilities, and desires. [proposed by U.S. social worker Margaret Blenkner (1909–1973)]

filial responsibility a sense of duty toward family members, with particular reference to child–parent obligations. Also called filial duty.

ficide n. the intentional killing of one’s children, a very rare event that is sometimes associated with severe major depressive disorder or certain psychotic disorders. Cultural and socioeconomic factors may also contribute.

filiform papillae the most common of the four types of PAPILLAE, covering most of the surface of the human tongue and giving that organ its rough surface. They have NO TASTE BUDS and are not involved in gustation.

filled-space illusion a source of distortion in estimating distance: Estimates increase as a linear function of the number of intervening points (as on a map).

fill-in questions a testing method in which students are provided with incomplete sentences relating to concepts or terms and are required to supply the missing words or phrases.

film color a filmlike, texture-free soft color that lacks localization, as contrasted with the color of a surface, which is an example of OBJECT COLOR.

filopodium n. (pl. filopodia) a very fine, tubular outgrowth from a cell, for example, from the GROWTH CONE of a neuron.

filter n. 1. a device or material that allows some elements of a mixture (e.g., of light, a liquid, or a gas) to pass through but not others. In acoustics, a low-pass filter passes all components below a specified cut-off frequency while attenuating higher frequencies, thus altering the amplitude spectrum of the input; a high-pass filter performs the opposite spectral alteration. A bandpass filter transmits the range of frequencies (passband) lying between specified high-pass and low-pass cut-off frequencies.
filtered speech

2. a hypothetical construct applied to cognitive channels of information that allow only certain aspects of a stimulus to pass into sensory consciousness. Filter metaphors aim to explain the ability to focus selectively on local and precise aspects of the environment (e.g., a conversation in a noisy room). 3. any analytical procedure used in time-series analysis to remove fluctuations from the data and separate out its trend and cyclical components.

filtered speech words that have been filtered to allow only specific frequency bands to pass through. Filtered speech is presented to the ear at a comfortably loud level to measure auditory processing abilities. See also distorted speech test.

filter theory 1. an early theory of attention proposing that unattended channels of information are filtered prior to identification. This theory continues to be influential in the form of its successor, the attenuation theory. See also early-selection theory. [proposed in 1958 by Donald E. Broadbent] 2. any explanation of mate selection that postulates a series of steps that rule out more and more potential mates until only one is left.

FIM abbreviation for functional independence measure.

fimbria n. (pl. fimbriae) 1. a structure that resembles a fringe. 2. the band of white matter along the medial edge of the ventricular surface of the hippocampus. Also called fimbria hippocampi.

final cause see cause.

final common path see motor neuron.

final free recall an unexpected test of memory given at the end of a memory assessment session, asking the individual to recall all of the materials that were studied and tested in the session.

finasteride see antandrogen.

fine motor describing activities or skills that require coordination of small muscles to control small, precise movements, particularly in the hands and face. Examples of fine motor skills include handwriting, drawing, cutting, and manipulating small objects. Compare gross motor.

fine tremor see tremor.

finger agnosia see tactile agnosia.

Finger Oscillation Test a 60-item neuropsychological test consisting of three parts: (a) The participant is asked to identify which finger is touched by the examiner; (b) the participant is blindfolded or otherwise prevented from using vision and then asked to identify which finger is touched; and (c) the participant again is blindfolded or otherwise prevented from using vision and then asked to identify which two fingers are simultaneously touched. Each hand is tested in each part of the test, which is scored for the number of correct identifications. It currently appears in a variety of forms and as part of several neuropsychological test batteries. Also called tactile finger recognition. [originally developed in 1983 by Arthur L. Benton and colleagues]

Finger Oscillation Test see finger tapping test.

fingerspelling n. the representation of the letters of the alphabet by shapes formed with the hand. Fingerspelling is used in conjunction with sign language to spell names and other words for which conventional signs do not exist. Many different manual alphabets are available, including the one-handed American Manual Alphabet, which is used in the United States and Canada, and the two-handed British Manual Alphabet, used in Great Britain, Australia, and New Zealand, each specifying distinct shapes for the different letters.

Finger Tapping Test a measure of fine motor speed in which the individual taps an index finger as quickly as possible against a response key. The test is part of the Halstead–Reitan neuropsychological battery. It was originally called the Finger Oscillation Test.

finite-state grammar a simple model of generative grammar discussed by Noam Chomsky in his Syntactic Structures (1957). In this model, it is supposed that the grammar generates sentences one unit at a time in a strict linear sequence (i.e., working from left to right); once the first unit has been selected, the choice of subsequent units will be circumscribed at each stage by the sum of the previous choices. Chomsky presented this model, with its obvious inadequacy as an account of sentence generation, to demonstrate the need for the more complex explanations provided by phrase-structure grammar and especially by transformational generative grammar. Psychologically interesting is the finite-state grammar stems largely from its similarity to certain principles of behaviorism and operationalism.

FINST theory a theory of visual attention that posits a preconceptual mechanism by which a small number of items in the visual field (usually about four) are “indexed”—that is, marked out as discrete—so that they can be accessed by higher order cognitive functions at subsequent stages of processing. The name is a contraction of fingers of instantiation: The visual indexes are proposed to aid orientation and tracking in a manner analogous to physical fingers. Also called visual indexing theory. [proposed in 1989 by Canadian cognitive scientist and philosopher Zenon W. Pylyshyn (1937— )]

fire-setting behavior a tendency to set fires. In young children, the behavior is often associated with curiosity and a lack of understanding of the consequences. In older children and adults, it is associated with a variety of disorders, such as conduct disorder, schizophrenia, and antisocial personality disorder. See also pyromania.

FIRO-B abbreviation for fundamental interpersonal relations orientation—behavior scale.

FIRO theory acronym for fundamental interpersonal relations orientation theory.

first admission a patient admitted for the first time to a mental institution.

first cranial nerve see olfactory nerve.

first-degree relative a parent, sibling, son, or daughter. Compare second-degree relative.

first-episode schizophrenia the first time that the criteria for a diagnosis of schizophrenia are met in an individual. First episodes are considered to be a critically important period during which prompt management of symptoms through drug treatment and psychosocial intervention can improve the course of the illness and mitigate its long-term impact on the individual.

first-generation antipsychotic see antipsychotic.

first impression one’s initial perception of another person, typically involving a positive or negative evaluation as well as a sense of physical and psychological characteristics. Such impressions are based on the earliest information
received about a person, often through a direct encounter, and tend to persist, even in the face of later information that outside observers would consider inconsistent with the initial perception. That is, there is a PRIMACY EFFECT in the impression formation. Some theoretical analyses account for this effect by holding that the first received information is given greater weight in the perceiver’s mind than the later information; others propose that the initial information shapes the meaning subsequently given to the later information.

**first-impression bias** see PRIMACY EFFECT.

**first-line medication** a drug that is the first choice for treating a particular condition because it is considered a very effective treatment for that condition with the least likelihood of causing side effects. A first-line medication may be a class of drugs (e.g., SSRIs for depression) as well as a single drug.

**first moment** see MOMENT.

**first-order factor** in FACTOR ANALYSIS, any of the LATENT VARIABLES (factors) that are derived from the CORRELATION (or covariance) among the MANIFEST VARIABLES, as opposed to SECOND-ORDER FACTORS, which are determined from the correlation (or covariance) among the factors. Also called primary factor.

**first-order interaction** an effect in which the pattern of values on one variable changes depending on the combination of values on two other variables. For example, an analysis could reveal that although gender and teaching style may each have some effect on performance, the specific degree or amount of the performance effect changes depending on the particular combination of gender and teaching method. Thus, male students may show moderately high performance regardless of teaching style, whereas female students may show high performance with a hands-on teaching style and low to moderate performance with a lecture teaching style. See also HIGHER ORDER INTERACTION.

**first-order neuron** the first neuron in a chain or tract of neurons. For example, in the somatosensory system, a first-order neuron receives peripheral input (e.g., sensations from the skin) and transmits it to the spinal cord. See also SECOND-ORDER NEURON.

**first-person perspective** the subjective point of view of a particular individual. Compare SECOND-PERSON PERSPECTIVE; THIRD-PERSON PERSPECTIVE.

**first-person perspective memory** see FIELD MEMORY.

**first quartile** see QUARTILE.

**first-rank symptoms** symptoms originally proposed by German psychiatrist Kurt Schneider (1887–1967) for the differential diagnosis of schizophrenia. They are audible thoughts; hearing voices arguing or commenting on one’s actions; thought withdrawal, diffusion, and other disturbances; delusional perceptions; somatic passivity (experiencing external forces as influencing or controlling one’s body); and other external impressions on feelings, inputs, and actions. It is now known that these symptoms can also occur in other psychotic disorders, in mood disorders, and in neurological disorders. Compare SECOND-RANK SYMPTOMS.

**first sleep** see SEGMENTED SLEEP.

**fishbowl technique** a procedure used in a GROWTH GROUP in which participants form two concentric circles. The individuals in the inner group (the fishbowl) engage in a discussion or other form of interaction while the members in the outer group observe. When the interaction has concluded, the outer group provides information and feedback to the inner group. Later, the groups may exchange places and repeat the exercise.

**Fisher exact test** a statistical procedure to determine whether two CATEGORICAL variables are related. Appropriate for small samples, it examines the associations between the rows and columns of data in a fourfold (2 × 2) CONTINGENCY TABLE. For example, the Fisher exact test could be used to assess whether there is a relationship between gender (male or female) and pizza topping preference (cheese or multitopping) in a group of 20 individuals. [Ronald Aylmer FISHER]

**Fisher least significant difference test** a statistical procedure to compare pairs of means, conducted after an F TEST has revealed that at least one pair of means is significantly different. The test calculates the smallest value that would be significantly different from chance when subtracting one mean from another mean. If the absolute value of the actual difference between a pair of means is larger than this least significant difference (LSD), a researcher can reject a NULL HYPOTHESIS that the means are equal and conclude that they are significantly different. Also called protected t test. [Ronald Aylmer FISHER]

**Fisher’s r to z transformation** a statistical procedure that converts a Pearson PRODUCT-MOMENT CORRELATION COEFFICIENT to a standardized Z SCORE in order to assess whether the correlation is significantly different from zero. The test is useful in providing a normally distributed statistic (called the Fisher transformed value or Fisher’s r) that can be used in HYPOTHESIS TESTING or in forming a CONFIDENCE INTERVAL. Also called Fisher transformation; Fisher z transformation; z transformation. [Ronald Aylmer FISHER]

**fission** n. 1. in biology, the reproduction of a cell or unicellular organism by splitting into two independent parts. 2. in audition, the separation of two simultaneous sounds into separate perceptual streams or auditory objects. When two streams are perceived as one, AUDITORY FUSION is said to occur (see also FUSION).

**fissure** n. a clef, groove, or indentation in a surface, especially any of the deep grooves in the cerebral cortex. See also SULCUS.

**fissure of Rolando** see CENTRAL SULCUS. [Luigi Rolando (1773–1831), Italian anatomist]

**fissure of Sylvius** see LATERAL SULCUS. [Franciscus Sylvius (1614–1672), Dutch physician and anatomist]

**fistula** n. an abnormal passageway between two internal organs or between an internal organ and the outside of the body. A fistula may develop as a result of an injury or infection, as a congenital defect, or as a result of a surgical procedure. Sexual violence may result in traumatic fistula (or traumatic gynecologic fistula).

**fit** n. 1. the degree to which values predicted by a model correspond with empirically observed values. For example, in STRUCTURAL EQUATION MODELING, a researcher may want to see how well his or her hypothesized model of the relationships among a set of variables actually fits the VARIATION and COVARIATION in the data. 2. n. a lay term for an epileptic seizure. 3. n. a colloquial name for an emotional outburst. 4. adj. see FITNESS.
**FIT**

FIT index a quantitative measure of how well a statistical model corresponds to the variation and covariation in a set of data. An index value greater than .90 (or preferably .95) indicates a model that explains the pattern of relationships in the data reasonably well. If the fit of a model is poor, then the model needs to be respecified and then reanalyzed. See GOODNESS OF FIT.

**fitness** n. 1. a set of attributes that people have or are able to achieve relating to their ability to perform physical work and to carry out daily tasks with vigor and alertness, without undue fatigue, and with ample energy to enjoy leisure pursuits. 2. in biology, the extent to which an organism or population is able to produce viable offspring in a given environment or ecological niche, which is a measure of that organism’s or population’s adaptation to that environment. Compare UNFITNESS. See DARWINIAN FITNESS; INCLUSIVE FITNESS; REPRODUCTIVE SUCCESS. —fit adj.

**fitness for duty evaluation** (FFDE) a psychological assessment of an employee's present mental state and functioning, used to estimate the employee's future functioning and determine whether that individual is able to safely and effectively perform his or her job duties. An FFDE is also used to determine if mental illness or emotional stress experienced by a person has interfered with his or her job performance. It is routinely conducted on police officers after they have had a traumatic experience in the line of duty. Also called fit for duty evaluation.

**Fit to Win Health Promotion Program** a U.S. Department of Defense educational program designed to promote health in Army personnel by reducing behavioral risk factors, such as smoking, excessive alcohol intake, and overconsumption of fatty foods.

**Fitts movement task** a motor-skills test that illustrates the relationship between speed and accuracy of movement. If a participant is asked to tap a pencil 20 times within the outline of a circle (the discrete version of the test), more pencil marks will fall outside the circle when the participant is asked to do the task quickly than when urged to be accurate. If a participant is asked to tap a pencil 20 times alternating between two circular outlines a fixed distance apart (the continuous version), accuracy will be similarly decreased. In current practice, the discrete version is almost always used in basic research, because the modeling issues are more straightforward, and the continuous version is usually used in neuropsychological testing and other more applied settings. The relationship between speed and accuracy for movement is formalized as FITTS’S LAW. [Paul Morris FITTS (1912–1965), U.S. psychologist]

**Fitts’s law** the principle of motor control that activities that are performed more quickly tend to be done less accurately (see SPEED—ACCUACY TRADEOFF). It is formulated as $MT = a + b \ln(DW)$, observed under a wide array of conditions to relate movement time (MT) linearly to a function $\ln(DW)$ of the ratio of movement distance (D) and target size (W). [Paul Morris FITTS]

**five-factor personality model** (FFM) a model of personality in which five dimensions of individual differences—EXTRAVERSION, NEUROTICISM, CONSCIENTIOUSNESS, AGREEABILITY, and OPENNESS TO EXPERIENCE—are viewed as core personality structures. Unlike the Big Five Personality Model, which views the five personality dimensions as descriptions of behavior and treats the five-dimensional structure as a taxonomy of individual differences, the FFM views the factors as psychological entities with causal force. The two models are frequently and incorrectly conflated in the scientific literature, without regard for their distinctly different emphases. [proposed by U.S. psychologists Robert R. McCrae (1949–) and Paul T. Costa Jr. (1942–)]

**five-number summary** in EXPLORATORY DATA ANALYSIS, the characterization of a data set through the use of five summary statistics: the two extreme scores, the upper and lower quartiles, and the MEDIAN or middle quartile. For example, suppose the scores on a test are 100, 93, 90, 82, 76, 72, 64, 61, 60, and 47. The five-number summary from highest to lowest numbers would be 100, 90, 74, 61, and 47—that is, 100 is the highest extreme score, 90 is the highest quartile (the midpoint in the top half of the data), 74 is the middle point, 61 is the lowest quartile (the midpoint in the bottom half of the data), and 47 is the lowest extreme score. These values provide the basic highlights of a set of data and can be used to create a BOX-AND-WHISKER PLOT.

**five-to-seven shift** the striking progress in children’s cognitive development between the ages of 5 and 7, when very significant advances in such areas as reasoning and logic, linguistic ability, memory, and problem solving occur. [introduced in 1965 by Sheldon H. WHITE]

**fixation** n. 1. an obsessive preoccupation with a single idea, impulse, or aim, as in an IDÉE FIXE. 2. a shortened name for VISUAL FIXATION. 3. in psychoanalytic theory, the persistence of an early stage of PSYCHOSEXUAL DEVELOPMENT or the inappropriate attachment to an early psychosexual object or mode of gratification, such as anal or oral activity; this fixation limits the person’s ability to negotiate the tasks of later psychosexual stages. —fixate vb.

**fixation pause** a period during which the eyes are focused directly on an object.

**fixation point** the point in space on which the eyes are focused. In experimental studies of visual perception, a specific fixation point is often provided while vision is tested in some other location in the visual field.

**fixation reflex** a reflexive orienting of the eyes to maintain fixation on a target. It involves cortical and subcortical regions. Also called fixation response. See OPTOKINETIC REFLEX; VESTIBULO-OCCULAR REFLEX.

**fixed action pattern** (FAP) in classical ethology, a stereotyped, genetically preprogrammed, species-specific behavioral sequence that is evoked by a releaser stimulus and is carried out without sensory feedback. In contemporary ethology, the term MODAL ACTION PATTERN is more often used.

**fixed-alternative question** a test or survey item in which several possible responses are given and participants are asked to pick the correct response or the one that best matches their preference. An example of a fixed-alternative question is “Which of the following most closely corresponds to your age: 12 or younger, 13 to 19, 20 to 39, 40 to 59, 60 to 79, or 80 or older?” A fixed-alternative question is sometimes referred to as a closed question, although this may also refer to any inquiry requesting a short, definite answer (e.g., “How old are you?”). Also called fixed-choice question; forced-choice question; multiple-choice question. Compare FREE-RESPONSE QUESTION; OPEN QUESTION.

**fixed belief** see IDÉE FIXE.
**fixed class society** a society with very little or no social mobility, as in the Hindu Caste system. Compare OPEN CLASS SOCIETY.

**fixed effect** an independent variable whose levels are specified by the researcher rather than randomly chosen within some level of permissible values. For example, a health researcher who specifically chose to examine the effect on weight loss of no exercise, 1 hour of exercise, or 3 hours of exercise per week would be treating time spent exercising as a fixed effect. In other words, all levels of interest are included in the design, and thus anyone wanting to replicate the study would have to use the same levels of exercise as in the original. Also called fixed factor. See fixed-effects model; random-effects model. Compare RANDOM EFFECT.

**fixed-effects analysis of variance** a statistical procedure to determine whether means for an outcome or dependent variable differ across a specific set of conditions (i.e., levels of the independent variable) that have been selected by a researcher. This is contrasted with a random-effects analysis of variance, in which the conditions have been randomly selected from a wide range of possible choices before any mean differences are examined.

**fixed-effects model** any statistical procedure or experimental design that uses independent variables whose levels are specifically selected by the researcher for study rather than randomly chosen from a wide range of possible values. For example, a researcher may wish to investigate the effects of the available dosages of a certain drug on symptoms alleviation. Fixed-effects models generally are intended to make inferences solely about the specific levels of the independent variables actually used in the experiment. Compare mixed-effects model; random-effects model.

**fixed factor** see fixed effect.

**fixed idea** see idée fixe.

**fixed-interval schedule (FI schedule)** in conditioning, an arrangement, formerly known as periodic reinforcement, in which the first response that occurs after a set interval has elapsed is reinforced. For example, “FI 3 min” means that reinforcement is given to the first response occurring at least 3 minutes after a previous reinforcement. Often, experience with FI schedules results in a temporal pattern of responding, characterized by little or no responding at the beginning of the interval, followed by an increased rate later on as reinforcement becomes more imminent. This pattern is often referred to as the fixed-interval scallop.

**fixedness** n. in problem solving, see functional fixedness.

**fixed parameter** a specific value assigned (as opposed to estimated) by a researcher when testing a statistical model. For example, in structural equation modeling, researchers may use a fixed parameter of 1.0 for one of the factor loadings or variances of each latent variable in a model. Compare free parameter.

**fixed-ratio schedule (FR schedule)** in conditioning, an arrangement in which reinforcement is given after a specified number of responses. “FR 1” means that reinforcement is given after each response; “FR 50” means that reinforcement is given after every 50 responses; and so on.

**fixed-time schedule (FT schedule)** in conditioning, an arrangement in which reinforcers are delivered at fixed time intervals independent of the organism’s behavior.

**fixed variable** a variable whose value is specified by a researcher or otherwise predetermined and not the result of chance. Compare random variable.

**FJA** abbreviation for functional job analysis.

**flaccid paralysis** a condition resulting from damage to lower motor neurons and marked by loss of muscle tone and absence of tendon reflexes. Compare spastic paralysis.

**flagellation** n. whipping another person or oneself or submitting to whipping. Flagellation may be a form of penance (as a religious ritual) or a means of achieving sexual excitement. Flagellation is a common practice among those who engage in bondage and discipline. Also called flagellantism.

**flanker task** a task in which stimuli are assigned one of two responses and the participant is required to respond to the target stimulus when this is flanked by other stimuli. The stimuli are presented at a known location (usually at fixation), and the flanking stimuli are associated with a response that is either the same as or different from that assigned to the target. Reaction time is slower if the stimuli flanking the target are assigned the alternative response than if they are assigned the same response as the target. This is known as the flanker compatibility effect. Also called Eriksen flankers task. [devised by U.S. psychologist Charles W. Eriksen (1923–)]

**flapping tremor** see asterixis.

**flashback** n. 1. the reliving of a traumatic event after at least some initial adjustment to the trauma appears to have been made. Memories may be triggered by words, sounds, smells, or scenes that are reminiscent of the original trauma (as in a backfiring car triggering a flashback to being in combat). Flashbacks may be associated with post-traumatic stress disorder. 2. the spontaneous recurrence of the perceptual distortions and disorientation to time and place experienced during a previous period of hallucinogen intoxication. Flashbacks may occur months or even years after the last use of the drug and are associated particularly with LSD.

**flashbulb memory** a vivid, enduring memory associated with a personally significant and emotional event, often including such details as where the individual was or what he or she was doing at the time of the event. People often believe that such memories have the quality of a photograph taken at the moment they experienced the event, and they believe with high confidence that these memories are accurate. However, recent research has shown that although flashbulb memories are more likely to be retained than the memory of an everyday event, they are not always accurate. [first described in 1977 by U.S. psychologists Roger Brown and James Kulik (1940–) in their study of people’s recollection of public events, such as U.S. President John F. Kennedy’s assassination]

**flash card** one of a series of small pieces of cardboard or paper with questions and answers written or printed on them, used as a learning aid. Often, a question is on the front of the flash card and the answer is on the back. A student reads the question, gives an answer, and then is able to turn the card over to see the correct answer. Flash cards are commonly used in rapid succession and aid memorization of a fact or concept.
flat affect

total or near absence of appropriate emotional responses to situations and events. See also SHALLOW AFFECT.

flat organizational structure an organization in which there are relatively few levels of management.

flavor n. a sensation produced by a combination of aroma, taste, texture, and temperature and involving olfactory, gustatory, and tactile sense organs.

flehmen n. a distinctive posture of nonhuman animals in which the head is raised and lips curled (from German, “to bare the upper teeth”), often accompanied by a snort or deep inhalation of air. Flehmen serves to deliver chemical cues to the vomeronasal system, an accessory olfactory organ that appears specialized to process species-specific olfactory cues. Flehmen is often seen in male ungulates inspecting female urine to determine if the female is in estrus.

Flesch index a system used for evaluating readability and reading level of a document by examining word and sentence length, vocabulary, and phrases. [Rudolph Flesch (1911–1986), U.S. philologist and psychologist]

flexeril n. a trade name for cyclobenzaprine.

flexibilitas cerea see catalepsy.

flexible correction model a theory postulating that corrections to bias in judgments occur when people are motivated and able to adjust their assessments of targets according to their naive theories of how the context influences their judgments. This may result in either assimilation or contrast effects depending on their perceptions of the magnitude and direction of bias. See also inclusion/exclusion model; set/reset model. [proposed by U.S. social psychologists Duane T. Wegener (1966–) and Richard E. Petty (1951–)]

flexion n. the bending of a joint in a limb (e.g., the elbow joint) so that two parts of the limb (e.g., the forearm and upper arm) are brought toward each other.

flexion reflex the abrupt withdrawal of a limb in response to painful stimulation. Compare extension reflex.

flexor n. a muscle whose contraction bends a part of the body, such as the biceps muscle of the upper arm. Compare extensor.

flextime n. an arrangement that gives employees a certain amount of discretion over when they arrive at and leave work, provided that an agreed period of core hours is spent in the workplace. Flextime allows workers to adjust their work schedules to nonwork demands, such as parental responsibilities. Also called flextime.

flicker discrimination the ability to perceive a change in brightness of a light source. The ability varies with the frequency of alternating changes in brightness until critical flicker frequency is reached, when the observer sees an apparently steady level of brightness.

flicker fusion frequency see critical flicker frequency.

flicker stimulus a periodically changing visual or auditory stimulus that produces a rapidly alternating sensation.

flight n. 1. a form of locomotion that allows some animals (notably birds, bats, and insects) to become airborne and travel varying distances. It has several forms: active flight, gliding, and hovering. Bones of flying vertebrates must be light and rigid. Flight is used for escaping danger, locating food, and migrating from one location to another as seasons change (see migration). 2. rapid departure as a means of escape from danger, whether by flying or some other form of locomotion. See also flight-or-flight response.

flight from reality a defensive reaction involving withdrawal into inactivity, detachment, or fantasy as an unconscious defense against anxiety-provoking situations. This may be expressed as a number of defensive behaviors, such as rationalization, daydreaming, or substance abuse. It may include a retreat into psychotic behavior as a means of avoiding real or imagined problems. Also called retreat from reality. See also escape from reality. Compare flight into fantasy: flight into reality.

flight into disease see flight into illness.

flight into fantasy a defensive reaction in which individuals experiencing disturbing thoughts and impulses retreat into fantasy (e.g., through daydreams) as a means of avoiding harming themselves or others by acting on these impulses. In this way, they can maintain control over their impulses. Compare flight from reality: flight into reality.

flight into health in psychotherapy, an abrupt “recovery” by a prospective client after or during intake interviews and before entry into therapy proper or, more commonly, by a client in ongoing therapy in order to avoid further confrontation with cognitive, emotional, or behavioral problems. Psychoanalytic theory interprets the flight into health as an unconscious defense mechanism. Also called transference cure: transference remission.

flight into illness 1. a tendency to focus on or exaggerate minor physical complaints as an unconscious means of avoiding stressful situations and feelings. 2. in psychotherapy, the sudden development of neurotic or physical symptoms by a client or prospective client. Psychoanalytic theory interprets this as an unconscious defense mechanism that is used to avoid examination of a deeper underlying conflict. Also called escape into illness: flight into disease.

flight into reality a defensive reaction in which an individual becomes involved in activity and work as an unconscious means of avoiding threatening situations or painful thoughts and feelings. Compare flight from reality: flight into fantasy.

flight into disease see flight into illness.

flight into illness 1. a tendency to focus on or exaggerate minor physical complaints as an unconscious means of avoiding stressful situations and feelings. 2. in psychotherapy, the sudden development of neurotic or physical symptoms by a client or prospective client. Psychoanalytic theory interprets this as an unconscious defense mechanism that is used to avoid examination of a deeper underlying conflict. Also called escape into illness: flight into disease.

flight of ideas a rapid, continuous succession of superficially related thoughts and ideas, manifest as hurried speech with frequent abrupt shifts in topic. A common symptom of a manic episode, such disturbed thinking occasionally is seen in other disorders as well, including schizophrenia.

floaters pl. n. see detached retina.

floating-limb response in standard hypnotic inductions, a positive response to the suggestion to allow the hand and arm to float upward. See also kohnstamm test.

floc villa n. aimless grasping and plucking at clothing or bedding, typically associated with dementia, delirium, and high fever. It is sometimes a sign of extreme
exhaustion and is considered a serious symptom, often associated with a poor prognosis. Also called carphology.

flocculonodular lobe one of the divisions of the cerebellum, lying below the posterior lobe. The flocculonodular lobe projects to the vestibular nuclei of the brainstem and is mainly involved with vestibular functions (posture and eye movements).

flocking n. the grouping of birds due to social attraction and interaction. It is related to colonial nesting (see colonial species) and contrasts with aggregation, which is due to some independent factor. The equivalent of flocking in mammals is known as herding (see herd instinct).

flooding n. a technique in behavior therapy in which the individual is exposed directly to a maximum-intensity anxiety-producing situation or stimulus, either described or real, without any attempt made to lessen or avoid anxiety or fear during the exposure. An individual with clausrophobia, for example, might be asked to spend extended periods of time in a small room. Flooding techniques aim to diminish or extinguish the undesired response to a feared situation or stimulus and are used primarily in the treatment of individuals with phobias and similar disorders. It is distinct from systematic desensitization, which involves a gradual, step-by-step approach to encountering the feared situation or stimulus while attempting throughout to maintain a nonanxious state. See also implosive therapy.

floor effect the situation in which a large proportion of participants perform very poorly on a task or other evaluative measure, thus skewing the distribution of scores and making it impossible to differentiate among the many individuals at that low level. For example, a test whose items are too difficult for those taking it would show a floor effect because most people would obtain or be close to the lowest possible score of 0. Compare ceiling effect.

floral adj. denoting one of the seven classes of odorants in the stereochemical smell theory.

flotation-REST n. see restricted environmental stimulation technique.

flotation tank an enclosed container filled with water (usually highly concentrated salt water) and insulated from all incoming stimuli (e.g., light, sound). It is used for both experimental and clinical purposes (see restricted environmental stimulation technique; sensory deprivation). Originally called isolation tank; sensory deprivation tank. [developed by U.S. physician John C. Lilly (1915–2001)]

flourishing n. a condition denoting good mental and physical health: the state of being free from illness and distress but, more important, of being filled with vitality and functioning well in one’s personal and social life. Compare languishing. —flourish v.b.

flow n. a state of optimal experience arising from intense involvement in an activity that is enjoyable, such as playing a sport, performing a musical passage, or writing a creative piece. Flow arises when one’s skills are fully utilized yet equal to the demands of the task, intrinsic motivation is at a peak, one loses self-consciousness and temporal awareness, and one has a sense of total control, effortlessness, and complete concentration on the immediate situation (the here and now). [proposed in 1990 by Mihaly Csikszentmihalyi]

flower-spray ending a type of nerve-fiber ending at the thin ends of a muscle spindle in which the fiber branches out across the surface of the spindle. Also called secondary sensory ending. Compare annulospiral ending.

florivorous adj. denoting one of the primary odor qualities in Henning’s odor prism.

flow pattern see optic flow.

fluctuating asymmetry the degree to which the symmetry of body parts of individuals varies from the norm for a given species. This provides information to others about the relative health or well-being of an individual: It is assumed that those with more symmetrical bodies are healthier and more vigorous than those with more asymmetry. Thus, fluctuating asymmetry is an important cue in mate-selection decisions.

fluctuation n. 1. variation in size or value. 2. a slight change that is associated with environmental factors rather than being an inherited trait. 3. in time-series analyses, an irregularity that is not related to any trend and is thus often removed via smoothing.

fluctuation of attention the tendency for objects or stimuli to pass in and out of attention even though stimulation is constant.

fluctuation of perception a tendency for perception to alternate between competing stimuli that cannot be integrated or synthesized. See bistable perceptual events.

fluency n. 1. the ability to generate ideas, words, mental associations, or potential solutions to a problem with ease and rapidity. It is usually considered to be an important dimension of creativity. See associative fluency. 2. facility in speaking or writing, as in a language that is not one’s native language. —fluency adj.

fluent aphasia see aphasia.

fluency speech speech that is essentially normal in quantity, stress, pitch, rhythm, and intonation.

fluid intelligence (fluid ability) see cattell–horn theory of intelligence.

flumazenil n. a drug used for the emergency reversal of symptoms of benzodiazepine overdose and in anesthesia to reverse benzodiazepine-induced sedation. It acts by displacing benzodiazepine (which acts as a gaba agonist) from binding sites on the gaba receptor complex (see benzodiazepine antagonist; gaba receptor). Because it is a short-acting agent, multiple doses may be required. It is not effective in managing benzodiazepine dependence, because its rapid action may precipitate a sudden withdrawal syndrome, nor does it antagonize the central nervous system effects of other gaba agonists (e.g., barbiturates) or reverse their effects. U.S. trade name: Romazicon.

flunitrazepam n. a benzodiazepine that is legally prescribed in some countries (but not the United States) for the short-term treatment of insomnia and as a preanesthetic medication. It is also used as a drug of abuse for its sedating and disinhibiting effects. When combined with alcohol, like many other CNS depressants, it can cause serious problems (see date-rape drug). Also known colloquially as roofie. Trade name: Rohypnol.

fluorescein angiography a diagnostic procedure used to examine the retinal vasculature. A fluorescent compound, fluorescein, is injected into the systemic circulation;
fluoxetine

as it flows through the blood vessels on the surface of the retina, these are photographed with a special camera.

**fluoxetine** n. an antidepressant that is the prototype of the SSRI s (selective serotonin reuptake inhibitors). It acts by inhibiting the serotonin transporter, preventing reuptake of serotonin into the terminal button (see axon) of the presynaptic neuron. This presumably results in higher levels of available neurotransmitter to interact with postsynaptic receptors. Fluoxetine differs from other SSRIs in that it and its biologically active metabolic product, norfluoxetine, have a prolonged half-life of 5 to 7 days after a single dose; thus, it takes 20 to 35 days for the drug to reach steady-state concentrations. Like other SSRIs, it should not be used with MAO inhibitors. U.S. trade names: Prozac, Sarafem.

**fluoxetine n.** a HIGH-POTENCY ANTIMUSCARINIC of the piperazine PHENOTHIAZINE class. It is as potent as HALOPERIDOL and has similar side effects, with neuromuscular and extrapyramidal symptoms predominating. Like haloperidol, it is also available in an oil-based injectable form. These so-called depot preparations are injected intramuscularly and are very slowly absorbed, allowing periods of several weeks between doses. U.S. trade name: Prolixin.

**fluoxetine n.** a BENZODIAZEPINE derivative used in the short-term treatment of insomnia. U.S. trade name: Dalmane.

**fluoxetine n.** see ANTIANDROGEN.

**flutter** n. see ROUGHNESS.

**flutter dysmetria** see OCULAR FLUTTER.

**fluttering hearts** a visual illusion in which figures of one color (typically red), presented on a background of the same brightness but a different color (typically blue), will appear to dance when the whole image is moved. The different response speeds of the retinal cones encoding the two colors is thought to be the basis of this illusion.

**fluvoxamine** n. a potent SSRI (selective serotonin reuptake inhibitor). Although its mechanism of action and antidepressant efficacy match those of other SSRIs, it is approved for and largely marketed for treating obsessive-compulsive disorder (see also CLOMIPRAMINE) and social anxiety disorder. U.S. trade name: Luvox.

**fly agaric** the highly poisonous mushroom *Amanita muscaria*, so called because it was once used as an insecticide to kill flies. MUSCARINE was the first active ingredient to be identified, but it is now known that IBOTENIC ACID and its metabolite MUSCIMOL, which is similar in structure to the inhibitory neurotransmitter GAMMA-AMINOBUTYRIC ACID (GABA) and acts as a GABA ANTAGONIST, are the principal active components. Effects on humans are initially stimulating, ranging from euphoria through hallucinations to hyperactivity or excitement, and then sedating, inducing deep sleep. Symptoms of poisoning include dizziness, abdominal pains, vomiting, muscle cramps, and movement difficulties; at higher doses, these symptoms may be followed by unconsciousness, asphyxiation, coma, and potentially death. Fly agaric has been variously identified as the substance taken by Norse berserkers before battle, as the plant SOMA worshipped in ancient times, and, in fiction, as the mushroom eaten by Alice before she perceived objects larger than life in Lewis Carroll’s *Alice in Wonderland*.

**flying flies** see MUSCAE VOLATANTES.

**Flynn effect** the gradual cross-cultural rise in raw scores obtained on measures of general intelligence. These increases have been roughly 9 points per generation (i.e., 30 years). The gains have been unequally distributed across the different kinds of abilities, with fluid abilities showing substantially greater gains than crystallized abilities (see CATTELL–HORN THEORY OF INTELLIGENCE). [James Flynn (1934– ), New Zealand philosopher who first documented its occurrence]

**F_max statistic** in an ANALYSIS OF VARIANCE, a value formed from the ratio of the largest variance over the smallest variance from the set of groups being assessed. The $F_{max}$ statistic is assessed for significance by looking up the CRITICAL VALUE in a statistical table for the relevant number of groups and DEGREES OF FREEDOM. If the calculated $F_{max}$ statistic is larger than the critical value, then there is evidence of HETEROGENEITY OF VARIANCE, which violates one of the assumptions of the analysis and renders its results invalid.

**FMEA** abbreviation for FAILURE MODES AND EFFECTS ANALYSIS.

**fMRI** abbreviation for FUNCTIONAL MAGNETIC RESONANCE IMAGING.

**fMRI measures of intelligence** measures of intelligence yielded by functional magnetic resonance imaging methods, which enable investigators to obtain relatively precise indications of which part or parts of the brain are being utilized in the solution of a cognitive task. Thus, the typical goal is to pinpoint that part of the brain in which processing is taking place for a given task at a given point in information processing for that task.

**FMS** abbreviation for FALSE MEMORY syndrome.

**focal attention** active concentration on particular stimuli to the exclusion of others. Information that is within one’s scope of attention is said to be in focal attention. Much research is devoted to determining the information capacity of focal attention and to understanding how it interacts with various memory systems after its capacity is exceeded. Also called focused attention. See also SELECTIVE ATTENTION.

**focal consciousness** those contents of experience that are the focus of attention at any given moment. The focal components of consciousness will typically be clear, discriminable, and detailed. Compare FRINGE CONSCIOUSNESS.

**focal degeneration** the development of a lesion or dysfunction in a specific area of the brain due to a degenerative process, such as dementia. The lesion may remain limited in focus or spread into neighboring regions.

**focal dermal hypoplasia** see GOLTZ SYNDROME.

**focal length** (symbol: f) the distance between the surface of a lens and the point at which it focuses the light passing through the lens.

**focal lesion** a lesion that is restricted to a specific area (e.g., of the brain).

**focal motor seizure** a simple PARTIAL SEIZURE that results in motor abnormalities and is due to localized seizure activity in brain areas important for movement.

**focal pathology** the study of changes in body tissues and organs involved in a disease at the focal point of the diseased area.

**focal psychotherapy** a form of BRIEF PSYCHOTHERAPY in which a single problem (e.g., excessive anxiety) is made
the target of the entire course of treatment. The therapist continually redirects the process to avoid deviations from this specifically identified aim.

**focal seizure** see PARTIAL SEIZURE.

**focal symptoms** symptoms limited to a specific area.

**focus n.** the concentration or centering of attention on a stimulus.

**focused attention** see FOCAL ATTENTION.

**focus gambling** in a task that requires the generation of hypotheses about what combination of features defines a concept, a strategy in which the participant changes more than one feature from one hypothesis to the next. Focus gambling contrasts with the more conservative strategy of varying one feature at a time to determine its relevance to the concept. See CONCEPT-DISCOVERY TASK.

**focus group** a small set of people, typically 8 to 12 in number, who share characteristics (e.g., working parents with 5- to 8-year-old children) and are selected to discuss a topic of which they have personal experience (e.g., their children’s reading abilities and school performance). A leader conducts the discussion and keeps it on target while also encouraging free-flowing, open-ended debate. Originally used in marketing to determine consumer response to particular products, focus groups are now used for determining typical reactions, adaptations, and solutions to any number of issues, events, or topics and are associated particularly with QUALITATIVE RESEARCH.

**focusing n.** in EXPERIENTIAL PSYCHOTHERAPY, a process in which the therapist guides a client to focus silently on the experience of a problem or symptom in a relaxed and non-judgmental way, often with eyes closed. The client explores intuitively what the problem or symptom is about, without attempting to analyze or control thought processes. The method is believed to lead the client to deeper feelings and greater insight about and peace with the problem or symptom. [developed by Austrian-born U.S. philosopher and psychologist Eugene T. Gendlin (1926- )]

**focusing effect** the ostensible phenomenon in which performance is better for trials in which the TARGET is the object of special attentional focus (perhaps because it has particular significance for the participant). The phenomenon is of particular interest in studies of EXTRASENSORY PERCEPTION and PSYCHOKINESIS. See also DECLINE EFFECT; DIFFERENTIAL EFFECT; POSITION EFFECT; PREFERENTIAL EFFECT; SHEEP- GOAT EFFECT; ZENER CARDS.

**focusing mechanism** the system of CILIARY MUSCLES, lens elasticity, and ocular-fluid pressure that enables the eye to focus an image sharply on the retina. The natural shape of the lens is spherical, which is required to focus near objects. When focusing distant objects, the lens is flattened by tension exerted on the ZONULAE as the ciliary muscles are relaxed and by fluid pressure within the eye.

**focusing power** the degree to which a converging lens causes parallel rays of light to be refracted (see REFRACTION). A high focusing power will cause light to be focused to a point close to the lens; a low focusing power causes the light to be focused farther from the lens. The focusing power of a lens is measured in DIOPTERS. The magnification power of a lens indicates how many times an object is enlarged when viewed through the lens; for example, a 4 × lens will produce an image four times the actual size of the object.

**focus of attention** that aspect of an internal or external event to which attention is directed.

**focus of convenience** in the personality theory of George A. Kelly, the set of phenomena to which a given theory best applies.

**FOK** abbreviation for FEELING OF KNOWING.

**foliate papillae** swellings along the lateral margins (sides) of the tongue, in humans numbering 5 to 7 on each side, each shaped like a leaf. The groove between each pair of papillae contains about 100 TASTE BUDS. See also PILLI.

**folie à deux** a rare psychotic disorder in which two intimately related individuals simultaneously share similar or identical delusions (French, “double insanity”). It is the most common form of SHARED PSYCHOTIC DISORDER. Rarer forms involving more than two intimately related individuals or members of the same family are called folie à trois (a delusion shared by three people), folie à quatre (a delusion shared by four people), and so on.

**folium n.** (pl. folia) a leaflike structure, especially one of the leaflike folds of the CEREBELLAR CORTEX.

**folk bilingualism** a type of BILINGUALISM associated mainly with working-class immigrant communities, in which the native language is primarily oral and its use is unsupported by formal education. Also called CIRCUMSTANTIAL BILINGUALISM. Compare ELITE BILINGUALISM.

**folklore n.** the body of beliefs, legends, tales, songs, and other traditions transmitted orally from generation to generation in a specific culture.

**folk medicine** health and healing strategies based on cultural tradition, usually practiced by people within the culture who have experience in applying these remedies but no formal training. Folk medicine is most strongly associated with herbal remedies, but animal, mineral, and spiritual remedies also fall into this category. When folk medicine is used outside of its originating culture, it is considered part of COMPLEMENTARY AND ALTERNATIVE MEDICINE. Also called traditional medicine.

**folk psychology** 1. the everyday, commonsense, implicit knowledge that enables the prediction or explanation of the behavior of others (and of oneself) by reference to the mental states involved. Although such an understanding is accepted in much of social and personality psychology, there are those who view it as illusory or mythological and hold its tenets unworthy of scientific consideration. In ELIMINATIVISM, the term folk psychology is used pejoratively for any explanatory language that refers to mental states such as beliefs and intentions, rather than to biological states. See also COMMONSENSE PSYCHOLOGY: POPULAR PSYCHOLOGY. 2. an obsolete name for a branch of psychology that deals with the influence of specific cultural experiences (e.g., legends, religious rituals, indigenous healing practices) on human behavior and psychological constructs. It is essentially equivalent to modern CROSS-CULTURAL PSYCHOLOGY. 3. a branch of the psychological system of Wilhelm Wundt, who believed that an understanding of higher mental processes could be deduced from the study of such cultural products as language, history, myths, art, government, and customs. As such, it is the historical predecessor to modern MULTICULTURAL PSYCHOLOGY.

**folk soul** in the FOLK PSYCHOLOGY of Wilhelm Wundt, a
folkways

group’s perpetual and fundamental characteristics, moralities, norms, and values, which cannot be explained solely in terms of the characteristics of the individual members of the group. Belief in a folk soul is usually seen as an example of the GROUP FALLACY. See also GROUP MIND.

folkways pl. n. the traditional modes of behavior in a particular culture, society, or group.

follicle n. a cluster of cells enclosing, protecting, and nourishing a cell or structure within, such as a HAIR FOLLICLE or a GRAAFIAN FOLLICLE. —follicular adj.

follicle-stimulating hormone (FSH) a GONADOTROPIN released by the anterior pituitary gland that, in females, stimulates the development in the ovary of GRAAFIAN FOLLICLES (see MENSTRUAL CYCLE). The same hormone in males stimulates SERTOLI CELLS in the testis to produce spermatozoa. Also called follitropin.

follicular phase see MENSTRUAL CYCLE.

follow-back study research that collects earlier data in order to understand the causes of an event of interest. For example, a researcher might conduct a follow-back study of deceased hospital patients, gathering additional information regarding cause of death so as to understand the progress of different diseases.

following behavior a species-specific trait of certain young animals that run or swim after a parent or surrogate parent. It is a manifestation of IMPRINTING.

follow-up counseling 1. the measures taken by a counselor or clinician in helping a client with ongoing problems or new manifestations of the original problems.

2. an evaluation of a client’s progress and the effectiveness of counseling to date.

follow-up history see CATAMNESIS.

follow-up study a long-term research project designed to examine the degree to which effects seen shortly after the imposition of an intervention persist over time. Follow-up studies are also used for the long-term study of participants in a laboratory experiment to examine the degree to which effects of the experimental conditions are lasting.

follow-up test see POST HOC TEST.

Folstein Mini-Mental State Examination see MINI-MENTAL STATE EXAMINATION.

fontanel (fontanelle) n. a soft, membrane-covered area in the incompletely ossified skull of a newborn infant. Fontanels typically close before the 2nd year of life, as the skull bones gradually fuse. Also called soft spot.

food addiction an eating disturbance characterized by a preoccupation with one’s body image and weight, obsessive thoughts about food, the use of food as a source of pleasure, and COMPELLING EATING. In addition, the individual may experience symptoms of withdrawal during attempts to reduce food intake or abstain from particular types of food. See also BINGE-EATING DISORDER: RUMINATION.

food caching the hiding or storing of food by a nonhuman animal for later use. Clark’s nutcracker, a bird of the southwestern United States, is said to cache up to 30,000 pine nuts each year and to retrieve enough of these to survive over winter. Food-caching birds have good SPATIAL MEMORY and an enlarged HIPPOCAMPUS. See hoarding.

food faddism any dietary practice based on exaggerated and often incorrect beliefs about the effects of food or nutrition on health, particularly for the prevention or cure of illness. This is often expressed as strange or inappropriate eating habits and the adoption of cult diets; it may lead to unhealthy weight loss or side effects arising from poor nutrition. It is sometimes associated with eating disorders, such as ANOREXIA NERVOSA.

food-intake regulation the ability to adjust daily intake of calories and other nutrients according to the temperature of the environment, energy expended at various tasks, and other factors, so that calorie intake and calorie loss, as well as other nutritional components (e.g., proteins, fats, vitamins, minerals), are constantly in balance. Food-intake regulation is one example of HOMEOSTASIS.

foot anesthesia see STOCKING ANESTHESIA.

foot-candle n. a former unit of illuminance now replaced by the LUX (1 foot-candle = 10.764 lux). Average street lights are approximately 1 foot-candle.

foot drop a characteristic of certain neuromuscular disorders in which the muscles that control movement of the foot or toes are weakened or paralyzed. The affected foot may fall forward and slap against the floor or ground, or the affected toes may tilt forward and drag along the floor or ground.

footedness n. preferential use of one foot rather than the other, for example, in kicking. See HANDINESS; LATERALIZATION.

foot fetishism a form of FETISHISM in which sexual excitement is achieved through contact with or masturbation near a shoe or foot. Shoes or feet are among the most common varieties of fetish, but there is little understanding of why this occurs. The condition is also called retifism, named for French writer Nicolas-Edme RéDé (1734–1806), also known as Rétif de la Bretonne, who is said to have had a sexual interest in women’s footwear.

foot-in-the-door technique a two-step procedure for enhancing COMPLIANCE in which a minor initial request is presented immediately before a more substantial target request. Agreement to the initial request makes people more likely to agree to the target request than would have been the case if the latter had been presented on its own. See also DOOR-IN-THE-FACE TECHNIQUE; LOW-BALL TECHNIQUE; THAT’S-NOT-ALL TECHNIQUE.

foraging n. the process of searching for, locating, capturing, and processing food for ingestion or for provisioning young. For example, fruit-eating animals must locate trees containing fruit ripe enough to eat and often process the fruit by removing husks or seeds prior to ingestion. OPTIMAL FORAGING THEORY provides a framework for predicting the costs and benefits of different decisions about where to forage and for how long.

foramen n. (pl. foramina) an anatomical opening or hole, particularly in a bone. For example, the foramen magnum is a large opening at the base of the skull through which the spinal cord and the vertebral arteries pass.

foramen of Monro see INTERVENTRICULAR FORAMEN. [Alexander Monro Jr. (1733–1817), Scottish anatomist]

foraminotomy n. the surgical enlargement of one of the foramina (openings) between adjacent vertebrae through which a spinal nerve passes, usually by enlarging the opening above the nerve root. The procedure is done to relieve nerve pressure, such as that causing lower back pain.
forced-choice question see fixed-alternative question.

forced compliance effect the tendency of a person who has behaved in a way that contradicts his or her attitude to subsequently alter the attitude to be consistent with the behavior. It is one way of reducing cognitive dissonance. Also called induced compliance effect. See also dissonance reduction.

forced copulation copulation by a male with a female against her choice. In scorpion flies, males have several tactics for obtaining mates: Larger males can monopolize resources and offer food to females that accept copulation; smaller males without access to food can use forced copulation, which leads to much less reproductive success. See also rape.

forced distribution a rating system in which raters must make a prescribed number of entries for each level of the rating scale used. For example, in employee evaluation, a forced distribution might be used in which it is required that 5% of employees are categorized as poor, 15% as below average, 60% as average, 15% as above average, and 5% as excellent.

forced treatment therapy administered without the informed consent of the recipient, such as to an individual with a mental disorder. Forced treatment may include court-ordered administration of psychoactive drugs to a person to restore his or her competency to stand trial or the involuntary hospitalization of a person considered dangerous to himself or herself or others. Many question the ethical acceptability of the practice, citing its infringement of autonomy and the right to refuse treatment and its lack of scientifically demonstrated effectiveness; such controversy has intensified in recent decades. Also called coercive treatment; involuntary treatment.

force field in field theory, the totality at any instant of coexisting factors that influence change (e.g., behavioral change).

forceps injury a defect, temporary or permanent, induced by the use of forceps to extract a newborn infant from the mother’s uterus during labor. Forceps injury is one of the causes of cerebral palsy.

forebrain n. the part of the brain that develops from the anterior section of the neural tube in the embryo, containing the cerebrum and the diencephalon. The former comprises the cerebral hemispheres with their various regions (e.g., basal ganglia, amygdala, hippocampus); the latter comprises the thalamus and hypothalamus. Also called prosencephalon.

foreclosure n. see identity foreclosure; identity status model.

foreground–background n. in perception, the distinction between the object of attention, which is in the subjective foreground, and the vague texture of the background, which is less likely to receive individual attention. See also figure–ground.

foregrounding n. the process or technique of highlighting certain aspects of a complex stimulus to make them the focus of attention. Foregrounding occurs, for example, when a speaker or writer gives prominence to some elements in a communication rather than others, usually by a combination of word order, sentence construction, and more explicit pointers. Discourse analysis is much concerned with the ways in which speakers and writers tend nonconsciously to foreground certain categories of information (see given–new distinction).

foreigner talk a speech register commonly adopted when speaking to those perceived as foreigners not competent in the language being used, typically characterized by short sentences, simplified grammar and vocabulary, and slow, loud delivery.

forensic assessment systematic evaluation by a mental health practitioner of a defendant, witness, or offender for the purpose of informing the court about such issues as competency to stand trial, criminal responsibility, and risk assessment.

forensic neuropsychology the application of clinical neuropsychology to issues of both civil and criminal law, particularly those relating to claims of brain injury.

forensic neuroscience an emerging field in which the regulation of certain behaviors, including criminal, antisocial, sociopathic, and psychopathic, is viewed in light of neural mechanisms that may determine such behaviors. Theoretically, these behaviors are seen as arising not from an individual’s failure to know right from wrong but from neural mechanisms that may be functioning improperly.

forensic psychiatry the branch of psychiatry concerned with abnormal behavior and mental disorders as they relate to legal issues, hearings, and trials. Major areas of concern include insanity pleas (see insanity defense) and the legal definition of insanity; procedures to commit individuals to mental hospitals; and questions of criminal responsibility, competency to stand trial, guardianship, conservatorship, and confidentiality. Also called legal psychiatry.

forensic psychology the application of psychological principles and techniques to situations involving the civil and criminal legal systems. Its functions include assessment and treatment services, provision of advocacy and expert testimony, policy analysis, and research on such topics as eyewitness accounts, offender behavior, interrogations, and investigative practices. Also called legal psychology. See also correctional psychology.

forensic social work the application of social work principles and techniques to legal issues or situations involving the law or legal systems (both criminal and civil). Its functions include providing consultation, education, or training to various individuals within the legal and correctional systems; making recommendations regarding child custody and related issues; providing expert testimony and advocacy; and conducting research and policy analysis.

foreplay n. activity engaged in prior to coitus, marked by psychological as well as physical stimulation. The purpose of foreplay, which includes kissing, stroking, fantasizing, and similar activities, is to encourage sexual arousal in the participants. It may last from a few minutes to several hours.

foreshortening n. the illusion that the length of a line appears shorter when viewed lengthwise.

foreskin n. a loose fold of skin that normally covers the glans penis but can retract during erection or coitus. It is a continuation of the skin covering the rest of the penis. It is synonymous with prepuce, a term also used to denote the clitoral hood. Also called preputium penis. See also circumcision.
forest plot

forest plot a graph, often used in META-ANALYSES, in which the authors or titles of the studies are listed along the left side, and the corresponding EFFECT SIZE for each is given on the right. The effect sizes for the individual studies are usually indicated by squares in which the size of the square is proportional to the size of the effect for a specific study. At the bottom, the overall effect size is given, usually in a diamond shape whose width indicates the outer points of a CONFIDENCE INTERVAL for the overall effect across all of the studies listed.

forethought n. the ability of an individual to anticipate the consequences of his or her actions and the actions of others. In SOCIAL-COGNITIVE THEORY, forethought is a key element in learning behavior.

forewarning of persuasive intent the receipt of information that a subsequent communication is intended to change the attitude of the recipient. This forewarning tends to decrease ATTITUDE CHANGE by predisposing ELABORATION against what is advocated in the message. See also BIASED ELABORATION; BIASING FACTOR.

forewarning of persuasive position the receipt of information that a subsequent communication will contain arguments for a particular attitudinal position. Forewarning that a communication will be a COUNTERATTITUDINAL ADVOCACY tends to decrease ATTITUDE CHANGE by predisposing ELABORATION against the message. See also BIASED ELABORATION; BIASING FACTOR.

forget cue see DIRECTED FORGETTING.

forgetting n. the failure to remember material previously learned. Numerous processes and theories have been proposed throughout the long history of study to account for forgetting, including DECAY THEORY and INTERFERENCE THEORY. Forgetting typically is a normal phenomenon but it may also be pathological, as, for example, in amnesia.

forgetting curve a graphic depiction of the amount of forgetting over time after learning has taken place. In his pioneering studies of forgetting, which involved lists of nonsense syllables, Hermann EBBINGHAUS was the first to show that there is generally a sudden drop in retention shortly after learning, followed by a more gradual decline thereafter. Also called Ebbinghaus curve.

forgiveness n. willfully putting aside feelings of resentment toward an individual who has committed a wrong, been unfair or hurtful, or otherwise harmed one in some way. Forgiveness is not equated with reconciliation or excusing another, and it is not merely accepting what happened or causing to be angry. Rather, it involves a voluntary transformation of one’s feelings, attitudes, and behavior toward the individual, so that one is no longer dominated by resentment and can express compassion, generosity, or the like toward the individual. Forgiveness is sometimes considered an important process in psychotherapy or counseling.

formal cause see CAUSE.

formal discipline a concept that certain subjects (e.g., mathematics and foreign languages) should be studied for the primary purpose of exercising and developing the mind.

formal fallacy see FALLACY.

formal grammar a description of language in terms of its form and structure as opposed to its function and meaning. Compare FUNCTIONAL GRAMMAR. See FORM–FUNCTION DISTINCTION.

formal group any group that is deliberately formed by its members or an external authority for some purpose. Unlike an ACCIDENTAL GROUP, a formal group is likely to use explicit terms to define its membership criteria, operating procedures, role structure, and goals. Also called planned group.

formalism n. the study of the outward form of works of art and literature, as opposed to their content or meaning. —formalist n. —formalistic adj.

formal language see ARTIFICIAL LANGUAGE.

formal logic a system of prescribed rules for generating valid conclusions or predictions from initial axiomatic assumptions or knowledge. It is often contrasted with more intuitive forms of thought, such as common sense. See DEDUCTIVE REASONING; LOGIC; SYMBOLIC LOGIC.

formal operational stage the fourth and final stage in the PIAGETIAN THEORY of cognitive development, beginning around age 12, during which complex intellectual functions, such as abstract thinking, logical processes, conceptualization, and judgment, develop. See also CONCRETE OPERATIONAL STAGE; PREOPERATIONAL STAGE; SENSOMOTOR STAGE.

formal organizational structure the official patterns of coordination and control, workflow, authority, and communication that channel the activity of members of an organization. The formal structure is embedded in the design of the organization and is seen as the pattern that should be followed by employees. It can be contrasted with the informal organizational structure, which is defined by patterns that are not officially recognized but that emerge from the daily interactions of employees.

formal parallelism a comparative approach to the concept of development that relates multiple modes of functioning (i.e., different modes of animal life, different kinds of sociocultural organization, or different types of consciousness) to different levels of organization and integration, rather than relating them to a single line of chronological development, as in RECAPITULATION THEORY. [proposed by Heinz WERNER]

formal reasoning reasoning that entails the use of formal logical operations. See DEDUCTIVE REASONING; LOGIC.

formal theory a model or set of rules and assumptions used to understand various behaviors in mathematical terms. Formal theories often are developed and studied in the field of political science and psychology. An example of a formal theory is the so-called PRISONER’S DILEMMA model, which can be applied to various situations in which participants have to decide between the costs and benefits of cooperating or competing. The model uses a series of rules to determine the outcomes of various behaviors when two suspects separately have the option to confess or refuse to speak about a potential crime.

formal thought disorder disruptions in the form or structure of thinking. Examples include DERRAIMENT and TANGENTIALITY. It is distinct from THOUGHT DISORDER, in which the disturbance relates to thought content.

formal universal see LANGUAGE UNIVERSAL.

formants pl. n. the frequency bands of speech sounds produced by the vocal cords and other physical features of the head and throat. A simple sound, such as the vowel /a/, may span several kilohertz of frequencies when recorded by a SOUND SPECTROGRAPH.
formative evaluation a process intended to improve or guide the development of a program in its early stages through the use of qualitative or quantitative research methodology. Ideally, the individual performing a formative evaluation will repeatedly interact, often informally, with the program personnel from the outset of the work to clarify goals, monitor implementation, and assess staff and resource requirements. Also called feedback evaluation. See also PROCESS EVALUATION, SUMMATIVE EVALUATION.

formative tendency the general drive toward self-improvement, growth, and self-actualization hypothesized by Carl Rogers in his CLIENT-CENTERED THERAPY.

formboard test a type of performance test in which the individual fits blocks or cut-outs of various shapes into depressions in a board.

form discrimination the ability to use one's senses, primarily vision and touch, to judge the shape, size, texture, and other features of an object.

form distortion a change in an image that results from the optical qualities of the eye or an artificial lens, so that the image appears different from the stimulus that gave rise to it.

form–function distinction a distinction between two fundamentally different ways of analyzing language, one with respect to its structural properties (form) and the other with respect to its communicative properties (function). For example, a formal analysis of the utterance Where are the pencils? would point to the use of where and the auxiliary verb to be to frame a wh-question and the agreement between that verb and the subject pencils; a functional analysis would need to judge whether the utterance is a request for information or a request for action. See FORMAL GRAMMAR; FUNCTIONAL GRAMMAR.

formication n. an acutely distressing sensation of ants or other insects crawling on the skin. It is a tactile (haptic) hallucination that occurs with cocaine abuse and in delirious states associated with acute alcoholic hallucinosis, meningitis, rheumatic fever, scarlet fever, diphtheria, and other infectious disorders. See also DELUSIONAL PARASITOSIS.

formicophilia n. sexual interest in and pleasure derived from small animals, insects, or snails crawling over one's body.

form perception the process by which the component elements of an object are bound together and perceived as a coherent entity that stands apart from the background and from other objects.

form quality the holistic character of a GESTALT, or whole, that makes it recognizable even after transformations. For example, a melody remains recognizable even after being transposed to a different key. [coined in 1890 by Christian von Ehrenfels]

forms of address conventional verbal formulas by which individuals address one another in written or spoken communication, such as Sir, Your Excellency, Mrs. Jones, and Darling. The forms used will reflect the relationship of those using them in various ways, such as whether they are of equal or unequal status; whether they are strangers, acquaintances, or intimates; and whether they wish to signal warmth, politeness, or displeasure. Certain forms of address may also be prescribed in specific situations, such as a courtroom. Very hierarchical and conser-vative societies (or parts of society) will often have elaborate conventions about the correct form to use when addressing those holding particular ranks or offices. In some languages, such as French and German, the form of the second person pronoun used (tu or Du as opposed to vous or Sie) will also be significant.

formula n. a precise statement about how two pieces of information, usually mathematical, are related. The most common type of formula is a mathematical EQUATION in which one variable is a weighted FUNCTION of another variable plus a constant. For example, the formula for a straight line is $y = mx + b$, where $y$ is an outcome plotted on a vertical or $y$-axis, $m$ is the slope of the line, $x$ is the value of a variable along the horizontal or $x$-axis, and $b$ is where the straight line crosses the vertical axis.

fornication n. consensual sexual intercourse between any two people who are not married to each other. The legal definition varies in different locales.

fornix n. (pl. fornices) any arch-shaped structure, especially the long tract of white matter in the brain arching between the HIPPOCAMPUS and the HYPOTHALAMUS, projecting chiefly to the MAMMARY BODIES.

FORTRAN n. FOR(mula) TRAN(slation) (language): the oldest high-level computer programming language still in use, originally developed at IBM in the late 1950s. Its primary application is the intensive mathematical modeling and problem solving needed for supercomputing in areas such as weather and climate modeling, computational physics, and plant and animal breeding. [created by U.S. computer scientist John Backus (1924–2007) and colleagues]

forward association the formation of an associative link between one item and an item that follows it in a series or sequence. Compare BACKWARD ASSOCIATION.

forward chaining see CHAINING.

forward conditioning in CLASSICAL CONDITIONING, the pairing of two stimuli such that the conditioned stimulus is presented before the unconditioned stimulus. Also called forward pairing. Compare BACKWARD CONDITIONING.

forward-conduction law see LAW OF FORWARD CONDUCTION.

forward displacement in parapsychology experiments using ZENER CARDS or similar targets, a result in which the participant’s “call” or guess, matches the outcome of the next trial in the series rather than the current one. If this occurs consistently, it may be cited as evidence of precognition. Compare BACKWARD DISPLACEMENT.

forward masking see MASKING.

forward pairing see FORWARD CONDITIONING.

forward selection a technique used in creating multiple regression models in which independent variables from a large set of such variables are added to the regression equation in the order of their predictive power (i.e., largest to smallest increase in the COEFFICIENT OF MULTIPLE DETERMINATION) until a preset criterion is reached and there is no further significant change in the model’s predictive power. Also called forward inclusion; forward stepwise regression; stepup selection. See also F-TO-ENTER; F-TO-REMOVE.

fossa n. (pl. fossae) a hollow or depressed area. In neuroanatomy, fossae range from relatively large areas, such as
fossil

the anterior cranial fossa, middle cranial fossa, and posterior cranial fossa in the base of the cranium for the lobes of the brain, to small regions, such as the ethmoid fossa for the olfactory bulb and the hypophyseal fossa for the pituitary gland.

fossil n. the remains or traces of an organism that lived in the past, often the remote past. Usually only the hard parts of organisms become fossilized (e.g., bones, shells, wood), but under certain circumstances, an entire organism is preserved. In some cases, the organism has been turned into stone, a process called fossilization. See also idiolect; interlanguage; language transfer.

—fossilize vb.

foster care temporary care provided to children in settings outside their family of origin and by individuals other than their natural or adoptive parents. Foster care is intended to protect children whose parents are unavailable, abusive, or incapable of proper care, with the ultimate goal being to find a secure and permanent home. Typically, a child is placed with a family approved for foster care and paid a fee for such by a public child welfare agency. Although these foster home arrangements are most common, children may also be placed in group homes or institutions. See also adult foster care.

foster-child fantasy the childhood belief or fantasy that the parents are actually adoptive or foster parents. See family romance.

fostering n. the process in which one provides care in a family environment to vulnerable children or adults to whom one is not related. See adult foster care; foster care.

foul adj. 1. in the zwärdemaker smell system, denoting an odor quality that is associated with bedbugs and French marigolds. 2. denoting one of the primary odor qualities in henning’s odor prism.

founder effect the occurrence of a gene at increased frequency in a group or colony that was initially established by a small number of members of a larger population. The limited number of founders results in limited genetic diversity and a nonrandom genetic sample of the original population. The presence of a founder effect leads to a characteristic genetic makeup, which can allow the tracing of the migration of a particular ethnic group or population over time. Its presence is also associated with the predisposition of some groups to certain diseases. A founder effect has been identified for mutations predisposing to breast cancer among the Jewish population of eastern Europe, for example.

FOUR abbreviation for full outline of unresponsive-ness score.

four As see fundamental symptoms.

four-card problem see Wason selection task.

four-fifths rule an arbitrary rule of thumb for determining a prima facie case of discrimination, as set forth in the uniform guidelines for employee selection procedures. If the employer hires a protected group (e.g., an ethnic minority, women) at a rate that is less than four fifths the rate at which the majority group (i.e., white males) is hired, the company must justify its hiring procedures by showing that they are job-related or of business necessity. If justification cannot be provided, the employer may be open to a charge of violating civil rights laws. See also adverse impact; affirmative action; equal employment opportunity commission; equal opportunity.

fourfold table see two-by-two table.

fourier analysis the mathematical analysis of complex waveforms using the fact that they can be expressed as an infinite sum of sine and cosine functions (a fourier series). It is accomplished via a fourier transform, a mathematical operation that analyzes any waveform into a set of simple waveforms with different frequencies and amplitudes. The reconstruction of complex waveforms from simple components is called fourier synthesis. Fourier analysis is particularly important in the study of sound (see sound spectrum), and Fourier analysis and synthesis are important for the theoretical understanding of visual analysis. [Jean Baptiste Joseph fourier (1768–1830), French mathematician and physicist]

fourier spectrum a graph of amplitude as a function of frequency for all the sine waves that comprise a fourier analysis of an image. [Jean Baptiste Joseph fourier]

fourth cranial nerve see trochlear nerve.

fourth moment see moment.

fourth ventricle see VENTRICLE.

foveal sparing see visual field sparing.

foveal vision see central vision.

FR abbreviation for fixed ratio. See fixed-ratio schedule.

fractal n. a geometric shape that can be divided into parts that each resemble the pattern of the whole shape. Thus, a fractal is a shape possessing the quality of self-similarity.

fractile n. see quantile.

fractional antedating goal response a reaction that develops progressively earlier in conditioning a series of responses and may become a conditioned stimulus for subsequent responses.

fractional escape see escape titration.

fractional factorial design a type of experimental design in which some conditions are omitted, such that not all levels of one or more of the independent variables are combined with all other levels of the other variables. A latin square is an example. Fractional factorial designs might be used because of a small overall sample available for study or because of difficulty obtaining participants or assigning them to some conditions. Additionally, there may simply be too many combinations to study (e.g., in a 3 × 4 × 2 × 5 design, there are 120 combinations of levels). Also called incomplete factorial design. Compare complete factorial design.

fractionation n. a psychophysical procedure to scale the magnitude of sensations in which an observer adjusts a variable stimulus to be half that of a standard stimulus.

fragile X syndrome a genetic condition that causes a range of developmental problems, including learning disabilities and cognitive impairment. The disorder is so named because of alterations in the fmr1 gene, on the arm of the
X chromosome, that abnormally expand and destabilize it. Males with fragile X syndrome have characteristic physical features that become more apparent with age, such as large ears, prominent jaw and forehead, a long and narrow face, and enlarged testicles. Both males and females with fragile X may exhibit hyperactivity, social anxiety, and attention deficits; some males also show autistic behavior.

**fragmentary delusion** a disorganized, undeveloped false belief or a series of such beliefs that are disconnected, inconsistent, and illogical. Compare **SYSTEMATIZED DELUSION**.

**fragmentation** n. division or separation into pieces or fragments. For example, fragmentation of thinking (typically termed **LOOSENING OF ASSOCIATIONS**) is a disturbance in which thoughts become disjointed to such an extent as to no longer be unified, complete, or coherent; fragmentation of personality (typically termed **PERSONALITY DISINTEGRATION**) occurs when an individual no longer presents a unified, predictable set of beliefs, attitudes, traits, and behavioral responses.

**fragrant adj.** 1. in the SWAARDMAKER SMELL SYSTEM, denoting an odor quality that is smelled in flowers and vanilla. 2. denoting one of the four primary odor qualities in the CROCKER–HENDRICKSON ODOR SYSTEM.

**frail elderly** older adults who are infirm and experience significant difficulties in performing **ACTIVITIES OF DAILY LIVING**, resulting in a lack of independence and the need for extensive assistive care.

**frame** n. 1. in cognitive psychology, a set of parameters defining either a particular mental **SCHEMA** or the wider **COGNITIVE STRUCTURE** by which an individual perceives and evaluates the world. See also **CONCEPTUAL SYSTEM**; **PERCEPTUAL SET**. 2. in artificial intelligence, a **KNOWLEDGE REPRESENTATION** scheme, much like an object system, used to represent and structure knowledge for a computational system. [first proposed in 1981 by U.S. mathematician and computer scientist Marvin Minsky (1927–)]

**frame of reference** in social psychology, the set of assumptions or criteria by which a person or group judges ideas, actions, and experiences. A frame of reference can often limit or distort perception, as in the case of **PREJUDICE** and **STEREOTYPES**.

**frame-of-reference training** training provided to those responsible for **EMPLOYEE EVALUATION** with the aim of improving the accuracy of their performance ratings. It involves providing raters with (a) a common reference standard to be used in performing evaluations and (b) practice in identifying good, average, and poor performances as defined by this standard.

**frame problem** a technical difficulty arising in artificial intelligence and **COMPUTATIONAL MODELS** of human cognition and involving the specification of the persistence of states that form the context in which thought takes place. The frame problem is essentially a question of how to use **FORMAL LOGIC** to specify or describe efficiently what remains unchanged in a given situation involving change, that is, what are the noneffects of a particular action on the properties of a situation (e.g., painting an object will not alter its position). In cognitive psychology and cognitive science, the term has been extended to the difficulty of modeling the human ability to quickly generate reasonable hypotheses that make sense of events in the environment and to respond sensibly to incoming information, using relevant knowledge to guide the formation of new beliefs. [described by U.S. philosopher and psychologist Jerry Alan Fodor (1935–)]

**framing** n. the process of defining the context or issues surrounding a question, problem, or event in a way that serves to influence how the context or issues are perceived and evaluated. Also called **FRAMING** effect. See also **RE-FRAMING**.

**framing effect** 1. see **ATMOSPHERE EFFECT**. 2. see **FRAMING**.

**Framingham Heart Study** an ongoing large-scale, long-range survey focused on understanding, preventing, and treating cardiovascular disease. Begun in 1948, the study has involved data collection from three generations of residents of the town of Framingham, Massachusetts. The data have identified primary risk factors involved with heart disease and stroke, such as cigarette smoking, physical inactivity, obesity, high cholesterol levels, diabetes, and hypertension. The study is regarded as one of the most reliable of its kind because it is of prospective design; that is, it enrolled people who were originally free of heart disease and recorded the dietary and other habits of the participants before signs of heart disease appeared.

**Franceschetti–Zwahlen–Klein syndrome** see **TREATHER COLLINS SYNDROME**. [Adolphe Franceschetti (1896–1968), Swiss ophthalmologist]

**Fraser syndrome** (Fraser–François syndrome) see **CRYPTOPHthalmOS SYNDROME**. [George R. Fraser (1932–1974), British geneticist; Jules François (1907–1984), Belgian ophthalmologist]

**fraternalistic relative deprivation** see **RELATIVE DEPRIVATION**.

**fraternal twins** see **DIZYGOTIC TWINS**.

**F ratio** (symbol: *F*) in an **ANALYSIS OF VARIANCE** or a **MULTIVARIATE ANALYSIS OF VARIANCE**, the amount of **EXPLAINED VARIANCE** divided by the amount of **ERROR VARIANCE**; that is, the ratio of between-groups variance to within-group variance. Its value determines whether to accept the null hypothesis stating that there is no difference between the treatment and control conditions, with a large value indicating the presence of a significant effect. Ideally, a researcher prefers to have rather small variation within each group and maximal variation between the groups in order to demonstrate significant group differences. Also called **F** statistic; **F** value.

**free and appropriate public education** provisions of U.S. educational law requiring that **SPECIAL EDUCATION** and related services be provided to each student with a disability at no extra cost to the student or parents. The services provided must meet standards established by the student’s state of residence and be consistent with decisions that are made at an **INDIVIDUALIZED EDUCATION PROGRAM** (IEP) meeting and specified in a written IEP plan.

**free association** a basic process in psychoanalysis and other forms of psychodynamic psychotherapy, in which the patient is encouraged to verbalize without censorship or selection whatever thoughts come to mind, no matter how embarrassing, illogical, or irrelevant. The object is to allow unconscious material, such as inhibited thoughts and emotions, traumatic experiences, or threatening impulses, to come to the surface where they can be interpreted. Free association is also posited to help the patient discharge
free-association test

some of the feelings that have given this material excessive control over him or her. See BASIC RULE; VERBALIZATION.

**free-association test** a test in which participants are offered a stimulus word and are expected to respond as quickly as possible with a word they associate with the stimulus.

**freebase** 1. n. a highly concentrated, chemically altered form of cocaine that is prepared by treating cocaine with ether and ammonia. It is ingested by smoking. Although purer than crack cocaine, its effects are similar. 2. vb. to smoke this form of cocaine.

**Freedom From Distractibility Index** an index historically calculated on the Wechsler Intelligence Scale for Children that measures short-term attention and concentration. In recent years, this index has been renamed the Working Memory Index to be more consistent with contemporary research and the adult versions of the Wechsler scales.

**freedom from harm** one of the basic rights of research participants that is ensured by an Institutional Review Board. Freedom from harm states that a research participant should not incur undue risk as a result of taking part in a study. See also PARTICIPANTS’ RIGHTS.

**freedom to withdraw** one of the basic rights of research participants that is ensured by an Institutional Review Board. Freedom to withdraw allows a research participant to drop out of a study at any time without penalty. See also PARTICIPANTS’ RIGHTS.

**free energy** in classical psychoanalytic theory, psychical energy that is located in the id, is mobile, and is associated with primary processes. Compare **bound energy**.

**free feeding weight** see ad lib.

**free field** in acoustics, a sound field that has no reflective boundaries.

**free-floating anxiety** 1. a diffuse, chronic sense of uneasiness and apprehension not directed toward any specific situation or object. It may be a characteristic of a number of anxiety disorders, in particular generalized anxiety disorder. 2. in psychoanalysis, general feelings of distress that have been disconnected from the original circumstances that caused them.

**free-floating attention** in psychoanalysis and in other forms of psychodynamic psychotherapy, the analyst’s or therapist’s state of evenly suspended attention during the therapeutic session. This attention does not focus on any one thing the client says, but it allows the analyst or therapist to listen to all the material being presented and tune into the client’s affects and unconscious ideas. Also called evenly hovering attention.

**free-floating emotion** a diffuse, generalized emotional state that does not appear to be associated with any specific cause. A common example is **free-floating anxiety**.

**free love** the practice of engaging in sexual relationships without legal ties or any other commitment to fidelity or permanence. Advocates of free love emphasize the individual’s right to sexual expression and have sometimes argued for alternative forms of marriage and family relationships.

**free morpheme** in linguistics, a morpheme that can stand alone, as a word in its own right. Free morphemes are contrasted with bound morphemes, such as the plural -s, which can only appear in combination.

**free nerve ending** a highly branched terminal portion of a sensory neuron. Found particularly in the different layers of skin, free nerve endings are the most common type of nerve ending and act as pain and temperature receptors.

**free operant** in OPERANT CONDITIONING, a response to a situation that may occur freely at any time.

**free-operant avoidance** see Sidman avoidance schedule.

**free parameter** a value that is estimated from data, usually in a modeling procedure such as structural equation modeling. A free parameter contrasts with a fixed parameter, which is kept at a known, specific value. For example, in confirmatory factor analysis, one factor loading for each latent variable is usually a fixed parameter of 1.0 and the other loadings are free parameters that are estimated.

**free play** spontaneous, unstructured play that is not controlled or directed by an adult. The various activities of a child at a playground provide an example. Compare structured play.

**free radical** an atom or molecule that has at least one “unpaired” electron in its outer shell. This makes it highly reactive and able to engage in rapid chain reactions that destabilize the molecules around it, thus causing the formation of more free radicals. Free radicals can damage cells and have been implicated in aging, inflammation, and the progression of various pathological conditions, including cancer.

**free recall** a type of memory task in which participants attempt to remember previously studied information in any order. One common finding in free-recall studies is that the first and last items that are presented in a study list are best remembered. Proponents of the dual-store model of memory attribute this to the fact that the last items are still in short-term memory, and hence recoverable, whereas the first items received the most rehearsal and were transferred to long-term memory.

**free-response question** a test or survey item that allows the respondent to answer entirely as he or she pleases, as opposed to a fixed-alternative question, in which the respondent must choose from several provided options.

**free rider** an individual who contributes little or nothing to a joint endeavor but nonetheless garners the same benefits as others who contribute their fair share. The resentment caused by free riders can hamper the efficiency of a group working on a collective task (the free-rider effect).

**free-running rhythm** a cycle of behavior or physiological activity that occurs if external stimuli do not provide entrainment. See also biological rhythm.

**free variation** in linguistics, the state in which variant forms of the same linguistic unit appear on an apparently random basis. The term is most often used in phonology. For example, in colloquial speech, many speakers will articulate or not articulate the final stop consonant of the past-tense morpheme -ed (as in walked, stalked, etc.) in an entirely arbitrary way. Compare complementary distribution.

**free will** the power or capacity of a human being for self-direction. The function of the will is to be inclined or disposed toward an idea or action. The concept of free will thus suggests that inclinations, dispositions, thoughts, and
actions are not determined entirely by forces over which people have no independent directing influence. Free will is generally seen as necessary for moral action and responsibility and is implied by much of our everyday experience, in which we are conscious of having the power to do or forbear (see PARADOX OF FREEDOM). However, it has often been dismissed as illusory by advocates of DETERMINISM, who hold that all occurrences, including human actions, are predetermined. See also AGENT; VOLITION.

freezing behavior a form of passive avoidance in which the individual remains motionless and makes no effort to run or hide. The behavior is most often observed as a severe reaction or FEAR RESPONSE to a threatening situation. Freezing behavior occurs in wild animals in response to ALARM CALLS signifying the approach of a predator or other risk. See also IMMOBILITY.

Fregoli’s phenomenon a MISIDENTIFICATION SYNDROME in which an individual identifies a persecutor successively in different people known to him or her (e.g., a neighbor, doctor, attendant), on the delusional assumption that the persecutor is capable of changing faces. [first identified in 1927 and named for Italian actor Leopoldo Fregoli (1867–1936), who was renowned for his ability to alter his appearance]

French kiss a type of sexual interaction in which the participants kiss with their mouths open so that their tongues can touch. Also called soul kiss; tongue kiss.

frenulum n. (pl. frenula) any membranous fold that supports or restrains an anatomical part, such as the membrane under the tongue (lingual frenulum) or the fold of tissue that limits the backward movement of the foreskin. Also called frenum.

frenzy n. a temporary state of wild excitement and mental agitation, at times including violent behavior. It has been associated with MANIA and is sometimes considered synonymous with this term.

frequency n. 1. (symbol: f) the number of occurrences of a phenomenon, particularly a CATEGORICAL VARIABLE such as sex. For example, it is often of interest to find the frequencies or counts of the men and women who are participating in a research study. See also RELATIVE FREQUENCY. 2. the number of repetitions of a periodic waveform in a given unit of time. In acoustics, the frequency of a PURE TONE is the number of cycles of a sinusoidal pressure variation that occur in 1 second. The standard measure of frequency is the hertz (Hz); this replaces, and is equivalent to, cycles per second (cps). For complex periodic waveforms, that is, those consisting of more than one frequency component (e.g., a square wave), the “frequency” is the rate of repetition of the waveform and is more appropriately called the fundamental frequency (or fundamental tone, or simply the fundamental). The period of a waveform is the time to complete one repetition and is the reciprocal of the frequency (or fundamental frequency). For waveforms that are not periodic, such as white noise, the frequency is undefined. In such cases, the spectral characteristics should be described. See also SOUND SPECTRUM.

frequency analysis analysis of the frequency changes in EVENT-RELATED POTENTIALS.

frequency discrimination see AUDITORY DISCRIMINATION.

frequency distribution a tabular representation of the number of times a specific value or datum point occurs. The left column lists the different categories of a CATEGORICAL VARIABLE or scores of a CONTINUOUS VARIABLE, and the right column lists the number of occurrences of each. When a frequency distribution is plotted on a graph, it is often called a frequency curve, frequency diagram, or FREQUENCY POLYGON. When represented mathematically via an equation, it is called a frequency function. Also called frequency table. See also CUMULATIVE FREQUENCY DISTRIBUTION; RELATIVE FREQUENCY DISTRIBUTION.

frequency judgment a participant’s judgment of how many times a particular stimulus was presented during a test. Such judgments are used in research on memory and sensory thresholds. See also WORD-FREQUENCY STUDY.

frequency law see LAW OF FREQUENCY.

frequency modulation see MODULATION.

frequency of response the number of countable responses per unit of time. For example, if an individual pressed a telegraph key 500 times in 5 minutes, the frequency of response would be 100 per minute.

frequency polygon a graph depicting a statistical distribution, made up of lines connecting the peaks of adjacent intervals. A LINE GRAPH connecting the midpoints of the bars of a HISTOGRAM is a frequency polygon.

frequency principle the principle that the greater the intensity of stimulation, the greater the frequency of nerve impulses elicited and the more intense the response of the organism.

frequency selectivity the property of a system that enables it to be “tuned” to respond better to certain frequencies than to others. The degree of selectivity of such filtering is sometimes specified as Q, which is the center or best frequency of a filter divided by its bandwidth: Higher values of Q correspond to higher frequency selectivity. The frequency selectivity of the auditory system is a fundamental aspect of hearing and has been a major research theme for many decades. Also called bandwidth selectivity. See AUDITORY FILTER; CRITICAL BAND; TONOTOPIC ORGANIZATION; TUNING CURVE.

frequency test see FREQUENCY DISTRIBUTION.

frequency theory a late 19th-century theory specifying that pitch is coded by the rate at which ACTION POTENTIALS are generated by auditory neurons within the BASILAR MEMBRANE of the ear. According to this theory, the wavelength (frequency) of a tone is precisely replicated in the electrical impulses transmitted through the AUDITORY NERVE. For example, a 100 Hz tone would be signaled by 100 impulses per second in the auditory nerve. However, frequency theory cannot explain the perception of sounds above 500 Hz because the REFRACTORY PERIOD of a neuron renders it incapable of firing at a rate greater than 500 impulses per second. This discrepancy was accounted for by the later VOLLEY THEORY. Also called telephone theory. [proposed in 1886 by William Rutherford (1839–1899), British physiologist]

frequentist n. a researcher who approaches issues of PROBABILITY in terms of the frequency (number of occur-
frequentist inference

ences) for a particular parameter over a period of time. This approach is contrasted with that of a BAYESIAN, who examines the data and assesses whether particular values are more credible or believable than others.

frequentist inference an approach to drawing conclusions from statistical samples that is based on the number of times an event is expected to occur in the long run if conditions for observing the event are held constant. It considers any research study to be one of a very large possible number of replications. Also called classical inference. Compare BAYESIAN INFERENCE.

Freudian approach (Freudianism) see PSYCHOANALYSIS.

Freudian slip in the popular understanding of psychoanalytic theory, an unconscious error or oversight in writing, speech, or action that is held to be caused by unacceptable impulses breaking through the ego’s defenses and exposing the individual’s true wishes or feelings. See PARAPRAXIS; SLIP OF THE TONGUE; SYMPTOMATIC ACT. [Sigmund Freud]

Freudian theory of personality the general psychoanalytic concept that character and personality are the product of experiences and fixations stemming from the early stages of PSYCHOSEXUAL DEVELOPMENT. See PSYCHOANALYSIS. [Sigmund Freud]

Frey esthesiometer see ESTHESIOMETRY. [Maximilian von Frey (1852–1912), German physiologist]

fricative 1. adj. denoting a speech sound made by forcing a stream of air through a narrow opening of the vocal tract against one or more surfaces, particularly the hard palate, ALVEOLAR RIDGE, teeth, or lips. A fricative has high-frequency vibrations. It may be VOICED (e.g., [f], [s], [zh]) or UNVOICED (e.g., [ʃ], [s], [ʃh]). 2. n. a fricative speech sound.

Friedrich’s ataxia a hereditary, progressive form of ATAXIA (muscular incoordination) that results from the degeneration of nerves in the spinal cord and nerves that connect the spinal cord to the arms and legs. Symptoms typically appear in childhood or early adolescence and may include clumsiness, balance problems, difficulty walking, unsteady gait, slurred speech, hearing and vision loss, and rapid involuntary eye movements. [Nikolaius Friedrich (1825–1882), German neurologist]

friendship n. a voluntary relationship between two or more people that is relatively long-lasting and in which those involved tend to be concerned with meeting the others’ needs and interests as well as satisfying their own desires. Friendships frequently develop through shared experiences in which the people involved learn that their association with one another is mutually gratifying.

friend with benefits see HOOKUP.

fright n. the emotional reaction that arises in the face of a dangerous or potentially dangerous situation or encounter. Fright differs from fear in that the danger is usually immediate, physical, concrete, and overwhelming. Physiological changes in the body associated with fright include trembling, widening of the eyes, and drawing away from the fear-producing stimulus.

frigidity n. in women, impairment of sexual desire or inability to achieve sexual arousal or orgasm. This term is considered offensive and has largely been abandoned in favor of FEMALE SEXUAL DYSFUNCTION. —frigid adj.

fringe consciousness those aspects of experience that lack focal qualities (e.g., clarity, discriminability) but are nevertheless usually reported with a high degree of confidence. Fringe experiences vary widely, from EFFORTFULNESS and FEELINGS OF KNOWING to mystical experiences. Compare FOCAL CONSCIOUSNESS.

fringe–focus structure a model of consciousness in which conscious experiences typically have a momentarily clear, discriminable, focal component (see FOCAL CONSCIOUSNESS), along with a vaguer component (see FRINGE CONSCIOUSNESS).

fringer n. a person on the margins of a social group, who is neither genuinely accepted nor clearly excluded.

Fröbelism n. a method of education developed by German educator Friedrich Fröbel (1782–1852), the originator of the kindergaten system. He believed that it was important for a child’s development to have an open environment that encouraged learning and physical activity.

frog-pond effect the tendency of high-performing individuals in a generally inferior group to evaluate themselves more favorably than do low-performing individuals in a generally superior group. Originally used to describe academic self-evaluations, the term has recently been broadened to refer to any appraisals that compare the self with local, as opposed to more general, standards. For example, a person might take particular pride in considering himself the best player on his office softball team of colleagues who are mediocre players. Yet the worst performer on an Olympic softball team might feel incompetent, even though he is among the best softball players in the world. See SELF-CONCEPT; SOCIAL COMPARISON THEORY. [term derived from the common phrase, big fish in a small pond]

Fröhlich’s syndrome a disorder caused by underfunctioning of the anterior lobe of the pituitary gland (hypopituitarism), often because of tumors on the hypothalamus. Major symptoms are underdeveloped genital organs and secondary sexual characteristics, general sluggishness, and obesity; in some cases, those with Fröhlich’s syndrome exhibit polyuria (frequent urination), polydipsia (frequent consumption of liquids), and intellectual disabilities. Also called Launois–le Cleret syndrome. [Alfred Fröhlich (1871–1953), Austrian neurologist]

frontal adj. 1. pertaining to the front, or anterior, portion of the body or of an organ. 2. pertaining to the frontal bone of the skull, or forehead.

frontal association area see PREFRONTAL CORTEX.

frontal cortex the CEREBRAL CORTEX of the frontal lobe. It is associated with decision making, planning, insight, judgment, the ability to concentrate, and impulse control. See also PREFRONTAL CORTEX.

frontal eye field a region of the brain anterior to the motor area involved in head and eye movements. A lesion in this region may result in unilateral blindness, with the effect observed on the side opposite the lesion.

frontal gyrus the ridge or convolution on the frontal region of a cerebral hemisphere, including the inferior, middle, and superior frontal gyri. See also INFERIOR FRONTAL GYRUS.

frontalis muscle a muscle that covers the scalp beneath the skin of the forehead.

frontal lisp see LISP.

frontal lobe one of the four main lobes of each cerebral
hemisphere of the brain, lying in front of the CENTRAL SULCUS. It is concerned with motor and higher order EXECUTIVE FUNCTIONS. See also PREFRONTAL LOBE.

**frONTAL LOBE SYNDROME** deterioration in personality and behavior resulting from lesions in the frontal lobe. Typical symptoms include loss of initiative, inability to plan activities, difficulty with abstract thinking, perseveration, impairments in social judgment and impulse control, and mood disturbances such as apathy or mania.

**frontal lobe syndrome** deterioration in personality and behavior resulting from lesions in the frontal lobe. Typical symptoms include loss of initiative, inability to plan activities, difficulty with abstract thinking, perseveration, impairments in social judgment and impulse control, and mood disturbances such as apathy or mania.

**frontal lobotomy** seeLOBOTOMY.

**frontal plane** see CORONAL PLANE.

**frontal release signs** the appearance in adults with frontal lobe lesions of certain primitive reflexes that are normally present only in infants and disappear within the first few months of life. These include the grasp, rooting, and sucking reflexes.

**frontal section** see CORONAL SECTION.

**front-clipping n.** see CLIPPING.

**frontometaphyseal dysplasia** see OTOPHALATODIGITAL SPECTRUM DISORDERS.

**frontonasal dysplasia** a congenital disorder characterized by defective fusion of structures in the midline of the face. The cleft may involve the eyes, the tip of the nose, the palate, and the premaxilla. About 20% of affected individuals have some degree of intellectual disability. Also called MEDIAN-CLEFT-FACE SYNDROME.

**frontotemporal dementia (FTD)** a clinical syndrome associated with shrinking of the frontal and temporal anterior lobes of the brain. Originally known as PICK’S DISEASE, the current designation of the syndrome groups together Pick’s disease, primary progressive APHASIA, and SEMANTIC DEMENTIA. The symptoms of FTD fall into two patterns. One involves impaired ability to modify one’s social behavior; symptoms include a lack of inhibition, repetitive or compulsive behaviors, and a lack of concern about one’s personal appearance and hygiene. The second pattern primarily features symptoms of language disturbance (e.g., difficulty speaking or comprehending speech), often together with the behavioral type’s symptoms. There is a strong genetic component to the disease, which often runs in families.

**frotteurism n.** in DSM–IV–TR, a PARAPHILIA in which an individual deliberately and persistently seeks sexual excitement by rubbing against other people. This may occur as apparently accidental contact in crowded public settings, such as elevators or lines. The person displaying this type of behavior is called a frotteur or a rubber. It is identified as FROTTEURISTIC DISORDER in DSM–5. Also called FROTTEEIS.

**frozen form** see IDIOM.

**frozen noise** a recorded sample of NOISE.

**fruity adj.** denoting one of the primary odor qualities in HENNING’S ODOR PRISM.

**frustration n.** 1. the thwarting of impulses or actions that prevents individuals from obtaining something they have been led to expect based on past experience, as when a hungry animal is prevented from obtaining food that it can see or smell or when a child is prevented from playing with a visible toy. Internal forces can include motivational conflicts and inhibitions; external forces can include the actions of other individuals, admonitions of parents or others, and the rules of society. 2. the emotional state an individual experiences when such thwarting occurs. 3. in classical psychoanalytic theory, the damming up of PSYCHIC ENERGY, which then seeks an outlet in wish-fulfilling fantasies and dreams or in various neurotic symptoms. —frustrate vb.

**frustration-aggression hypothesis** the theory, proposed in 1939 by John Dollard and colleagues, that (a) frustration always produces an aggressive urge and (b) aggression is always the result of prior frustrations. Neal E. Miller, one of the proponents of this theory, later noted that frustration can lead to several kinds of actions but maintained that the urge to aggression will become more dominant as the thwarting continues. In 1989, U.S. psychologist Leonard Berkowitz (1926—) proposed that the frustration must be decidedly unpleasant to evoke an aggressive urge. Also called aggression-frustration hypothesis.

**frustration effect** see FRUSTATIVE NONREWARD HYPOTHESIS.

**frustration tolerance** the ability of an individual to delay gratification or to preserve relative equanimity when encountering obstacles. The growth of adequate frustration tolerance generally occurs as part of a child’s cognitive and affective development but may also be strengthened to more adaptive levels later in life through therapeutic intervention.

**frustrative nonreward hypothesis** the proposition that withholding previously given reinforcement of responses during operant or instrumental conditioning leads to an internal state of frustration, which sometimes paradoxically motivates the subject (the frustration effect), at least for a while. [proposed by Abraham Amsel (1922–2006), U.S. behavioral psychologist]

**fry n.** a tobacco cigarette or marijuana joint dipped into a liquid containing PCP (see EMBALMING FLUID) and then dried and smoked. This is known by various other names, including illie (or illie) and sherm. A wet is a similarly treated cigarette or joint that is smoked before it dries.

**Frye test** a test for the admissibility of scientific evidence in U.S. courts, derived from the case Frye v. United States (1923) in which an early form of lie-detector evidence (see POLYGRAPH) was ruled inadmissible because it had not yet “gained general acceptance in the field in which it belongs.” This “general acceptance” test became the chief standard for ruling on admissibility of scientific evidence in both state and federal courts until 1993, when it was replaced by the DAUBERT TEST in most jurisdictions.

**F Scale** (Fascism Scale) a SELF-REPORT measure of AUTHORITY PERSONALITY with subscales pertaining to conventionalism, authoritarian submission, authoritarian aggression, anti-intraception, superstition and stereotypy, power and toughness, destructiveness and cynicism, projectivity, and sex. The F Scale predicts anti-Semitism, ethnocentrism, racism, prejudice, and conservative political views. [devised in 1950 by German-born U.S. philosopher and social theorist Theodor Adorno (1903–1969), Polish-born U.S. psychologist Else Frenkel-Brunswick (1908–1958), and colleagues]

**FSD** abbreviation for FEMALE SEXUAL DYSFUNCTION.

**FSH** abbreviation for FOLLICLE-STIMULATING HORMONE.

**FSS** abbreviation for FEAR SURVEY SCHEDULE.

**F statistic** see F RATIO.
**FT**

**FT** abbreviation for fixed time. See **FIXED-TIME SCHEDULE**.

**FTA** abbreviation for **FAULT TREE ANALYSIS**.

**FTD** abbreviation for **FRONTOTEMPORAL DEMENTIA**.

**F test** any of a class of statistical procedures, such as **ANALYSIS OF VARIANCE** or **MULTIPLE REGRESSION**, that rely on the assumption that the calculated statistic—the **F RATIO**—follows the **F DISTRIBUTION** when the null hypothesis is true. F tests are tests of hypotheses about population variances or of whether **REGRESSION COEFFICIENTS** are zero.

**F-to-enter** n. in model-building procedures such as **FORWARD SELECTION**, the specific ratio of variances needed to justify adding a variable as a predictor. Generally, an F-to-enter value around 4.0 is sufficient to allow a variable to be included in an analysis.

**F-to-remove** n. in model-building procedures such as **BACKWARD ELIMINATION** or **STEPWISE REGRESSION**, the specific ratio of variances needed to justify keeping a variable as a predictor. Generally, an F-to-remove value around 4.0 is sufficient to allow a variable to be retained in an analysis.

**FTS** abbreviation for **FETAL TOBACCO SYNDROME**.

**FTT** abbreviation for **FAILURE TO THRIVE**.

**fugitive literature** see **GRAY LITERATURE**.

**fugue** n. 1. see **DISSOCIATIVE FUGUE**. 2. a brief period in which an individual appears to be in a semiconscious state, sometimes engaging in routine activity, and subsequently has no memory for events during that period. This condition is typically associated with epilepsy but may occur in other conditions, such as alcohol intoxication and cata-tonic excitement.

**fulfillment** n. the actual or felt satisfaction of needs and desires, or the attainment of aspirations. See also **WISH FULFILLMENT**. —fulfill vb.

**fulfillment model** a basic type of personality theory based on the assumption that the primary motivation for behavior is self-fulfillment, as manifest in a drive to realize based on the assumption that the primary motivation for

**Fullerton–Cattell law** a psychophysical generalization regarding the **DIFFERENCE THRESHOLD**, stating that errors of observation are proportional to the square root of the magnitude of the stimulus. The Fullerton–Cattell law was proposed in 1892 as a replacement for **WEBER’S LAW**. [George S. Fullerton (1859–1925), U.S. philosopher; James McKeen Cattell]

**full inclusion** the practice of providing children with disabilities with services in their home school and of educating them in a regular classroom on a permanent, full-time basis. See also **LEAST RESTRICTIVE ENVIRONMENT**; **MAINSTREAMING**.

**full model** a statistical representation that includes all of the variables of interest, or all of the main **PARAMETERS** (e.g., **REGRESSION COEFFICIENTS**), among a set of variables. For example, in **STRUCTURAL EQUATION MODELING**, a full model might include estimated regression parameters between a set of **INDEPENDENT VARIABLES**, **MEDIATORS**, and **DEPENDENT VARIABLES**. When there are as many parameters estimated in a full model as there are **DEGREES OF FREEDOM**, it is said to be a **SATURATED MODEL**. Also called **UNRESTRICTED MODEL**.

**Full Outline of Unresponsiveness Score (FOUR)** a rating scale used to assess the level of consciousness in patients with brain damage. Scores range from 0 to 16, with lower scores related to lower levels of consciousness. Clinicians rate patients on four domains: eye responses, motor responses, brainstem reflexes, and respiration. Unlike the **GLASGOW COMA SCALE**, which requires the rating of verbal responses, FOUR can be used with patients who have endotracheal intubation. [proposed in 2005 by Dutch-born U.S. neurologist Eelco F. M. Wijdicks and colleagues]

**full term** see **TERM**.

**fully functioning person** a person with a healthy personality, who experiences freedom of choice and action, is creative, and exhibits the qualities of **EXISTENTIAL LIVING**. [as defined in the **CLIENT-CENTERED THERAPY** of Carl Rogers]

**fulvestrant** n. see **ANTIESTROGEN**.

**fun** n. a perception of pleasure and happiness brought on by achieving one's desires from an activity.

**function** n. 1. the use or purpose of something. 2. in biology, an activity of an organ or an organism that contributes to the organism's **FITNESS**, such as the secretion of a sex hormone by a gonad to prepare for reproduction or the defensive behavior of a female with young toward an intruder. 3. (symbol: f) a mathematical procedure that relates or transforms one number, quantity, or entity to another according to a defined rule. For example, if \( y = 2x + 1 \), \( y \) is said to be a function of \( x \). This is often written \( y = f(x) \). Here \( y \) is the dependent variable and \( x \) is the independent variable.

**functional adj.** 1. denoting or referring to a disorder for which there is no known physiological or structural basis. In psychology and psychiatry, functional disorders are improperly considered equivalent to **PSYCHOCHEMIC DISORDERS**. 2. based on or relating to use rather than structure.

**functional activities** actions associated with basic daily home and work requirements: an umbrella term encompassing both **ACTIVITIES OF DAILY LIVING** and **INSTRUMENTAL ACTIVITIES OF DAILY LIVING**.

**functional age** an individual's age as determined by measures of functional capability indexed by age-normed standards. Functional age is distinct from **CHRONOLOGICAL AGE** and represents a combination of physiological, psychological, and social age. The functional age of a child is measured in terms of the developmental level he or she has reached. It may be compared with his or her chronological age as a means of gauging the existence and extent of any impairment or developmental problem. In older adults, it is calculated by measuring a range of variables that correlate closely with chronological age, such as eyesight, hearing, mobility, cardiopulmonary function, concentration, and memory. Following the passing of the **AGE DISCRIMINATION IN EMPLOYMENT ACT**, functional age, rather than chronological age, has been made a criterion for employment in some jobs.

**functional amblyopia** poor vision that occurs in an otherwise normal eye because of disuse or improper use of the eye during early life. Causes of functional amblyopia include **STRABISMUS**, **ANISOMETROPIA**, and sensory deprivation, when no image is allowed to reach the eye (e.g., in unilateral cataract).

**functional amnesia** loss of memory for events one has
personally experienced that occurs in the absence of any identifiable neurological pathology. Functional amnesia is thought to arise as a defense against anxiety and distress or as a way of escaping from specific situations. It is often used as a synonym of *psychogenic amnesia* and dissociative amnesia.

**functional analysis** 1. the detailed analysis of a behavior to identify contingencies that sustain the behavior. 2. a synthesis of a client’s behavior problems and the variables that are associated with or hypothesized to cause them.

**functional analytic causal model (FACM)** a vector diagram that visually presents a clinician’s conjectures or theories about an individual’s maladaptive behaviors, the objectives of those behaviors, and the variables affecting them. Use of FACM graphically organizes and elucidates contingencies affecting the design of therapeutic interventions and provides an alternative or supplement to clinical case conceptualization.

**functional analytic psychotherapy (FAP)** an interpersonal approach to therapy based on the theoretical framework of radical behaviorism. Initially, the therapist generates a number of hypotheses about groups, or classes, of a client’s *clinically relevant behavior* (CRB). Such behaviors are (a) problem behaviors in a session that are like those the client engages in outside of therapy (CRB1s); (b) improvements in the client’s behavior that occur in session (CRB2s); and (c) client descriptions of what variables affect his or her behavior, leading to those problems or improvements (CRB3s). It is the therapist’s task to look for occurrences of CRBs, to assess the impact that CRB1s have on the therapist, and to reinforce alternative ways of interacting (CRB2s) that have a more positive impact and help meet the client’s goals of improved interpersonal relationships, [developed in the 1980s by U.S. clinical psychologists Robert J. Kohlenberg (1937–) and Mavis Tsai]

**functional approach to attitudes** a theoretical perspective postulating that attitudes are formed to serve one or more different functions and that these functions can influence such processes as attitude change and attitude-behavior consistency. See also ego-defensive function of an attitude; knowledge function of an attitude; social-adjustive function of an attitude; utilitarian function of an attitude; value-expressive function of an attitude.

**functional asymmetry** activity-related differences between the two cerebral hemispheres, as demonstrated by disparities in various behavioral competencies such as task performance. For example, studies have shown right-ear advantage for word stimuli, indicating left-hemisphere superiority for language processing.

**functional autonomy** 1. the ability of a person to perform independently the various tasks required in daily life, a core concept in rehabilitation. See activities of daily living; instrumental activities of daily living. 2. as defined in 1973 by Gordon W. Allport, a general principle of motivation stating that during the performance of purposeful, goal-oriented behavior, various derivative drives emerge as independent units from the original drive that inspired the behavior. For example, studying motivated by the desire to obtain high grades may be gradually replaced by the desire for (and therefore pursuit of) knowledge for its own sake.

**functional behavioral assessment (FBA)** 1. an assessment approach that identifies the functions fulfilled by a particular maladaptive or problematic behavior by examining the circumstances and consequences associated with its occurrence. The circumstances (i.e., antecedents), behavior, and consequences are typically defined in measurable terms, and combinations of particular types of antecedents and consequences may be presented systematically as part of the assessment. Thus, circumstances and consequences (i.e., motivational factors) associated with increases or decreases in the particular behavior can be identified. Results of these assessments provide information of immediate utility in designing interventions or treatments to address the behavior. 2. any of a variety of assessment methods used in applied behavior analysis.

**functional blindness** visual deterioration without any apparent change or disease affecting the structural integrity of the visual system: one of the most frequent symptoms in somatization disorder. In addition to loss of acuity, visual functional phenomena may include photophobia; burning, painful, or tired eyes; monocular diplopia (double vision); ptosis; blepharospasm; convergence problems; and severe concentric visual field constriction in one or both eyes. Despite the symptoms, the pupils continue to react to light, and the patient automatically avoids (i.e., is able to detect and thereby avoid) objects that would cause injury. Complete functional blindness is rare. The condition was formerly known as hysterical blindness or psychic blindness.

**functional brain imaging** the use of brain imaging techniques to localize areas of cognitive or emotional activation. See functional magnetic resonance imaging; positron emission tomography.

**functional classification** see complementary classification.

**functional communication training** a behavior therapy technique used with children and adults diagnosed with developmental impairments, such as autism or intellectual disability, who are exhibiting aggressive, self-injurious, or highly disruptive behavior. The technique assesses the function that the negative behavior serves and uses positive reinforcement to replace it with more appropriately adaptive communication or behavior that meets the same need.

**functional conformance** in environmental design, the provision of the objects and equipment required to adapt an environment to a given set of functional uses, as, for example, by furnishing a study with a desk, lights, and a comfortable chair.

**functional connectivity mapping** recording (e.g., via functional magnetic resonance imaging or positron emission tomography) the connections between noncontiguous brain regions during particular activities or at rest. A variety of statistical methods have been developed to analyze the resultant maps.

**functional data analysis** (FDA) an area of statistics in which mathematical functions are used to study how things change across time. It usually involves the use of derivatives to form curves that model the pattern of change in some phenomenon (e.g., health, achievement).

**functional deafness** loss of hearing that is not associated with any known structural abnormality in the auditory system.

**functional disorder** a disorder for which there is no known physiological basis. In psychology and psychiatry,
**functional distance**

Functional disorders are improperly considered equivalent to psychogenic disorders.

**functional distance** the degree to which the arrangement or configuration of residential facilities influences the probability of unplanned social interaction. Physical distance can affect functional distance, as can the juxtaposition of entrances and proximity to gathering points (e.g., a lounge, common mailboxes, the intersection of hallways).

**functional dyspareunia** a sexual dysfunction of men or women in which there is recurrent and persistent genital pain during coitus but no structural genital abnormality to account for the pain.

**functional dyspepsia** see Dyspepsia.

**functional electric stimulation** (FES) the application of electric current to peripheral nerves through the use of electrodes in order to generate muscle contractions, which can create functional movements in the extremities. For example, FES has been used to enable individuals withparaplegia to pedal adapted exercise bicycles or, in combination with custom leg braces, to walk.

**functional family therapy** a type of family therapy that focuses on family interaction patterns and on the benefits family members may derive from problem behavior. Using reframing and cognitive behavior therapy methods, functional family therapy focuses primarily on at-risk and behaviorally troubled youth and their families.

**functional fixedness** the tendency to perceive an object only in terms of its most common use. For example, people generally perceive cardboard boxes as containers, thus hindering them from potentially flipping the boxes over for use as platforms upon which to place objects (e.g., books). See alternate-use test.

**functional grammar** an approach to grammar using categories that reflect nonlinguistic factors, such as intention and social context, rather than categories based solely on a formal linguistic analysis. Compare formal grammar. See also form–function distinction; Pragmatics.

**functional hyperinsulinism** see Hypoglycemia.

**functional illiteracy** see ILLITERACY.

**Functional Independence Measure** (FIM) an instrument used in rehabilitation to evaluate specific routine motor, cognitive, and self-care skills and provide a measure of functional status. It consists of 18 items related to eating, grooming, bathing, dressing, toileting, bladder and bowel management, transfers, locomotion, comprehension, expression, social interaction, problem solving, and memory that are each rated on a 7-point scale ranging from dependent to independent.

**functional invariant** in the piagetian theory of cognitive development, either of the processes of accommodation and assimilation, which are conceptualized as characterizing all biological systems and operating throughout the lifespan.

**functionalism** n. a general psychological approach that views mental life and behavior in terms of active adaptation to environmental challenges and opportunities. Functionalism was developed at the University of Chicago by psychologists John Dewey, James R. Angell, and Harvey A. Carr at the beginning of the 20th century as a revolt against the atomistic point of view of structuralism, which limited psychology to the dissection of states of consciousness and the study of mental content rather than mental activities. The focus of functionalism reveals its debt to evolutionary concepts, to the act psychology of Franz Brentano, and to the approach detailed by William James. Functionalism emphasizes the causes and consequences of human behavior; the union of the physiological with the psychological; the need for objective testing of theories; and the applications of psychological knowledge to the solution of practical problems, the evolutionary continuity between animals and humans, and the improvement of human life. Also called functional psychology. See also Chicago school.

**functionalist approach to emotion** the view that emotional behavior adaptively serves the function of establishing, maintaining, or altering the relation between an organism and its environment. For example, a hiker’s startled reaction to losing footing on a rocky path is an adaptive response that helps to focus the hiker’s attention and efforts to reestablish footing in the environment. [proposed in 1984 by U.S. developmental psychologists Joseph J. Campos and Karen Caplovitz Barrett]

**functional job analysis** (FJA) a form of job analysis in which tasks are rated on the degree of complexity they entail in dealing with people, data, and things. Such an analysis is commonly used in drawing up personnel specifications and job descriptions.

**functional leader** any member of a group, whether a designated leader or not, who performs the activities associated with a leadership role, including developing and maintaining communication; recruiting members and satisfying their interpersonal needs; defining purposes, objectives, and goals; and assigning task roles to improve team performance. Compare nominal leader.

**functional level** see optimal level.

**functional limitation** restriction or lack of ability in performing an action as a result of a disability. For example, a person who is unable to move safely about his or her home or community or is otherwise unable to travel independently has a functional limitation in mobility.

**function allocation** the systematic process of applying a knowledge of human factors to determine those system functions that can be performed by human operators and those that require automation, or that require an interaction between the human operator and the equipment. Function allocation is carried out early in the system development cycle. See also adaptive task allocation; clumsy automation.

**functional magnetic resonance imaging** (fMRI) functional MRI a form of MAGNETIC RESONANCE IMAGING used to localize areas of cognitive activation, based on the correlation between brain activity and blood property changes linked to local changes in blood flow to the brain. During periods of cognitive activation, blood flow is always increased to a greater extent than oxygen extraction. In consequence, the proportion of oxygenated hemoglobin in the red blood cells transiently increases in an active region, leading to a local increase in the signal detected by fMRI. See blood oxygenation level-dependent.

**functional measurement** a procedure that measures the subjective experience of stimuli as that experience changes across different contexts. Two or more stimuli are presented in various combinations to an observer who assigns ratings to each. These ratings are then integrated
the health status of the brain. thought to depend on several factors, including age and a given developmental state or set of environmental or psychological functioning, characteristic of a person in circumstances. specific neurological or other physical pathology has been demonstrated. disorder for which no specific neurological or other physical pathology has been identified four functions, one of which typically dominates the conscious ego while the others remain unconscious. Jung identified four functions, one of which typically dominates the conscious ego while the others remain unconscious. The individuated person (see INDIVIDUATION) will have integrated all the functions into his or her conscious personality. The functional types are (a) the FEELING TYPE; (b) the THINKING TYPE; (c) the SENSATION TYPE; and (d) the INTUITIVE TYPE. See QUATERNITY. See also ATTITUdINAL TYPES.

functional unity the state or condition in which a set of parts, traits, or processes work together as an integrated unit.

functional universal see PSYCHOLOGICAL UNIVERSAL.

functional vaginismus a sexual dysfunction characterized by recurrent and persistent involuntary spasms of the musculature of the outer third of the vagina, which interfere with coitus and are not caused by a physical disorder.

function coefficient a quantitative value that multiplies a variable and that can change depending on other variables or COVARIATES. A function coefficient differs from other coefficients (e.g., a REGRESSION COEFFICIENT) in that it can vary, whereas the others are constant over all entities or participants. A function coefficient is often used in such statistical methods as REGRESSION ANALYSIS and TIME-SERIES ANALYSIS, particularly when the data change over time or space.

function word in a language, a word that has little or no meaning of its own but plays an important grammatical role: Examples include the articles (a, an, the), prepositions (in, of, etc.), and conjunctions (and, but, etc.). Function words are of high frequency, are typically short, and do not generally admit new members (see CLOSED-CLASS WORDS). The distinction between function words and CONTENT WORDS is of great interest to the study of language disorders, language acquisition, and psycholinguistic processing. Psycholinguists are especially interested in function words because of their role in facilitating sentence parsing. In combination with nonsense words, they can be used to create sentence frames whose GRAMMATICALITY can be recognized but whose content is meaningless, such as He zipped from the flow by sibbing the flux. Also called empty word: functional moneme; functor: relational word: structure word.

fundamental attribution error in attribution theory, the tendency to overestimate the degree to which an individual’s behavior is determined by his or her abiding personal characteristics, attitudes, or beliefs and, correspondingly, to minimize the influence of the surrounding situation on that behavior (e.g., financial or social pressures). There is evidence that this tendency is more common in some societies than in others. Also called correspondence bias: overattribution bias. See also ULTIMATE ATtribution ERROR. [coined by U.S. social psychologist Lee D. Ross (1942– )]

fundamental frequency see FREQUENCY.

Fundamental Interpersonal Relations Orientation–Behavior Scale (FIRO–B) a self-report inventory to assess a person’s interactional needs in a group setting. It evaluates both expressed (demonstrated to others) and wanted (desired from others) dimensions for each of three fundamental social needs—affection, control, and inclusion—via statements that the respondent grades from 0 to 9, with larger numbers reflecting greater importance of the characteristic. Initially developed in 1958 by U.S. psychologist William C. Schutz (1925–2002), the FIRO–B was revised a few decades later to reflect modifications of the FUNDAMENTAL INTERPERSONAL RELATIONS ORIENTATION THEORY upon which it is based. Both the revised version, called FIRO Element B, and the original version of the tool are
Fusion frequency see critical flicker frequency.

Future lives in perspectives deriving from a belief in re-incarnation, those of a human being's multiple lives that have yet to be lived. See also metempsychosis.

Future-mindedness n. the ability to engage in means–ends thinking about the future, that is, to think ahead to what the future may hold and how it might come to pass.

Future orientation a time perspective that is focused on the future, especially on how to achieve one's desired goals.

Future shock the personal confusion and social disorientation that accompany very rapid technological and social change. [Defined by U.S. futurist Alvin Toffler (1928– ).]

Fuzzy logic a logic-based knowledge representation scheme founded on the axiom that set membership is based on a probability distribution (as opposed to traditional set theory, in which an element is either in a set or not in that set). An example of fuzzy logic is that a certain person can be a member of the set of tall people with 75% confidence and also be a member of the set of short people with 5% confidence. Fuzzy logic also breaks the assumption of the law of excluded middle in philosophy, in that an element can be a member of both a set and the opposite of that set at the same time. Fuzzy logic is often used to support the design of expert systems as well as to control algorithms. [First proposed in 1965 by Romanian-born computer engineer Lotfi A. Zadeh (1921– )]

Fuzzy set theory an approach to set theory that allows gradations of membership in a set, instead of only assigning a 0 or a 1 that would indicate nonmembership or absolute membership, respectively. Some phenomena are more readily modeled with fuzzy set theory than conventional binary set theory. For example, in designation of a mental illness, fuzzy set theory may be employed to allow for cases in which individuals could be classified somewhere between having an absence and full diagnosis of a particular condition.

Fuzzy trace theory a theory proposing that information is encoded on a continuum from precise, literal memory representations (verbatim traces) to gistlike, imprecise representations (fuzzy traces), with verbatim traces less easily accessed, generally requiring more effort to use, and more susceptible to interference and forgetting than fuzzy traces. The theory also proposes that developmental differences in many aspects of cognition can be attributed to age differences in encoding and to differences in sensitivity to output interference. [Proposed by U.S. psychologists Charles Brainerd (1944– ) and Valerie Reyna (1955– ).]
**GABA agonists.** Activation of GABAB receptors results in not having binding sites for benzodiazepine or barbiturate GABAB receptors, which are on the receptor complex. GABA on the receptor complex.

**GABA antagonist** a compound that exerts an antagonistic (augmentative) effect at gamma-aminobutyric acid (GABA) receptor sites (see GABA A RECEPTOR; GABA B RECEPTOR) or on the action of GABA. Several classes of GABA agonists exist. Direct GABA agonists (e.g., muscimol) act at the GABA binding site on the receptor; indirect GABA agonists facilitate, in various ways, the release or activity of GABA. Of the indirect GABA agonists, the benzodiazepines, which act as allosteric modulators (see ALLOSTERIC MODULATION) at the GABA receptor complex, are in the most common clinical use.

**GABA antagonist** a substance that exerts an antagonistic (inhibitory) effect at gamma-aminobutyric acid (GABA) receptor sites (see GABA A RECEPTOR; GABA B RECEPTOR) or on the action of GABA. Like GABA agonists, GABA antagonists can be direct or indirect. Direct GABA antagonists block the GABA receptor; the best known of these is bicuculline, which acts as a competitive antagonist for GABA at its receptor site. Indirect GABA antagonists include picrotoxin, which is a noncompetitive antagonist at the GABA A receptor complex and blocks the effects of GABA on the receptor complex.

**GABA receptor** one of the two main types of receptor protein that bind the neurotransmitter gamma-aminobutyric acid (GABA), the other being the GABA B receptor. It is located at most synapses of most neurons that use GABA as a neurotransmitter. The predominant inhibitory receptor in the central nervous system, it functions as a chloride channel (see ION CHANNEL). GABA agonists, such as the barbiturates and benzodiazepines, enhance the binding of GABA to GABA A receptors, allowing for increased conductance of chloride through the ion channel and thereby hyperpolarizing the neuron and inhibiting its activity. GABA antagonists, such as bicuculline and picrotoxin, block the inhibitory effects of GABA at this receptor. Many other substances, including alcohol (ethanol), are thought to exert at least part of their effect via interaction at the GABA A receptor.

**GABA receptor** one of the two main types of receptor protein that bind the neurotransmitter gamma-aminobutyric acid (GABA), the other being the GABA B receptor. GABA receptors, which are G PROTEIN-coupled receptors, are less plentiful in the brain than GABA A receptors and do not have binding sites for benzodiazepine or barbiturate GABA agonists. Activation of GABA A receptors results in relatively long-lasting neuronal inhibition, but few psychotropic substances exert their effect at these receptors. Baclofen is a relatively selective agonist at GABA B receptors and is used clinically as a skeletal muscle relaxant.

**gabapentin** a drug used for the treatment of seizures (see ANTICONVULSANT) and for the relief of pain associated with shingles (see HERPETIC NEURALGIA). Its mechanism of action is unknown: It is a chemical analog of the neurotransmitter gamma-aminobutyric acid (GABA) that is a potent ligand at alpha 2 delta sites on voltage-gated N and P/Q channels. Gabapentin is currently being investigated for the treatment of certain other disorders, including restless-legs syndrome, anxiety disorders, and fibromyalgia, but it is largely discredited as a mood stabilizer for bipolar disorder. Side effects are primarily sedation, dizziness, ataxia, and fatigue: abrupt withdrawal may precipitate seizures. U.S. trade name: Neurontin.

**GAD** abbreviation for GENERALIZED ANXIETY DISORDER.

**GAF Scale** abbreviation for GLOBAL ASSESSMENT OF FUNCTIONING SCALE.

**GAI** abbreviation for GUIDED AFFECTIVE IMAGERY.

**Gaia hypothesis** the hypothesis that the earth, its living things, and its physical environments constitute a single self-regulating entity. In contrast to Darwinian theories of evolution, which hold that living things adapt themselves to the extant environment, the hypothesis suggests that the earth has adapted to, and been transformed by, the living things that are a part of it. This perspective has been influential in modern ecological movements but is rejected by mainstream scientists. The hypothesis is named for Gaia, the Earth, a primordial Greek goddess who emerged from Chaos. [formulated and named by British scientist James E. Lovelock (1919– )]

**gain–loss theory** a theory of interpersonal attraction stating that people’s like (or dislike) for another person is more strongly affected by the degree to which they believe they have gone up (or down) in that individual’s estimation than by the unvarying degree to which they think they are attractive (or unattractive) to that person. [first studied in 1965 by U.S. psychologists Elliot Aronson (1932– ) and Darwyn E. Lind (1939– )]

**gain score** see DIFFERENCE SCORE.

**gainsharing** n. a reward system in which employees are provided with monetary incentives in the form of bonuses that are tied to the performance of a business unit or organization. See INCENTIVE SYSTEM; SCANLON PLAN. See also AGENCY THEORY.

**gait** n. a manner of walking.

**gait apraxia** impairment or loss of the ability to walk that does not involve sensory impairment or paralysis.

**galactopoiesis** n. see LACTATION.

**galactorrhea** n. abnormal expression of breast milk, which may occur either in women at times other than when nursing or in men. Lactation is stimulated by the pituitary hormone PROLACTIN, and the neurotransmitter dopamine normally acts to inhibit the release of prolactin. Therefore, administration of DOPAMINE-RECEPTOR ANTAGONISTS (e.g., conventional antipsychotics), which inhibit the effects of dopamine, may cause galactorrhea. Pituitary tumors or injury to the pituitary gland, causing excessive secretion of prolactin, may also result in galactorrhea. The dopamine-receptor agonist BROMOCRIPTINE may be used to treat the condition.
galactosemia

Galactosemia n. an autosomal recessive disease in which the body is unable to metabolize the sugar galactose, which therefore accumulates in the blood. Untreated, this results in cataracts, jaundice, lethargic and hypotonic behavior, and intellectual disability; the condition is associated with a high infant death rate. Treatment is based on restricted intake of dietary galactose.

galanin n. a NEUROPEPTIDE that is implicated in a variety of functions, including normal growth of the nervous system, recovery of function after nerve injury, and regulation of functions, including normal growth of the nervous system. 

Galton bar an instrument that measures the DIFFERENCE THRESHOLD (just noticeable difference) for visual linear distances. [Francis Galton]

Galton's questionnaire a set of questions sent by Francis Galton to 200 eminent men of science in Britain. The recipients were asked about matters ranging from their physiology (e.g., hat size) to their religious and political background and their reasons for undertaking a career in science. This study, published in 1874 as Enqul Men of Science, is acknowledged as the first use of a questionnaire for psychological research.

galvanic skin response (GSR) a change in the electrical properties (conductance or resistance) of the skin in reaction to stimuli, owing to the activity of sweat glands located in the fingers and palms. Though strictly an indication of physiological arousal, the galvanic skin response is widely considered a reflection of emotional arousal and stress as well. Also called electrodermal response (EDR); psychogalvanic reflex or response (PGR).

galvanotropism n. an orienting response of an organism toward electrical stimulation. It is distinct from galvanotaxis, which is active, directed movement of an organism in response to electrical stimulation. —galvanotropic adj.

GAM abbreviation for GENERALIZED ADDITIVE MODEL.

Gamblers Anonymous (GA) an organization of men and women who share experiences, strength, and hope with each other to recover from compulsive gambling, following the TWELVE-STEP PROGRAM. See GAMBLING DISORDER; PATHOLOGICAL GAMBLING.

gamblers' fallacy a failure to recognize the independence of chance events, leading to the mistaken belief that one can predict the outcome of a chance event on the basis of the outcomes of past chance events. For example, a person might think that the more often a tossed coin comes up heads, the more likely it is to come up tails in subsequent tosses, although each coin toss is independent of any other and the true probability of the outcome of any toss is still just 50%.

gambling disorder DSM-5’s term for PATHOLOGICAL GAMBLING, categorized as a nonsubstance-related addiction rather than an impulse-control disorder (as in DSM-IV-TR). DSM-5 criteria for the disorder include persistent, recurrent gambling not related to manic episodes, along with significant impairment or distress. Associated behaviors may include betting increasing amounts of money, inability to limit or stop gambling, and preoccupation with gambling.

game n. 1. a social interaction, organized play, or transaction with formal rules. See ZERO-SUM GAME. 2. in psychotherapy, a situation in which members of a group take part in some activity designed to elicit emotions or stimulate revealing interactions and interrelationships. In PLAY THERAPY, games are often used as a projective or observational technique. 3. in TRANSACTIONAL ANALYSIS, a recurrent and often deceitful ploy adopted by an individual in his or her dealings with others. 4. in GESTALT THERAPY, an exercise or experiment designed to increase self-awareness, such as acting out frightening situations or participating in the HOT-SEAT TECHNIQUE.

game reasoning the reasoning that governs acceptable behavior within a sporting context. As sport is deemed to be outside real life, the level of morality applied to behavior in sport is different from and usually lower than that applied to behavior in real life. See BRACKETED MORALITY.

gamete n. either of the female or male reproductive cells that take part in fertilization to produce a zygote. In humans and other animals, the female gamete is the OVUM and the male gamete is the SPERMATOZOID. Gametes contain the diploid number of chromosomes rather than the haploid number found in body (somatic) cells. See also GERMLINE.

gamete intrafallopian transfer (GIFT) an alternative to IN VITRO FERTILIZATION in which ova and sperm are introduced directly into the fallopian tubes, where fertilization takes place. Compare ZYGOTE INTRAFALLOPIAN TRANSFER.

game theory a branch of mathematics concerned with the analysis of the behavior of decision makers (called players) whose choices affect one another. Game theory is often used in both theoretical modeling and empirical studies of conflict, cooperation, and competition, and it has helped structure interactive decision-making situations in numerous disciplines, including economics, political science, organizational and social psychology, and ethics. A simple game theory example is a scenario from a reality television show in which the final two players are each asked privately to make a decision to share or keep the entire game prize. The players are told that the outcome will be decided by the following rules: (a) If one player decides to keep the entire prize and the other decides to share, then the first player gets the entire prize; (b) if both players decide to share the prize, then the prize is split; and (c) if both players decide to keep the entire prize, then both leave empty-handed. The players must therefore base their decisions on what they think the other will choose to do.

gametogenesis n. the process resulting in the formation of gametes from germ cells, which normally involves MEIOSIS. In mammals, gametogenesis in the female is known as OOGENESIS and occurs in the ovaries; in the male, it is called SPERMATOGENESIS and occurs in the testes.

Gamma (symbol: γ) n. 1. the distance of a stimulus from the threshold in a psychophysical procedure. 2. any of several different statistical indices, most commonly GOODMAN–KRUSKAL’S GAMMA. 

gamma alcoholism see JELLINEK’S ALCOHOLISM SPECIES.

gamma-aminobutyric acid (GABA) a major inhibitory NEUROTRANSMITTER in the mammalian nervous sys-
temp and found widely distributed in both invertebrate and vertebrate nervous systems. It is synthesized from the amino acid GLUTAMIC ACID. See also GABA$_A$ RECEPTOR; GABA$_B$ RECEPTOR.

gamma-aminobutyric acid agonist see GABA AGONIST.

gamma-aminobutyric acid antagonist see GABA ANTAGONIST.

gamma coherence see GAMMA SYNCHRONY.

gamma-cystathionase deficiency see CYSTATHION-INURIA.

gamma distribution a pattern of data that can be depicted on vertical and horizontal axes when information is known about two parameters, scale and shape, both of which are values equal to zero or higher. For example, a standard gamma distribution is one in which the shape and location parameters of the continuous probability function are 0 and 1, respectively. Gamma distributions are common in BAYESIAN statistics and are often used to describe waiting times and reaction times.

gamma-endorphin n. see ENDORPHIN.

gamma-hydroxybutyrate n. see GHB.

gamma motor neuron see MOTOR NEURON.

gamma movement see APPARENT MOVEMENT.

gamma synchrony the coordinated oscillations of cortical populations of neurons at frequencies from 25 to 60 Hz (GAMMA WAVES). This pattern of electrical activity, as recorded via intracranial electrodes or scalp ELECTROENCEPHALOGRAPHY, predominates during periods of focused mental activities. Growing evidence suggests that gamma synchrony may be a general mechanism for the integration of cognitive processes. Cross-frequency synchrony, including gamma synchrony, has been suggested as the neural correlate of consciousness. Gamma coherence is gamma synchrony with a brief phase lag.

gamma wave in the brain’s electromagnetic field activity, a type of low-amplitude BRAIN WAVE ranging from 25 to 60 Hz (peaking near 40 Hz) that is associated with cognitive activities such as perception and learning. Also called gamma rhythm.

gamonotomania n. an abnormally strong desire or urge to marry.

gamy suffix marriage (e.g., POLYGAMY).

gang n. a social group composed of members with a high degree of personal contact who share common interests and standards of behavior, which in some cases (e.g., street gangs) are antisocial.

ganglion n. (pl. ganglia) a collection of CELL BODIES of neurons that lies outside the central nervous system (the BASAL GANGLIA, however, are an exception). Many invertebrates have only distributed ganglia and no centralized nervous system. Compare NUCLEUS. —ganglionic adj.

ganglion cell see RETINAL GANGLION CELL.

ganglionic blocking agent any of a group of drugs that inhibit the action of the neurotransmitter ACETYLCHOLINE at synapses in the AUTONOMIC GANGLIA. Among other effects, this causes a decrease in heart rate and a lowering of blood pressure, and these drugs were at one time widely used in the treatment of hypertension. However, because of the severity of their side effects, their use is now rare. See MECAMYLAMINE.

ganglionic layer see CORTICAL LAYERS.

ganglioside n. any of a group of glycosphingolipids (sugar-containing lipids) that occur mainly in the tissues of the central nervous system. —gangliosidic adj.

gangliosidosis n. a disorder of lipid metabolism marked by the excessive accumulation of gangliosides in the nervous system. Gangliosidosis occurs in a number of different forms, each associated with a specific ganglioside; TAY-SACHS DISEASE is one type of gangliosidosis.

ganja n. one of the more potent forms of CANNABIS, made from the dried flowering tops of female cannabis plants.

Ganzfeld n. 1. a homogeneous visual field, resulting from stimulation of both retinas by diffuse, uniform illumination. This is typically accomplished by looking through white spheres (or the halves of a ping-pong ball) in a dimly lit room. 2. in parapsychology experiments, a technique in which the participant is isolated from the sensory environment (e.g., by covering the eyes and placing headphones, usually playing white or pink NOISE, over the ears). [German, “whole field”; coined by Wolfgang METZGER]

gap detection the detection of a temporal interruption in a quasi-continuous sound. For individuals with typical hearing in laboratory situations, a gap of approximately 3 ms is just detectable.

gap junction a type of intercellular junction consisting of a gap of about 2 to 4 nm between the plasma membranes of two cells, spanned by protein channels that allow passage of electrical signals. See ELECTRICAL SYNAPSE.

garbage in, garbage out (GIGO) an expression indicating that if the data used in analyses are not reliable or coherent, the results will not prove useful. The phrase was first used in computer science, cautioning users against trusting computer output derived from unreliable input. Although the term is not used much currently, it remains a relevant reminder to researchers to pay attention to how studies are designed and how data are collected, and not to depend on analyses to produce meaningful results when the input data are not themselves meaningful.

garbage can see waste.

garcia effect an alternative but less common name for CONDITIONED TASTE AVERSION. [John Garcia (1917–2012), U.S. psychologist]

garden-path sentence a sentence in which structural cues, lexical ambiguity, or a combination of both mislead
Gardner–Diamond syndrome

the reader or listener into an incorrect interpretation until a disambiguating cue appears later in the sentence. For example, in the sentence *As the car drove past the church clock could be heard striking*, the appearance of the verb phrase *could be heard* indicates that a parsing of the sentence in which *past* is interpreted as governing the *church* is erroneous. Such sentences have proved useful in psycholinguistic research into the role of memory in sentence parsing.

**Gardner–Diamond syndrome** a condition in which an individual bruises easily (purpura simplex) and the black and blue patches (ecchymoses) tend to enlarge and result in pain in the affected tissue. It is thought to be triggered by severe emotional distress. Also called **autoerythrocYTE sensITIzation syndrome: painful bruising syndrome: psychogenic purpura.** [Louis Klein Diamond (1902–1995) and Frank H. Gardner (1919–2013), U.S. physicians]

gargoylism *n.* the facial appearance of people with **hurler syndrome**: psychogenic purpura. The features include an abnormally long and narrow skull due to premature closure of the sagittal suture; a broad nose bridge; an open mouth with a large protruding tongue; thick lips; and clouded corneas.

**GAS abbreviation for** *general adaptation syndrome.*

gas chromatography *a method of chemical analysis used to separate and identify the components of a mixture.* The substance being tested is placed at one end of a long tube, and its components are volatilized by an inert gas injected into the tube. Components can be identified by the time they take to pass through the tube. The technique is used to separate and quantify barbiturates, steroids, and fatty acids.

gaslight vb. to manipulate another person into doubting his or her perceptions, experiences, or understanding of events. The term once referred to manipulation so extreme as to induce mental illness or to justify commitment of the gaslighted person to a psychiatric institution, but it is now used more generally. It is usually considered a colloquialism, though occasionally it is seen in clinical literature, referring, for example, to the manipulative tactics associated with antisocial personality disorder. —gaslighted adj.

[from *Gaslight*, a 1938 stage play and two later film adaptations (1940, 1944) in which a wife is nearly driven to insanity by the deceptions of her husband]

gasoline intoxication *a euphoric reaction induced by inhalation of gasoline vapor.* It also results in headache, weakness, depression of the central nervous system, confusion, nausea, and respiratory disorders. See *inhalant.*

gastric motility *movements of the stomach muscles, particularly those caused by digestive processes.* Such movements may also occur in the absence of food in the stomach, as in the reaction of an individual to stress.

gastric neuropathy *a form of diabetic gastropathy marked by delayed emptying of the stomach and irregular food absorption.*

gastrin *n.* a hormone, synthesized in the G cells of the stomach wall, that regulates the release of gastric juice by the stomach. See also *secretin.*

gastro-(gastr-) combining form stomach.

gastrocolic reflex *the reflex wave of contraction that passes along the colon when food enters a fasting stomach or even in anticipation of a meal.*

gastroduodenal ulceration *ulceration of the mucosa lining of the stomach and duodenum caused by hydrochloric acid and the digestive enzyme pepsin, which are secreted by the stomach. Although in some cases gastroduodenal ulceration is due to secretion of excess acid, in many others secretion is normal but the mucosa is more susceptible to the acid’s effects. Factors implicated in this increased susceptibility include infection with *Helicobacter pylori* bacteria and long-term use of NSAIDs (nonsteroidal anti-inflammatory drugs: e.g., aspirin, ibuprofen); there may also be a familial or genetic factor. Gastric (stomach) ulcers tend to develop later in life and are less likely to be associated with increased acid secretion than are duodenal ulcers. See also *dispepsia; ulcer.*

gastroenteritis *n.* inflammation of the lining of the stomach and intestines. It may be caused by food poisoning, infectious diseases, allergic reactions, or psychological factors such as fear, anger, or other emotional disturbance. Symptoms may include headache, nausea and vomiting, diarrhea, and gas pain.

gastrointestinal motility *the involuntary forward movement of the contents of the gastrointestinal tract, which are propelled mainly by the alternate contraction and relaxation of the bands of circular and longitudinal muscle fibers that form the walls of the tract.*

gastrointestinal problems *disorders associated with dysfunction of the gastrointestinal tract, such as diarrhea, malabsorption syndrome, colitis, flatulence, dysphagia, gastroenteritis, and peptic ulcer.*

gastrula *n.* an early embryo showing differentiation of cells into the three germ layers that will give rise to all of the major tissue systems in the adult organism.

gastirulation *n.* a stage of embryonic development in which the blastula—essentially a hollow ball of cells—is reorganized to form the gastrula, which contains the basic plan of the future organism.

gate *n.* a device or circuit (e.g., an ion channel or a neural circuit) that controls the passage of a substance or signal. See *gate-control theory; gated channel; ligand-gated ion channel; voltage-gated ion channel.*

gate-control theory *the hypothesis that the subjective experience of pain is modulated by large nerve fibers in the spinal cord that act as gates, such that pain is not the product of a simple transmission of stimulation from the skin or some internal organ to the brain. Rather, sensations from noxious stimulation impinging on pain receptors have to pass through these spinal gates to the brain in order to emerge as pain perceptions. The status of the gates, however, is subject to a variety of influences (e.g., drugs, injury, emotions, possibly even instructions coming from the brain itself), which can operate to shut them, thus inhibiting pain transmission, or cause them to be fully open, thus facilitating transmission. Compare *pattern theory; specificity theory.* See also *gating mechanism.* [first proposed in 1965 by Canadian psychologist Ronald Melzack (1929– ) and British neuroscientist Patrick D. Wall (1925–2001)]

gated channel *a channel in a cell membrane that can open or close to regulate the passage of certain ions or molecules.*

gatekeeper *n.* a health care professional, usually a primary care provider associated with a managed care organization, who determines a patient’s access to health
gaze n. 1. the act or process of maintaining the eyes upon a fixation point. 2. the orientation of the eyes within the face, which can be used by others to interpret where an individual is looking. Gaze direction is an effective way of communicating the location of hidden objects and is functionally similar to pointing. Some nonhuman animals, such as dogs and dolphins, appear to understand the function of gaze direction. See also eye contact.

Gaze palsy an inability to move the eyes, either by saccades or smooth-pursuit eye movements, past midposition in a particular direction, although the eye muscles are capable of contraction. Typical forms are vertical gaze palsy (affecting up-down movements) and horizontal gaze palsy (affecting left–right movements). In complete gaze palsy, gaze shifts are restricted in all directions. Gaze palsy can be caused by injury to the brainstem, thalamus, or posterior occipitotemporal, parietal, or frontal cortex. It leads to a restriction of the field of regard. Also called gaze paresis.

GBMI abbreviation for GUILTY BUT MENTALLY ILL.

GCS abbreviation for GLASGOW COMA SCALE.

GDS abbreviation for GERIATRIC DEPRESSION SCALE.

GDSS abbreviation for GROUP DECISION SUPPORT SYSTEMS.

Gegenhalten n. in neurology, involuntary resistance to passive movement of the extremities. [German, “resisting”]

Geisteswissenschaftliche Psychologie one of two branches of the subject matter of psychology as defined by German academics in the 19th century. Variously translated, the term literally means a psychology dealing with the science of the mind or spirit; as such it was intended to encompass the moral, spiritual, historical, and human aspects of behavior now known as SOCIAL SCIENCE. Compare NATURWISSENSCHAFTLICHE PSYCHOLOGIE. See also VERSCHIEDENE PSYCHOLOGIE.

Gelasmus n. spasmodic laughter in individuals with certain psychogenic disorders, schizophrenia, and some diseases of the brain (especially the medulla oblongata). When occurring as an aspect of a psychomotor seizure, this type of spasmodic laughter is termed gelastic epilepsy.

gel electrophoresis a method of separating molecules of differing size or electrical charge by forcing them to flow through a gel under the influence of an electric field.

gematria n. an occult practice in which the numerical values of letters, words, and phrases are calculated and those values are used to uncover “hidden” significances in words, names, or texts (most often the Hebrew scriptures). It is a form of numerology.

Gemeinschaft n. a type of society or social group based on a community of feeling resulting from shared life experiences and similar beliefs and values (from German, “community”). Familial and kinship relations are an example, although the term can also apply to friendship networks and neighborhood relations. Compare GESELLSCHAFT. [First described in 1887 by German sociologist Ferdinand Julius Tönnies (1855–1936)]

Gemeinschaftsgefühl n. social interest or community spirit: a spirit of equality, belonging, and unity (German, literally: “feeling for community”).
gemellology  
n. the study of twins and the phenomenon of twinning.

-gen suffix producing (e.g., ANTIGEN).

gender  n. 1. the condition of being male, female, or neuter. In a human context, the distinction between gender and sex reflects the usage of these terms: Sex usually refers to the biological aspects of maleness or femaleness, whereas gender implies the psychological, behavioral, social, and cultural aspects of being male or female (i.e., masculinity or femininity). 2. in linguistics, a grammatical category in inflected languages that governs the agreement between nouns and pronouns and adjectives.

gender assignment  classification of an infant at birth as either male or female. Children born with AMBIGUOUS GENITALIA are usually assigned a gender by parents or physicians. See also GENDER REASSIGNMENT.

gender bias  any one of a variety of stereotypical beliefs about individuals on the basis of their sex, particularly as related to the differential treatment of females and males. These biases often are expressed linguistically, as in use of the phrase physicians and their wives (instead of physicians and their spouses, which avoids the implication that physicians must be male) or of the term he when people of both sexes are being discussed.

gender coding  assigning particular traits or behaviors exclusively or predominantly to males or females.

gender concept  an understanding of the socially constructed distinction between male and female, based on biological sex but also including the roles and expectations for males and females in a culture. Children begin to acquire concepts of gender, including knowledge of the activities, toys, and other objects associated with each gender and of how they view themselves as male or female in their culture, possibly from as early as 18 months of age.

gender consistency  the understanding that one’s own and other people’s maleness or femaleness is fixed across situations, regardless of superficial changes in appearance or activities.

gender constancy  a child’s emerging sense of the permanence of being a boy or a girl, an understanding that occurs in a series of stages: GENDER IDENTITY, GENDER STABILITY, and GENDER CONSISTENCY.

gender differences  typical differences between men and women that are specific to a particular culture and influenced by its attitudes and practices. Gender differences emerge in a variety of domains, such as careers, communication, and interpersonal relationships. See also SEX DIFFERENCES.

gender discrimination  an improper but frequently used synonym of SEX DISCRIMINATION.

gender dysphoria  1. discontent with the physical or social aspects of one’s own sex. 2. in DSM–5, a diagnostic class that replaces GENDER IDENTITY DISORDER and shifts clinical emphasis from cross-gender identification itself to a focus on the possible distress arising from a sense of mismatch, or incongruence, that one may have about one’s experienced gender versus one’s assigned gender. Diagnostic criteria for gender dysphoria in children include significant distress or impairment due to marked gender incongruence, such as a strong desire to be—or a belief that one is—the other gender, preference for the toys, games, roles, and activities stereotypically associated with the other gender, and a strong dislike of one’s sexual anatomy. In adults, the manifestations of gender dysphoria may include a strong desire to replace one’s physical sex characteristics with those of the other gender (see SEX REASSIGNMENT), the belief that one has the emotions of the other gender, and a desire to be treated as the other gender or recognized as having an alternative gender identity.

gender identification  the process of identifying oneself as male or female and adopting the roles and values of that gender. Compare SEXUAL IDENTIFICATION. See also GENDER-ROLE SOCIALIZATION.

gender identity  one’s self-identification as male or female. Although the dominant approach in psychology for many years had been to regard gender identity as residing in individuals, the important influence of societal structures, cultural expectations, and personal interactions in its development is now recognized as well. Significant evidence now exists to support the conceptualization of gender identity as influenced by both environmental and biological factors. See CIGENDER; GENDER CONSTANCY; TRANSGENDER. See also GENDER ROLE.

gender identity discordance  a continuing sense that one’s anatomical sex is wrong, with a persistent wish to be the other sex. This phrase is sometimes used in place of GENDER IDENTITY DISORDER and TRANSSEXUALISM to avoid connotations of pathology. See also GENDER DYSPHORIA.

gender identity disorder  in DSM–IV–TR, a disorder characterized by clinically significant distress or impairment of functioning due to cross-gender identification (i.e., a desire to be or actual insistence that one is of the other sex) and persistent discomfort arising from the belief that one’s sex or gender is inappropriate to one’s true self (see TRANSEXUALISM). The disorder is distinguished from simple dissatisfaction or nonconformity with gender roles. The category gender identity disorder not otherwise specified is used to classify gender-related disorders distinct from gender identity disorder, such as GENDER DYSPHORIA related to congenital INTERSEX, stress-related cross-dressing behavior (see TRANVESTISM), or preoccupation with castration or penectomy (removal of the penis). In DSM–5, gender dysphoria entirely replaces gender identity disorder as a diagnostic class and emphasizes the clinical significance not of cross-gender identification per se but, instead, the possible distress arising from the sense of incongruence that one may have between one’s experienced gender and one’s assigned gender.

gender nonconformity  behavior that differs from that of others of the same sex or from cultural expectations of male and female behavior.

gender pay gap  the percentage difference between female and male median annual earnings that is thought to result from undervaluing and underpaying work done by women. Also called gender wage gap. See also COMPARABLE WORTH.

gender psychology  the exploration of the concepts of masculinity and femininity across cultures and the influence of those concepts on behavior, health, interpersonal relationships, and psychological processes. Although gender psychology originally denoted the analysis of biological sex differences between men and women, the field has grown to encompass the social construction of gender as well. Current topics of study are broad, including within-sex variability, GENDER IDENTITY and GENDER ROLES, sexuality and sexual orientation, gender stereotypes and their
origins, and other explorations of men’s and women’s experiences, attitudes, and attributes. Modern gender psychology is also methodologically and theoretically diverse, using various quantitative and qualitative techniques and incorporating a variety of perspectives from foundational areas (e.g., social, developmental, and cognitive psychology) and applied fields (e.g., clinical, counseling, and educational psychology).

gender reassignment 1. the changing of an individual’s label as male or female because of incorrect gender assignment at birth, due to the presence of anomalous genitalia (as in INTERSEX). 2. see SEX REASSIGNMENT.

gender research the study of issues related to femininity, masculinity, sexuality, and gay, lesbian, and transgender concerns. Gender research may involve qualitative studies that use focus groups or interviews to understand behavior as well as quantitative analyses that examine potential gender group differences or prediction models. For example, traditional research has assessed whether there are significant group differences between men and women on math and science performance. More recently, more complex prediction models have been examined to demonstrate that multiple factors are needed to understand performance, such as cultural norms and expectations.

gender role the pattern of behavior, personality traits, and attitudes that define masculinity or femininity in a particular culture. It frequently is considered the external manifestation of the internalized GENDER IDENTITY, although the two are not necessarily consistent with one another.

gender-role socialization the conditioning of individuals to the roles, expectations, and behaviors that society prescribes for males and females.

gender schema the organized set of beliefs and expectations that guides one’s understanding of maleness and femaleness.

gender script a temporally organized, gender-related sequence of events. Stereotypically female gender scripts may include doing laundry or preparing dinner in the kitchen, whereas stereotypically male scripts may include building a birdhouse or barbecuing. See also SCRIPT.

gender similarities hypothesis the notion that males and females are more psychologically alike than they are different. This directly contradicts the popular gender differences model stating that men and women differ enormously in cognitive ability, communication style, personality, social behavior, and dozens of other characteristics. The similarities hypothesis has been criticized, however, as lacking a theoretical basis (given that it is derived exclusively from META-ANALYSIS) and as overly dismissive of contextually based gender differences. [proposed in 2005 by U.S. psychologist Janet Shibley Hyde (1948– )]

gender stability the understanding that one’s own or other people’s maleness or femaleness does not change over time. See GENDER CONSTANCE.

gender stereotype a relatively fixed, overly simplified concept of the attitudes and behaviors considered normal and appropriate for a male or female in a particular culture. Gender stereotypes often support the social conditioning of GENDER ROLES. See also SEX-ROLE STEREOTYPE.

gender typing 1. expectations about people’s behavior that are based on their biological sex. 2. the process through which individuals acquire and internalize such expectations.

gene n. the basic unit of heredity, responsible for storing genetic information and transmitting it to subsequent generations. The observable characteristics of an organism (i.e., its PHENOTYPE) are determined by numerous genes, which contain the instructions necessary for the functioning of the organism’s constituent cells. Each gene consists of a section of DNA, a large and complex molecule that, in higher organisms, is arranged to form the CHROMOSOMES of the cell nucleus. Instructions are contained in the chemical composition of the DNA, according to the GENETIC CODE. In classical genetics, a gene is described in terms of the trait with which it is associated and is investigated largely by virtue of the variations brought about by its different forms, or ALLELES. At the molecular level, most genes encode proteins, which carry out the functions of the cell or act to regulate the expression of other genes. A minority encode vital components of the cell’s protein-assembling apparatus, such as ribosomes. Recent advances in genetic technology and the work of the HUMAN GENOME PROJECT have done much to illuminate the mechanism of gene action and have pinpointed genes associated with various inherited diseases. See also DOMINANT ALLELE, RECESSIVE ALLELE.

genealogy n. the study of the ancestry of an individual or group with emphasis on family history and relationships rather than hereditary traits. —genealogical adj. —genealogist n.

gene cloning see CLONING.

gene–environment interaction an interaction between one or more genes and factors in the environment, such as may be needed to trigger the onset of a disease, condition, or characteristic.

gene expression see EXPRESSION.

gene–gene interaction an interaction between two or more genes, such as may be responsible for the development of a disease, condition, or characteristic.

gene imprinting the phenomenon in which the expression of a gene is different depending on whether it was inherited from the mother or the father.

gene knockdown see KNOCKDOWN.

gene knockout see KNOCKOUT.

gene linkage the tendency for genes or GENETIC MARKERS that are located physically close to each other on a chromosome to be inherited together. Linkage data can provide high-risk family members with estimates of their individual risk for the disease or condition conveyed by the gene.

gene mapping the creation of a schematic representation of the arrangement of genes, genetic markers, or both as they occur in the genetic material of an organism. For humans and other higher organisms, three different types of map are made. A GENETIC MAP (or linkage map) shows the relative positions of genes along each chromosome. A PHYSICAL MAP shows the absolute physical distances between genes along the DNA molecule. A CYTOGENETIC MAP depicts the banded appearance of stained chromosomes; the bands can be correlated with the location of particular genes.

gene mosaicism the presence in an individual of two or more cell lines that are distinct in respect to their genetic
gene mutation

and chromosomal makeup and are derived from a single zygote.

gene mutation see MUTATION.

gene pool the total number of genes and their variants (ALLELES) that occur within a given population of a species at a particular time.

genera pl. n. see GENUS.

general ability a measurable ability believed to underlie skill in handling all types of intellectual tasks. See also GENERAL FACTOR.

general ability tests tests designed to measure the general factor of intelligence. They usually require, among other things, understanding and applying relations among relatively abstract stimuli, such as geometric forms.

general adaptation syndrome (GAS) the physiological consequences of severe stress. The syndrome has three stages: alarm, resistance, and exhaustion. The first stage, the alarm reaction (or alarm stage), comprises two substages: the shock phase, marked by a decrease in body temperature, blood pressure, and muscle tone and loss of fluid from body tissues; and the countershock phase, during which the sympathetic nervous system is aroused and there is an increase in adrenocortical hormones, triggering a defensive reaction, such as the fight-or-flight response. The resistance stage (or adaptation stage) consists of stabilization at the increased physiological levels. High blood pressure can develop into hypertension, with risk of cardiovascular disturbance. Resources may be depleted and permanent organ changes produced. The exhaustion stage is characterized by breakdown of acquired adaptations to a prolonged stressful situation; it is evidenced by sleep disturbances, irritability, severe loss of concentration, restlessness, trembling that disturbs motor coordination, fatigue, jumproing, low startle threshold, vulnerability to anxiety attacks, depressed mood, and crying spells. [first described by Hungarian-born Canadian endocrinologist Hans Selye (1907–1982)]

general aptitude see APTITUDE.

general arousal level of energy expenditure, proposed as one of the two dimensions in terms of which all human behavior can be explained (see AROUSAL), the other being approach–withdrawal.

general behavior theory see BEHAVIOR THEORY.

general drive see NONREGULATORY DRIVE.

general effect an overall scientific finding about a relationship between phenomena. For example, a researcher examining the relationship between various teaching styles and academic performance may conclude the existence of a general effect in which better student performance is obtained with an applied, hands-on style. See also INTERACTION EFFECT; MAIN EFFECT.

general extrasensory perception (GESP) in parapsychology, a paranormal outcome that cannot be assigned to any specific process of extrasensory perception. For example, in an experiment with ZENER CARDS, it may be impossible to determine whether the RECEIVER has perceived the contents of the deck directly through Clairvoyance, received the thoughts of the SENDER through Telepathy, or predicted the future card turns through Precognition.

general factor (symbol: g) a hypothetical source of individual differences in GENERAL ABILITY, which represents individuals’ abilities to perceive relationships and to derive conclusions from them. The general factor is said to be a basic ability that underlies the performance of different varieties of intellectual tasks, in contrast to SPECIFIC FACTORS, which are alleged each to be unique to a single task. Even theorists who posit multiple mental abilities have often suggested that a general factor may underlie these (correlated) mental abilities. See TWO-FACTOR THEORY. [postulated in 1904 by Charles Spearman]

general genetic law of cultural development the idea that a child’s development, as a process embedded in culture, occurs on two planes: first the social, between individuals, and later the psychological, as thought is internalized by the child. [proposed by Lev Vygotsky]

General Health Questionnaire (GHQ) a measure developed in the 1970s to diagnose psychiatric disorders, intended for use with patients in community and nonpsychiatric clinical settings (e.g., by primary physicians). The original version consists of 60 items (e.g., on depression, anxiety, social functioning); there are also 30-item, 28-item, and 12-item versions of the questionnaire. [developed by British psychiatrist David Goldberg (1934– ) at the Maudsley Hospital]

generalizability n. the extent to which results or findings obtained from a sample are applicable to a broader population. For example, a theoretical model of change would be said to have high generalizability if it applied to numerous behaviors (e.g., smoking, diet, substance use, exercise) and varying populations (e.g., young children, teenagers, middle-age and older adults). A finding that has greater generalizability also is said to have greater external validity, in that conclusions pertain to situations beyond the original study.

generalizability theory a framework of principles and assumptions about how to determine the RELIABILITY of a set of data. Researchers investigate the various facets of a study (items, raters, settings, etc.) to understand specific sources of error and to determine the conditions under which observations will be consistent and applicable across different contexts (e.g., age groups, geographic regions, socioeconomic status).

generalization n. 1. the process of deriving a concept, judgment, principle, or theory from a limited number of specific cases and applying it more widely, often to an entire class of objects, events, or people. See INDUCTIVE REASONING. 2. a judgment or principle derived and applied in this way. 3. in conditioning, see STIMULUS GENERALIZATION.

—generalize vb.

generalization gradient a graph marking the similarity or difference between two stimuli versus the similarity or difference in their elicited responses. An excitatory gradient (or excitation gradient) graphs an increased tendency to respond to a stimulus and to other stimuli that resemble it, whereas an inhibitory gradient (or inhibition gradient) graphs a decreased tendency. In general, the more similar two stimuli, the more similar the responses. See also STIMULUS GENERALIZATION.

generalized additive model (GAM) an extension of the GENERAL LINEAR MODEL that allows a researcher to posit and assess various nonlinear patterns in a data set and discern which pattern most closely approximates the data. A generalized additive model assumes that there is an ADDI-
TIVE EFFECT of the independent variables on the dependent variable.

generalized anxiety disorder (GAD) excessive anxiety and worry about a range of concerns (e.g., world events, finances, health, appearance, activities of family members and friends, work, school) accompanied by such symptoms as restlessness, fatigue, impaired concentration, irritability, muscle tension, and disturbed sleep. For a formal diagnosis of GAD, the worry is often experienced as difficult to control, and the various symptoms that accompany the worry and anxiety occur on more days than not for a period of 6 months or more.

generalized imitation imitation of forms of behavior that, until presented by a model, had been previously unseen. Presumably this results from a history of reinforcement for imitating.

generalized least squares regression a procedure used to estimate REGRESSION COEFFICIENTS and other PARAMETERS when ERROR VARIANCES are correlated or show HETEROGENEITY OF VARIANCE such that a conventional ordinary LEAST SQUARES REGRESSION procedure will produce biased results.

generalized linear model (GLM) a broad class of statistical procedures that allow variables to be related in a prediction or REGRESSION ANALYSIS by taking into account the variance of each. The generalized linear model extends ordinary LEAST SQUARES REGRESSION to include other procedures—such as LOGISTIC REGRESSION and POISSON REGRESSION—that allow for the use of categorical dependent variables having very lopsided distributions, in which most people endorse a particular category (e.g., no heroin use) or fail to endorse a particular category (e.g., heroin use).

generalized matching law in behavioral studies, a formula in the form of a power function \( y = ax^b \) that describes the choice between two alternatives in terms of the ratio \( y \) of rates of occurrence of (or time spent in) each alternative and the ratio \( x \) of the rates of reinforcement of the two alternatives. The exponent \( b \) of the function indexes sensitivity to reinforcement rates, and the coefficient \( a \) indexes inherent bias for one of the alternatives. When both \( a \) and \( b \) are equal to 1.0, the formula makes the same prediction as the MATCHING LAW.

generalized motor program the hypothesized, abstract form of a MOTOR PROGRAM whose expression can be varied depending on the concurrent choice of parameters, such as overall extent or speed.

generalized other in SYMBOLIC INTERACTIONISM, the aggregation of people’s viewpoints. It is distinguished from specific other people and their individual views.

generalized seizure a seizure in which abnormal electrical activity involves the entire brain rather than a specific focal area. The two most common forms are ABSENCE SEIZURES and some TONIC–CLONIC SEIZURES.

generalizing assimilation in Jean Piaget’s theory of SENSORIMOTOR INTELLIGENCE, the incorporation of increasingly varied objects into a reflex SCHEME, as, for example, when an infant generalizes a sucking scheme to his or her hand, a blanket, or a toy.

general knowledge test a type of IMPPLICIT MEMORY TEST that asks participants to answer factual questions about previously studied items (e.g., words) and assesses how many more questions are answered correctly for the studied material than for unstudied material. It is often categorized as a verbal CONCEPTUAL TEST.

general language disability see LANGUAGE DISABILITY.

general linear model (GLM) a large class of statistical techniques, including REGRESSION ANALYSIS, ANALYSIS OF VARIANCE, and CORRELATION ANALYSIS, that describe the relationship between a DEPENDENT VARIABLE and one or more explanatory or INDEPENDENT VARIABLES. It is a more specific type of GENERALIZED LINEAR MODEL. Most statistical techniques employed in the behavioral sciences can be subsumed under the general linear model.

general medical condition in DSM–IV–TR, a disorder that has known physical causes and observable psychopathology. Examples include hypertension and diabetes. The equivalent term in DSM–5 is another medical condition. Thus, for example, the DSM–5 diagnosis for a patient who experiences significant anxiety symptoms (e.g., panic attacks) as a consequence of having a neurological disorder (e.g., Parkinson’s disease) would be “anxiety disorder due to another medical condition.”

General Neuropsychological Deficit Scale a scale that combines a series of tests from the HALSTED–REitan NEUROPSYCHOLOGICAL BATTERY to generate an overall estimate of cognitive impairment: The higher the score, the greater the impairment.

general neurotic syndrome a diagnostic classification for a combined anxiety, depressive, and personality disorder. Also called negative affect syndrome.

general paresis dementia associated with advanced neurosyphilitic infection of the brain (see NEUROSYPHILIS), a condition that is now extremely rare because syphilis is usually diagnosed and treated in its early stages. The first symptoms of general paresis appear 5 to 30 years after the primary infection. Psychological signs are irritability, confusion, fatigue, and forgetfulness, followed by headaches, confabulation, and deterioration in behavior and judgment. If untreated with antibiotics, physical signs gradually develop, including ARGYLL ROBERTSON PUPILS, sagging facial muscles, vacant expression, slurred speech, poor handwriting, and LOCOMOTOR ATAXIA, followed by inability to dress, paralysis, convulsions, loss of bladder and bowel control, and gradual deterioration to a vegetative state. General paresis was formerly known as general paralysis of the insane. dementia paralytica, paralytic dementia, and paretic psychosis. Also called general paralysis.

general practitioner (GP) see FAMILY MEDICINE.

General Problem Solver (GPS) a computer program so named because its approach to problem solving using MEANS–ENDS ANALYSIS was intended to address many different problems and problem types. It employs a general recursive goal-reduction search procedure that looks to a problem-specific table of connections for goal and subgoal solution formulas. [built in 1961 by U.S. cognitive and computer scientist Allen Newell (1927–1992) and Herbert A. Simon]

general psychology the broad study of the basic principles, problems, and methods underlying the science of psychology, including areas such as behavior, human growth and development, emotions, motivation, learning, the senses, perception, thinking processes, memory, intelligence, personality theory, psychological testing, behavior disorders, social behavior, and mental health. The study is
viewed from various perspectives, including physiological, historical, theoretical, philosophical, and practical.

**general semantics** an early attempt in the philosophy of language to establish the relationship between words and referents on a scientific basis. It proved influential in a number of disciplines in the 1930s and 1940s. See SEMANTICS; SEMIOTICS. [introduced by Polish-born U.S. philosopher and scientist Alfred Korzybski (1879–1950) in his *Science and Sanity* (1933)]

**general slowing** an explanation of COGNITIVE AGING that attributes poorer performance of older adults on a variety of cognitive tasks to reduced speed of COGNITIVE PROCESSES.

**general systems theory** an interdisciplinary conceptual framework focusing on the wholeness, pattern, relationship, hierarchical order, integration, and organization of phenomena. It was designed to move beyond the reductionistic and mechanistic tradition in science (see REDUCTIONISM) and integrate the fragmented approaches and different classes of phenomena studied by contemporary science into an organized whole. In this framework, an entity or phenomenon should be viewed holistically as a set of elements interacting with one another (i.e., as a system), and the goal of general systems theory is to identify and understand the principles applicable to all systems. The impact of each element in a system depends on the role played by other elements in the system, and order arises from interaction among these elements. Also called SYSTEMS THEORY. [formulated by Austrian biologist Ludwig von Bertalanffy (1901–1972)]

**general transfer** the transfer of general skills or principles acquired in one task or situation to problems in a totally different field. An example is applying the capacity for logical thought acquired in a philosophy course to problems arising in business (see TRANSFER OF TRAINING). Also called TRANSFER BY GENERALIZATION: TRANSFER OF PRINCIPLES. Compare SPECIFIC TRANSFER. See also COGNITIVE GENERALIZATION.

**generate-recognize model** see TWO-PROCESS MODEL OF RECALL.

**generation n.** 1. the act or process of reproduction or creation. 2. all of the offspring that are at the same stage of descent from a common ancestor. See also FERTILIZATION. 3. the average time interval between the birth of parents and the birth of their offspring.

**generation effect** the finding that memory for items to be remembered in an experiment is enhanced if the participants help to generate the items. For example, the word *hot* will be better remembered if the studied item is “Opposite of COLD: __” than if the word *hot* is simply read. Though generation often yields a memory benefit, there are circumstances in which it does not increase retention relative to studying the items.

**generation gap** the differences in values, morals, attitudes, and behavior apparent between younger and older people in a society. The term was first used with reference to the burgeoning YOUTH CULTURE of the late 1960s.

**generative grammar** an approach to linguistics in which the goal is to account for the infinite set of possible grammatical sentences in a language using a finite set of generative rules. Unlike earlier inductive approaches that set out to describe and draw inferences about grammar on the basis of a corpus of natural language, the theories of generative grammar developed by Noam Chomsky in the 1950s and 1960s took for their basic data the intuitions of native speakers about what is and is not grammatical (see COMPETENCE; GRAMMATICALITY). In taking this mentalist approach, Chomsky not only repudiated any behaviorist account of language use and acquisition but also revolutionized the whole field of linguistics, effectively redefining it as a branch of COGNITIVE PSYCHOLOGY. Much research in PSYCHOLINGUISTICS has since focused on whether the various models suggested by generative grammar have psychological reality in the production and reception of language. See also FINITE-STATE GRAMMAR; GOVERNMENT AND BINDING THEORY; PHRASE-STRUCTURE GRAMMAR; TRANSFORMATIONAL GENERATIVE GRAMMAR.

**generativity versus stagnation** the seventh stage of ERICKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT. Generativity is the positive goal of middle adulthood, interpreted in terms not only of procreation but also of creativity and fulfilling one’s full parental and social responsibilities toward the next generation, in contrast to a narrow interest in the self, or self-absorption. Also called GENERATIVITY VERSUS SELF-ABSORPTION.

**generator potential** see RECEPTOR POTENTIAL.

**generic knowledge** see SEMANTIC KNOWLEDGE.

**generic name** the nonproprietary name for a pharmaceutical compound. In the United States, the name is adopted by the United States Adopted Name Council and, if recognized by the United States Pharmacopoeia, becomes the official name of the compound. Compare PROPRIETARY DRUG; TRADEMARK.

**generosity** n. the quality of freely giving one’s support or resources to others in need. See also KINDNESS. —generous adj.

**-genesis suffix** creation, origin, or development (e.g., PAR-THENOGENESIS).

**gene splicing** the technique of inserting genetic material, in the form of DNA, into an existing DNA molecule. This is commonly performed in GENETIC ENGINEERING when genetic material from one organism is introduced into another organism, usually of a different species. The resultant RECOMBINANT DNA may create new sources of drugs or similar organic substances from microorganisms or may correct genetic defects.

**gene therapy** the insertion of segments of healthy DNA into human body cells to correct defective segments responsible for disease development. A carrier molecule (VECTOR) is used to deliver the therapeutic gene to the patient’s target cells, restoring them to a normal state of producing properly functioning proteins. The most common vector is a virus that has been specifically altered to carry normal human DNA, but several nonviral options are being explored as well. Though experimental, current gene therapy holds significant promise as an effective treatment for a variety of pathological conditions, including neurodegenerative disorders. It is not, however, without its share of challenges and limitations: (a) difficulties integrating therapeutic DNA into the genome and the rapidly dividing nature of many cells have prevented any long-term benefits; (b) if the body’s immune system response to foreign objects is triggered, benefits of the therapy may be mitigated; and (c) conditions that arise from mutations in a single gene are the best candidates for gene therapy, yet some of the most commonly occurring disorders (e.g., heart disease, high blood pressure, Alzheimer’s disease, arthritis, diahe—
tests) are caused by the combined effects of variations in many genes. There are also ethical, legal, and social concerns associated with the practice. See also GENETIC ENGINEERING.

**genetic adj.** relating to GENES or GENETICS.

**genetic algorithm** a search procedure from ARTIFICIAL INTELLIGENCE in which populations of solutions to a problem (usually encoded in strings of 0s and 1s) are combined to make new possible solutions for the problem. A fitness measure is used to determine which solutions are suitable for making the new populations of solutions. Genetic operators, such as crossover (where sections of two solutions are interchanged) and mutation (where various bits in a solution are switched), are used to produce the new generations of solutions. This approach to creating problem solutions is intended to be an analogue of NATURAL SELECTION in actual evolutionary processes.

**genetic clock** see TELOMERE.

**genetic code** the instructions in genes that "tell" the cell how to make specific proteins. The code resides in the sequence of bases occurring as constituents of the genetic material, DNA or RNA. These bases are represented by the letters A, T, G, and C (which stand for ADENINE, THYMINE, GUANINE, and CYTOSINE, respectively). In messenger RNA, URACIL (U) replaces THYMINE. Each unit, or CODON, of the code consists of three consecutive bases. Hence, there are 64 possible triplet combinations of the four bases, which specify the amino acids that make up each protein molecule.

**genetic counseling** an interactive method of educating a prospective parent about genetic risks, benefits and limitations of genetic testing, reproductive risks, and options for surveillance and screening related to diseases with potentially inherited causes. Genetic counseling is most often provided by GENETICISTS or genetic counselors who are trained to discuss hereditary disease with individuals, take PEDIGREES, and help individuals and families make decisions about the options open to them with regard to genetic disease. If genetic testing is performed, genetic counselors also assess the psychological implications of risk notification and the need for further psychological counseling following disclosure of test results. Also called genetic guidance. See also PRETEST COUNSELING; POSTTEST COUNSELING.

**genetic defect** any abnormality (MUTATION) in a gene or a chromosome. Generally, the defect is expressed in a failure to synthesize a normally functioning enzyme that is required for a specific step in building a certain body cell or for a vital stage in the metabolism of a food element.

**genetic determinism** the doctrine that human and nonhuman animal behavior and mental activity are largely (or completely) controlled by the genetic constitution of the individual and that responses to environmental influences are for the most part innately determined. See BIOLOGICAL DETERMINISM; DETERMINISM; NATURE–NURTURE.

**genetic disorder** any disease or condition that is due to an abnormality of a gene or chromosome (see MUTATION). Also called inherited disorder.

**genetic engineering** techniques by which the genetic contents of living cells or viruses can be deliberately altered, either by modifying the existing genes or by introducing novel material (e.g., a gene from another species). Genetic engineering is undertaken for many different reasons, including basic research on genetic mechanisms, the large-scale production of particular gene products (e.g., medically useful proteins), and the genetic modification of crop plants. There have also been attempts to modify defective human body cells in the hope of treating certain genetic diseases. There remains, however, considerable public concern about the risks and limits of genetic engineering in plants and animals, including humans. See also GENETIC MONOGAMY; MONOGAMY.

**genetic predisposition** a tendency for certain traits to be inherited, including physical and mental conditions and
disorders. Schizophrenia, for example, is a mental disorder with a genetic predisposition that affects less than 1% of the general population; however, increasingly larger percentages of distant relatives, siblings, and identical twins of individuals are affected. Also called hereditary predisposition.

genetic programming a search process for generating problem solutions based on research in GENETIC ALGORITHMS. In this situation, problem solutions are represented by computer code. Genetic operators, including the exchange of components of code between two solutions as well as the mutation of pieces of a solution code, are used to produce new solutions. A fitness metric is used to determine which solutions are most appropriate for use in producing each new generation of solutions.

genetic programming theory a group of theories that describe aging as resulting from genetic encoding within an individual’s DNA whereby one is born with a predetermined tendency toward a developmental timetable. Also called planned obsolescence theory. Compare VARIABLE RATE THEORY.

genetic psychology the study of the development of mental functions in children and their transformation across the lifespan. In the 19th and early 20th centuries, the term was preferred over the synonymous DEVELOPMENTAL PSYCHOLOGY.

genetics n. the branch of biology that is concerned with the mechanisms and phenomena of heredity and the laws that determine inherited traits. See also BEHAVIORAL GENETICS; BIOGENESIS; POLITICAL GENETICS; SOCIOGENETICS.

genetic sequence the order of base pairs along a particular strand or segment of a DNA or MESSENGER RNA molecule.

genetics of intelligence a research area concerned with the influence of one’s genetic makeup on intelligence. Investigators have identified precise genes or genetic sequences thought to be involved in generating individual differences in intelligence, but these findings remain speculative.

genetic theory 1. the view that behavior can be explained in hereditary and developmental terms. 2. the theoretical principles accepted in the science of genetics.

genetic underclass see UNDERCLASS.

genetic variation differences in the observable characteristics (PHENOTYPE) of the members of a population or species due to spontaneous or environmentally induced genetic alterations or rearrangements. Genetic variation is the basis for NATURAL SELECTION. In one set of conditions, those with certain features will have higher REPRODUCTIVE SUCCESS, but if conditions change, then individuals with other features might be favored.

genetotrophic disease any disease due to an inherited inability of enzymes to break down the nutrients necessary to meet an organism’s metabolic requirements. PHENYLKETONURIA and other inborn errors of metabolism are examples of genetotropic diseases.

-genic suffix produced by or producing (e.g., PSYCHOGENIC).

geniculate nucleus any of four small oval clusters of nerve cell bodies on the underside of the THALAMUS in the brain. There are two pairs—the LATERNAL GENICULATE NUCLEI and the MEDIAL GENICULATE NUCLEI—with one of each pair on either lobe of the thalamus; these relay, respectively, visual impulses and auditory impulses to the cerebral cortex. Also called geniculate body.

genistein n. a phytoestrogen (see ESTROGEN) found in soy beans and other legumes. The effects of genistein in mitigating against learning and memory deficits associated with Alzheimer’s disease and in alleviating menopause-related hot flashes, as well as other potential uses, are being studied.

genital adj. relating to the sex organs. See GENITALIA.

genital arousal in sleep penile erection in men and clitoral enlargement and vaginal lubrication in women that occur during REM SLEEP. Absence of nocturnal penile tumescence is a marker of a physical cause of ERECTILE DYSFUNCTION.

genital character see GENITAL PERSONALITY.

genital disorder any adverse condition affecting the genitalia. Such a condition may be congenital, caused by infection, sexually transmitted, or the result of injury.

genital herpes a HERPES INFECTION that involves the genititals, usually caused by herpes simplex Type 2. However, genital infection with herpes simplex Type 1 is becoming more common. Genital herpes is incurable, although medications are available to manage outbreaks.

genitalia pl. n. the reproductive organs of the male or female. The male genitalia include the penis, testes and related structures, prostate gland, seminal vesicles, and bulbourethral glands. The female genitalia consist of the vulva, vagina, vestibular glands, uterus, ovaries, fallopian tubes, and related structures. The external genitalia comprise the vulva (including the clitoris, labia, and vestibule of the vagina) in females and the penis and testicles in males. Also called genitals. See also AMBIGUOUS GENITALIA.

genitality n. the capacity to experience erotic sensation in the genital organs, starting with childhood masturbation and culminating in adult sexuality.

genital love in classical psychoanalytic theory, sexually mature love of another person achieved during the GENITAL STAGE of psychosexual development. See also GENITAL PERSONALITY.

genital mutilation the destruction or physical modification of the external genitalia, especially when done for cultural reasons (as in CIRCUMCISION or FEMALE GENITAL MUTILATION) or as a form of self-punishment.

genital personality in classical psychoanalytic theory, the sexually mature, adult personality that ideally develops during the GENITAL STAGE of psychosexual development. Individuals who have reached this stage of development are posited to have fully resolved their OEDIPUS COMPLEX and to exhibit a mature sexuality that involves true intimacy and expresses equal concern for their own and their partner’s satisfaction. Also called genital character. See also GENITAL LOVE.

genital stage in classical psychoanalytic theory, the final stage of PSYCHOSEXUAL DEVELOPMENT, ideally reached in puberty, when the OEDIPUS COMPLEX has been fully resolved and erotic interest and activity are focused on intercourse with a sexual partner. Also called genital phase. See also GENITAL LOVE; GENITAL PERSONALITY.
**genital stimulation** stimulation of the genitilia to produce sexual pleasure and response.

**genital zone** any of the external reproductive organs and adjacent areas that are capable of producing erotic or sexual sensations. See also EROGENOUS ZONE.

**genitive** n. a CASE of nouns, pronouns, and noun phrases that expresses a possessor–possessed relation. In English, unlike more inflected languages, the genitive case is apparent only in the possessive pronouns (my/mine, your/yours, our/ours, etc.) and the use of the noun ending -‘s or -‘s to indicate possession. Compare ACCUSATIVE; DATIVE; NOMINATIVE.

**genitofemoral nerve** a nerve that receives sensory impulses from the genitalia and the leg. It divides into femoral and genital branches. In men, the genital branch innervates the cremaster muscle and skin of the scrotum; in women it accompanies one of the ligaments of the uterus. The femoral branch subdivides into smaller nerves of the leg.

**genito-pelvic pain/penetration disorder** a DSM–5 diagnosis that combines VAGINISMUS and DYSPAREUNIA based on their frequent comorbidity and similar presentation.

**genius** n. an extreme degree of intellectual or creative ability, or any person who possesses such ability.

**genocide** n. the intentional and systematic annihilation of a racial, ethnic, national, or religious group. Thus defined, genocide was declared an international crime by the United Nations Genocide Convention of 1948. See also ETHNIC CLEANSING. —genocidal adj.

**genocopy** n. a GENOTYPE at one position (or locus) of a chromosome that produces a nearly identical PHENOTYPE, or observable characteristic, to that produced by a genotype at another position.

**genogram** n. a diagrammatic representation of a family that not only includes PEDIGREE information—that is, individual histories of illness and death—but also incorporates aspects of the interpersonal relationships between family members.

**genome** n. all of the genetic material contained in an organism or cell. The HUMAN GENOME PROJECT mapped the estimated 20,000 to 25,000 genes in human DNA.

**genotype** n. the genetic composition of an individual organism as a whole or at one or more specific positions or loci on a chromosome. Compare PHENOTYPE. See also PARATYPE. —genotypic adj.

**genotype–environment effects** the effects of genetic constitution on experience, based on the proposal that an individual’s genotype influences which environments he or she encounters and the type of experiences he or she has. Three types of genotype–environment effects are proposed: passive (through environments provided by biologically related parents); evocative (through responses elicited by individuals from others); and active (through the selection of different environments by different individuals). [proposed in 1983 by U.S. psychologists Sandra Scarr (1936– ) and Kathleen McCartney (1955– )]

**genotype–phenotype correlation** a correlation between the location or nature of a mutation in a gene and the expression of that mutation in the individual, based on observations of affected individuals and their genotypes. Attempts at such correlations are made to elucidate which characteristics of a mutation affect, for example, the age of onset or severity of diseases with a genetic etiology.

**gentrification** n. the physical upgrading of neighborhoods and housing that accompanies an influx of wealthier residents. It is theorized that an important adverse effect of gentrification is the displacement of many long-term residents who can no longer afford to live in the gentrified area. —gentrify vb.

**genus** n. (pl. genera) 1. the knee, or an anatomical structure that resembles a knee. 2. the anterior portion of the CORPUS CALLOSUM as it bends forward and downward.

**geocentric theory** the theory, attributed to Alexandrian astronomer, geographer, and mathematician Ptolemy (2nd century CE), that the earth is the center of the universe and that the heavenly bodies move around it. Also called Ptolemaic theory. Compare HELIOCENTRIC THEORY.

**Geodon** n. a trade name for ZIPRASIDONE.

**geographical mobility** the capacity or facility of individuals to move from one geographic region to another. See also SOCIAL MOBILITY.

**geometric distribution** the PROBABILITY DISTRIBUTION of the number of failed trials before the first success in a series of BERNOULLI TRIALS.

**geometric illusion** any misinterpretation by the visual system of a figure made of straight or curved lines. Examples of such illusions are the MÜLLER-LYER ILLUSION and the ZÖLLNER ILLUSION.

**geometric mean** a measure of CENTRAL TENDENCY calculated for k numbers $x_1, \ldots, x_k$ as $(x_1 \times x_2 \times \cdots \times x_k)^{1/k}$. A geometric mean is similar to an arithmetic mean except that the latter involves the sum of the quantities divided by the number of quantities, whereas the former is the product of the quantities with the product raised to the power of 1 divided by the number of quantities. Thus, for the numbers 1, 2, and 3, the arithmetic mean is $6/3 = 2$, and the geometric mean is the cube root of $(1)(2)(3) = 6^{1/3} = 1.817$. See also HARMONIC MEAN.

**geon** n. a simple three-dimensional element (e.g., sphere, cube) regarded as a fundamental component in the perception of a more complex object. See RECOGNITION BY COMPONENTS THEORY. [first proposed by U.S. psychologist Irving Biederman (1939– )]

**geophagy** n. the eating of dirt or clay. It is most commonly seen in individuals with intellectual disability, young children, and occasionally in pregnant women. It is usually a symptom of PICA, but in some cultures, it is an accepted practice.

**geostatistics** n. a set of methods for analyzing data related to the physical environment. In psychology, for example, geostatistics could be used to understand which factors in the environment can bring about or exacerbate behavioral conditions, such as substance abuse, or spread diseases, such as AIDS.

**geotaxis** n. the involuntary movement of an organism that helps it maintain a postural orientation related to the force of gravity. See TAXIS.

**geriatric assessment** a multidisciplinary evaluation of...
Geriatric Depression Scale

an older person’s medical history as well as current physical and mental health, functional and cognitive abilities, and psychosocial stressors (e.g., loss of spouse) that is used to diagnose and to plan treatment for cognitive, emotional, and social problems that the individual may have.

Geriatric Depression Scale (GDS) an assessment instrument specifically designed for use with adults ages 65 years and older. It is self-administered and comprises a series of 30 yes–no questions (e.g., “Do you often get bored?”; “Is it easy for you to make decisions?”; “Do you enjoy getting up in the morning?”) about depressive symptoms that excludes somatic disturbances often experienced by older adults. [originally developed in 1982 by psychologist T. L. Brink (1949 – ), psychiatrist Jerome A. Yesavage, and colleagues]

geriatric disorder any disease or chronic condition that occurs commonly, but not exclusively, among older people. Examples of geriatric disorders include glaucoma, arthritis, and Alzheimer’s disease and other dementias. geriatrician n. a physician, psychologist, or other health care provider who specializes in the biopsychosocial treatment and management of older adults.

geriatric neuropsychology an applied subspecialty in neuropsychology addressing the assessment and intervention of COGNITIVE DYSFUNCTION in older adults and aimed at improving their functioning and quality of life. geriatric psychology see GEROPSYCHOLOGY.

geriatric psychopharmacology the branch of pharmacology that studies the use of and response to psychotropic agents in older adults, as well as the mechanisms of action responsible. Metabolic changes associated with aging can affect a drug’s biological activity and may increase the sensitivity of the individual’s central nervous system to drugs.

geriatric psychotherapy the use of talk therapy to treat the mental disorders of older adults. Geriatric psychotherapy requires an understanding of age-related and cohort-related differences (see COHORT EFFECT) in symptoms and behavior.

geriatric rehabilitation the process of using somatic therapies (e.g., OCCUPATIONAL THERAPY, PHYSICAL THERAPY) to restore to the fullest extent possible the functional abilities of older adults following an illness or injury that resulted in lost or diminished independence.

geriatrics n. the branch of medicine that deals with the diagnosis and treatment of disorders in older adults. —geriatric adj.

geriatric screening a program or system administered by a hospital, community center, county health center, or other such agency to provide physical examinations and care, psychological evaluations, and financial counseling to older adults.

German measles a disease that is caused by the rubella virus and that produces symptoms similar to measles, although it is less contagious. A woman who develops German measles during pregnancy has a 25% chance of giving birth to a child with congenital rubella. The rate of malformation in the fetus ranges from a low of 6% if the virus is contracted during the 3rd month of pregnancy to as high as 50% in the 1st month. The birth defects include malformations of the eyes, ears, and central nervous system (see CONGENITAL RUBELLA SYNDROME). Also called rubella.

germin cell any of the cells in the gonads that give rise to the GONADOTROPINS by a process involving growth and METABOLISM. See OOGENESIS; SPERMATOGENESIS.

germinial stage 1. in humans, the first 1 to 2 weeks of prenatal life after fertilization, in which the fertilized egg (zygote) migrates to the uterus and becomes implanted in the ENDOMETRIUM. The EMBRYONIC STAGE follows the germinial stage. 2. in plants, the season during which germination occurs.

germin layer any of the three layers of cells in an animal embryo at the GASTRULA stage, from which the various organs and tissues develop. The outermost layer is the ECTODERM, the middle layer is the MESODERM, and the inner layer is the ECTODERM.

germ plasm 1. the region of cytoplasm in an egg cell that is destined to give rise to the GERM CELLS during subsequent embryological development. Compare SOMATOMATURM. 2. the hereditary material that, according to German cytologist August Weismann (1834–1914) in his germ plasm theory (also known as continuity of germ plasm or Weismannism), passes unchanged from generation to generation in the germ cells. It is now identified as DNA.

germination theory the doctrine that infectious diseases are caused by the presence and activity of microorganisms, such as bacteria, viruses, or fungi, in body tissues. geront-(gero-) combining form old age.

gerontology n. the scientific interdisciplinary study of old age and the aging process. Those involved in gerontology include psychologists, biologists, sociologists, medical scientists, medical practitioners, geriatric service providers, and scholars from the humanities and social sciences. See also SOCIAL GERONTOLOGY. —gerontological adj. —gerontologist n.

gerophilia n. sexual attraction to much older partners. Also called gerontophilia.

geropsychology n. a specialization in psychology dealing with enhancing the welfare and mental health of older adults via the provision of various psychological services. Also called geriatric psychology. —geropsychological adj. —geropsychologist n.

Gerstmann’s syndrome a set of four symptoms associated with lesions of a specific area of the (usually left) PARietallobe. They are inability to recognize one’s individual fingers (finger agnosia; see TACTILE AGNOSIA), inability to distinguish between the right and left sides of one’s body (RIGHT–LEFT DISORIENTATION), inability to perform mathematical calculations (ACALCULIA), and inability to write (AGRAPHIA). The existence of Gerstmann’s syndrome as a true independent entity is subject to debate. [Josef G. Gerstmann (1887–1969), Austrian neurologist]

Gesamtvorstellung n. the act of holding in mind the entire content of a sentence before the first word is spoken.
[German, literally: “complete representation”; coined by Wilhelm Wundt]

Geschwind’s theory the hypothesis that excessive intrauterine exposure to androgens inhibits development of the thymus gland and left cerebral hemisphere, explaining why autoimmune disorders tend to be associated with learning disabilities (including dyslexia) and are more frequent in males than in females. [proposed in 1984 by U.S. neuroscientists Norman Geschwind (1926–1984) and Albert Galaburda (1948–)]

Gesellschaft n. a type of society (the literal meaning of this German word) or social group in which people feel relatively isolated from each other. Their relationships are primarily contractual in nature, being guided chiefly by rational self-interest and the logic of the marketplace. Compare GEMEINSCHAFT. [first described in 1887 by German sociologist Ferdinand Julius Tönnies (1855–1936)]

GESP abbreviation for GENERAL EXTRASENSORY PERCEPTION.

gestalt n. an entire perceptual configuration (from German: “shape,” “configuration,” “totality,” “form”), made up of elements that are integrated and interactive in such a way as to confer properties on the whole configuration that are not possessed by the individual elements. See PERCEPTUAL ORGANIZATION. See also GESTALT PRINCIPLES OF ORGANIZATION; GESTALT PSYCHOLOGY.

Gestalt completion test a visual-perceptual task in which the participant is required to synthesize elements from fragmented, ambiguous pictures of items to form a “whole.” Poor performance on this test (i.e., inability to report complete objects) may indicate impairment of right-hemisphere brain function. This testing technique was initially developed in 1931 by U.S. psychologist Roy F. Street but has since been adapted by others. The original Street Gestalt Completion Test (also known as the Street Gestalt Test or Street test) consists of 13 incomplete silhouettes of common objects.

gestalt grouping factor a condition (e.g., proximity) that favors perception of a gestalt figure, that is, of wholeness or entirety.

gestalt homology in GESTALT PSYCHOLOGY, the notion that components of two different structures can have the same role in their respective structures and be defined by that role. For example, a hypotenuse has the same function in a right triangle and is defined by its relationship to the right angle opposite.

Gestalt principles of organization principles of perception, derived by the Gestalt psychologists, that describe the tendency to perceive and interpret certain configurations at the level of the whole rather than in terms of their component features. They include the laws of grouping identified by German psychologist Max Wertheimer in 1923: for example, the laws of closure, common fate, good continuation, proximity, similarity, and symmetry. Also called gestalt laws of organization. See also GOODNESS OF CONFIGURATION; PRAGNANZ.

Gestalt psychology a psychological approach that focuses on the dynamic organization of experience into patterns or configurations (from German Gestalt[pl. Gestalten]: “shape,” “form,” “configuration,” “totality”). This view was espoused by German psychologists Wolfgang Köhler, Kurt Koffka, and Max Wertheimer in the early 20th century as a revolt against structuralism, which analyzed experience into static, atomistic sensations, and also against the equally atomistic approach of behaviorism, which attempted to dissect complex behavior into elementary conditioned reflexes. Gestalt psychology holds instead that experience is an organized whole of which the pieces are an integral part. A crucial demonstration (1912) was that of Wertheimer with two successively flashed lights, which gave the illusion of motion between them rather than of individually flashing lights. Later experiments gave rise to principles of perceptual organization, which were then applied to the study of learning, insight, memory, social psychology, and art.

gestalt therapy a form of psychotherapy in which the central focus is on the totality of the client’s functioning and relationships in the here and now rather than on investigation of past experiences and developmental history. One of the themes is that growth occurs by assimilation of what is needed from the environment and that psychopathology arises as a disturbance of contact with the environment. Gestalt techniques, which can be applied in either a group or an individual setting, are designed to bring out spontaneous feelings and self-awareness and promote personality growth. Examples of such techniques are ROLE PLAY, the EMPTY-CHAIR TECHNIQUE, and the HOT-SEAT TECHNIQUE. [first proposed in the 1940s by German-born U.S. psychiatrist Frederick (Fritz) S. Perls (1893–1970)]

gestation n. the development of the embryo and fetus in the uterus until birth. See PREGNANCY. —gestational adj.

gestational age the age of a fetus calculated from the date of conception. Also called fetal age. See also MENSTRUAL AGE.

gestational surrogate a woman who is implanted with an embryo produced by in vitro fertilization using the ova and sperm of another couple.

gestation period the period during which an offspring is carried in the uterus of the mother. Gestation periods range from 20 days for the shrew to 550 days for the African rhinoceros and 22 months for the elephant. In human beings, the expected date of birth is usually calculated as 280 days or 9 calendar months from the beginning of the woman’s last menstruation.

gestural communication nonverbal transmission and reception of messages (ideas, feelings, signals) by means of body movements. SIGN LANGUAGE is an example.

gesture n. 1. a movement, such as the clenching of a fist, the waving of a hand, or the stamping of a foot, that communicates a particular meaning or indicates the individual’s emotional state or attitude. Gestures can enhance, clarify, or moderate the meaning of verbal communication. See EMBLEM; ICONIC GESTURE. See also NONVERBAL BEHAVIOR. 2. a statement or act, usually symbolic, that is intended to influence the attitudes of others (as in a gesture of goodwill). —gestural adj.

GHB abbreviation for GROWTH HORMONE.

GHB gamma-hydroxybutyrate: sodium oxybate, a potent CNS depressant that is a metabolic product of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA). It is currently used for treatment of narcolepsy and management of alcohol withdrawal, and in some countries (although not the United States), it has been used as an intravenous general anesthetic. It is commonly encountered as a drug of abuse that produces euphoria and sedation and purportedly enhances sexual arousal. Its abil-
ity to induce amnesia or unconsciousness has led it to be characterized as a date-rape drug. Signs of severe toxicity may occur at levels greater than 40 to 60 mg/kg, and deaths have been reported, usually when the substance is mixed with alcohol. Withdrawal syndromes, characterized by anxiety, tremor, confusion, and rarely seizures, have also been reported. U.S. trade name: Xyrem.

Gheel colony a colony of people with serious mental illness at Gheel in Belgium, a town of refuge where they are given shelter in individual homes and employed in various capacities. This practice dates from the 13th century and is associated with the legend of St. Dymphna, who was martyred at Gheel and became the patron saint of mentally ill, incest victims, and runaways. The colony became a government institute in 1850. See SAINT DYPHNA’S DISEASE.

ghost n. any APPARITION of a disembodied figure that retains some general bodily characteristics of a previously living person. Ghosts are rarely “seen” by more than one individual at a time, even when others are present, and tend to be perceived in periods of emotional crisis. The image often includes some implausible physical factors: for example, the ghost wears clothing, rides a horse, or carries a heavy object.

ghost in the machine a phrase used to emphasize the problems associated with CARTESIAN DUALISM, in which the mind is seen as a nonphysical entity (a “ghost”) that somehow inhabits and interacts with a mechanical body (the “machine”). See DUALISM: MIND–BODY PROBLEM. [coined by British philosopher Gilbert Ryle (1900–1976)]

ghost sickness a CULTURE-BOUND SYNDROME found in Native American communities and attributed to ghosts or sometimes witchcraft. Symptoms include recurring nightmares, weakness, loss of appetite, fear, anxiety, hallucinations, confusion, and a sense of suffocation.

GHQ abbreviation for GENERAL HEALTH QUESTIONNAIRE.

ghrelin n. a peptide secreted by endocrine cells in the stomach that binds to growth hormone receptors in the hypothalamus and anterior pituitary, stimulating appetite and the release of growth hormone.

Giant cell arteritis see ARTERITIS.

GIFT acronym for GAMETE INTRAFALLOPIAN TRANSFER.

giftedness n. the state of possessing a great amount of natural ability, talent, or intelligence, which usually becomes evident at a very young age. Giftedness in intelligence is often categorized as an IQ of two standard deviations above the mean or higher (130 for most IQ tests), obtained on an individually administered IQ test. Many schools and service organizations now use a combination of attributes as the basis for assessing giftedness, including one or more of the following: high intellectual capacity, academic achievement, demonstrable real-world achievement, creativity, task commitment, proven talent, leadership skills, and physical or athletic prowess. The combination of several attributes, or the prominence of one primary attribute, may be regarded as a threshold for the identification of giftedness. —gifted adj.

gigantism n. an abnormally large body size due to excessive secretion of growth hormone by the pituitary gland during childhood.

GIGO abbreviation for GARBAGE IN, GARBAGE OUT.

giole n. a man who is paid to be a woman’s social companion or escort, or to provide sexual services for her, or both.

Gilles de la Tourette’s syndrome see Tourette’s disorder.

Gillespie syndrome see ANIRidia, GIBBERELLAR ATAXIA, AND MENTAL DEFICIENCY. [described in 1965 by Frederick D. Gillespie (1927– ), U.S. ophthalmologist]

Gindler method a series of exercises involving breathing, gentle touch, and posturing intended to foster personal growth and enhance sensory awareness. [Elsa Gindler (1885–1961), German gymnastics teacher]

ginkgo n. a tree. Ginkgo biloba, that is indigenous to Asia but now cultivated widely. An extract of the leaves has been used for centuries by Chinese herbalists and is reputed to possess medicinal and psychotropic properties. It is also a popular dietary supplement primarily used to improve mental acuity, although clinical evidence supporting this effect is largely lacking. The active compounds in ginkgo extract have anticoagulant properties, and ginkgo has been investigated as a treatment for vascular disorders, both peripheral and cerebral (e.g., vascular dementia), the latter with equivocal results. Ginkgo may also have neuroprotective properties, but studies have not shown beneficial effects relative to placebo in preventing neurological disorders such as Alzheimer’s disease. Side effects of ginkgo use are rare and may include headaches or mild gastrointestinal disturbances. However, data suggest that continual long-term use of ginkgo may be associated with excessive bleeding or spontaneous hemorrhage. Additionally, there are several known and potential interactions of ginkgo with other agents, including anticoagulants, anticonvulsants, monoamine oxidase inhibitors, and NSAIDS. Ginkgo may also lower seizure thresholds and should not be used by people who have a history of seizures.

ginseng n. the root of various plants of the genus Panax, valued for its medicinal properties, particularly in Asian cultures. It has a reputation as an aphrodisiac and is also used to enhance overall physical and mental well-being, boost energy, and relieve stress, but there is little clinical evidence supporting its effectiveness for any of these purposes. Some studies, however, have suggested that ginseng may help regulate blood glucose levels, which has prompted investigation of its potential use as a treatment for diabetes, and may improve immune function. Side effects of ginseng use are infrequent but may include nausea and vomiting, diarrhea, insomnia, headaches, nosebleeds, and blood pressure abnormalities. Additionally, ginseng may interact with anticoagulants, caffeine, monoamine oxidase inhibitors, and oral hypoglycemics.

girdle sensation the sensation of feeling a tight band around the trunk, sometimes experienced in multiple sclerosis.

give-and-take process see INTERPERSONAL ACCOMMODATION.

given–new distinction in a sentence or other linguistic structure, the distinction made between information that is probably new to the recipient and that which is probably already known (or can be regarded as given by the context). A speaker’s or writer’s assumptions about which information falls into which category will usually affect word order, stress, and other observable features of language. The distinction is important in PRAGMATICS and DISCOURSE ANALYSIS. See FOREGROUNDING.
glabrous skin the tough, thick, hairless skin that is found on the soles of the feet and the palms of the hands.

gland n. an organ that secretes a substance for use by or discharge from the body. EXOCRINE GLANDS release their products through a duct onto internal or external body surfaces, whereas ENDOCRINE GLANDS are ductless and secrete their products directly into the bloodstream.

glans penis the roughly mushroom-shaped cap at the tip of the penis. It consists of the expanded extremity of the corpus spongiosum associated with connective tissue and is covered in skin (see foreskin).

glare n. a quality of intense brightness, due either to a reflection from a glass or metallic surface or to any strong and harsh light that hinders visual acuity (e.g., high-beam headlights). See also direct glare.

Glasgow Coma Scale (GCS) a standardized observational tool widely used to assess level of consciousness following a head injury. Scores range from 3 to 15 and represent the sum of clinician ratings of three aspects of patient functioning: eye-opening response (graded 1–4), motor response (1–6), and verbal response (1–5). Scores of 8 or below are indicative of severe brain injury and coma, scores of 9 to 12 are indicative of moderate injury, and scores of 13 or higher are indicative of mild injury. Although the GCS is the most popular method of evaluating impairment severity, monitoring neurological status, and evaluating prognosis in traumatic brain injury—having been widely validated and shown to have good reliability—it is not without limitations. Shortcomings, such as the inability of the GCS to test brainstem reflexes or to obtain a verbal subscore in intubated patients, have prompted the development of other instruments to assess neurological alterations associated with trauma, notably the GLASSY COMA SCALE, the full outline of unresponsiveness score, and the Wessex Head Injury Matrix (see vegetative state). [introduced in 1974 by British neurologists Graham Michael Teasdale (1940–) and William Bryan Jennett (1926–2008) while at the University of Glasgow, Scotland]

Glasgow Outcome Scale (GOS) a rating scale to assess social activity and independent functioning after traumatic brain injury. The five categories of the original scale are death, persistent vegetative state, severe disability, moderate disability, and good recovery. An extended GOS that divides each of the latter three levels into an upper and lower degree of disability is also available. [originally developed in 1975 by British neurologist William Bryan Jennett (1926–2008) and British psychiatrist Michael R. Bond (1936– ) at the University of Glasgow, Scotland]

glass ceiling an unofficial, intangible psychological, social, or organizational barrier that prevents able and ambitious individuals, particularly women and members of minority groups, from rising to the highest positions of authority in many organizations. Compare leadership labyrinth.

Glass’s d an effect size measure that represents the standardized difference between means (i.e., the difference in average values for two samples divided by the standard deviation of the second sample). It is often used in meta-analysis and other research in which it is important to determine whether an effect persists across studies in order to consolidate a result. Also called Glass’s delta. See also Cohen’s d; Hedges’s g. [Gene V. Glass (1940– ), U.S. statistician]

glaucoma n. a common eye disease marked by raised intracocular pressure in one or both eyes and, in uncontrolled glaucoma, severe peripheral visual field loss. Age, myopia, and vascular disease are among the risk factors for glaucoma, and there is a higher incidence of the disease among those of African ancestry than in those of other groups. The acute form causes pain and abrupt reduction of visual acuity, visual blurring, and, if untreated, severe visual impairment. Chronic glaucoma is characterized by progressive visual failure without accompanying pain. See also congenital glaucoma; tunnel vision.

glia n. nonneural tissue in the nervous system that provides structural, nutritional, and other kinds of support to neurons. It may consist of very small cells (microglia) or relatively large ones (macroglia). The latter include astrocytes, ependymal cells, and the two types of cells that form the myelin sheath around axons: oligodendrocytes in the central nervous system and schwann cells in the peripheral nervous system. Also called neuroglia. —glial adj.

glioma n. a form of brain tumor that develops from support cells (glia) of the central nervous system. There are three main types, grouped according to the form of support cell involved: astrocytoma (from astrocytes), ependymoma (from ependymal cells), and oligodendroglioma (from oligodendrocytes). Astrocytomas are classified from Grade I to Grade IV by severity and rate of growth: Grade I tumors (also called pilocytic astrocytomas), Grade II astroblastomas, Grade III anaplastic astrocytomas, and Grade IV glioblastomas. Glioma is the most common type of brain cancer and accounts for about a quarter of spinal cord tumors. Also called neuroglioma.

glomerular filtration rate a measure of the ability of the kidney to filter blood. It is usually measured by the clearance of a substance that is secreted at a given rate into the bloodstream and then filtered by the glomeruli. The most commonly used substance is inulin, a carbohydrate that is not absorbed by the intestinal tract.

glomerulus n. a cluster of capillaries that forms at the ends of the Bowman's capsule. The glomerulus is the site of filtration of the blood, and the resulting filtrate becomes urine.

glomerulonephritis n. an inflammation of the glomeruli, the microscopic clusters of blood vessels in the kidneys. Glomerulonephritis is usually caused by an immune response to a foreign substance, such as a virus or a protein. The immune system produces antibodies that attack the glomeruli, causing inflammation and damage.

glomerulonephritis n. an inflammation of the glomeruli, the microscopic clusters of blood vessels in the kidneys. Glomerulonephritis is usually caused by an immune response to a foreign substance, such as a virus or a protein. The immune system produces antibodies that attack the glomeruli, causing inflammation and damage.

Global Assessment of Functioning Scale (GAF Scale) a scale used for treatment planning and outcome evaluation on Axis V of DSM-IV-TR’s multiaxial evaluation system. Scores (1–100) reflect the clinician’s judgment of a patient’s overall level of psychological, social,
Global Deterioration Scale

and occupational functioning at the time of assessment. The GAF scale is also used to measure the highest level of such functioning in the past year.

**Global Deterioration Scale (GDS)** a 7-point scale used to indicate the severity of a primary degenerative dementia, such as Alzheimer’s disease, in an older adult, based on caregivers’ observations of behaviors in the individual. The scale ranges from *no cognitive decline (1) to very severe cognitive decline (7).* [developed in 1982 by U.S. geriatric psychiatrist Barry Reisberg (1947–)]

global intelligence verbal and nonverbal intelligence, especially as measured by the verbal and performance subtests in various WISCERL scales.

globalization n. 1. the process by which goods, information, labor, services, business, finance, natural resources, and cultural products move transnationally. Globalization is usually considered a defining characteristic of the contemporary world. 2. the integration of regional economies, societies, and cultures into a global network of ideas as a result of advances in communication, trade, and transportation. The process of globalization has set in motion the gradual disappearance of traditional boundaries between individual societies and those in different parts of the world. See CULTURAL EROGONOMICS. —globalize vb.

global memory model a mathematical model of the structure and organization of memory that is intended to explain data from a range of experimental tasks and manipulations, as opposed to more restricted models of single phenomena. See also MINERVA; SEARCH OF ASSOCIATIVE MEMORY.

global neuronal workspace a variation of GLOBAL WORKSPACE THEORY: a proposed cognitive architecture in which long-distance neurons connect multiple specialized processors into a neural computational space, synchronizing their individual signals and distributing them to the brain as a whole to produce a global transmission of information that is experienced as consciousness. According to the model, workspace neurons can sustain only a single global representation at a time, making the transition to consciousness an all-or-none occurrence that depends on attention; Neural activity must be robust and focused enough to trigger the large-scale and self-sustained synchrony that elevates processing from subliminal to reportable. Although distributed throughout the brain, long-distance workspace neurons are particularly dense in the PREFRONTAL CORTEX, ANTERIOR CINGULATE CORTEX, and PARietal CORTEX. [developed by French cognitive neuroscientist Stanislas Dehaene (1965–), French neuroscientist Jean-Pierre Changeux (1936–), and colleagues]

global perception overall perception of an object or a situation, focusing on the totality rather than the parts.

global workspace theory a theory suggesting that consciousness involves the distribution of information processed in and recruited from specialized, nonconscious parts of the brain; this is widely broadcast to other parts of the brain (i.e., the global workspace) wherein the information is then made consciously accessible. [originated by U.S. psychologist Bernard J. Baars (1946–)]

globus pallidus one of the BASAL GANGLIA. It is the main output region of the basal ganglia: Its output neurons terminate on thalamic neurons, which in turn project to the cerebral cortex.

globus pharyngeus a sensation of having a lump in the throat for which no medical cause can be identified. It can be a symptom of CONVERSION DISORDER. Also called globus hystericus.

G-LOC abbreviation for GRAVITY-INDUCED LOSS OF CONSCIOUSNESS.

glomerulus n. (pl. glomeruli) 1. a small tuft or cluster in which Olfactory nerve fibers terminate in part of the olfactory bulb. 2. a small tuft or cluster of blood capillaries enclosed in a kidney capsule. —glomerular adj.

glosso- (gloss-) forming 1. tongue (e.g., GLOSSOPHARYNGEAL NERVE), 2. speech (e.g., GLOSSOLALIA).

glossodynia n. a feeling of pain in the tongue or in the tongue and buccal mucous membranes without any observable cause. Also called glossalgia.

glossolalia n. utterances that have a phonetic similarity to human language but no intelligible semantic content. Glossolalia is found in religious ecstasy (“speaking in tongues”) and in hypnotic or medicinal trances. See also NEOLINGUISTIC; WORD SALAD.

glossopharyngeal nerve the ninth CRANIAL NERVE, which supplies the pharynx, soft palate, and posterior third of the tongue, including the taste buds of that portion. It contains both motor and sensory fibers and is involved in swallowing and conveying taste information.

glossosynthesis n. the creation of nonsense words.

glottal 1. adj. pertaining to or involving the glottis or larynx. 2. n. a speech sound produced by constriction of the glottis, as in the [h] sound in *hobble.*

glottal stop a PLOSIVE speech sound produced by complete closure of the glottis followed by sudden release of the breath stream. Although this is a standard speech sound in some languages, in English it occurs mostly in certain dialects, as in the Cockney pronunciation of the [t] in *daughter*, or in certain words “loaned” from other languages, such as the native pronunciation of *Hawai‘i*, in which the stop is indicated by the single quote.

glottis n. the opening between the VOCAL CORDS or, by extension, the vocal cords themselves or the collective elements of the larynx that are involved in voice production.

glove anesthesia a SENSORY CONVERSION SYMPTOM in which there is a functional loss of sensitivity in the hand and part of the forearm (i.e., areas that would be covered by a glove). See also STOCKING ANESTHESIA.

GLS abbreviation for generalized least squares. See GENERALIZED LEAST SQUARES REGRESSION.

glucacon n. a polypeptide hormone, secreted by the A cells of the islets of LANGERHANS, that increases the concentration of glucose in the blood. It opposes the effects of INSULIN by promoting the breakdown of glycogen and fat reserves to yield glucose. Glucagon is administered therapeutically to relieve symptoms of HYPOGLYCEMIA.

glucocorticoid n. any CORTICOSTEROID hormone that acts chiefly on carbohydrate metabolism. Glucocorticoids include CORTISOL, CORTICOSTERONE, and CORTISONE.

glucoreceptor n. any of certain cells in the HYPOTHALAMUS that bind glucose. Glucoreceptors are a putative mechanism for detecting levels of circulating glucose and conveying this information to brain areas. Also called glucodetector; glucostat.
glucose n. a soluble sugar, abundant in nature, that is a major source of energy for body tissues. The brain relies almost exclusively on glucose for its energy needs. Glucose is derived from the breakdown of carbohydrates, proteins, and—to a much lesser extent—fats. Its concentration in the bloodstream is tightly controlled by the opposing actions of the hormones insulin and glucagon. See also blood sugar.
glucose transporter a molecule that spans the plasma membrane of a cell and transports glucose molecules across the membrane.
glucostat n. see GLUCORECEPTOR. —glucostatic adj.
glucostatic theory the theory that short-term regulation of food intake is governed by the rate of glucose metabolism (i.e., utilization) rather than by overall blood levels of glucose. See also LIPOSTATIC HYPOTHESIS. [proposed in the 1950s by French-born U.S. nutritionist Jean Mayer (1924–1993)]
glucuronidation n. a metabolic process by which drugs or other substances are combined with glucuronic acid to form more water-soluble compounds, which are more readily excreted by the kidneys or in bile. Glucuronidation is the most prevalent of the Phase II reactions of drug metabolism.
glue sniffing a form of substance abuse in which the fumes of certain adhesives, particularly plastic model glue, are inhaled for their stimulant and euphoric effects. See also glue sniffing.
glutamate n. a salt or ester of the amino acid glutamic acid that serves as the predominant excitatory neurotransmitter in the brain. Glutamate plays a critical role in cognitive, motor, and sensory functions. It exerts its effects by binding to GLUTAMATE RECEPTORS on neurons. Excessive activity of glutamate at these receptors is associated with damage to nerve tissue (neurotoxicity) and cell death (see EXCITOTOXICITY), possibly the result of calcium ions flooding into the cell following overstimulation of NMDA RECEPTORS.
glutamate hypothesis the theory that decreased activity of the excitatory neurotransmitter glutamate is responsible for the clinical expression of schizophrenia. The hypothesis, supported by a number of studies, developed as a result of observations that administration of NMDA RECEPTOR antagonists, such as PCP (phencyclidine) and ketamine, produce psychotic symptoms in humans. See also DOPAMINE HYPOTHESIS.
glutamate receptor any of various receptors that bind and respond to the excitatory neurotransmitter glutamate. Glutamate receptors are found on the surface of most neurons. There are two main divisions of these receptors: ionotropic receptors and metabotropic receptors. Ionotropic glutamate receptors are further divided into three classes: NMDA receptors, AMPA receptors, and kainate receptors. Metabotropic glutamate receptors (mGlu or mGluR) are subdivided into several classes denoted by subscript numbers (i.e., mGlu1, mGlu2, etc.).
glutamatergic adj. responding to, releasing, or otherwise involving glutamate. For example, a glutamatergic neuron is one that uses glutamate as a neurotransmitter. Also called glutaminergic.
glutamic acid an amino acid that is regarded as nonessential in diets but is important for normal brain function. It is converted into gamma-aminobutyric acid (GABA) in a reaction catalyzed by the enzyme glutamic acid decarboxylase and requiring pyridoxal phosphate. Formed from vitamin B6 (pyridoxine), as a coenzyme.
glutamic acid decarboxylase the enzyme responsible for the formation of the neurotransmitter gamma-aminobutyric acid (GABA) from glutamic acid.
glutamic–oxaloacetic transaminase see ASPARTATE AMINOTRANSFERASE.
glutethimide n. one of the nonbarbiturate sedatives introduced in the early 1950s. Structurally similar to and pharmacologically interchangeable with the barbiturates, glutethimide offered no advantages for treatment of anxiety or insomnia. Now rarely used clinically, it is sometimes encountered as a drug of abuse. U.S. trade name: Diorien.
glycine n. an amino acid that serves as one of the two major inhibitory neurotransmitters in the central nervous system (particularly the spinal cord), the other being gamma-aminobutyric acid (GABA). Glycine is also a cotransmitter with glutamate at excitatory NMDA receptors. Glycine synthesis occurs via two different pathways: in the most important of these, glycine is synthesized from the amino acid serine in a single reaction catalyzed by the enzyme serine hydroxymethyltransferase.
glycogen n. a polysaccharide formed in the liver from glucose and stored in the liver and other body tissues as a primary source of chemical energy. It is easily broken down into glucose molecules as needed for energy. Also called animal starch.
glycosaminoglycan see MUCOPOLYSACCHARIDOSIS.
G418 gangliosidosidase see TAY-SACHS DISEASE.
GNAT abbreviation for GO/NO-GO ASSOCIATION TASK.
gnostic neuron see GRANDMOTHER CELL.
gnothi se auton know thyself (Greek). These words, which were inscribed over the porch of the temple of Apollo at Delphi in ancient Greece, have been ascribed to various sources. The pursuit of self-knowledge, or knowledge of the psyche, became a key element in the philosophical project of Socrates. In a sense, this project is the fundamental undertaking of psychology.
GnRH abbreviation for GONADOTROPIN-RELEASING HORMONE.
goal n. 1. the end state toward which a human or nonhuman animal is striving: the purpose of an activity or endeavor. It can be identified by observing that an organism ceases or changes its behavior upon attaining this state. 2. a target of proficiency to be achieved in a task within a set period of time. See GOAL SETTING.
goal-attainment model in evaluation research, a process that focuses on the achievement of a particular time-limited goal and measures the degree to which that goal has been achieved (e.g., by a program).
goal-based evaluation an evaluation that determines the extent to which a program has achieved its goals. This approach relies heavily on stated program goals and objectives, and as such it might overlook other aspects of the program. Compare GOAL-FREE EVALUATION. See also QUANTITATIVE EVALUATION.
goal-directed behavior

**goal-directed behavior** behavior that is oriented toward attaining a particular goal. It is typically identifiable by observing that an organism ceases search behavior and engages in detour behavior when it encounters obstacles to the goal.

**goal-free evaluation** an evaluation of a program that is conducted without special knowledge of the program's stated goals and objectives and is therefore less subject to the preconceptions or biases of the researcher. Instead, the evaluation attempts to assess the program's actual effects on its clients and, importantly, any unintended negative side effects emerging from the program. Also called value-free evaluation. Compare GOAL-BASED EVALUATION. See also QUALITATIVE EVALUATION.

**goal gradient** systematic changes in behavior that occur as a function of spatial or temporal distance from a reinforcer.

**goal model of evaluation** a system of assessing organizational effectiveness by focusing on the organization’s public goals or expectations rather than its private goals. See also GOAL-BASED EVALUATION; GOAL-FREE EVALUATION.

**goal object** that which an individual is seeking to attain, particularly the ultimate goal following a series of subgoals.

**goal orientation** 1. the tendency to physically or mentally position oneself toward a goal. 2. the characteristic of individuals who tend to direct their behaviors toward attaining goals, particularly long-term goals.

**goal response** 1. in HULL'S MATHEMATICO-DEDUCTIVE THEORY OF LEARNING, the unconditioned response elicited by a GOAL STIMULUS. 2. more generally, the final response in a chain of behavior directed toward obtaining a goal. In conditioning, it specifically refers to the response given to a positive reinforcing stimulus. See also CONSUMMATORY RESPONSE.

**goal setting** a process that establishes specific, time-based behavior targets that are measurable, achievable, and realistic. In work-related settings, for example, this practice usually provides employees with both (a) a basis for motivation, in terms of effort expended, and (b) guidelines or cues to behavior that will be required if the goal is to be met. Goal setting is effective only if individuals concerned are aware of what is to be accomplished and accept the goals for themselves, believing in their attainability. See also LOCKE’S THEORY OF GOAL SETTING; PERFORMANCE GOAL.

**goal specificity** the degree to which a goal is defined.

**goal stimulus** 1. in HULL'S MATHEMATICO-DEDUCTIVE THEORY OF LEARNING, a desired object or goal. 2. more generally, a proprioceptive or other interoceptive stimulus arising from GOAL-DIRECTED BEHAVIOR.

**go-around n.** a technique used in group psychotherapy in which each member in turn is requested to react to another member, a discussion theme, or a described or enacted situation.

**goblet figure** see RUBIN’S FIGURE.

**Gödel's proof** a proof that in any logic system at least as powerful as arithmetic it is possible to state theorems that can be proved to be neither true nor false, using only the proof rules of that system. Published in 1931, this incompleteness result was very challenging to the mathematics of the time. British mathematician Alan Turing (1912–1954), with his proof of the un decidability of the halting problem, extended this result to computation (see TURING MACHINE). [Kurt Gödel (1906–1978), Austrian-born U.S. mathematician]

**goiter n.** a swelling in the front part of the neck caused by enlargement of the thyroid gland. See EXOPHTHALMOS; GRAVES' DISEASE; THYROTOXICOSIS.

**Golden Rule** the principle of reciprocity in ethics. In the Christian tradition, it is usually expressed as "Do unto others as you would have them do unto you," but versions are found in most world religions and many ethical systems. Immanuel KANT proposed a similar principle in the CATEGORICAL IMPERATIVE.

**goldenseal n.** a shrub, Hydrastis canadensis, with medicinal properties. Indigenous to the eastern United States, it has a long history as a folk remedy to control uterine bleeding, and its leaves are commonly used as a poultice and antibacterial agent. There are few clinical studies evaluating the efficacy of goldenseal, but its active ingredients, the alkaloids berberine and hydrastine, have been studied extensively. Berberine has been shown to have antimicrobial properties and may also be effective in preventing the growth of cancer cells. Hydrastine has vasoconstrictive and abortifacient effects and, when taken orally, has been shown to induce labor in pregnant women. At recommended doses, goldenseal appears to have minimal adverse effects (e.g., irritation of the mouth, throat, and stomach; tingling of the skin), but at higher doses it may cause hypotension and increase heart rate. It has also been associated with seizures and other evidence of overstimulation of the central nervous system, and at very high doses may be toxic, potentially causing paralysis, respiratory failure, and death. Chronic long-term use may inhibit vitamin B absorption. Additionally, goldenseal may interact with other agents, including anticoagulants, antihypertensives, and drugs metabolized by the CYTOCHROME P450 3A4 enzyme (e.g., clonidine, nefazodone, St. John’s wort).

**golden section** the division of a line or area so that the ratio of the smaller to the larger portion is equal to the ratio of the larger portion to the whole line or area. Since classical times, this ratio has been regarded as having aesthetic value. Also called golden mean.

**golem n.** in medieval Jewish folklore, a being created from inanimate material, specifically clay, and used as a servant by its creator. In spite of such disadvantages as an inability to speak or think and act on their own, golems were often associated with holiness, wisdom, and magical powers. More recently, the term has come to signify a brainless, clumsy oaf or an automaton.

**Golgi apparatus** an irregular network of membranes and vesicles within a cell that is responsible for modifying, sorting, and packaging proteins produced within the cell. [Camillo Golgi (1843–1926), Italian histologist]

**Golgi tendon organ** a receptor in muscle tendons that sends impulses to the central nervous system when a muscle contracts. When tension in the tendon becomes high enough to cause damage to tissues, Golgi tendon organs send inhibitory messages to the motor neurons of the attached muscle. Also called Golgi corpuscle. [Camillo Golgi]

**Golgi Type I neuron** see PROJECTION NEURON. [Camillo Golgi]

**Golgi Type II neuron** see LOCAL CIRCUIT NEURON. [Camillo Golgi]
Goltz syndrome a congenital multisystem disorder marked by eye anomalies, absent or extra digits, and especially skin lesions, particularly nodules of herniated subcutaneous fat in thin skin areas. About 5% of affected individuals tested have been found to have intellectual disability. Also called local dermal hypoplasia; Goltz–Gorlin syndrome. [Robert William Goltz (1923– ) and Robert James Gorlin (1923–2006), U.S. physicians]

Gomperz curve a function or curve used to describe a pattern of growth that is slow at the beginning and end but rather rapid or steep in the middle, thus forming a shape resembling a leaning letter S. For example, the adoption of a fashion fad may follow a Gompertz curve: Few people purchase the product initially, but there is a subsequent period of highly increased sales that precedes a lessening of interest in the product and ultimately very low sales as the fad dies out. Gompertz curves often are used in survival analysis. Also called Gompertz distribution: Gompertz function. [Benjamin Gompertz (1779–1865), British mathematician]

Gompertz hypothesis a hypothesis suggesting that the probability of human mortality increases exponentially with age in a geometric proportion, doubling every 8 years, between the ages of 20 and 80. Also called Gompertz equation. [Benjamin Gompertz]

gonad n. either of the primary male and female sex organs—that is, the testis or the ovary, respectively. —gonadal adj.

gonal dysgenesis see Turner Syndrome.

gonadal hormones the primary male and female sex hormones.

gonadopause n. the cessation of endocrine-related reproductive function that occurs with age in either sex. See also climacteric, male climacteric.

gonadostat theory a mechanism, associated with the initiation of puberty, by which ovarian or testicular hormones regulate hypothalamic and pituitary secretions. [proposed in 1955 by neuroendocrinologist Geoffrey Wingfield Harris (1913–1971)]

gonadotrope n. any of several hormones that stimulate functions of the gonads. Gonadotropins include follicle-stimulating hormone and luteinizing hormone, produced by the anterior pituitary gland in response to gonadotropin-releasing hormone and chorionic gonadotropin, which is produced by the placenta (see human chorionic gonadotropin). Also called gonadotropic hormone. See also human menopausal gonadotropin. —gonadotropic adj.

gonadotropin-releasing hormone (GnRH) a hypothalamic hormone that controls the release of luteinizing hormone and follicle-stimulating hormone from the anterior pituitary gland. See also releasing hormone.

goniometer (gonoeometer) n. 1. an instrument for measuring angles, particularly the arc or range of motion of a joint. Also called arthrometer. 2. an instrument for measuring balance, consisting of a gradually raised plank. It is used to test for disease of the vestibular system.

go/no-go in conditioning, denoting two-stimulus discrimination procedures in which a particular action is reinforced in the presence of one stimulus (the go stimulus) and not reinforced in the presence of the other (the no-go stimulus). In neurological assessment, a go/no-go task assesses the ability to inhibit a simple motor response after it has been established. A common go/no-go task requires the participant to display two fingers when the examiner presents one finger (go) and to display no fingers when the examiner presents two fingers (no-go). Performance on these tasks is generally impaired following frontal lobe damage or disease.

Go/No-go Association Task (GNAT) an implicit attitude measure based on performance of a joint categorization task in which people judge if the target words are members of a specified category (e.g., insects) as well as if a second set of intermixed words, selected to be highly evaluative in nature, represent a designated evaluative category (e.g., good). Respondents are required to hit (go) a response key if a stimulus word represents the target category of interest or the designated evaluative category or to do nothing (no-go) if the stimulus does not represent either category. In one phase of the test, words from the category of interest are jointly judged with a positive evaluative designation. In a second phase, the category of interest is jointly judged with a negative evaluative designation. Attitudes are inferred from the relative speed in performing the task when the target category being judged is paired with the good versus bad evaluative category. The GNAT is conceptually similar to the implicit association test. [developed by U.S. psychologists Brian A. Nosek and Mahzarin R. Banaji (1956– )]

gonorrea n. a sexually transmitted disease caused by the bacterium Neisseria gonorrhoeae (the gonococcus). The primary focus of infection is the genital tract. Untreated, gonorrhea can lead to sterility and gonococcal conjunctivitis, a serious condition that can cause blindness. See also urethritis.

good behavior game an intervention to decrease vocal interruptions, unexcused seat leaving, fighting, and other disruptive actions in elementary school classrooms. Children are divided into teams and informed of the specific behaviors that are not allowed during the game. Teachers penalize teams for misbehavior by any member and award special privileges to the teams with the most points at the game’s conclusion. The amounts of time and the situations in which the game is played are gradually extended throughout the course of the school year, until ultimately the intervention is withdrawn altogether.

good-boy–nice-girl orientation see conventional level.

good breast in the psychoanalytic theory of Melanie Klein, the internalized representation (see introjection) of the mother’s breast as nourishing and satisfying. According to Klein, the infant first experiences the mother and the nourishing breast as part-objects with positive qualities—the good breast—and negative qualities—the bad breast. Klein thought that the development of these internalized representations of the breast was the first manifestation of splitting.

good continuation one of the gestalt principles of organization. It states that people tend to perceive objects in alignment as forming smooth, unbroken contours. For example, when two lines meet in a figure, the preferred interpretation is of two continuous lines: A cross is interpreted as a vertical line and a horizontal line rather than as two right angles meeting at their vertices. Also called law (or principle) of continuity: law (or principle) of good continuation.
good death

**good death** an end of life that is in accordance with the dying person’s values and is consistent with his or her wishes with regard to medical and surgical interventions, life-support technology (e.g., ventilation, feeding tube), pain management and alleviation of suffering, location where he or she wants to die (e.g., home, hospice, hospital), and emotional, spiritual, religious, or other available support prior to and during the dying process. See also APPROPRIATE DEATH.

good enough mother in the **OBJECT RELATIONS THEORY** of British psychoanalyst Donald Winnicott (1896–1971), the ordinary, devoted mother who provides an adequate or good enough environment for the growth of the infant’s ego to express its true self. The good enough mother begins mothering by adapting entirely to the infant and providing an environment free of impingements, but later she gradually and inadvertently creates small failures of adaptation that allow the infant to tolerate the frustrations of reality.

good enough parent a parent who cares for his or her child in any way that is adequate for proper development. [proposed by U.S. psychologist Sandra Scarr (1936–1)]

good-faith bargaining under the **NATIONAL LABOR RELATIONS ACT** of the United States, the principle that employers recognizing a union as the representative of their employees must treat that union as the exclusive representative of the employees and agree to bargain with that union in an honest, open manner over the terms and conditions of employment. See COLLECTIVE BARGAINING.

good figure see **LAW OF GOOD FIGURE**.

good genes hypothesis a hypothesis of female mate selection arguing that certain features of male behavior and body structure reflect **GENETIC VARIATIONS** that are correlated with positive survival attributes such as health and strength and that females choose males with such features, thereby enhancing their offspring’s chances of survival. Compare RUNAWAY SELECTION. [proposed in 1982 by British evolutionary biologist William D. Hamilton (1936–2000) and U.S. behavioral ecologist Marlene Zuk (1956–1)]

good gestalt the quality possessed by an arrangement of stimuli that is complete, orderly, and clear, with a high degree of GOODNESS OF CONFIGURATION. Although this is related to the principle of PRÄGNANZ, it is distinct in that the arrangement of stimuli need not be the simplest one possible. See also GESTALT; GESTALT PRINCIPLES OF ORGANIZATION.

**Goodman–Kruskal's gamma** a measure of association between two **CATEGORICAL VARIABLES**, where 0 represents no relationship and 1 represents perfect association. For example, a marketing researcher may want to assess the relationship between the location of a store and the type of clothes purchased. A Goodman–Kruskal’s gamma of .30 or higher would indicate a medium-sized correlation, such that clothes distributors desiring to maximize sales should provide specific kinds of clothes at specific locations. Also called Goodman–Kruskal's tau. [Leo A. Goodman (1928–) and William Henry Kruskal (1919–2005), U.S. statisticians]

good me in the **SELF-SYSTEM** theory of Harry Stack Sullivan, the child’s personification of behaviors and impulses that meet with the approval of the parents. The good me is posited to develop as a part of the socialization process and to protect the child from anxiety about himself or herself. Compare BAD ME; NOT ME.

goodness of configuration the quality of a shape or form that has high levels of simplicity, regularity, symmetry, or continuity. Gestalt psychologist Wolfgang Köhler speculated that the mind tends to perceive more goodness of configuration than may actually exist in a shape. See also CLOSURE; GESTALT PRINCIPLES OF ORGANIZATION; PRÄGNANZ.

goodness of fit the degree to which values predicted by a model agree with empirically observed values. For example, a researcher may wish to assess whether a pattern of frequencies from a study is the same as theoretically expected, whether two **CATEGORICAL VARIABLES** are independent, or whether a ***REGRESSION EQUATION*** correctly predicts obtained data. A small, nonsignificant value from a statistical goodness-of-fit test indicates a well-fitting model.

good object in the **OBJECT RELATIONS THEORY** of Melanie Klein, an introjected **PART-OBJECT** that is perceived as benevolent and satisfying (see **INTRODUCTION**). It is an early object representation that derives from the object **SPLITTING** into parts containing positive and negative qualities. The good object forms the core of the infant’s immature ego. Compare BAD OBJECT.

good shape one of the **GESTALT PRINCIPLES OF ORGANIZATION**. It states that people tend to perceive figures in the most uniform and stable forms possible. Also called law (or principle) of good shape.

goose bumps (goose flesh; goose pimples) see PILOERECTION.

**Gordon Diagnostic System (GDS)** an assessment device that aids in the diagnosis of attention deficits. It provides information about an individual’s ability to sustain attention and exert self-control on a continuous performance test. The GDS is a microprocessor-based, portable unit that administers a series of tasks in the form of games. [Michael Gordon (1952–), U.S. psychologist]

**GOS** abbreviation for **GLASGOW OUTCOME SCALE**.

gossip 1. n. personal talk or communication of often unsubstantiated information. Gossip may be scandalous in content or malicious in intention, but it need not be so. Many of the functions of gossip have significant implications for group processes, including bonding, norm transmission, and norm reinforcement. 2. vb. to engage in such talk.

**Gottschaldt Figures Test** see CLOSURE FLEXIBILITY TEST.

government and binding theory an enhanced version of **GENERATIVE GRAMMAR** involving multiple levels of abstraction that seeks to explain, among other things, the relation between universals and particulars that accounts for the generativity of all human languages.

**GP** abbreviation for general practitioner. See **FAMILY MEDICINE**.

**GPA** abbreviation for grade-point average. See **POINT–HOUR RATIO**.

**G-protection device** an aerodynamic device to counter the effects of gravity during flight. The faster the speed, the greater the acceleration due to gravity (acceleration of free fall). Inflatable pressure cuffs in the flight suit help counter some of the gravity effects in order to keep the pilot from losing consciousness.

**G protein** any of a class of proteins that are coupled to
the intracellular portion of a type of membrane receptor (G-protein-coupled receptor) and are activated when the receptor binds an appropriate ligand (e.g., a neurotransmitter) on the extracellular surface. G proteins thus have a role in signal transduction, being involved, for example, in indirect chemical neurotransmission. They work in conjunction with the nucleotides guanosine diphosphate (GDP) and guanosine triphosphate (GTP) and serve to transmit the signal from the receptor to other cell components (e.g., ion channels) in various ways, such as by controlling the synthesis of second messengers within the cell.

GPS abbreviation for GENERAL PROBLEM SOLVER.

GPT abbreviation for GROOVED PEGBOARD TEST.

graafian follicle a small pouchlike cavity in an ovary in which an ovum develops (see oogenesis). At ovulation, one of the follicles ruptures and releases a mature ovum into a fallopian tube, where it may be fertilized. The ruptured follicle becomes the site of the corpus luteum. Also called ovarian follicle. [Reijner de Graaf (1641–1671), Dutch histologist]
graceful degradation a property of cognitive networks in which damage to a portion of the network produces relatively little damage to overall performance, because performance is distributed across the units in the network and no one unit is solely responsible for any aspect of processing. It is a property of the neural network model of cognition and of models derived from the parallel distributed processing hypothesis. See also distributed processing.
gracile fasciculus the medial portion of either of the dorsal columns of the spinal cord, composed of ascending fibers that terminate in the nucleus gracilis of the medulla oblongata. Also called fasciculus gracilis. See also Cuneate Fasciculus.
gracile nucleus see NUCLEUS GRACILIS.
gracile tubercle an elongated swelling on the upper end of the gracile fasciculus in the medulla oblongata. The tubercle contains the nucleus gracilis, which receives dorsal root fibers from sensory receptors in the leg. Also called clava.

gradation method the psychophysical technique of measuring change in small equal units.
graded potential any change in electric potential of a neuron that is not propagated along the cell (as is an action potential) but declines with distance from the source. Kinds of graded potential include receptor potentials, postsynaptic potentials, and subthreshold potentials.
grade equivalent a measure of achievement or performance expressed in terms of the average grade level at which the observed score is typically obtained by a student. For example, if a third-grader’s score conforms to fifth-grade norms, the grade equivalent is expressed as five. Also called grade score.
grade-equivalent scale a standardized scale with scores expressed in terms of the grade norm. Also called grade scale.
grade inflation a trend that results in higher grades being awarded for lower levels of scholarship. Also called upward grade homogenization.
graceful degradation a property of cognitive networks in which damage to a portion of the network produces relatively little damage to overall performance, because performance is distributed across the units in the network and no one unit is solely responsible for any aspect of processing. It is a property of the neural network model of cognition and of models derived from the parallel distributed processing hypothesis. See also distributed processing.
gracile fasciculus the medial portion of either of the dorsal columns of the spinal cord, composed of ascending fibers that terminate in the nucleus gracilis of the medulla oblongata. Also called fasciculus gracilis. See also Cuneate Fasciculus.
gracile nucleus see NUCLEUS GRACILIS.
gracile tubercle an elongated swelling on the upper end of the gracile fasciculus in the medulla oblongata. The tubercle contains the nucleus gracilis, which receives dorsal root fibers from sensory receptors in the leg. Also called clava.

gradation method the psychophysical technique of measuring change in small equal units.
graded potential any change in electric potential of a neuron that is not propagated along the cell (as is an action potential) but declines with distance from the source. Kinds of graded potential include receptor potentials, postsynaptic potentials, and subthreshold potentials.
grade equivalent a measure of achievement or performance expressed in terms of the average grade level at which the observed score is typically obtained by a student. For example, if a third-grader’s score conforms to fifth-grade norms, the grade equivalent is expressed as five. Also called grade score.
grade-equivalent scale a standardized scale with scores expressed in terms of the grade norm. Also called grade scale.
grade inflation a trend that results in higher grades being awarded for lower levels of scholarship. Also called upward grade homogenization.

grade norm the standard score or range of scores that represent the average achievement level of students of a particular grade.
grade-point average (GPA) see POINT–HOUR RATIO.
grade points 1. numbers equivalent to letter-grade assignments for academic coursework. Usually A = 4, B = 3, C = 2, D = 1, and F = 0. The resulting average allows the appropriate reward to be given or disciplinary action to be taken on the basis of academic performance. 2. letter grades converted to a numerical value, typically as follows: A = 90 to 100 (superior work that is clearly above average); B = 80 to 89 (good work, meeting all requirements and eminently satisfactory); C = 70 to 79 (competent work, meeting requirements); D = 60 to 69 (fair work, minimally acceptable); F = 59 and below (failing work). See also POINT–HOUR RATIO.
grade skipping see EDUCATIONAL ACCELERATION.

gradient n. 1. the slope of a line or surface. 2. a measure of the change of a physical quantity (e.g., temperature). 3. in motivational psychology, a graduated change in the strength of a drive resulting from a change in the environment, such as time interval, distance from a situation, and degree of conflict. See also APPROACH GRADIENT; AVOIDANCE GRADIENT.
gradi ent of effect the principle that, in a stimulus-response sequence in which one of the responses is reinforced, the responses closely preceding or following the reinforced response are likely to show the effects of the re-inforcement procedure to a greater extent than those that are remote from that response.
gradi ent of reinforcement the generalization that the closer in time a response is to reinforcement, the stronger it will be.
gradi ent of texture the progressively finer appearance of textures and surface grains of objects as the viewer moves away from them. See also VISUAL TEXTURE.
grading n. the process by which an instructor assigns a performance rank to a student’s work. A definitive way of portraying a student’s acquired knowledge, grading is usually based on both quantitative achievements (e.g., test results, essay completion, attendance) and qualitative considerations (e.g., class participation, teacher’s perception).
gradual withdrawal see TAPERING.
graduated and reciprocated initiatives in tension reduction (GRIT) an approach to intergroup conflict reduction that encourages the parties to communicate cooperative intentions, engage in behaviors that are consistent with these intentions, and initiate cooperative responses even in the face of competition. GRIT is usually recommended when disputants have a prolonged history of conflict, misunderstanding, misperception, and hostility. [originated in 1962 by Charles E. Osgood]

Graduate Record Examinations (GRE) a collection of aptitude tests used in the graduate school admissions process to make decisions regarding applicants. The GRE General Test, currently consisting of two essay writing tasks and approximately 60 multiple-choice questions, evaluates critical thinking, analytical writing, verbal reasoning, and quantitative reasoning abilities. The eight GRE Subject Tests (biochemistry, biology, chemistry, computer science, literature in English, mathematics, physics, psy-
Grady Coma Scale

chology), currently consisting of between 66 and 230 multiple-choice questions, evaluate knowledge specific to particular disciplines.

Grady Coma Scale a scale used to rate level of consciousness, with five grades corresponding to confusion (Grade I), stupor (Grade II), deep stupor (Grade III), DECEREBRATE RIGIDITY (Grade IV), and COMA (Grade V). Compare GLASGOW COMA SCALE. [developed in the 1970s at Grady Memorial Hospital in Atlanta, Georgia]

Graeco-Latin square (Graeco-Latin square) an experimental design that superimposes one LATIN SQUARE upon another. In this type of FRACTIONAL FACTORIAL DESIGN, two sets of elements are arranged in the same set of cells in such a way that every row and every column contains each element of both sets once and once only, and each cell contains a different ordered pair. Graeco-Latin squares are used in research to minimize or eliminate the influence of extraneous variables and to balance ORDER EFFECTS.

Graefenberg spot (Gräfenberg spot; G-spot) an area on the anterior wall of the vagina, about 4 cm (1–2 in.) into the vagina, stimulation of which some women find very sexually pleasurable. See also FEMALE EJACULATION. [Ernst Gräfenberg (1881–1957), German gynecologist]

grammatical adj.
grammaticality n. the quality of adhering to the rules of grammar. In the linguistics of Noam Chomsky, the grammaticality (or otherwise) of a sentence can be intuited by native speakers and explained by the rules of FORMAL GRAMMAR. A sentence can be recognized as grammatical even when it is otherwise meaningless, as in the case of Chomsky’s famous example Colorless green ideas sleep furiously.

grandiose delusion see DELUSION OF GRANDEUR.

grandiosity n. an exaggerated sense of one’s greatness, importance, or ability. In extreme form, it may be regarded as a DELUSION OF GRANDEUR.

grand mal seizure see TONIC–CLONIC SEIZURE.

grand mean a numerical average (MEAN) of a group of averages. For example, if the average test score for one classroom is 75 and the average score for another classroom is 73, the grand mean of the two classrooms is (75 + 73)/2 = 74. Similarly, if an ANALYSIS OF VARIANCE reveals average values of 3, 10, and 20 on a response or DEPENDENT VARIABLE for three groups of study participants, the grand mean of scores—that is, the average of all participants’ responses regardless of the condition of the INDEPENDENT VARIABLES—is (3 + 10 + 20)/3 = 11.

grandmother cell any hypothetical neuron in the VISUAL ASSOCIATION CORTEX that is stimulated only by a single highly complex and meaningful stimulus, such as a particular individual (e.g., one’s grandmother) or a particular well-known object (e.g., the Sydney Opera House). It is an extension of the FEATURE DETECTOR concept to a degree that has been dismissed by many as overly simplistic and untenable. However, research on the activity patterns of single neurons in memory-linked areas of the brain has provided support for the concept by revealing a much higher degree of neuronal specificity than previously believed. [coined in 1969 by U.S. cognitive scientist Jerome Yerofel Lettvin (1920–2011), although the concept itself was proposed two years earlier by Polish neurophysiologist Jerzy Konorski (1903–1973), who referred to it as a gnostic neuron]

grandmother hypothesis the proposition, based on evolutionary theory, that the contribution of grandparents (particularly grandmothers) to the care of their grandchildren has been a factor in extending the human lifespan. [proposed by U.S. evolutionary biologist George C. Williams (1926–2010)]

Grundy–Merkel corpuscle see MERKEL’S TACTILE DISK.

Grani theory of color vision a theory that the perception of color relies on the activation of three types of cells: (a) scotopic dominators, which are RETINAL RODS most sensitive to wavelengths of 500 nm; (b) photopic dominators, which are RETINAL CONES most sensitive to wavelengths of 560 nm; and (c) photopic modulators, other cones sensitive to very narrow frequency ranges. [Ragnar Arthur Granit (1900–1991), Finnish-born Swedish physiologist]

granular cortex the portion of the cerebral cortex that contains GRANULE CELLS, which are located in layers II and IV of the cortex (see CORTICAL LAYERS). The term refers particularly to primary sensory cortex, in which layer IV (the major input area) is very thick. Compare AGRAINULAR CORTEX.

granular layer see DENTATE GYRUS.

granule cell a type of small, granulike neuron found in certain layers of the cerebral cortex and cerebellar cortex.

granulocyte n. see LEUKOCYTE.

grapevine n. the unofficial channel of communication in which information, especially rumors and gossip, is passed informally from person to person.

graph n. 1. a visual representation of the relationship between numbers or quantities, which are plotted on a drawing with reference to axes at right angles (see X-AXIS; Y-AXIS) and linked by lines, dots, or the like. BAR GRAPHS, HISTOGRAMS, and FREQUENCY POLYGONS are commonly used examples. 2. in computer programming, a data structure consisting of a set of nodes (not necessarily finite in number) and a set of arcs that connect pairs of nodes. In a directed graph, the arcs have a unique direction from one node (the parent) to the other node (the child). The set of child nodes of one parent are called siblings of each other. A path is a sequence of connected parent–child arcs, in which each child in the sequence is also a parent of the next state in the sequence. A rooted graph has a unique node from which all paths in the graph originate. A tip node or leaf node in the graph is a node without children.

The graph structure is often used for representing SEARCH in games or other situations of problem solving or for capturing relationships, as in SEMANTIC NETWORKS. See also TREE.

graph- combining form writing or drawing.

grapheme n. a minimal meaningful unit in the writing system of a particular language. It is usually a letter or fixed combination of letters corresponding to a PHONEME in that language. —graphemic adj.
**grapheme–color synesthesia** see SYNESTHESIA.

**graphemic cued-recall test** see PERCEPTUAL TEST.

**graphesthesia** n. the recognition of numbers or letters that are spelled out on the skin, as with finger movements or a dull pointed object. This form of PASSIVE TOUCH has been used as a diagnostic tool for brain damage. In addition, people with both visual and hearing impairment are taught to communicate with those who are unfamiliar with sign language by digitally spelling out words on the skin.

**graphical user interface (GUI)** an interface that enables a user to operate a computer system using visual devices such as windows, icons, and pull-down menus. Compare PERCEPTUAL USER INTERFACE; TANGIBLE USER INTERFACE.

**graphic rating scale** a series of anchored points (usually from low to high) on a continuum, often used to evaluate the performance or behavior of individuals in a work or learning environment. For example, a graphic rating scale for assessing an employee’s overall performance during the past year might take the form of a line with the response options of 1 (poor), 2 (below average), 3 (average), 4 (above average), and 5 (excellent) listed. The supervisor would mark the line to indicate the employee’s performance level.

**graphology** n. the study of the physical characteristics of handwriting, particularly as a means of inferring the writer’s psychological state or personality characteristics. Graphology is based on the premise that writing is a form of expressive behavior, although there is little empirical evidence for its validity. Also called handwriting analysis.

—graphological adj. —graphologist n.

**graphomania** n. a pathological impulse to write, which may degenerate into graphophobia—the compulsive writing of incoherent and meaningless words.

**graphomotor apraxia** inability to perform the motor activities involved in writing or drawing despite normal capacity to hold and manipulate a writing implement. Also called apraxic agraphesthia.

**graphopathology** n. the interpretation of personality disorders by studying handwriting. See also GRAPHOLOGY.

**graphospasm** n. a rare name for WRITER’S CRAMP.

**graph theory** the study of the use of visual representations (graphs) to describe relationships, structures, and dynamics. Applications in psychology include BALANCE THEORY, SOCIOGRAPHY, and analyses of SOCIAL NETWORKS, NEURAL NETWORKS, and LIFE SPACE.

**grasp reflex** an involuntary grasping by an individual of anything that touches the palm. This reflex is typical of infants, but in older individuals, it may be a sign of FRONTAL LOBE damage or disease.

**gratification** n. the state of satisfaction following the fulfillment of a desire or the meeting of a need. See DELAY OF GRATIFICATION; IMMEDIATE GRATIFICATION.

**gratification of instincts** see SATISFACTION OF INSTINCTS.

**grating** n. in vision, a stimulus that consists of parallel light and dark bars.

**gratitude** n. a sense of thankfulness and happiness in response to receiving a gift, either a tangible benefit (e.g., a present, favor) given by someone or a fortunate happening (e.g., a beautiful day).

**Graves’ disease** a disorder characterized by enlargement and overactivity of the thyroid gland and marked by a swelling in the neck (GOITER), abnormal protrusion of the eyeballs (EXOPHTHALMOS), and rapid pulse and other symptoms of THYROTOXICOSIS. [Robert J. Graves (1796–1853), Irish physician]

**graviceptor** n. any of various specialized nerve endings and receptors located in the inner ear, joints, muscles, and tendons that provide the brain with information regarding body position, equilibrium, and gravitational forces. Also called gravireceptor.

**gravidia** n. a pregnant woman. The use of a Roman numeral after the term indicates the number of pregnancies a particular woman has undergone (e.g., gravida IV indicates a woman in her fourth pregnancy). In contrast, the term gravid (adj.) is used primarily to describe an egg-laying organism, usually a fish or reptile, when it is carrying eggs. See also MULTIGRAVIDA; PRIMIGRAVIDA.

**gravidity** n. see PREGNANCY.

**gravity-induced loss of consciousness (G-LOC)** loss of consciousness associated with g-forces (forces of gravity) resulting from acceleration. When acceleration is of high value and rapid onset, loss of consciousness may occur suddenly and without warning, before any other physiological symptoms are noticed. See ACCELERATION EFFECTS.

**gray** n. a visual sensation that has neither hue (color) nor saturation and can vary from black to white.

**gray commissure** a bundle of nerve fibers that surrounds the central canal of the spinal cord and connects the anterior and dorsal horns of GRAY MATTER in each half of the cord.

**gray literature** research findings that are not readily available because they have not been published in archival sources. Examples include dissertations, papers presented at meetings, papers either rejected or not submitted for publication, and technical reports. Gray literature contributes to the FILE-DRAWER PROBLEM in META-ANALYSIS, the situation in which analytic results are biased because researchers have no access to nonsignificant findings from such nonarchival sources. Also called fugitive literature.

**gray matter** any area of neural tissue that is dominated by CELL BODIES and is devoid of myelin, such as the CEREBRAL CORTEX and the H-shaped PERIAQUEDUCTAL GRAY of the spinal cord. Compare WHITE MATTER.

**grayout** n. an increasing loss of peripheral vision to the point that one seems to be looking through a small tube (see TUNNEL VISION). It results from reduced blood flow to the head, as may be experienced, for example, by pilots performing high-speed turning maneuvers in an aircraft.

**gray ramus** a short nerve in the autonomic nervous system that carries unmyelinated postganglionic fibers from a SYMPATHETIC GANGLION to an adjacent spinal nerve. The fibers within a gray ramus are called gray rami communicantes.

**GRE** abbreviation for GRADUATE RECORD EXAMINATIONS.

**great chain of being** a construction, attributed to Greek philosopher PLATO and elaborated by many subsequent philosophers, that sees creation as a continuous
great commissure

linked hierarchy that descends from God at the top, through heavenly beings, humans, animals, and plants to nonliving matter. The classic work on the history of this idea is the 1936 study by U.S. philosopher Arthur O. Lovejoy (1873–1963).

great commissure n. in vertebrate brains, the CORPUS CALLOSUM, so called because it is by far the largest COMMISSURE that connects the two cerebral hemispheres. 2. in insect brains, the commissure that connects the two lateral protocerebr.a

greater superficial petrosal nerve (GSP nerve) n. the sensory nerve that carries taste information from the soft palate. The GSP nerve merges with the CHORDA TYPANII (the nerve that innervates TASTE BUDS on the front of the tongue) to form the INTERMEDIATE NERVE (or NERVE OF WRISBERG), the sensory component of the predominantly motor FACIAL NERVE (seventh cranial nerve).

great imitator n. slang for a disease that is difficult to diagnose due to nonspecific symptoms; such diseases include lupus erythematosus, Lyme disease, and syphilis.

great man theory n. a view of political leadership and historical causation that assumes that history is driven by a small number of exceptional individuals (traditionally associated with British historian Thomas Carlyle (1795–1881)) view of history, in contrast, supposes that history is largely determined by economics, technological development, and a broad spectrum of social influences. [associated with British historian Thomas Carlyle (1795–1881)]

Greco-Latin square n. see GRAECO-LATIN SQUARE.

Greek cross n. a simple figure resembling an equal-armed cross (+), the drawing of which is used to measure basic constructive ability or to screen for UNILATERAL NEGLIGENT.

green brand n. a product (or suite of products) that is created to be environmentally friendly, such as a hybrid car or food containers made from recycled material. Apart from serving as a manufacturer’s response to environmental and social concerns, green brands are designed to enhance consumer appeal for a product and to boost the manufacturer’s image.

greeting behavior n. a form of ATTACHMENT BEHAVIOR that in humans begins to manifest itself clearly at about 6 months of age, when the infant responds to the arrival of a parent or caregiver.

gregariousness n. the tendency for human beings to enjoy the company of others and to want to associate with them in social activities. Gregariousness gives people security, companionship, acceptance, and a sense of belonging. In nonhuman animals, gregariousness is seen in the tendency to congregate in herds or flocks. See NEED FOR AFFILIATION; SOCIAL INSTINCT. —gregarious adj.

grid cell n. a type of neuron that encodes abstract spatial information about distances, forming a gridlike array of activity presumably used by other brain structures in spatial computations. Originally found in the medial ENTORHINAL CORTEX, which acts as a gateway regulating the flow of information from sensory cortices to the hippocampus, grid cells have since been identified in areas of the SUBICULUM as well. They have response properties independent of any particular environment; each cell fires selectively at multiple spatial locations, which are geometrically arranged to form a hexagonal lattice representing an organism’s surroundings. Several theories have been proposed to account for the precise mechanisms by which grid cells code trajectories through space, such as the OSCILLATORY INTERFERENCE MODEL and the MOIRE INTERFERENCE MODEL. See also SPATIAL COGNITION. [discovered in rats in 2005 by Norwegian physiologist Torkel Hafting (1972– ), U.S.-born Norwegian neuroscientist Marianne Fyhn, Norwegian physician Sturla Molden, and Norwegian neuroscientists May-Britt Moser (1961– ) and Edvard I. Moser (1962– )]

grid organizational development (grid OD) n. a comprehensive organizational intervention based on the BLAKE–MOUTON MANAGERIAL GRID. The aim is to increase managers’ concerns for both production and people, thereby improving ORGANIZATIONAL EFFECTIVENESS. It consists of six phases conducted in the following order: (a) a seminar on the Blake–Mouton grid, (b) teamwork development, (c) intergroup development, (d) development of an ideal strategic corporate model, (e) implementation of the ideal strategic model, and (f) systematic critique. [designed by U.S. psychologists Robert R. Blake (1918–2004) and Jane S. Mouton (1930–1987)]

grief counseling n. the provision of advice, information, and psychological support to help individuals whose ability to function has been impaired by someone’s death, particularly that of a loved one or friend. It includes counseling for the grieving process and practical advice concerning arrangements for the funeral and burial of the loved one. Grief counseling is sometimes offered by staff in specialized grief counseling departments for the bereaved. See also BEREAVEMENT THERAPY.

grief cycle model see STAGES OF GRIEF.

grief work (grief work) n. the theoretical process through which bereaved people gradually reduce or transform their emotional connection to the person who has died and thereby refocus appropriately on their own ongoing lives. Originally conceived by Sigmund Freud in his 1917 essay “Mourning and Melancholia” as a process in which the successful outcome is the bereaved’s emotional detachment from the deceased, grief work has in recent years evolved around the notion of a CONTINUING BOND. That is, the bereaved does not sever all emotional connections with the deceased but instead transforms the relationship symbolically as an ongoing bond that provides a sense of meaning and value conducive to forming new relationships.

grievance n. 1. a feeling of resentment arising from a sense of having been unjustly treated, 2. in industrial and organizational psychology, a complaint filed by an employee according to rules and procedures set forth by the
management of the organization or in a contract negotiated with the union representing that employee.

**Griggs v. Duke Power Co.** a case resulting in an influential 1971 ruling by the U.S. Supreme Court regarding discrimination in hiring practices. The ruling established that proof of discrimination does not require the plaintiff to show that the defendant had intention or motives to discriminate if the selection practices had an adverse impact on a particular group (e.g., those defined by ethnicity, age, or sex).

**Grip Strength Test** a test in which the strength of hand grip is assessed with a dynamometer. It is part of the Halstead–Reitan Neuropsychological Battery. Also called **Hand Dynamometer Test**.

**Grit Scale** a 17-item self-report measure used to assess perseverance and passion for achieving long-term goals. Grit entails working strenuously to overcome challenges and maintaining interest and effort over time despite failures, adversities, and plateaus in progress. Recent studies suggest this trait may be more relevant than intelligence in determining a person's high achievement. For example, grit may be particularly important to accomplishing an especially complex task when there is strong motivation to give up altogether.

**GRIT** acronym for **GRADUATED AND RECIPROCATED INITIATIVES IN TENSION REDUCTION**.

**Grit Scale** a 17-item self-report measure used to assess perseverance and passion for achieving long-term goals. Participants use a 5-point scale, ranging from *not like me at all* (1) to *very much like me* (5), to rate how much they agree with statements such as: “I finish whatever I begin.” “I have overcome setbacks to conquer an important challenge.” and “My interests change from year to year.” The instrument yields an overall grit score as well as subscale scores for consistency of interest and perseverance of effort. There is also an eight-item version of the measure called the **Short Grit Scale (GRIT-S)**. [developed in 2007 by U.S. psychologists Angela Lee Duckworth, Christopher Peterson, Michael D. Matthews (1953— ), and Dennis R. Kelly]

**grooming** n. 1. a basic function of self-care that includes maintaining one's body, hair, clothes, and general appearance. This includes such activities as bathing, shaving, toothbrushing and flossing, hair brushing and styling, nail trimming, and applying cosmetics. Reacquiring grooming skills that have been lost or compromised due to mental or physical impairment is a central aspect of many rehabilitation programs. 2. behavior in which a nonhuman animal picks through its own or another animal's hair, fur, or feathers. Whereas the main function of self-grooming is hygienic (i.e., to remove dirt and parasites); grooming of other members of an animal's group may serve both hygienic and social functions. See **ALLOGROOMING**.

**Grooved Pegboard Test (GPT)** a cognitive-motor test measuring psychomotor speed, fine motor control, and rapid visual-motor coordination. The task is to insert, with each hand, 25 metal pegs with ridges along the sides into a 5 × 5 matrix of slotted holes that are angled in different directions. Completion times for the dominant and nondominant hands are compared, with a shorter completion time expected for the dominant hand. [developed in the 1960s by Halgrim Klove (1927—2010). Norwegian neuropsychologist]

**gross motor** describing activities or skills that use large muscles to move the trunk or limbs and control posture to maintain balance. Examples of gross motor skills include waving an arm, walking, hopping, and running. Compare **FINE MOTOR**.

**ground n.** the relatively homogeneous and indistinct background of **FIGURE–GROUND** perceptions.

**ground rules** in psychotherapy, the elements of the contract for therapy, including but not limited to the fee; the time, location, and frequency of the sessions; and therapist confidentiality.

**group** n. any collection or assemblage, particularly of items or individuals. For example, in social psychology the term refers to two or more interdependent individuals who influence one another through social interactions that commonly include structures involving roles and norms, a degree of cohesiveness, and shared goals. Such social groups thus are contrasted with aggregations. Similarly, in animal behavior, a group refers to an organized collection of individuals that moves together or otherwise acts to achieve some common goal (e.g., protection against predators) that would be less effectively achieved by individual action, and in research, it denotes a collection of participants who all experience the same experimental conditions and whose responses are to be compared to the responses of one or more other collections of research participants.

**group abilities** abilities, such as verbal-comprehension, spatial, and memory abilities, that are sources of individual differences in some groups of intelligence tests.

**group acceptance** the degree to which group members approve of a new, prospective, or potential member as reflected in his or her admission to the group and relative status and role within it.

**group-analytic psychotherapy** a type of group psychotherapy that focuses on the communication and interaction processes taking place in the group as a whole. Interventions make use of group rather than individual forces as the principal therapeutic agent. Also called **therapeutic group analysis**. [originated in the 1940s by German-born psychoanalyst Sigmund Heinrich Foulkes (1898—1976)].

**group attribution error** the tendency for perceivers to assume that a specific group member's personal characteristics and preferences, including beliefs, attitudes, and decisions, are similar to those of the group to which he or she belongs. For example, observers may assume that an individual who is a member of a group that publicly an-
nounces its opposition to an issue also opposes the issue, even though the group’s decision to take the stated position may not have been unanimous. See also GROUP FALLACY: OUTGROUP HOMOGENEITY BIAS. [originally described in 1985 by U.S. social psychologists Scott T. Allison and David M. Messick.]

**group behavior** actions performed by a group as a whole or by individuals when part of a group. In the latter case, it applies particularly to those actions that are influenced (either directly or indirectly) by the group and are atypical of actions performed by the same individuals when alone.

**group boundary** the implicit and explicit standards that set limits on aspects of the group, including who can be members, the expected duties of members, and the types of actions that the group will permit members to perform.

**group-centered leader** see DEMOCRATIC LEADER.

**group climate** the relative degree of acceptance, tolerance, and freedom of expression that characterizes the relationships within a counseling or therapy group. Interpersonal behavioral boundaries are generally freer and broader than in nontherapeutic social contexts, and the meaning of interpersonal behavior is often the specific focus of group discussion.

**group cohesion** the unity or solidarity of a group, including the integration of the group for both social and task-related purposes. Group cohesion is indicated by the strength of the bonds that link members to the group as a whole, the sense of belongingness and community within the group, the feelings of attraction for specific group members and the group itself as experienced by individuals, and the degree to which members coordinate their efforts to achieve goals, although these factors are neither necessary nor sufficient conditions for cohesion. In many cases, the higher the cohesion, the stronger the members’ motivation to adhere to the group’s standards and the more stable the group’s membership. Group cohesion frequently is considered essential to effective GROUP THERAPY. Also called **group cohesiveness**. See also ESPRIT DE CORPS; GROUP SOLIDARITY.

**group-comparison design** a type of research approach that investigates potential differences across sets of individuals who are often randomly assigned to a CONTROL CONDITION or to one or more specific EXPERIMENTAL CONDITIONS. Data from a group-comparison design are often analyzed with statistical methods such as a T TEST or ANALYSIS OF VARIANCE. Also called **group-difference design**.

**group consciousness** 1. the awareness exhibited by individual group members about the group, its members, and their commonalities. Just as SELF-CONSCIOUSNESS pertains to awareness of the self, so group consciousness pertains to awareness of the collective. 2. see GROUP MIND.

**group contagion** see SOCIAL CONTAGION.

**group counseling** a method of providing guidance and support for clients organized as a group, as opposed to individual counseling. Group counseling can be used, for example, to assist high school students in choosing a college or to assist employees of an organization in stating dissatisfactions and proposing solutions to managers and employers.

**group decision support systems (GDSS)** technology used to improve the quality, speed, and efficiency of group decision making and to help the group avoid common sources of error, such as pressures to conform. GDSS most often comes in the form of computer software modules that help the group to communicate freely about an issue, identify key stakeholders and their assumptions, formulate ideas, and evaluate and vote on alternatives.

**group development** 1. naturally occurring patterns of growth and change that unfold across the lifespan of a group. The term usually implies a progressive movement toward a more complete or advanced state, with different theorists characterizing this movement (a) as either discontinuous and occurring in distinct stages or continuous and incremental and (b) as either irreversible or cyclical and repetitious. See also EQUILIBRIUM MODEL OF GROUP DEVELOPMENT. 2. a strategic intervention designed to alter the processing and functioning of a group: this usually involves assessing the group’s current level of development, helping to clarify its mission and goals, and reviewing its operating procedures. See also TEAM BUILDING.

**group difference** any observed variation between groups of participants in an experiment when considering each group as a single entity. See GROUP-COMPARISON DESIGN.

**group dynamics** 1. the processes, operations, and changes that occur within social groups, which affect patterns of affiliation, communication, conflict, conformity, decision making, influence, leadership, norm formation, and power. The term, as used by Kurt LEWIN, emphasizes the power of the fluid, ever-changing forces that characterize interpersonal groups. See also INTERGROUP DYNAMICS. 2. the field of psychology devoted to the study of groups and group processes. 3. a conceptual and clinical orientation in group psychotherapy that explicitly recognizes and explores group-level processes in the treatment group.

**grouped data** information that is grouped into one or more sets in order to analyze, describe, or compare outcomes at a combined level rather than at an individual level. For example, data from a FREQUENCY DISTRIBUTION may be arranged into CLASS INTERVALS. See also GROUP-COMPARISON DESIGN.

**grouped frequency distribution** a description of how often a set of specific responses, organized into equal-sized subsets of possible responses, occur in a sample. It is a type of FREQUENCY DISTRIBUTION that is particularly useful when there are a large number of response choices (e.g., 10–20 or more) and researchers wish to present the information more concisely. For example, suppose that a researcher wants to summarize the individuals in a sample in which age ranges from 16 to 85 years. Instead of listing all 69 different ages, the researcher could combine the data into 5-year intervals, which would produce 14 subsets of ages (e.g., 16–20, 21–25, 26–30, . . . 81–85), thus reducing a large number of scores into smaller, more manageable groups.

**group effect** a research finding specific to the group of individuals to which a participant belongs. A group effect could appear in an assigned subset, such as a treatment or intervention, or in a naturally occurring subset, such as age level or classroom. For example, a researcher might be interested in a group effect of a specific reading intervention, or in a group effect of book reading for students in the current decade who may be reading less than previous sets of students owing to more common use of the computer and television.
**group experience** in group psychotherapy and counseling, the interactions that give each client in the group an opportunity to gain insight into his or her problems by sharing with and learning from other members. The group experience is particularly valuable in helping clients understand how they are perceived by other people. When group therapy or counseling is given in addition to individual intervention, it allows the therapist or counselor to observe the client’s emotional difficulties as revealed in group interactions.

**group experiment** an experiment in which subsets of individuals serve as the unit of analysis. For example, a researcher could compare the performance of different classrooms rather than of specific students.

**group factors** the psychometric entities underlying GROUP ABILITIES.

**group fallacy** 1. the assumption, regarded as erroneous, that the actions and experiences of people in groups cannot be understood completely through analysis of the qualities of the individual members. 2. the mistaken assumption that a group is totally uniform, whereas in fact members differ from one another in many respects. See also OUTGROUP HOMOGENEITY BIAS.

**group health plan** an insurance plan that offers health care coverage to a group of individuals under a single insurance contract. In the United States, group health plans are often offered by employers to their employees as a fringe benefit. Membership organizations, such as unions, alumni associations, and professional associations, may also offer group health plans as a benefit of membership.

**group home** a residential facility that offers housing and personal care services, such as meals, supervision, and transportation. Also called group residence.

**group hypnosis** the simultaneous hypnosis of several people by the same practitioner. It is sometimes used for therapeutic purposes, as in the treatment of drug addiction. Also called collective hypnosis.

**group hysteria** see COLLECTIVE HYSterIA.

**group identification** 1. the act or process of associating oneself with a group and its members, such that one imitates and internalizes the group’s actions, beliefs, standards, objectives, and so forth. This process can lead to an enhanced sense of group belonging, group pride, and group commitment as well as to AUTOSTEREOTYPING. 2. more rarely, the act of considering another group’s perspective or outlook even though one is not a member of that group.

**group identity** 1. the image of a group (e.g., reputation, appraisal, expectations about) held by its members or by those external to the group. 2. an individual’s sense of self as defined by group membership. See SOCIAL IDENTITY.

**grouping** n. 1. in education, the process of assigning pupils to grades, classes, or subgroups. 2. in statistics, the process of arranging scores in categories, intervals, classes, or ranks.

**group intelligence test** an INTELLIGENCE TEST administered simultaneously to all the individuals in a group.

**group interview** an interview in which one or more questioners elicit information from two or more respondents in an experimental or real-life situation. The participation and interaction of a number of people, particularly if they are acquainted with each other as members of a club or similar group, is believed to yield more informative responses than are typically obtained by interviewing individuals separately.

**group marriage** a family pattern found in some indigenous cultures and certain minority religious groups in which several men and women live together, sharing the burdens of the household, the tasks of child rearing, and a common sexual life. See also COMMUNE; POLYGAMY.

**group medical practice** the practice of medicine by a group of physicians, typically various specialists, associated not only for administrative reasons but also for such clinical purposes as cooperative diagnosis, treatment, and prevention. Also called group practice.

**group mind** a hypothetical explanation for the apparent uniformity of individuals’ emotional, cognitive, and behavioral reactions when in large crowds and collectives; it supposes that a crowd of people can, in certain instances, become a unified entity that acts as if guided by a single consciousness created by the fusion of the individual minds in a collective. This controversial idea, often seen as a prime example of the GROUP FALLACY, assumes that in fact mind is greater than the sum of the psychological experiences of the individuals and that it can become so powerful that it can overwhelm the will of the individual. Also called collective consciousness; collective mind; group consciousness. See also FOLK SOUL.

**group morale** group members’ overall level of enthusiasm (confidence, dedication, zeal) for the group, its tasks, and its goals.

**group network** 1. the relatively organized system of connections linking members of a group, unit, or collective, including social or interpersonal evaluations (e.g., friendship, acquaintance, dislike), communication, transfer of resources, and formal role relationships (e.g., supervisor–subordinate). 2. in SOCIAL NETWORK ANALYSIS, the entire set of connections linking all individuals or nodes in the specific group or collective being studied. Also called sociocentric network. Compare EGO-CENTERED NETWORK.

**group norm** see SOCIAL NORM.

**group personal space** see GROUP SPACE.

**group polarization** the tendency for members of a group discussing an issue to move toward a more extreme version of the positions they held before the discussion began. As a result, the group as a whole tends to respond in more extreme ways than one would expect given the sentiments of the individual members prior to deliberation. Polarization is sustained by social comparison (see SOCIAL COMPARISON THEORY), by exposure to other members’ relatively extreme responses (see PERSuSIVE ARGUMENTS THEORY), and by groups’ implicit SOCIAL DECISION SCHEMES. See CHOICE SHIFT; RISKY SHIFT.

**group potency** the expectations held in common by group members about the group’s COLLECTIVE EFFICACY; that is, the group’s overall confidence or “can do” attitude.

**group practice** see GROUP MEDICAL PRACTICE.

**group pressure** direct or indirect SOCIAL PRESSURE exerted by a group on its individual members to influence their choices. Such pressure may take the form of rational argument and persuasion (INFORMATIONAL INFLUENCE), calls for conformity to group norms (NORMATIVE INFLUENCE), or more direct forms of influence, such as demands,
**group problem solving**

threats, personal attacks, and promises of rewards or social approval *(INTERPERSONAL INFLUENCE).*

**group problem solving** the use of a social group to resolve matters that involve doubt, uncertainty, or unknown difficulties. The typical stages involved in group problem solving include: (a) identification of the problem and the process to use in solving it, (b) gathering of information and evaluation of alternatives through discussion, (c) selection of the solution, and (d) implementation of the solution.

**group process** the interpersonal component of a group session, in contrast to the content *(such as decisions or information)* generated during the session.

**group-randomized trial** a research design in which groups of individuals are randomly assigned to TREATMENT conditions or CONTROL CONDITIONS. In educational or organizational settings, for example, a group-randomized trial could be used to study classrooms or departments, evaluating the data by means of HIERARCHICAL LINEAR MODELING and similar analyses that take the larger group membership *(e.g., classroom, department)* into account. It is similar to a RANDOMIZED CLINICAL TRIAL, but distinct in assigning intact clusters of participants, rather than individual participants, to the specific conditions. Also called **cluster-randomized trial.**

**group relations theory** the view that behavior is influenced not only by one's unique pattern of traits but also by one's need to conform to social demands and expectations. Social determinants become particularly evident in group therapy, which tends to challenge attitudes, such as prejudices, that are based on conformity and restricted thinking. [proposed by Gordon W. Allport]

**group residence** see **GROUP HOME.**

**group risk taking** embarking on a hazardous, dangerous, or uncertain course of action as a social group. Studies of GROUP POLARIZATION and CHOICE SHIFT indicate that group decisions tend toward greater extremity or risk than individual decisions. See RISKY SHIFT.

**group role** a coherent set of behaviors expected of a person in a specific position within a group. In addition to the basic roles of leader and follower, groups usually allocate TASK ROLES pertaining to the group's tasks and goals and RELATIONSHIP ROLES that focus on the group members' interpersonal and emotional needs.

**group selection** the concept that social groups can act as adaptive units in NATURAL SELECTION. See **KIN SELECTION.** Compare INDIVIDUAL SELECTION.

**group sequential design** a research design in which a treatment is randomly assigned to different groups at varying times, such that every group receives the treatment eventually. A group sequential design is useful when it is important for each participant to have an opportunity to benefit from the treatment, but a comparison group nonetheless is required: The portion of the sample that receives the treatment later acts as a CONTROL GROUP initially.

**group-serving bias** any one of a number of cognitive tendencies that contribute to an overvaluing of one's group, particularly the tendency to credit the group for its successes but to blame external factors for its failures. Also called **sociocentric bias.** Compare SELF-SERVING BIAS. See also **ULTIMATE ATTRIBUTION ERROR; INGROUP BIAS.**

**group sex** sexual activity among a group of people who obtain sexual stimulation through such means as observing each other, experimenting with different techniques, and having multiple partners either simultaneously or in succession.

**group socialization 1.** the process of interaction between an individual and a group that begins when he or she first considers joining the group and ends when he or she leaves it. The individual learns to adjust to various group norms and behave in a manner acceptable to group members. 2. the process by which an individual, from infancy onward, acquires social skills, beliefs, values, and behaviors through interaction with and observation of others in a group context.

**group socialization theory** a theory of personality development proposing that children are primarily socialized by their peers and that the influences of parents and teachers are filtered through children's peer groups. According to this theory, children seek to be like their peers rather than like their parents. [proposed by U.S. developmental psychologist Judith Rich Harris *(1938– *)]

**group solidarity** a sense of fellowship and community displayed by members of a collective who are united by shared purposes, responsibilities, and interests. See also **GROUP COHESION; ESPIRIT DE CORPS.**

**group space** territory defined by the temporary boundary that forms around interacting groups and serves as a barrier to unwanted intrusion by nonmembers. Also called **group personal space; interactional territory.**

**group structure** the arrangement of individuals and their relationships, both implicit and formalized, in a group, including positions, roles, and patterns of authority, attraction, and communication. See also **SOCIAL STRUCTURE.**

**group superego** in psychoanalytic theory, the portion of the SUPEREGO acquired from peer groups as opposed to the part derived from parental IDENTIFICATIONS. In a group, the collective superego or lack thereof is seen as superordinate to the superegos of the individuals that comprise the group.

**group synergy** 1. a social process that occurs when a group, by acting in concert, achieves an outcome that is superior to what would be achieved by the most capable member or by any simple pooling of individual member efforts, often summarized by the phrases "the whole is greater than the sum of the parts" or "2 + 2 = 5." See also **ASSEMBLY BONUS EFFECT.** 2. in Raymond B. Catell's group psychology, the sum of all individual members' energy going into the group: that is, the total available group energy or investment in itself.

**group territorial behavior** the tendency for ethnic and other groups to establish and defend areas as separate or shared territories. Such behavior can be observed, for instance, in the neighborhoods of large cities and in the activities of city street gangs. A form of intragroup territorial behavior is often seen in family settings and workplaces, where individuals may regard certain rooms or areas or even certain chairs as their personal territory.

**group therapy** treatment of psychological problems in which two or more participants interact with each other on both an emotional and a cognitive level in the presence of one or more psychotherapists who serve as catalysts, facilitators, or interpreters. The approaches vary, but in general they aim to provide an environment in which
G-statistic a value used to assess the presence of spatial clustering or autocorrelation in a data set. A large G statistic with a small accompanying probability level, or p value (e.g., < .05), suggests there are subsets of dependence or clustering.

G-tolerance limits the maximum gravitation effects (g-forces) that an individual can withstand before blacking out as a result of acceleration drawing blood out of the head toward the feet (the +Gz direction). Pilots of high-performance aircraft can tolerate +9 Gz with use of G-suits and straining maneuvers. The duration of G-exposure and the type of safety protection used are important in determining whether or not blackout will occur.

guanfacine n. a drug used for the treatment of hypertension. It acts as an agonist at alpha-adrenergic receptors, directly stimulating alpha-adrenoceptors to restrict the flow of impulses in peripheral sympathetic nerves supplying the arteries, thus causing them to relax (widens); most of the other commonly prescribed antihypertensive drugs act as beta blockers or diuretics. Guanfacine is also a sedating agent used in the treatment of attention-deficit/hyperactivity disorder; it may, however, cause excess sedation and hypotension (low blood pressure). The drug has also been investigated for the management of posttraumatic stress disorder, Tourette’s disorder, and Alzheimer’s disease. U.S. trade names: Intuniv, Tenex.

guanine (symbol: G) n. A purine compound in the nucleotides of living organisms. It is one of the four bases in DNA and RNA constituting the genetic code, the others being adenine, cytosine, and thymine or uracil.

guarana n. A shrub (Paulinia cupana) indigenous to the Brazilian Amazon, the seeds of which were originally thought to contain guaranine, a methylxanthine compound that is essentially indistinguishable from caffeine. It is now known that guarana in fact contains a significant amount of caffeine, which is its primary active ingredient, as well as lesser amounts of the methylxanthines theophylline (the active ingredient in tea) and theobromine. Used as a stimulant and appetite suppressant, guarana is available in many over-the-counter preparations in the United States and other Western nations. At recommended doses, it appears to have the same mild adverse effects known to be associated with other sympathomimetic stimulants (e.g., restlessness, increased urination, gastrointestinal distress) but may interact with medications, particularly monoamine oxidase inhibitors. Additionally, additive effects and potential toxicity may occur when guarana is combined with other caffeine-containing products, and there is growing concern that use of guarana-containing products may cause such serious adverse events as chest pain, irregular heartbeat, seizures, coma, and possibly death.

guardian ad litem an individual appointed by the court to represent in a lawsuit someone who is incapacitated either by age or by mental or physical disability. The individual’s status as guardian ad litem is temporary and is dissolved upon resolution of that lawsuit.

guardianship n. A legal arrangement that places the care of a person and his or her property in the hands of another. When people are minors or are deemed incompetent by the court and therefore unable to make decisions about their own care or to manage their own affairs, a guardian is appointed by the court to manage their property, make personal decisions on their behalf, and provide for their care and well-being. See also conservatorship; limited guardianship.
**Guérin–Stern syndrome** see ARTHROGYROSIS MULTIPLEX CONGENITA. [Jules René Guérin (1801–1886), French orthopedist, and Walter G. Stern, U.S. physician]

**guess-who technique** a type of personality rating device used chiefly in schools. Students are given short word pictures depicting a variety of personality types and are directed to identify the classmates whose personalities seem to correspond most closely to those descriptions.

**GUI** abbreviation for GRAPHICAL USER INTERFACE.

**guidance** n. direction, advice, and counseling provided in cooperation with the recipient, often using personal data and interviews as important auxiliary tests.

**guidance program** the cumulative resources of staff and techniques used by a school to assist students in resolving scholastic or social problems. A specialized approach will include professionally trained counselors, social workers, and test administrators who each have specified functions within the overall program. In some programs, the use of specialists may be minimized, with teachers and administrators filling guidance functions.

**guidance specialist** an individual who has been trained in a counselor education program or whose credentials and experience are adequate to provide guidance.

**guided affective imagery** (GAI) in psychodynamic psychotherapy, a technique of using imagery to draw on emotional fantasies, or waking dreams, and to facilitate the cathartic release of emotions that are present but painful for the client to discuss. The therapist suggests concentration on past images that would bring up the emotional state or, in some cases, images of desired future successes. See also VISUALIZATION. [developed by German psychiatrist Hanscarl Leuner (1919–1996)]

**guided imagery** a mind–body technique involving the deliberate prompting of mental images to induce a relaxed, focused state with the goal of achieving such varied purposes as managing stress or pain, promoting healing, or enhancing performance. See also VISUALIZATION.

**guided participation** a process in which the influences of social partners and sociocultural practices combine in various ways to provide children and other learners with direction and support, while the learners themselves also shape their learning engagements. It occurs not only during explicit instruction but also during routine activities and communication in everyday life. See SOCIOCULTURAL PERSPECTIVE. [proposed in the early 1980s by U.S. developmental psychologist Barbara Rogoff (1950–)]

**guided performance** the process in which a learner is assisted with information or guidance to minimize errors, as when a teacher guides the learner’s movements or steps in solving a problem.

**guided-search theory** a two-stage model of visual processing in which initial parallel search mechanisms direct subsequent serial search mechanisms. In the first stage, basic stimuli features are processed simultaneously at all locations across the visual field; then, in the second, limited-capacity serial stage, processing is more complex and restricted to a particular item or location based on information obtained in the previous stage. For example, during a VISUAL SEARCH for a red circle among green circles and red squares, the model suggests that a color processor scans for all red items while a shape processor simultaneously scans for all circles, and the combination of these two sources of information then narrows subsequent attentional focus to that item most likely to be the target; if that item proves not to be the target, attention proceeds to the next most promising item. Guided search departs from FEATURE-INTEGRATION THEORY and other models that consider second-stage serial resources to be deployed from item to item relatively randomly. [proposed in 1989 by British-born U.S. cognitive psychologist Jeremy M. Wolfe (1955–), Kyle R. Cave, and Susan L. Franzel]

**guiding fiction** a personal principle that serves as a guideline by which individuals can understand and evaluate their experiences and determine their lifestyle. In individuals considered to be in good or reasonable mental health, the guiding fiction is assumed to be realistic and adaptive. In those who are not, it is assumed to be unrealistic and nonadaptive. [term originally used by Alfred ADLER]

**Guilford dimensions of intelligence** three dimensions of intelligence postulated by Joy Paul GUILFORD to underlie individual differences in scores on intelligence tests, namely, contents, operations, and products. Each mental ability represents a combination of these three facets. For example, performance on a verbal- analogies test would represent a combination of cognition (operation) of verbal (content) relations (product). The number of mental abilities initially proposed by Guilford was 120; this was later increased to 150. The validity of this theory was subsequently called into question by the work of U.S. psychologist John L. Horn (1928–2006), which suggested that the existence of the proposed factors is not supported by research results. See also STRUCTURE OF INTELLIGENCE MODEL.

**Guilford–Zimmerman Temperament Survey (GZTS)** a personality inventory for use with individuals ages 16 years and older, measuring 10 traits identified by FACTOR ANALYSIS: ascendance, sociability, friendliness, thoughtfulness, personal relations, masculinity, objectivity, general activity, restraint, and emotional stability. It comprises 300 descriptive statements to which participants respond yes, no, or ? [originally developed in 1949 by U.S. psychologists Joy Paul GUILFORD and Wayne S. ZIMMERMAN (1916–)].

**Guillain–Barré syndrome** an acute, progressive, demyelinating type of PERIPHERAL NEUROPATHY that starts with muscular weakness and loss of normal sensation in the extremities, spreading inward as the disease progresses. The condition often begins in the feet and ascends toward the head. These symptoms can increase in intensity until the muscles cannot be used at all and the individual is almost totally paralyzed, in which case the disorder is life threatening. Because the syndrome often develops after an infection, it may result from an immune reaction. [Georges Guillaum (1876–1961) and Jean Barré (1880–1967), French neurologists]

**guilt** n. a SELF-CONSCIOUS EMOTION characterized by a painful appraisal of having done (or thought) something that is wrong and often by a readiness to take action designed to undo or mitigate this wrong. It is distinct from SHAME, in which there is the additional strong fear of one’s deeds being publicly exposed to judgment or ridicule.

**guilt by association** responsibility for a misdeed ascribed to an innocent person solely because he or she has some connection with the perpetrator (or perpetrators) of the wrong. The observer’s negative attitude toward the wrongdoer generalizes to the associated person.

**guilt culture** a trend or organizing principle in a society
characterized by the use of guilt to promote socially accept-
able behavior. Guilt cultures emphasize both self-control in
the face of temptation and self-initiated responsibility for
one’s actions if transgressions should occur. Compare
SHAME CULTURE.
guilty but mentally ill (GBMI) a court judgment that
may be made in some states when defendants plead insan-
ity (see INSANITY DEFENSE). Defendants found guilty but
mentally ill are treated in a mental hospital until their
mental health is restored; they then serve the remainder of
their sentence in the appropriate correctional facility.
guilty knowledge test a form of lie detection in which
knowledge about the details of a crime is tested. A POY-
OGRAPH examiner presents examinees with multiple-choice
questions concerning the crime, to which only the guilty
party should know the correct answers; it is assumed that
innocent examinees will see all options as equally plausi-
able. The polygraph examiner measures the examinees’
physiological arousal as each option is presented and iden-
tifies which option produces the highest physiological re-
response. Over a series of questions, if an individual
consistently shows the greatest response to the correct op-
tion, the examiner may identify that person as untruthful
in his or her denial of knowledge of the details of the
crime. See also CONTROL QUESTION TEST; RELEVANT–IRREL-
VENT TEST.

Gulf War syndrome a collection of unexplained symp-
toms experienced by some veterans of the 1991 Gulf War.
Symptoms may include headaches, fatigue, joint pain, skin
rashes, and memory loss.

Günther’s disease a congenital form of PORPHYRIA in
which excess porphyrin is formed in the bone marrow. Psy-
chological and neurological changes often accompany
pain, nausea, and other symptoms. [Hans Günther (1884–
1929), German physician]
guru n. 1. in Hinduism and Sikhism, a spiritual teacher or
leader, specifically one charged with keeping alive the oral
teachings. 2. a form of spiritual leader, particularly one regarded as having spe-
cial knowledge. [Sanskrit, literally: “teacher”]
gustation n. the sense of TASTE. Taste is at the threshold
between the external (chemical) and internal (biochemi-
 cal) worlds; it serves an organism’s nutritional needs and
protects it from poisons. —gustatory adj.
gustatory agnosia the inability to identify or categorize
gustatory (taste) stimuli, despite the capacity to experience
them.
gustatory encoding see VISUAL ENCODING.
gustatory hallucination a false and enduring taste
sensation, usually of bitterness or sourness. It is often at-
tributable to tonic stimulation of TASTE CELLS or of the pe-
ripheral taste nerves.
gustatory nerve see LINGUAL NERVE.
gustatory neuron types categories into which taste
neurons of the peripheral and central nervous system can
be grouped according to their sensitivities to PRIMARY
TASTE qualities. About 40% of the taste neurons in pri-
mates are most responsive to sweet stimuli, 35% to those
that are salty, 20% to bitter chemicals, and 5% to acids.
Therefore, some 75% of neurons are devoted to detecting
nutrients and 25% to avoiding toxins.
gustatory qualities the range of taste sensations to
which humans are sensitive. These are often categorized
into basic, or primary, tastes—thought to be SWEET, SALTY,
UMAMI, SOUR, and BITTER—although the full range of taste
perceptions may exceed these categories.
gustatory stimulus a chemical capable of activating
TASTE CELLS. Gustatory stimuli include sugars (SWEET),
salts of sodium (SALTY) and heavier elements (BITTER or
rarely sweet), acids (SOUR), alkaloids (bitter), and monoso-
odium glutamate (UMAMI), among others. Also called sapid
stimulus; taste stimulus.
gustatory system the primary structures and processes
involved in an organism’s detection of and responses to
gustatory stimuli. The gustatory system includes lingual
PAVILLAE, TASTE BUDS and TASTE CELLS, TASTE TRANS-
DUCTION, neural impulses and pathways (see GREATER SUPERFI-
CIAL PETROSAL NERVE), and associated brain areas and their
functions (see TASTE CORTEX; SOLITARY NUCLEUS; THALAMIC
TASTE AREA). The responses of this system can be modified
to an extent by an organism’s physiology, its immediate
needs, and its experiences. Also called taste system.
gustatory transduction see TASTE TRANSDUCTION.
gustometer n. an instrument used to deliver a predeter-
mined volume and concentration of a taste (gustatory)
stimulus to the tongue over a specified period of time.
gut hormone any hormone that is released by the stom-
ach or intestines, sometimes in response to food.

Gutmann scale a type of attitude measure that consists of
multiple verbal statements ordered to reflect increasing
levels of positive evaluation. Endorsement of a particular
statement implies endorsement of all statements less ex-
treme than that statement. For example, Item 1 could state
“I believe that education is valuable.” Item 2 could state “I
believe that people who are educated are more productive,”
and Item 3 could state “I believe that I would be more pro-
ductive if I had more education.” A person who agreed
with the third statement thus would also agree with the
first and second statements. Although generally used to
measure attitudes, Gutman scales can also be used to as-
se ss other properties of a target of judgment. Also called
cumulative scale; scalogram. [first described in 1944 by
Louis Gutman (1916–1987), U.S. experimental psycholo-
gist]
gutturophonia n. a form of DYSPHONIA characterized by
a throaty or low-pitched voice.
gynemic acid an extract of the Indian plant Gymnema
sylvestris, noted for its capacity to block sweet taste. It is
one of a family of triterpene saponins (plant glucosides
producing a soapy lather) that also includes ziziphin, gur-
marin, and hodacin.
gynandromorph n. an organism, especially an insect,
with both male and female physical characteristics.—
gynandromorphism n.
gynecology n. the branch of medicine concerned with
diseases and disorders of the reproductive organs of
women. —gynecological adj. —gynecologist n.
gynecomastia n. abnormal development of breast tissue
in males. In young men, the condition usually occurs on
both sides, whereas in men over age 50, gynecomastia
tends to be unilateral. It may occur as a result of a hormo-
nal imbalance related to a tumor or as a side effect of ther-
apy with ANTIANDRGENS or with DOPAMINE-RECEPTOR
ANTAGONISTS, which include many antipsychotic drugs.
Dopamine inhibits the release from the anterior pituitary of the hormone prolactin; therefore, inhibition of dopaminergic activity may result in excess secretion of prolactin, leading to engorgement of breast tissue and possibly expression of breast milk (see Galactorrhea). Gynecomastia may also be observed (though rarely) with administration of SSRI s.

**gynemimesis** n. a boy or man displaying or taking on the bodily appearance, dress, or behavior typical of a female, including passing as a woman. Also called **gynecomimesis**.

**gynemimetophilia** n. sexual interest in and arousal by men who are cross-dressing and playing the role of women.

**gynetresia** n. the condition of having imperforate female genitalia (i.e., the vagina lacks an opening).

**gyno-** (gyn-) combining form women or female.

**gyrus** n. (pl. gyri) a ridged or raised portion of the cerebral cortex, bounded on either side by a sulus.

**gyrus cinguli** see CINGULATE CORTEX.

**gyrus fasciolaris** see FASCICULUS GYRUS.

**GZTS** abbreviation for Guilford–Zimmerman Temperament Survey.
Haab's pupillary reflex the normal contraction of both pupils when the eyes focus on a bright object in a darkened room. [Otto Haab (1850–1931), Swiss ophthalmologist]

Habeas corpus a writ requiring a court to determine whether there is sufficient cause to hold someone in a correctional or other facility (Latin, literally: “you may have the body”). In the context of forensic psychology, it is typically used to determine whether confinement to a mental institution has been carried out with due process.

Habituation n. the process of enhancing the independence, well-being, and level of functioning of an individual with a disability or disorder by providing appropriate resources, such as treatment or training, to enable that person to develop skills and abilities he or she had not had the opportunity to acquire previously. The term is often used specifically to refer to the functional training of children with congenital disabilities, such as congenital visual impairment, compare rehabilitation.

Habitability n. the degree to which a specific environment meets the functional and aesthetic requirements of its occupants. See also environmental design.

Habitat n. the external environment in which an organism lives. Nonhuman animals are assumed to select habitats that provide optimal features for survival and reproduction. An organism’s habitat includes other animals and plant species that are important to it, as well as the physical aspects of the environment, including soil, substrate, and climate.

Habit disorder any repetitive maladaptive behavior that may interfere with social or educational functioning or other important activities.

Habit family hierarchy the concept that several different routes to the same goal—or more generally, responses to the same stimulus—are available, each having a particular strength that determines its arrangement in a preferential order and hence its potential for expression. Also called habit hierarchy. [developed by Clark L. Hull]

Habit formation the process by which, through repetition or conditioning, animals or humans acquire a behavior that becomes regular and increasingly easy to perform.

Habit-forming drug a drug with abuse potential.

Habit hierarchy 1. see habit family hierarchy. 2. the arrangement of simple habits into progressively more complex habit patterns.

Habit regression the act of returning to a previously discontinued habit or automatic pattern of behavior, often as a result of emotional distress.

Habit reversal a technique of behavior therapy in which the client must learn a new, correct response to a stimulus and stop responding to a previously learned cue. Habit reversal is used, for example, to control such unwanted behavior as overeating, smoking, hair pulling (trichotillomania), and nail biting.

Habit strength a hypothetical construct said to reflect learning strength, which varies with the number of reinforcements, the amount of reinforcement, the interval between stimulus and response, and the interval between response and reinforcement. [proposed in 1943 by Clark L. Hull]

Habit tic a brief, recurrent movement that is psychogenic in nature, as contrasted with tics of neurological origin. Examples are grimacing, blinking, and repeatedly turning the head to one side.

Habituation n. 1. in general, the process of growing accustomed to a situation or stimulus. 2. the diminished effectiveness of a stimulus in eliciting a response, following repeated exposure to the stimulus. Compare disHabituation. 3. the process of becoming psychologically dependent on the use of a particular drug, such as cocaine, but without the increasing tolerance and physiological dependence that are characteristic of addiction; the preferred term is psychological dependence. 4. the elimination, through repetition and practice, of extraneous responses that interfere with learning a skill.

Habitus n. 1. in social psychology, a person’s view of the world and of his or her place in it, formed through socialization during childhood and reinforced throughout life. 2. the general appearance of the body. 3. a susceptibility to certain types of physical disorders associated with particular somatotypes.

Habitation n. the external environment in which an organism lives. Nonhuman animals are assumed to select habitats that provide optimal features for survival and reproduction. An organism’s habitat includes other animals and plant species that are important to it, as well as the physical aspects of the environment, including soil, substrate, and climate.

Hair cell 1. any of the sensory receptors for hearing, located in the organ of Corti within the cochlea of the inner ear. They respond to vibrations of the basilar membrane via movement of the fine hairlike structures (stereocilia) that protrude from them. In humans, there are 12,000 outer hair cells and 3,500 inner hair cells. Almost all auditory nerve fibers communicate only with inner hair cells. The outer hair cells appear to be capable of movement and may provide amplification of the vibration that stimulates the inner hair cells. 2. any of the sensory receptors for balance, similar in structure to the cochlear hair cells. They are located in the inner ear within the ampullae of the semicircular canals (forming part of the crista) and within the saccule and utricle (forming part of the macula).

Habitation n. 1. in general, the process of growing accustomed to a situation or stimulus. 2. the diminished effectiveness of a stimulus in eliciting a response, following repeated exposure to the stimulus. Compare disHabituation. 3. the process of becoming psychologically dependent on the use of a particular drug, such as cocaine, but without the increasing tolerance and physiological dependence that are characteristic of addiction; the preferred term is psychological dependence. 4. the elimination, through repetition and practice, of extraneous responses that interfere with learning a skill.

Habitus n. 1. in social psychology, a person’s view of the world and of his or her place in it, formed through socialization during childhood and reinforced throughout life. 2. the general appearance of the body. 3. a susceptibility to certain types of physical disorders associated with particular somatotypes.
**Hair follicle**

The protective casing of the root of a hair. Inside the follicle, the end of the hair shaft is surrounded by a flower-spray ending, one of the basic types of somatosensory receptors. As part of defense behavior, a follicular nerve ending stimulates muscle fibers that contract and cause piloerection.

**Hair-pulling disorder** see Trichotillomania.

**Halazepam** n. a benzodiazepine used for the management of anxiety disorders and the short-term treatment of insomnia. As with most of the long-acting benzodiazepines, halazepam is metabolized to the active intermediate compound desmethyldiazepam (nordiazepam), which has a very long half-life (and therefore duration of action). This allows halazepam to be taken only once a day but also is associated with its accumulation in older adults and other people who have a reduced ability to metabolize the long-acting benzodiazepines. U.S. trade name: Paxipam.

**Halcyon** n. a trade name for triazolam.

**Haldol** n. a trade name for haloperidol.

**Half-life** (symbol: \( t_{1/2} \)) n. in pharmacokinetics, the time necessary for the concentration in the blood of an administered drug to fall by 50%. Half-life is a function of the rate of clearance of a drug and its volume of distribution in various body systems: it is expressed by the equation \( t_{1/2} = \frac{0.693 \times \text{volume of distribution}}{\text{clearance}} \). Clinically, half-life varies among individuals as a result of age, disease states, or concurrent administration of other drugs. Half-life is useful in predicting the duration of effect of a drug and the time required for a drug to reach a state of equilibrium (steady state) in the body—that is, when the amount of drug administered is equal to that excreted. Generally, steady state is predicted to be achieved after 4 to 5 half-lives of a drug; for example, if a drug has a measured half-life of 8 hours (and its dosing schedule remains the same), steady state would be anticipated within 32 to 40 hours.

**Half-show** n. a form of child psychotherapy in which a psychological problem is presented as a puppet-show drama, which is stopped at a crucial moment. The child is then asked to suggest how the story should end.

**Halfway house** a transitional living arrangement for people, such as individuals recovering from alcohol or substance abuse, who have completed treatment at a hospital or rehabilitation center but still require support to assist them in restructuring their lives.

**Hallermann–Streiff syndrome** a very rare congenital disorder marked by craniofacial anomalies, including a small, beaked nose, small eyes, and low-set ears. In many affected individuals, the skull sutures are slow to close and may remain open into puberty. Short stature and eye problems leading to blindness are common among those with Hallermann–Streiff syndrome. Intellectual disability is present in about 15% of these individuals. [Reported in 1948 by Wilhelm Hallermann (1901–1976), German physician, and in 1950 by Enrico Bernardo Streiff (1908–1988), Swiss ophthalmologist]

**Hallucinogen** n. a substance capable of producing a sensory effect (visual, auditory, olfactory, gustatory, or tactile) in the absence of an actual stimulus. Because they produce alterations in perception, cognition, and mood, hallucinogens are also called psychedelic drugs or psychedelics (from the Greek, meaning “mind-manifesting”). They are a group of heterogenous compounds, many of which are naturally occurring; others are produced synthetically. Many hallucinogens are structurally similar to one of several neurotransmitters, which may be used as a mechanism of categorization. For example, serotonin-like hallucinogens include the indolealkylamines, exemplified by lysergic acid diethylamide (see LSD), psilocin, DMT, 5-MeO-DMT, and bufotenin; catecholamine-like hallucinogens include the phenylethylamines and their derivatives, such as Mescaline, DOM, MDA, and MDMA. Both classes in general produce visual hallucinations via activity on sub-types of serotonin receptors. Other hallucinogens include PCP and various natural substances, including ayahuasca.

**Hallucinogenic adj.**

**Hallucinogen abuse in DSM–IV–TR** a pattern of drug use marked by recurrent significant adverse consequences related to the repeated ingestion of hallucinogens. This diagnosis is preempted by the diagnosis of HALLUCINOGEN DEPENDENCE: If the criteria for hallucinogen abuse and hallucinogen dependence are both met, only the latter diagnosis is given. In DSM–5, however, both have been combined into single “use disorders” (e.g., phencyclidine use disorder) and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

**Hallucinogen-affective disorder** see HALLUCINOGEN-INDUCED MOOD DISORDER.

**Hallucinogen dependence in DSM–IV–TR** a pattern of repeated or compulsive use of hallucinogens despite significant behavioral, physiological, and psychosocial problems associated with their use, as well as tolerance and characteristic withdrawal symptoms if use is suspended. In DSM–5, hallucinogen dependence has been combined with HALLUCINOGEN ABUSE into single “use disorders” (e.g., phencyclidine use disorder); they are no longer considered distinct diagnoses. See also SUBSTANCE DEPENDENCE.

**Hallucinogen hallucinosis** see HALLUCINOGEN-INDUCED PSYCHOTIC DISORDER.

**Hallucinogen-induced mood disorder** a prominent and persistent disturbance of mood experienced during and after HALLUCINOGEN INTOXICATION. It may be characterized by depression or anxiety, self-reproach, feelings of guilt, and tension. Also called HALLUCINOGEN-AFFECTIVE DISORDER.

**Hallucinogen-induced psychotic disorder** prominent hallucinations, delusions, or both due to HALLUCINOGEN INTOXICATION that are not recognized by the individual as having been induced by hallucinogens. The hallucinations and delusions exceed those usually associated with such intoxication, being sufficiently severe to warrant clinical attention. Also called HALLUCINOGEN HALLUCINOSIS.

**Hallucinogen intoxication in DSM–IV–TR and DSM–5** a reversibly syndrome that is due to the recent ingestion of a specific hallucinogen and is marked by euphoria, subjective intensification of perceptions, hallucinations, synesthesia, pupillary dilation, increased heart rate,
sweating, palpitations, blurring of vision, tremors, and incoordination. With higher levels of intoxication, clinically significant behavioral or psychological changes can include marked anxiety or depression, DELUSION OF REFERENCE, difficulty focusing attention, fear of losing one’s mind, paranoia, and impaired judgment. See also PHENCYclidine intoxication; Substance intoxication.

hallucinosis n. a pathological condition characterized by prominent and persistent hallucinations without alterations of consciousness, particularly when caused by the direct physiological effects of a substance or associated with neurological factors.

halo effect a rating bias in which a general evaluation (usually positive) of a person, or an evaluation of a person on a specific dimension, influences judgments of that person on other specific dimensions. For example, a person who is generally liked might be judged as more intelligent, competent, and honest than he or she actually is.

haloperidol n. a high-potency antipsychotic of the BUTYROPHENONE class, in use in Europe in the 1950s and in the United States from 1965. Haloperidol and other high-potency antipsychotics were preferred over lower potency PHENOTHIAZINES because of their lack of cardiovascular and ANTICHOLINERGIC EFFECTS; however, they were associated more with EXTRAPYRAMIDAL SYMPTOMS and tardive dyskinesia than lower potency agents. The increased safety profile of the second-generation ATYPICAL ANTIPSYCHOTICS has led to a decline in use of haloperidol, although it is still used individually and in conjunction with newer agents. Some argue that few differences exist between the newer agents and haloperidol if the latter is used in much lower doses than has been customary. U.S. trade name: Haldol.

Halstead Category Test see CATEGORY TEST.

Halstead–Reitan Neuropsychological Battery (HRNB) a set of tests used to diagnose and localize brain damage by providing a comprehensive assessment of cognitive functioning. The battery includes five core subtests (the CATEGORY TEST, TACTUAL PERFORMANCE TEST, SEASHORE RHYTHM TEST, SPEECH SOUNDS PERCEPTION TEST, and FINGER TAPPING TEST) and five optional subtests (the TRAIL MAKING TEST, REITAN INDIANA APHASIA SCREENING TEST, REITAN–KLOVE SENSORY PERCEPTUAL EXAMINATION, GRIP STRENGTH TEST, and Lateral Dominance Examination) purportedly measuring elements of language, attention, motor dexterity, sensory–motor integration, abstract thinking, and memory. The MINNESOTA MULTIPhasic PERSONality INVENTORY and either the WECHSLER ADULT INTELLIGENCE SCALE or the WECHSLER INTELLIGENCE SCALE FOR CHILDREN are often administered as well. There is a version of the HRNB for adults, for children ages 5 to 8 years, and for children ages 9 to 14 years. [Ward C. Halstead and Ralph M. Reitan]

halving method see FRACTIONATION.

Hamilton Rating Scale for Depression (HAM-D; HRSD) an interview-based, clinician-administered measure of the severity of DEPRESSION, insomnia, weight loss, and other symptoms in individuals who have been diagnosed with depression. It is the most widely used measure of the effectiveness of antidepressant medication in clinical trials. A 38-item self-report version, the Hamilton Depres-

hand dominance see HANDINESS.

hand Dynamometer Test see GRIP STRENGTH TEST.

handedness n. the consistent use of one hand rather than the other in performing certain tasks. The preference usually is related to a DOMINANCE effect of the MOTOR CORTEX on the opposite side of the body. Also called hand dominance; manual dominance. See CEREBRAL DOMINANCE; LATERALITY; LEFT-HANDEDNESS; RIGHT-HANDEDNESS.

handicap 1. n. any disadvantage or characteristic that limits or prevents a person from performing various physical, cognitive, or social tasks or from fulfilling particular roles within society. For example, a nonaccessible building entrance or exit for a person in a wheelchair would be considered a handicap, as would the person’s inability to walk. The term generally is considered pejorative and its use has fallen into disfavor. See also DISABILITY, 2. vb. to place an individual or group of individuals at a disadvantage, or to hinder or impede progress. —handicapped adj.

handicap principle the idea that nonhuman animals use high-cost HONEST SIGNALS to demonstrate their potential as mates. The long, loud, continuous song of songbirds, the tails of peacocks, and the loud roars of howler monkeys are all energetically costly and make the caller conspicuous to predators. However, if these “handicaps” provide accurate information about the condition or quality of the animal, superior individuals will become preferred mates, and the conspicuous and costly traits will be maintained in future generations.

hand-tool dexterity test a test of the ability to use hand tools effectively.

hand-washing compulsion a persistent and irrational preoccupation with washing the hands, characteristic of OBSESSIVE-COMPULSIVE DISORDER.

handwriting analysis see GRAPHOLOGY.

hanging rootogram a type of HISTOGRAM in which the horizontal x-axis is slightly elevated and the vertical y-axis depicts the square root of frequencies using bars that “hang” downward from a curve showing the expected NORMAL DISTRIBUTION. A hanging rootogram allows researchers to see how well their observed distribution (e.g., of debt for a group of middle-class families) fits an expected THEORETICAL DISTRIBUTION. If the observed data differ from the expected pattern, the hanging histogram bars will drop below the elevated horizontal axis, thereby indicating places of poor match between the observed and theoretical
hangover

The physiological effects experienced after cessation of heavy drinking, usually appearing within hours and lasting up to a day. Symptoms include malaise, thirst, headache, dizziness, fatigue, loss of appetite, nausea, and vomiting. A hangover is different from ALCOHOL WITHDRAWAL, particularly in the duration of alcohol use required for it to develop. **—hung over adj.**

Hans *n.* See CLEVER HANS; LITTLE HANS.

haphazard sampling Any method of selecting research participants that is neither random nor systematic and hence is likely to be biased. CONVENIENCE SAMPLING is an example. Thus, if researchers decide to solicit participants from an Internet advertisement, the process would be biased toward individuals who own a computer and who are more likely to respond to computer-based communications. Depending on the prevalence and likelihood of computer use in various facets of the population, the sample could be biased by gender, ethnicity, geographical location, economic status, or age, among other possible variables.

haplodiploidy *n.* The state in which individuals of one sex have only one set of chromosomes (i.e., are HAPLOID), because they have developed from an unfertilized egg, and individuals of the other sex have two sets of chromosomes (i.e., are DIPLOID). Haplodiploidy is common in bees and wasps, in which males are haploid. Their female offspring inherit identical paternal genes and thus share 75% of their genes (siblings of diploid parents share only 50% of their genes). This provides a genetic basis for EUSOCIALITY.

—haplodiploid *adj.*

haploid *adj.* Describing a nucleus, cell, or organism that possesses only one representative of each chromosome, as in a sperm or egg cell. In most organisms, including humans, fusion of the haploid sex cells following fertilization restores the normal diploid condition of body cells, in which the chromosomes occur in pairs. Hence for humans, the haploid number is 23 chromosomes, which is half the full complement of 46 chromosomes.

happiness *n.* An emotion of joy, gladness, satisfaction, and well-being. **—happy adj.**

happy-puppet syndrome See ANGELOMAN SYNDROME.

haptic *adj.* Relating to the sense of touch and the cutaneous sensory system in general. It typically refers to ACTIVE TOUCH, in which the individual intentionally seeks sensory stimulation, moving the limbs to gain information about an object or surface.

haptic hallucination See TACTILE HALLUCINATION.

haptic horizontal–vertical illusion An illusion in touch in which verticals may be judged as different in length from horizontals. The illusion depends upon figural characteristics and is especially strong when one feels inverted T shapes.

haptic illusion Any mistaken perception arising from voluntary, directed contact with an object (see ACTIVE TOUCH). The HAPTIC MÜLLER-LYER ILLUSION is an example. Compare TACTILE ILLUSION.

haptic map A tactile map that can be felt by people with visual impairment. Such maps may be two-dimensional, comprising raised lines, or they can use three-dimensional landmarks.

haptic Müller-Lyer illusion An illusion in touch in which tangible lines that end in a pattern with arrowheads that face toward each other are judged as longer than lines that end with arrowheads that face away from each other. See also HAPTIC ILLUSION. [Franz Müller-Lyer (1857–1916), German psychiatrist and sociologist]

haptic perception Perception by active touch and intentional exploration of objects and surfaces. See also TOUCH SENSE.

haptic picture A picture produced with raised lines so that it can be felt by people with visual impairment.

haptics *n.* The study of touch, particularly as a means of actively exploring and gaining information about the environment, and the applications of this study in communication systems.

hard colors Yellows and reds.

hard data Information that is QUANTITATIVE and specific, usually obtained from rigorous EXPERIMENTAL RESEARCH, systematic measurement, and STATISTICAL ANALYSIS. Hard data are sometimes contrasted with SOFT DATA, which may be more QUALITATIVE and involve anecdotal evidence that is not obtained systematically.

hard determinism The doctrine that human actions and choices are causally determined by forces and influences over which a person exercises no meaningful control. The term can also be applied to nonhuman events, implying that all things must be as they are and could not possibly be otherwise. Compare SOFT DETERMINISM. See DETERMINISM.

hard drug A colloquial name for a psychoactive drug of abuse that produces PHYSICAL DEPENDENCE and is associated with high rates of adverse consequences. In contrast, a soft drug does not produce physical dependence but may produce PSYCHOLOGICAL DEPENDENCE. Whether a drug is perceived as hard or soft may depend on the social and cultural connotations surrounding its use and on its legal restrictions, if any, in particular locations. For example, alcohol fits the definition of a hard drug but remains legal and is considered by many not to be a drug at all. See SUBSTANCE ABUSE; SUBSTANCE DEPENDENCE.

hardiness *n.* An ability to adapt easily to unexpected changes combined with a sense of purpose in daily life and of personal control over what occurs in one’s life. Hardiness dampens the negative effects of stress and can be a PROTECTIVE FACTOR against illness. See also RESILIENCE. **—hardy adj.**

hard palate The bony anterior portion of the roof of the mouth, covered above and below, respectively, by the mucous membranes of the nasal and oral cavities. Also called PALATUM DURUM. Compare SOFT PALATE.

hard problem In philosophy of mind, the difficulty of explaining the emergence of the qualitative nature (see QUALIA) of subjective experience on the basis of the physical nature of the brain. [terminology proposed by Australian philosopher David Chalmers (1966–)]

hard psychology A colloquial name for EXPERIMENTAL PSYCHOLOGY in contradistinction to so-called SOFT PSYCHOLOGY, which is seen as having a more subjective, less rigorous approach.

hard sell An attempt to sell a product or service by using strong persuasive or compliance techniques, such as setting artificial deadlines or offering special deals to encour-
age potential buyers to commit themselves. A hard sell can be compared to a soft sell, in which more unobtrusive methods are used and little pressure is placed on the consumer to make an immediate decision.

**hardware** *n.* the physical equipment in which an information-processing program is implemented, such as the physical components of a computer system or the brain. Compare SOFTWARE.

**hard-wired** *adj.* 1. referring to electrical or electronic circuits in which the connections among components are permanently established and which are usually designed to perform a specific function. 2. in neurophysiology, referring to fixed, inflexible NEURAL NETWORKS or NEURAL CIRCUITS.

**Hardy–Rand–Rittler pseudoisochromatic plates** (H–R–R plates) embedded figures composed of small elements that can be distinguished from identical small background elements only on the basis of hue. The figures are used to test for color blindness. Also called American optical H–R–R plates. See also ISHIHARA TEST FOR COLOR BLINDNESS. [developed in the 1950s by LeGrand H. Hardy (1895–1954), U.S. ophthalmologist; Gertrude Rand (1886–1970), U.S. experimental psychologist; and M. Catherine Rittler (1905–1987)].

**harem** *n.* in animal behavior, a group of females controlled by or associated with one or two males, as seen in highly polygynous species. See POLYGAMY.

**harmaline** *n.* see AYAHUASCA.

**harm avoidance** see CLONINGER’S PSYCHOBIOLOGICAL MODEL OF PERSONALITY; TEMPERAMENT AND CHARACTER INVENTORY.

**harmine** *n.* a naturally occurring hallucinogen derived from the plants Peganum harmala, native to the Middle East, and Banisteriopsis caapi, native to the South American tropics. Harmine is a potent MONOAMINE OXIDASE INHIBITOR and is a principal ingredient in AYAHUASCA, a psychoactive beverage.

**harmonic** *n.* a PURE-TONE component whose frequency is an integer multiple of the fundamental FREQUENCY. For example, the third harmonic of 500 Hz is 1500 Hz. An overtone is a harmonic, but the numbering is different: 1500 Hz is the second overtone of 500 Hz.

**harmonic mean** a measure of CENTRAL TENDENCY. It is computed for *n* scores by dividing the scores by the sum of their RECIPROCALS; that is, *n* divided by the sum of 1/*x*₁ + 1/*x*₂ + ... + 1/*x*ₙ. See also GEOMETRIC MEAN; MEAN.

**harmony** *n.* 1. friendly or cooperative relations among people, such that social interactions are congruous and conflict free. 2. in a design, work of art, or the like, an arrangement of parts (e.g., lines or musical tones) into a whole pattern that is considered to be balanced and pleasing. —harmonious *adj.*

**harm reduction** an approach designed to reduce the adverse effects of risky behaviors (e.g., alcohol use, drug use, indiscriminate sexual activity), rather than to eliminate the behaviors altogether. Programs focused on alcohol use, for example, do not advocate abstinence but attempt instead to teach people to anticipate the hazards of heavy drinking and learn to drink safely.

**HAROLD** acronym for HEMISPHERIC ASYMMETRY REDUCTION IN OLDER ADULTS.

**Harrisburg Seven** seven Vietnam War protesters who were arrested and tried in Harrisburg, Pennsylvania, in 1972 for various antiraw activities. Their trial was one of the earliest occasions of the use of social science methods to help attorneys select jurors (see SCIENTIFIC JURY SELECTION).

**Harris v. Forklift Systems Inc.** a case resulting in a 1993 U.S. Supreme Court ruling that in SEXUAL HARASSMENT cases the victim is not required to show psychological injury as a consequence of the offensive behavior and that a REASONABLE PERSON STANDARD should be used to judge the offensiveness of the conduct. See also HOSTILE WORK ENVIRONMENT.

**Harvey Impostor Phenomenon Scale** (HIPS) see IMPOSTOR PHENOMENON.

**hashish** *n.* the most potent CANNABIS preparation. It contains the highest concentration of delta-9-THC because it consists largely of pure resin from one of the species of the Cannabis plant from which it is derived.

**hasty generalization** see CONVERSE ACCIDENT.

**hate** *n.* a hostile emotion combining intense feelings of detestation, anger, and often a desire to do harm. Also called hatred.

**hate crime** violence motivated by hatred or prejudice toward the group to which the victim of the violence belongs. Examples of hate crimes are killing a person because he or she is (or is thought to be) gay and bombing a place of worship of a religious minority.

**haunted swing illusion** an illusory perception of self-movement that occurs when an individual is seated on a stationary swing and the surrounding environment is moved. See INDUCED MOVEMENT.

**HAVS** abbreviation for HAND–ARM VIBRATION SYNDROME.

**Hawthorne effect** the effect on the behavior of individuals of knowing that they are being observed or are taking part in research. The Hawthorne effect is typically positive and is named after the Western Electric Company’s Hawthorne Works plant in Cicero, Illinois, where the phenomenon was first observed during a series of studies on worker productivity conducted from 1924 to 1932. These Hawthorne Studies began as an investigation of the effects of ILLUMINATION CONDITIONS, monetary incentives, and rest breaks on productivity, but evolved into a much wider consideration of the role of worker attitudes, supervisory style, and GROUP DYNAMICS. The HUMAN RELATIONS THEORY of management is usually considered to have developed from these studies.

**Hay method** a JOB EVALUATION technique used in determining the pay structure in an organization. Jobs are evaluated on the extent to which they require know-how, problem solving, and accountability, then compensated accordingly. The method combines elements of the FACTOR-COMPARISON METHOD and the POINT METHOD. [Edward N. Hay (1891–1958). U.S. management expert]

**hazard** *n.* a potential source of danger, injury, illness, or equipment damage or malfunction. —hazardous *adj.*
**hazard analysis** an analysis used to identify the level of risk associated with some process or new product (e.g., a new food item). It involves identifying potential hazards, determining their probability, and evaluating the likely severity of their effects. Also called hazard modeling.

**hazard-assessment matrix** see RISK-ASSESSMENT MATRIX.

**hazard control** the process of identifying, evaluating, and eliminating hazards from an environment, system, or product (ENGINEERING CONTROLS) or of protecting users and workers from exposure to hazards where these cannot be completely eliminated (ADMINISTRATIVE CONTROLS). See also SAFETY ENGINEERING.

**hazard-control protocol** the order of priority that applies in the process of eliminating or protecting against hazards. The protocol is design out, guard against, warn, and train. See ADMINISTRATIVE CONTROLS; ENGINEERING CONTROLS.

**hazard function** a mathematical formula that describes the relationship between the risk of a particular event occurring and time. It is one element of SURVIVAL ANALYSIS. It is used to determine the immediate potential or risk of an event’s occurrence at a particular instance in time. It often is used in health studies and will vary depending on the time point of interest. For example, a hazard rate may be used to determine whether an individual who is abstinent from alcohol or drugs at 6 months is likely to relapse in the near future.

**hazing** n. the initiation of new members into a group by subjecting them to rituals that involve mental or physical discomfort, harassment, embarrassment, ridicule, or humiliation. Hazing is thought to promote group-relevant skills and attitudes, reinforce the status hierarchy, and create social dependency.

**Hb** abbreviation for HEMOGLOBIN.

**HCBS** abbreviation for HOME AND COMMUNITY-BASED SERVICES.

**HCFA** abbreviation for Health Care Financing Administration. See CENTERS FOR MEDICARE AND MEDICAID SERVICES.

**HIV** abbreviation for HUNTINGTON’S DISEASE.

**HDI** abbreviation for Hamilton Depression Inventory. See HAMILTON RATING SCALE FOR DEPRESSION.

**headache** n. a pain in the head from any cause. Examples include CLUSTER HEADACHES, MIGRAINE HEADACHES, and TENSION HEADACHES.

**head banging** the act or habit of repeatedly striking the head on a crib, wall, or other object, observed in infants and young children as a stereotyped behavior (see STEREOTYPY) or during a temper tantrum. See also STEREOTYPIC MOVEMENT DISORDER.

**head-direction cell** a type of neuron that discharges as a function of the orientation of an animal’s head within the environment. Head-direction cells are located in several regions of the brain, including the THALAMUS and MAMMALIAN BODIES of the limbic system and the ENTRORHINAL CORTEX and SUBICULUM of the medial temporal lobe memory system. Each has a preferred direction of maximal firing, and their combined activity is influenced by visual and other sensory inputs, motor feedback signals, and internally generated cues from the VESTIBULAR SYSTEM and other INTEROCEPTIVE and PROPRIOCEPTIVE sources. It has been suggested that the information head-direction cells provide is used by the animal to map its external space and that this representation of the environment then guides the animal’s navigational and other spatial behavior. [initially discovered in rats in 1984 by neuroscientist James B. Ranck Jr.]

**head injury** any physical injury to the scalp or skull or any brain damage that may result. Head injuries are usually caused by blunt force, such as a blow to the head, but may result from significant acceleration or deceleration in the absence of physical contact (see ACCELERATION–DECELERATION INJURY). They are commonly classified as either closed, in which the head strikes an object (e.g., a CONCUSSION), or open (penetrating), in which a foreign object passes through the skull and enters the brain (e.g., a gunshot wound). A variety of transient or permanent neuro-psychological consequences may result, including changes in emotion, behavior, and personality; disturbances of EXECUTIVE FUNCTIONS; memory and attention difficulties; and sensory and motor deficits. Also called head trauma.

**head nystagmus** the slow movement of the head in the opposite direction after an individual is rotated, followed by a rapid movement of the head in the direction of rotation.

**head-of-the-table effect** the propensity for group members to associate the leadership role and its responsibilities with the seat located at the head of the table. As a result, individuals who occupy such positions tend to emerge as leaders in groups without designated leaders. See also STEINZOR EFFECT.

**head-related transfer function** (HRTF) a function that describes the spectral characteristics of sound measured at the TYPANIC MEMBRANE when the source of the sound is in three-dimensional space. It is used to simulate externally presented sounds when the sounds are introduced through headphones. The HRTF is a function of frequency, azimuth, and elevation and is determined primarily by the acoustical properties of the external ear, the head, and the torso. HRTFs can differ substantially across individuals but, because measurement of an individual HRTF is expensive, an averaged HRTF is often used.

**head retraction** reflex withdrawal of the head when receptors in the nasal cavities are sharply irritated.

**head rolling** repeated movements of the head from side to side as manifested by some children before going to sleep. The condition has been attributed to inhibition of movement in the crib, lack of stimulating play, and possibly fetal passivity during intrauterine life. Also called jactatio capitis nocturnis.

**headshrinking** n. the shrinking of severed heads, usually human, through the application of heat or herbal liquids, as practiced among various indigenous societies, mainly in southeast Asia and South America. The heads are used for various ritual purposes, including healing rituals. The slang SHRINK (short for headshrinker), meaning a psychiatrist or psychologist, is probably derived from this practice.

**head-slaved adj.** describing a VIRTUAL REALITY environment in which head movements by the user produce corresponding changes in the virtual scene. See also PERCEPTUAL USER INTERFACE.

**Head Start** a U.S. government-funded program designed to enhance early childhood education and foster school readiness, with special emphasis on high-risk, inner-city.
and minority children up to 5 years of age and their families. It was initially designed in 1965 by developmental psychologist Edward Zigler, with the intention of breaking the cycle of poverty by providing preschool children of low-income families with a comprehensive program to meet their emotional, social, health, nutritional, and psychological needs in an 8-week summer program. In 1977, the program became bilingual, and by 1998, it had expanded to full-day, full-year services. Head Start has served more than 30 million children since its inception and now includes a variety of services and program options, including Early Head Start, a home visit- and center-based program for children up to age 3 and their families. Head Start serves more than a million children and their families each year in urban and rural areas in all 50 states, the District of Columbia, Puerto Rico, and the U.S. territories. Also called Project Head Start. See also PROJECT FOLLOW THROUGH.

headstick n. a type of PHYSICAL EXTENSION DEVICE used by individuals with disabilities who have adequate head function. The stick is mounted on a headpiece and can be used to press against, grasp, pull, or point to an object.

head trauma see HEAD INJURY.

head-up display (HUD) a type of machine display in which critical information is presented within the forward view of the operator, as, for example, on the windshield of a vehicle. Head-up displays are used to reduce the need for the operator to look away from the forward field. See also LOOK ANGLE.

head voice the upper reaches, or higher range, of the speaking or singing voice, in which tone resonates primarily in the mouth, nasal cavity, and bones of the skull. An excited or anxious speaking tone is generally produced in a head voice. Compare CHEST VOICE.

healing group broadly, any of a variety of groups formed for the purpose of improving or promoting the mental and emotional health and well-being or interpersonal relationships of the members, as in GROUP THERAPY, SELF-HELP GROUPS, ENCOUNTER GROUPS, and CONSCIOUSNESS-RAISING GROUPS.

health n. the condition of one’s mind, body, and spirit, the ideal being freedom from illness, injury, pain, and distress.

health activities questionnaire any questionnaire designed to measure an individual’s current repertoire of health-related behaviors. In health care there is an increased emphasis on prevention, and many inventories exist to measure an individual’s compliance with physical activity, dietary control, preventive inoculations, and screening for potential health problems, such as mammography and prostate or colon cancer testing.

health anxiety excessive or inappropriate anxiety about one’s health, based on misinterpretation of symptoms (e.g., pain, gastrointestinal distress) as indicative of serious illness. Health anxiety is often associated with HYPOCHONDRIASIS.

health–belief model a model that identifies the relationships of the following issues to the likelihood of taking preventive health action: (a) individual perceptions about susceptibility to and seriousness of a disease, (b) sociodemographic variables, (c) environmental cues, and (d) perceptions of the benefits and costs. See also EXERCISE–BEHAVIOR MODEL.

health care services and delivery related to the health and well-being of individuals and communities, including preventive, diagnostic, therapeutic, rehabilitative, maintenance, monitoring, and counseling services. In its broadest sense, health care relates to both physical and mental health and is provided by medical and mental health professionals. See also MENTAL HEALTH CARE; MENTAL HEALTH SERVICES.

Health Care Financing Administration (HCFA) see CENTERS FOR MEDICARE AND MEDICAID SERVICES.

healthcare information system (HIS) see INFORMATION SYSTEMS.

health care proxy see ADVANCE DIRECTIVE.

health care psychology see HEALTH PSYCHOLOGY.

health care reform movement the social and political efforts to improve health and mental health care access, advance quality of care, and control health and mental health care costs.

health education 1. instruction in the care and hygiene of the human body, with emphasis on illness prevention. 2. any type of education regarding physical, mental, and emotional health. Conducted in school, institutional, and community settings, this education may cover stress management, smoking cessation, nutrition and fitness, reproductive health, self-esteem, relationship issues, health risks, personal safety (e.g., self-defense and rape prevention), and minority health issues.

health home an evolving concept, originating in 1967 with the idea of the American Academy of Pediatrics (AAP) of archiving each child’s medical records in a central (“home”) location, intended to provide patients of all ages with access to continuous, comprehensive, family-centered, coordinated, compassionate, and culturally effective care. The AAP together with the American Academy of Family Physicians, American College of Physicians, and American Osteopathic Association jointly endorsed the following principles of this medical approach: that (a) each patient have a personal physician; (b) the personal physician direct a team of practitioners, who collectively are responsible for providing the patient’s ongoing medical and mental health care (i.e., acute, chronic, and preventative services); (c) the personal physician take a whole-person approach to the patient’s care, either personally treating the patient or arranging for care from other qualified professionals; and (d) the patient’s physical and mental health care be coordinated or integrated across the health care system and the patient’s community, such that care is received where and when the patient wants it and in an appropriate manner (e.g., in the patient’s preferred language, in a culturally relevant way). Ideally, benefits of this approach are higher quality care, improved safety, enhanced access to care (e.g., through expanded hours, open scheduling, and new methods of communication between the patient and the medical and mental health teams), reduced costs in service delivery, and better reimbursement for services provided. Also called MEDICAL HOME; PATIENT-CENTERED MEDICAL HOME.

health insurance a contractual relationship in which an insurance company undertakes to reimburse the insured for health care expenses in exchange for a premium. Such payment protections might include, for example, medical expense, outpatient mental health, accident, dental, disability income, and accidental death and dismemberment insurances.
health locus of control

the perceived source of control over health, either personal behaviors or external forces. See also LOCUS OF CONTROL.

health maintenance organization see HMO.

health plan an organized program that provides a defined set of health care benefits. Health plans may be HMOs, PPOs, insured plans, self-insured plans, or other plans that cover health care services.

Health Plan Employer Data and Information Set (HEDIS) a set of annual performance measures for health plans originally developed for the NATIONAL COMMITTEE FOR QUALITY ASSURANCE (NCQA) in 1991 and designed to standardize the way health plans report data to employers. HEDIS consists of 76 measures across five major areas of health plan performance: quality, access and patient satisfaction, membership and utilization, finance, and descriptive information on health plan management.

health professional an individual who has received advanced training or education in a health-related field, such as direct patient care, administration, or ancillary services.

health promotion education, wellness programs, public policies, fiscal measures, legislation, or other coordinated actions that aim to give people more control over their physical and mental health, with the goal of improving their overall health and well-being.

health psychology the subfield of psychology that focuses on (a) the examination of the relationships between behavioral, cognitive, psychophysiological, and social and environmental factors and the establishment, maintenance, and detriment of health; (b) the integration of psychological and biological research findings in the design of empirically based interventions for the prevention and treatment of illness; and (c) the evaluation of physical and psychological status before, during, and after medical and psychological treatment. Also called health care psychology.

health risk appraisal 1. information collected to assess an individual's risk for various medical conditions. It may be limited to information from a HEALTH ACTIVITIES QUESTIONNAIRE or may include measurements such as cholesterol levels and triglycerides as well as other physical data. 2. the perception by individuals of the extent to which they believe that they are susceptible to a health condition resulting in HEARING LOSS or DEAFNESS.

health screen testing and examinations performed on a person who is at risk of a disease or disorder but who may not yet show symptoms.

health visitor a health professional, usually associated with a VISITING NURSE association, who visits families where health supervision is needed, for example, to ensure that children are not abused or neglected.

hearing n. the ability of an organism to sense sound and to process and interpret the sensations to gain information about the source and nature of the sound. In humans, hearing refers to the perception of sound. Also called audition.

hearing aid an electronic device that amplifies sounds for people with hearing loss. The basic parts of a hearing aid include a microphone to collect sounds, a replenishable battery power supply, an amplifier to increase the volume of sounds, and a receiver to transmit the amplified sounds to the ear. Hearing aids are available in four different styles (behind the ear, in the ear, in the canal, and completely in the canal) and four different types: (a) conventional, which is the most basic and amplifies all sounds; (b) programmable, which adjusts the level of amplification of sounds according to a customized listening program; (c) digital, which automatically adjusts amplification and volume, is free from distortion, and provides enhanced sound clarity and improved selective listening in noisy environments; and (d) disposable, which is comparable to a conventional hearing aid but must be replaced entirely once the battery wears out. See also ASSISTIVE LISTENING DEVICE; COCHLEAR IMPLANT.

hearing disorder any disease, injury, or congenital condition resulting in HEARING LOSS or DEAFNESS.

hearing level see AUDIODEGRUM.

hearing loss the inability to hear a normal range of tone frequencies, a normally perceived level of sound intensity, or both.

hearing mute an obsolete and pejorative name for an individual who is unable or unwilling to speak but is able to hear.

hearing protection a device or method used to control noise exposure by reducing the intensity of noise reaching the ear. Techniques range from simple barrier methods (e.g., earplugs) to ACTIVE NOISE PROTECTION.

hearing theories theories related to the sensation and perception of sound. Until the 1960s, such theories related almost exclusively to sound processing in the inner ear; they include PLACE THEORY, FREQUENCY THEORY, VOlLEY THEORY, and traveling wave theory. Contemporary theories and models relate to various aspects of hearing, including pitch perception, intensity coding, and BINAURAL hearing.

heart attack sudden, severe chest pain that occurs when one of the coronary arteries becomes blocked. The condition may result in a myocardial infarction (i.e., death of a section of heart muscle), depending on the extent of damage to the surrounding muscle.

heart block see ARRHYTHMIA.

heart rate reactivity changes in heart rate associated with particular emotional states. It is usually held that heart rate increases in states of fear, anger, and scorn and decreases in states of attentiveness, positive emotional reaction, and interest. However, the actual relation between heart rate and emotion is complex and largely mediated by the energy demands of the bodily musculature of the organism in an emotional state. Thus, a frightened animal that reacts with tonic immobility (death feigning) and limpness will show a reduction in heart rate in its reaction to a threat, whereas an animal that is immobile but poised for flight typically shows acceleration of heart rate. States of laughter, although pleasurable, are typically associated with an accelerated heart rate owing to the involvement of large muscle groups in the act of laughing.

heat n. 1. a thermal sensation produced by a stimulus that is above body temperature. 2. see ESTRUS.

heat dolorimeter a device for the measurement of heat-induced pain.

heat effects changes in mental or physical conditions due to perceived or actual ambient temperatures above the
normal comfort range. Perceived heat may be affected by humidity or individual cognitive factors; high humidity usually makes excessive heat less tolerable. The main physiological heat effects are HEAT-INDUCED ASTHENIA, HEAT-STROKE, HEAT EXHAUSTION, and severe circulatory disorders (e.g., heart attacks) caused by excessive demands on the cardiovascular system to circulate blood near external surfaces for a cooling effect. Because of variable perceived heat effects, studies of psychological effects are less conclusive, although performance appears to improve with increasing ambient temperatures up to a level of around 32 °C (90 °F), after which arousal and performance decline. High temperatures can have adverse effects on feelings and emotions and can influence aggression, although no consensus exists in the scientific literature on the exact degree of this influence. Some researchers believe that aggression increases with temperature in a linear manner, whereas others hold that beyond a certain temperature, the desire for escape or relief from the heat supersedes the tendency toward aggression. See ACCLIMATIZATION; OVERHEATING.

heat exhaustion a condition resulting from exposure to excessive heat. Dehydration and salt depletion in the body cause such symptoms as headaches, weakness, dizziness, and blurred vision. Heat exhaustion typically is temporary and not life threatening because it does not involve elevation of body temperature, as occurs in HEATSTROKE.

heat-induced asthenia a condition associated with prolonged exposure to heat and characterized by general physical and mental impairment, fatigue, lethargy, irritability, insomnia, headache, and possible loss of appetite.

heat stress any stress effect on an organism that results from exposure to excessive ambient temperatures, particularly HEAT-INDUCED ASTHENIA, HEAT EXHAUSTION, and HEATSTROKE.

heatstroke n. a serious condition caused by a breakdown of the body's temperature-regulation ability following exposure to excessive heat. The body is no longer able to cool itself by sweating, the skin feels hot and dry, and the person may experience convulsions or seizures and potentially lose consciousness. The elevated body temperature may cause brain damage or death. Emergency treatment involving cooling the patient must be started immediately.

Hebbian synapse a junction between neurons that is strengthened when it successfully fires the postsynaptic cell. See DUAL TRACE HYPOTHESIS. [Donald O. Hebb]

hebephrenia n. see DISORGANIZED SCHIZOPHRENIA.

hebetude n. a state of severe emotional dullness, lethargy, and lack of interest.

Hecht’s theory of vision the theory that incremental discrimination of light intensity results from incremental changes in the photochemical materials, such as RHODOPHISIN, present in the photoreceptors. [proposed in 1934 by Selig Hecht (1892–1947), Polish-born U.S. biophysicist]

hedge n. a statement in which the speaker qualifies its apparent meaning or uses various linguistic devices to make it evasive or noncommittal.

Hedges's g an EFFECT SIZE measure that represents the standardized difference between means. Hedges's g differs from the more widely used COHEN'S d in that, whereas both use a pooled STANDARD DEVIATION in the denominator, the former uses n – 1 and the latter uses n when calculating the standard deviations. Thus, Hedges's g tends to be considered as having less bias than Cohen’s d. See also GLASS’S d. [Larry V. Hedges, U.S. statistician]

HEDIS acronym for HEALTH PLAN EMPLOYER DATA AND INFORMATION SET.

hedonic contingency hypothesis a theory of affect and information processing postulating that people consider the pleasant or unpleasant implications when determining whether to elaborate information. When people are in positive mood states, they tend to be highly attentive to the impact information will have on their mood. If the information is seen as uplifting, they will engage in extensive ELABORATION to maintain their positive mood, but if it is seen as unpleasant, they will engage in little elaboration. When people are in negative mood states, they tend to elaborate information with little attention to its hedonic consequences because such information is unlikely to make their mood more negative and might make it more positive. [originally proposed by U.S. social psychologists Duane T. Wegener (1966– ) and Richard E. Petty (1951– )]

hedonic contrast the concept that preference for a “good” stimulus is enhanced if it is preceded or accompanied by a less pleasing stimulus. Hedonic contrast is only found when the two stimuli are extremely similar (e.g., shades of the same hue).

hedonic level the degree of pleasantness or unpleasantness aroused by an interaction or a thought. See HEDONIC THEORY.

hedonic psychology a psychological perspective that focuses on the spectrum of experiences ranging from pleasure to pain and includes biological, social, and phenomenological aspects and their relationship to motivation and action. See HEDONISM.

hedonic relevance the extent to which a situation or activity has bearing on the attainment or maintenance of a positive mood. According to the HEDONIC CONTINGENCY HYPOTHESIS, happy people consider the hedonic relevance of an activity they might carry out before actually engaging in that behavior, because they want to maintain their good mood.

hedonics n. the branch of psychology concerned with the study of pleasant and unpleasant sensations and thoughts, especially in terms of their role in human motivation.

hedonic theory the view that a fundamental motivational principle in human beings and nonhuman animals is the level of pleasantness or unpleasantness aroused by an interaction or thought. See also HEDONISM. [proposed by Paul Thomas Young]

hedonic time-order error a preference for one of two otherwise equally preferred stimuli that arises because of the time interval that separates their presentation. The first stimulus is preferred when the interval is brief, and the second stimulus is preferred when the interval is lengthier.

hedonic tone a property of a sensory or other experience relating to its pleasantness or unpleasantness.

hedonic treadmill a metaphor for a hypothesis proposing that people’s happiness tends to return to a preexisting baseline level after positive or negative LIFE EVENTS have occurred. According to this concept, positive and negative events may produce short-term shifts in mood, but these shifts tend to erode in a relatively brief period of time. This process of adaptation is thought to be responsible for the
hedonic well-being

The persistence of mood states over time, often in the face of considerable efforts to change them. Although there is good evidence for this hypothesis, research has demonstrated that people do not always return to baseline after the occurrence of mood-changing events. See also SET POINT. [Coined by Canadian-born U.S. psychologist Philip Brickman (1943–1982) and Donald Campbell in a 1971 essay]

hedonic well-being the type of happiness or contentment that is achieved when pleasure is obtained and pain is avoided. Compare EUDAIMONIC WELL-BEING.

hedonism n. 1. In philosophy, the doctrine that pleasure is an intrinsic good and the proper goal of all human action. One of the fundamental questions of ethics has been whether pleasure can or should be equated with the good in this way. 2. In psychology, any theory that suggests that pleasure and the avoidance of pain are the only or the major motivating forces in human behavior. Hedonism is a foundational principle in psychoanalysis, in behaviorism, and even in theories that stress self-actualization and need fulfillment. To the extent that human beings are hedonistic, it is difficult to admit the possibility of genuine altruism. Also called hedonistic psychology. See EUDAIMONISM; HEDONISTIC PSYCHOLOGY. —hedonistic adj.

hegemony n. The dominance of one individual, group, or state over others. In some 20th-century Marxist writings, the term refers particularly to the success of the dominant social class in imposing its ideology on other classes, so that this comes to seem part of the “natural” order of things. See also DOMINANT IDEOLOGY THESIS. —hegemonic adj.

height phobia see ACROPHOBIA.

Heinz dilemma a story about an ethical dilemma faced by a character named Heinz that was used by Lawrence Kohlberg to assess the moral reasoning skills of those he asked to respond to it. Having exhausted every other possibility, Heinz must decide whether to steal an expensive drug that offers the only hope of saving his dying wife. See KOHLBERG’S THEORY OF MORAL DEVELOPMENT.

Heisenberg principle see UNCERTAINTY PRINCIPLE.

helicotrema n. A small opening at the apex of the cochlea where the scala vestibuli and scala tympani communicate. This opening limits the ability of the basilar membrane to vibrate in response to sounds of very low frequency.

heliocentric theory the cosmological theory that the sun is the center of the solar system and that the earth and other heavenly bodies orbit around it. The theory, which originated in ancient Greece, was revived by Polish astronomer Nicolaus Copernicus (1475–1543) and elaborated by Italian physicist and astronomer Galileo Galilei (1564–1642). It was controversial in the 16th and 17th centuries because it opposed the traditional doctrine of the Catholic Church that the earth was stationary at the center of the universe (see EARTH-CENTERED THEORY). Also called COPERNICAN THEORY.

heliotropism n. see TROPISM.

Helleborus n. Any plant of the genus Veratrum but particularly Veratrum viride, a poisonous plant indigenous to North America that has a history of use by Native Americans for various medicinal purposes. It contains more than 20 alkaloids, including veratrine, which has analgesic properties when used topically but produces prolonged muscle contractions when ingested. The hellebore alkaloids were also used medicinally in England as well as America in the 18th and 19th centuries in the treatment of numerous conditions, including seizures, neuralgia, headaches, and respiratory problems. They have been used more recently to lower blood pressure but generally are avoided because of their potential toxicity. The name hellebore is also given to poisonous ornamental plants of the Eurasian genus Helleborus.

Helmholtz chessboard see CHESSBOARD ILLUSION. [Hermann von HELMHOLTZ]

Helmholtz color mixer a device that enables the intensity and wavelength of two light sources to be independently adjusted, mixed, and presented by means of a prism as a single homogenous field to an observer, who views the field through a modified telescope. [Hermann von HELMHOLTZ]

Helmholtz square illusion a square made up of parallel horizontal lines that looks like a vertically oriented rectangle (i.e., taller than a square), or a square made up of parallel vertical lines that looks like a horizontally oriented rectangle (i.e., wider than a square). [Hermann von HELMHOLTZ]

Helmholtz theory in audition, the still-controversial theory that pitch is determined by the place of stimulation along the basilar membrane. The theory is clearly flawed in certain aspects, such as its inability to account for the pitch of a missing fundamental (see VIRTUAL PITCH), but the essential notion remains viable. See PLACE THEORY. [Hermann von HELMHOLTZ]

helper n. In animal behavior, see ALLOPARENTING.

helping n. A type of prosocial behavior in which one or more individuals act to improve the status or well-being of one or more others. Although helping behavior is typically in response to a small request that involves little individual risk, all helping behavior incurs some cost to the individual providing it. See also ALTRUISM; EGOISTIC HELPING.

helping model a broadly based educational approach that has much in common with humanistic models in its emphasis on the development of the complete individual and the realization of a student’s full potential. The helping model is concerned with motor development, perceptual skills, cognitive development, emotional maturity, interpersonal skills, expression, creativity, and ethical values.

helping professions occupations that provide health and education services to individuals and groups, including occupations in the fields of psychology, psychiatry, counseling, medicine, nursing, social work, physical and occupational therapy, teaching, and education.

helping relationship a relationship in which at least one of the parties intends to promote the growth, development, maturity, or improved functioning of the other. The parties may be either individuals or groups. [Defined in 1961 by Carl Rogers]

helplessness n. A state of incapacity, vulnerability, or powerlessness associated with the perception that one cannot do much to improve a negative situation that has arisen. Theorists have suggested that helplessness underlies various forms of anxiety, dependence, withdrawal, and demoralization. See also COPING POTENTIAL; LEARNED HELPLESSNESS. —helpless adj.

helplessness theory see LEARNED HELPLESSNESS.
handedness

hem-, combining form see HEMO-.

hematoma n. an abnormal accumulation of blood as a result of vessel leakage or rupture. In the brain, hematomas can cause substantial behavioral deficits, and even death, by increasing INTRACRANIAL PRESSURE. Although some may spontaneously reabsorb and disappear, others must be surgically evacuated. See EPIDURAL HEMATOMA; SUBDURAL HEMATOMA.

hematophobia n. see BLOOD PHOBIA.

hemeralopia n. a condition in which a person has difficulty seeing in bright light but has good vision in dim light.

hemianalgesia n. a loss of pain sensation on one side of the body.

hemianesthesia n. a loss of sensitivity to stimuli on one side of the body.

hemianopia (hemianopsia; hemiopia) n. a visual field defect marked by loss of vision in half the normal visual field. Hemianopia may result from a lesion in the OPTIC CHASM or the OPTIC RADIATIONS. See also BINASAL HEMIANOPA; BITEMPORAL HEMIANOPA; HETERONYMOUS HEMIANOPA; HOMONYMOUS HEMIANOPA. —hemianopic adj. —hemianoptic adj.

hemicerebral atrophy see PARACENTRAL SCOTOMA.

hemisomatognosia n. see ASOMATOGNOSIA.

hemiballismus n. see BALLISMUS.

hemichorea n. a disorder involving choreic movements on only one side of the body. See CHOREA.

hemicrania n. pain or aching on only one side of the head, characteristic of a typical migraine headache.

hemidecortication n. surgical removal of the CEREBRAL CORTEX on one side of the brain.

hemimegalencephaly n. see MEGALENCEPHALY.

hemineglect n. see UNILATERAL NEGLECT.

hemiparesis n. weakness or partial paralysis affecting one side of the body. See SPASTIC HEMIPARESIS.

hemiplegia n. complete paralysis that affects one side of the body, most often as a result of a STROKE. The paralysis is typically opposite (contralateral) to the side of the brain affected. —hemiplegic adj.

hemispatial neglect see UNILATERAL NEGLECT.

hemispheric roles in emotion the different roles of the left and right hemispheres of the brain in the generation and regulation of emotions. In particular, the frontal lobe of the left hemisphere is believed to be linked to positive emotions; injury or damage to this region results in loss of positive AFFECT. By contrast, the frontal lobe of the right hemisphere is more related to negative emotions (e.g., sadness, fear), with lesions to this portion of the brain resulting in loss of negative AFFECT. Alternatively, the left frontal region is regarded as controlling emotions involving approach, and the right frontal region as controlling emotions involving avoidance.

hemisphere n. either of the symmetrical halves of the cerebrum (see CEREBRAL HEMISPHERE) or the CEREBELLUM. —hemispheric or hemispherical adj.

hemispherectomy n. surgical removal of either one of the cerebral hemispheres of the brain, most often the non-dominant hemisphere for treatment of intractable epilepsy.

hemispheric asymmetry the idea that the two cerebral hemispheres of the brain are not identical but differ in size, shape, and function. The functions that display the most pronounced asymmetry are language processing in the left hemisphere and visuospatial processing in the right hemisphere.

hemispheric asymmetry reduction in older adults (HAROLD) a model of the effects of aging on brain activity, proposing that prefrontal activity during cognitive performance tends to be less lateralized and to occur more often on both sides of the brain in older adults than in younger adults. The model is based on findings from functional neuroimaging and behavioral studies on memory, perception, and inhibitory control. The model proposes that age-related hemispheric asymmetry reduction in older adults may reflect both compensatory and dedifferentiation processes. See COMPENSATION; DIFFERENTIATION–DEDIFFERENTIATION HYPOTHESIS. [proposed by Roberto E. Cabeza (1960– ), Argentinian-born U.S. psychologist]

hemispheric communication the continuous exchange of neural signals between the two cerebral hemispheres, typically via the CORPUS CALLOSUM.

hemispheric dominance see DOMINANCE; HEMISPHERIC LATERALIZATION.

hemispheric encoding–retrieval asymmetry (HERA) the hypothesis that the left cerebral hemisphere is especially active during the encoding of a memory, whereas the right hemisphere is especially active during the retrieval of the memory. [proposed by Endel TULVING]

hemispheric lateralization the processes whereby some functions, such as manual control (HANDEDNESS) or speech production, are controlled or influenced more by one cerebral hemisphere than the other. Researchers now prefer to speak of hemispheric lateralization or hemispheric specialization for particular functions, rather than hemispheric dominance or lateral dominance (see DOMINANCE). Also called cerebral lateralization.

hemlock n. see SORCERY DRUG.

hemo- (hem-, haemo-, haem-) combining form blood.
hemodynamic response changes in blood flow to the brain, as measured via functional magnetic resonance imaging.

hemoglobin (Hb) n. an iron-rich pigment of red blood cells that transports oxygen molecules and is responsible for the color of blood. When saturated with oxygen, the pigment becomes bright red.

hemoglobinopathy n. any of various inherited disorders associated with genetic defects in the characteristics of hemoglobin. A common effect of hemoglobinopathies is anemia, which may be severe in homozygous individuals and mild in heterozygous carriers. Sickle-cell anemia and Cooley’s anemia are examples of hemoglobinopathies.

hemophilia n. see blood phobia.

hemorrhage n. bleeding: any loss of blood from an artery or vein. A hemorrhage may be external, internal, or within a tissue, such as the skin; a bruise is a sign of bleeding within the skin. A hemorrhage from a ruptured artery is bright red in color and erupts in spurts that coincide with heart contractions; it is generally more serious than hemorrhage from a vein, which shows as a relatively slow, steady flow of dark red blood. Brain hemorrhages may arise from head injuries or aneurysms, causing widespread damage in some cases (see cerebral hemorrhage).

—hemorrhagic adj.

hemorrhagic stroke a stroke resulting from rupture of a cerebral vessel, causing intracranial bleeding. Intracerebral hemorrhage accounts for approximately 10% of strokes and tends to occur deep in the basal ganglia, internal capsule, and brainstem.

hemothymia n. a lust for blood and a morbid desire to commit murder. See also homicide.

hemp n. the plant Cannabis sativa, native to Asia, from which marijuana (Cannabis) is derived. Hemp is a colloquial term for marijuana.

henbane n. a poisonous plant, Hyoscyamus niger, native to the Mediterranean and southern Europe and a source of the anticholinergic alkaloids scopolamine, atropine, hyoscyamine, and scopoletine. Although traditionally used in small doses as an analgesic, sedative, and smooth muscle relaxant, henbane in larger quantities is highly toxic, producing effects similar to those of poisoning with scopolamine, including delirium, hallucinations, convulsions, coma, and possibly death. It has long been associated in folklore with witchcraft and magic and even enjoyed a reputation for use as an aphrodisiac.

Henle fiber the cytoplasmic extension that allows a retinal cone in the region of the fovea centralis to reach one of the retinal bipolar cells, all of which are laterally displaced from the fovea. [Friedrich Gustav Jakob Henle (1809–1885), German anatomist]

Henning’s odor prism a prism-shaped graphic representation of six primary odors and their relationships. Burnt, spicy, resinous, foul, fruity, and flowery are the primary odors that occupy the corners of the prism, and each surface represents the positions of odors that are similar to the primaries at the corners of that surface. Also called Henning’s smell prism. [Hans Henning (1885–1946), German psychologist]

Henning’s taste tetrahedron an arrangement to represent four putative primary tastes: sweet, salty, sour, and bitter. These basic tastes are at the apices of the tetrahedron: a combination of two qualities, such as salty–bitter (e.g., the taste of potassium chloride), are along the edges; and tastes combining three qualities, such as salty–sweet–bitter (e.g., the taste of sodium saccharin), are on the faces. The tetrahedron is hollow because Henning believed no chemical could generate all four basic tastes. [proposed in 1927 by Hans Henning]

hepatitis n. inflammation of the liver, marked by diffuse or patchy areas of dead liver cells in the liver lobules. Symptoms, when experienced, range from mild, flu-like symptoms to liver failure, which can be fatal. Jaundice and Bilirubin coloring of the urine are usual signs. The different forms of viral hepatitis are identified by letters indicating the virus responsible. Hepatitis A is contracted by ingesting contaminated food or water, whereas hepatitis B is usually transmitted by transfusions of contamined blood, by the use of dirty hypodermic needles, or by sexual contact with an infected person. The hepatitis C virus (HCV) is one of the most important causes of chronic liver disease in the United States; its modes of transmission are similar to those of hepatitis B. Nonviral hepatitis can be caused by toxic substances (e.g., alcohol, medications, chemicals), gall bladder or pancreas disorders, or autoimmune disorders.

HERA abbreviation for Hemispheric Encoding–Retrieval Asymmetry.

herb ecstasy an over-the-counter stimulant purchased through mail-order catalogs and often confused with MDMA.

herd instinct a drive in nonhuman animals to congregate in flocks and in humans to form social groups. See Gregariousness. [defined by William McDougall]

here and now the immediate situation. In psychotherapy, it comprises the cognitive, affective, and behavioral material arising at any given point in a session, as well as the relationship between the therapist and client at the corresponding point in time. When the here-and-now approach is used in psychotherapy, the emphasis is placed on understanding present feelings and interpersonal reactions as they occur in an ongoing treatment session, with little or no emphasis on or exploration of past experience or underlying reasons for the client’s thoughts, emotions, or behavior. The approach is often used in psychodynamic psychotherapy with regard to the therapeutic relationship, Gestalt therapy, and many forms of family therapy to heighten client awareness.

hereditarianism n. the view that genetic inheritance is the major influence on behavior. Opposed to this view is the belief that environment and learning account for the major differences between people. The question of heredity versus environment or “nature versus nurture” continues to be controversial, especially as it applies to human intelligence. See genetic determinism; nature–nurture. —hereditarian adj.

hereditary ataxia any in a group of heritable disorders characterized by the inability to perform coordinated movements (ataxia), among other clinical features. Exam-
ples include ATAXIA TELANGECTASIA and FRIEDREICH’S ATAXIA.

**hereditary hyperuricemia** (hereditary choreoathetosis) see LEŚCH–NYHAN SYNDROME.

**hereditary myopathy** see MYOPATHY.

**hereditary predisposition** see GENETIC PREDISPOSITION.

**heredity** n. 1. the transmission of traits from parents to their offspring. Study of the mechanisms and laws of heredity is the basis of the science of GENETICS. Heredity depends upon the character of the genes contained in the parents’ CHROMOSOMES, which in turn depends on the particular GENETIC CODE carried by the DNA of which the chromosomes are composed. 2. loosely, the sum of the characteristics transmitted from parents to their offspring.

**heredity–environment controversy** see NATURE–NURTURE.

**Hering–Breuer reflex** a nervous mechanism involved in normal breathing, with stimuli from sensory endings in lung tissue limiting inspiration and expiration. [Ewald HERING; Josef BREUER]

**Hering grays** a set of 50 gray papers ranging in subjectively equal steps from extreme white to extreme black. [Ewald Hering]

**Hering illusion** a misperception that occurs when two parallel straight lines are superimposed on a pattern of lines that radiate from a central point. When the two lines are placed equidistant from one another on opposite sides of the center point, they appear to be bowed outward from the center, rather than straight. Also called Hering–Helmholtz illusion. [Ewald Hering; Hermann von Helmholtz]

**Hering’s afterimage** a positive athersensation of the same hue and saturation as the original stimulus. See AFTERIMAGE. [Ewald Hering]

**Hering theory of color vision** a theory of color vision postulating that there are three sets of receptors, one of which is sensitive to white and black, another to red and green, and the third to yellow and blue. The breaking down (catabolism) of these substances is supposed to yield one green, and the third to yellow and blue. The breaking down of which is sensitive to white and black, another to red and yellow. [Ewald Hering]

**hereditability** n. 1. the capacity to be inherited. 2. a statistical estimate of the contribution of inheritance to a given trait or function in a population (but not in particular individuals). Heritabilities can range from 0, indicating no contribution of heritable factors, to 1, indicating total contribution of heritable factors. Also called heritability estimate.

**heritage** n. 1. any cultural tradition, custom, or resource passed from preceding to successive generations. 2. artworks, historic buildings or monuments, and natural landscapes that are regarded as having special value and are accordingly preserved for future generations. See CULTURAL HERITAGE; SOCIAL HERITAGE. See also CULTURAL CONSERVE.

**hermaphroditism** n. the condition of possessing both male and female sex organs (in humans, e.g., possessing both ovarian and testicular tissue). Hermaphroditism is very rare and should not be confused with the more common pseudohermaphroditism, in which the gonads are of one sex but the external genitalia are either ambiguous or of the other sex. See also INTERSEX. —*hermaphrodite* n.

**hermeneutics** n. the theory or science of interpretation. Hermeneutics is concerned with the ways in which humans derive meaning from language or other symbolic expression. Originally, the term was confined to the interpretation of Scripture, with an emphasis on generating methods of interpretation that would yield the correct meaning of the text. Subsequently, two main strains of hermeneutic thought developed. One originates from the work of German philosopher Friedrich Schleiermacher (1768–1834), who broadened hermeneutics by applying it to the interpretation of texts in general rather than to religious writings in particular. This project was expanded by German philosopher Wilhelm Dilthey (1833–1911) into the interpretation of all forms of cultural expression, including artworks, institutions, and historical events. A key concept in this tradition of hermeneutics is the so-called hermeneutic circle—the notion that interpretation is always circular, in that particulars will necessarily be interpreted in the light of one’s understanding of the whole, and the understanding of the whole will be altered by the understanding of the particulars. Another key assumption is the need to gain insight into the mind of the person or people whose expression is the subject of interpretation. This approach has been criticized on the grounds that such insight is impossible, because there is no access to the mind of another; thus, the methods of hermeneutics will always be imprecise and their results relativistic.

A second, more radical, strain of hermeneutics derives from the PHENOMENOLOGY of Edmund Husserl (1859–1938) and the work of German philosopher Martin Heidegger (1889–1976). Heidegger expanded the project of interpretation to include DASEIN or human being itself. This suggests that all human behavior can be understood as meaningful expression, much as one would understand a written text. It also turns the process of interpretation back on the interpreter, as the understanding of the being of human beings entails interpretations of interpretive acts. This shift has given rise to a broad movement within philosophy, psychology, and literary criticism in which richness of interpretation is considered more valuable than consistent methodology or arriving at the “correct” interpretation. Such an approach is a clear alternative to a natural scientific psychology. This type of hermeneutics has informed other contemporary movements, notably EXISTENTIALISM, POSTMODERNISM, and POSTSTRUCTURALISM. —*hermeneutic* adj.

**herniation** n. the abnormal protrusion of an organ or other bodily structure through an opening in a membrane, muscle, or bone.

**hero** n. in PSYCHODRAMA, the person (protagonist) who is portraying a problem.

**heroin** n. a highly addictive opioid that is a synthetic analog of MORPHINE and three times more potent. In many countries, including Great Britain and Canada, it is used clinically for pain management (see DIACETYL MORPHINE), but it is not legally available in the United States due to concerns about its potential for abuse. Its rapid onset of action leads to an intense initial high, followed by a period of euphoria and a sense of well-being. As a street drug, heroin is commonly injected intravenously or subcutaneously
herpes infection

A disease produced by a herpes virus. A herpes infection may be manifested as chicken pox, cold sores, shingles, ulceration of the cornea, encephalitis, stomatitis, or vulvovaginitis (genital herpes). The major strains are herpes varicella-zoster, which causes both chicken pox and shingles; herpes simplex type 1, the cause of cold sores and sometimes genital herpes; and herpes simplex type 2, the most frequent cause of genital herpes. See also perinatal herpes-virus infection.

herpes-simplex encephalitis

A form of encephalitis (inflammation of the brain) caused by infection with the herpes-simplex virus. Seizures occur repeatedly early in the course of the disease, and there may be serious memory impairment. The virus tends to affect the temporal and frontal lobes. Also called herpes encephalitis.

herpetic neuralgia

Pain associated with shingles, caused by reactivation of the herpes varicella-zoster virus (see herpes infection). Following an attack of chicken pox, the virus lies dormant in a dorsal nerve root and ganglion of the spinal cord; when reactivated, it spreads down the sensory nerve, causing vesicle formation and severe, burning, lancinating pain. This acute pain typically resolves in 3 to 5 weeks, but patients often develop the chronic, debilitating pain known as postherpetic neuralgia.

hertz

(Symbol: Hz) n. The unit of frequency equal to one cycle per second. [Heinrich Rudolf Hertz (1857–1894), German physicist]

Heschl’s gyrus

One of several transverse ridges on the upper side of the temporal lobe of the brain that are associated with the sense of hearing. [Richard Heschl (1824–1881), Austrian pathologist who first traced the auditory pathways of humans to this convolution]

heteral fantasy

A fantasy in which a woman plays the role of a courtesan. In the male version of the fantasy, the man possesses a courtesan. Also called courtesan fantasy. Also called courtesan fantasy.

hetero- combining form other or different.

heterochronic iridocyclitis

See iridocyclitis.

heterochrony

n. 1. A difference in the rate of two processes, such as the conduction of nerve impulses. 2. Any evolutionary change in the relative time of appearance of maturational features or events or in the rate of development of an organism. Also called heterochronia.

heteroeroticism

n. An attraction toward the opposite sex, as in heterosexuality. Compare homosexualism. Also called heteroerotic. —heteroerotic adj.

heterogametic

adj. Referring to the sex that has two different sex chromosomes, such as the male sex in mammals and the female sex in birds. Compare homogametic.

heterogamy

n. A marriage between partners from dissimilar ethnic, racial, religious, educational, or socioeconomic backgrounds. Compare homogamy.

heterogeneity

n. The quality of having very different characteristics or values. For example, HETEROGENEITY OF VARIANCE is present in an analysis of variance when the average squared distance of each score from the mean differs for each group in the study (e.g., control group vs. treatment group). Compare homogeneity.

heterogeneity of variance

The situation in which the variance of a random variable is different at each level or value of another variable. Var(x|y) is not the same for all values of x; that is, the variance in y is a function of the variable x. Heterogeneity of variance violates one of the basic assumptions of regression analysis and other statistical procedures. Also called heteroscedasticity. Compare homogeneity of variance.

heterogeneous group

An aggregate of individuals or other elements that are different from one another in a number of significant respects. In a social context, for example, a heterogeneous group might differ in age, socioeconomic background, values, work experience, education, and so on. In an educational context, heterogeneous groups may be entire classes or smaller groups of students of varying ability who work together in a specific area, such as art or reading. Compare homogeneous group.

heterohypnosis

n. A state of hypnosis induced in one person by another. Compare self-hypnosis.

heterolalia

n. See heterophemy.

heteromorphosis

n. 1. Abnormal shape or structure. 2. The development of a regenerated organ or structure that is different from the one that was lost.

heteronomous adj. Under the control of or influenced by various external factors. Compare autonomous.

heteronomous stage

In Jean Piaget’s theory of moral development, the stage during which the child, approximately 6 to 10 years of age, equates morality with the rules and principles of his or her parents and other authority figures. That is, the child evaluates the rightness or wrongness of an act only in terms of adult sanctions for or against it and of the consequences or possible punishment it may bring. Also called heteronomous morality. See also immanent justice; moral absolutism; moral realism. Compare autonomous stage; premoral stage.

heteronomy

heteronormativity

n. The assumption that heterosexuality is the standard for defining normal sexual behavior and that male–female differences and gender roles are the natural and immutable essentials in normal human relations. According to some social theorists, this assumption is fundamentally embedded in, and legitimates, social and legal institutions that devalue, marginalize, and discriminate against people who deviate from its normative principles (e.g., gay men, lesbians, bisexuals, transgendered persons). See also heterosexism. [Coined in 1991 by U.S. social theorist Michael Warner]

heteronymous hemianopia

A visual field defect in which vision in either the left or right half of both eyes is absent due to a lesion in the optic chiasm. See hemianopia.

heteronymous reflex

A reflex elicited by stimulation in one muscle of a synergistic group that results in contraction of another muscle in the same group. Compare homonymous reflex.

heterophony

n. The act of saying or writing a word or phrase other than the words intended. Often, the substitu-
tion conveys the opposite meaning to what the individual intended. Also called heterolalia: heterophasia: heterophemia. See also freudian slip; slip of the tongue.

heterophilia n. love of, or attraction to, members of the opposite sex.

heterophily n. 1. any tendency for individuals who differ from one another in some way to make social connections. It is less common than homophily. Complementarity, which occurs when people with different but complementary characteristics form a relationship, is an example of heterophily. 2. the degree of dissimilarity between individuals who share social ties.

heterophoria n. the deviation of an eye because of an imbalance in the extrinsic eye muscles.

heteroscedasticity n. see HETEROGENEITY OF VARIANCE.

heterosociality n. relationships on a social (rather than a sexual or romantic) level between people of opposite sexes.

heterostasis n. an organism’s seeking of maximal stimulation. [defined by A. Harry Klopf]

heterotopia n. the congenital development of gray matter in the area of the brain and spinal cord normally consisting of white matter.

heterotropia n. see STRABISMUS.

heterozygous adj. possessing different forms of a gene (i.e., different alleles) at a given genetic locus on each of a pair of homologous chromosomes. One allele is inherited from the mother and the other from the father. In such individuals, the dominant allele is expressed, and the recessive allele is not. Compare HOMOZYGOUS.

Heyman's law the generalization that sensitivity to one stimulus decreases with increases in the intensity of another concurrent stimulus. [Cornelle Heymans (1892–1968), Belgian physiologist]

Heywood case any correlation coefficient, regression coefficient, factor loading, or similar parameter estimate having a value that is impossible or very rare (e.g., a negative ERROR variance estimate). Heywood cases may indicate any of the following: a sample that is too small to adequately estimate the parameters; data that do not have a normal DISTRIBUTION or that contain OUTLIERS; a misspecified model that is not appropriate for the data; or a parameter whose true value is so close to a boundary (e.g., 1 or 0) in the population that its estimate exceeded this limit due to sampling fluctuation.

HFA abbreviation for HIGH-FUNCTIONING AUTISM.

HGPRT abbreviation for HYPOXANTHINE–GUANINE PHOSPHORIBOSYLTRANSFERASE.

5-HIAA abbreviation for 5-HYDROXYINDOLEACETIC ACID.

hibernation n. a period of inactivity accompanied by a significant decrease in body temperature that occurs in certain warm-blooded vertebrates in temperate or arctic environments during winter. Body temperature may drop to within a few degrees of freezing. Activity of endocrine glands decreases during this period, but no single gland has been found to control hibernation. Some species (e.g., bears) consume large quantities of food before hibernation and maintain bodily functions with energy from fat deposits, but others (e.g., golden hamsters) store food and leave hibernation periodically to feed. Cold-blooded animals become dormant in cold temperatures.

Hick’s law in experiments or tasks involving CHOICE REACTION TIME, the finding that the time required to classify a stimulus as being from a particular set increases proportionally with the number of stimuli in the set. Also called Hick–Hyman law. [William Edmund Hick (1912–1974),
hidden-clue test

British psychologist; Ray Hyman (1928– ). U.S. cognitive psychologist

**hidden-clue test** a test in which the participant must discover a particular feature of the stimulus situation that is the clue to a reward.

**Hidden Figures Test** see EMBEDDED FIGURES TEST.

**hidden grief** see DISENFRANCHISED GRIEF.

**hidden observer** an intrapsychic entity with awareness of experiences that occur outside of an individual’s consciousness, hypothesized to explain the dissociative phenomenon in which a hypnotized person who has been told to block certain stimuli (e.g., pain induced by ice-cold water) still registers the blocked sensation via hand signals even while verbally denying it. It is as if a dissociated observer is registering the stimuli that the hypnotized person has successfully blocked. Posthypnotically, such individuals may recall auditory, visual, or tactile stimuli to which they appeared oblivious at the time. See also NEODISSOCIATION THEORY. [investigated by Ernest R. Hilgard]

**hidden profile task** a group problem-solving task whose solution can only be obtained when group members effectively pool their individual information about alternatives. A hidden profile is said to exist when the group collectively has more information supporting one alternative over others, but the superiority of this alternative is obscured from individual members unless information is shared. [first identified in 1985 by U.S. social psychologists Harold Stasser (1947– ) and William Titus]

**hidden variable** an undiscovered causative variable. When a relationship is found between variables \( x \) and \( y \), variable \( x \) may erroneously be thought to be the cause of \( y \). However, the cause of \( y \) may be a hidden variable \( z \) that is correlated with variable \( x \). Also called lurking variable; third variable. See third-variable problem.

**hierarchical clustering** a multistage procedure in which entities are grouped into ever larger and more heterogeneous clusters or separated into ever smaller and more homogeneous clusters (see cluster analysis). The most common form of hierarchical clustering is agglomerative clustering, in which the individual entities are first paired, then these pairs are paired, and so on until ultimately all entities form a single large group or cluster. A second form of hierarchical clustering is divisive clustering, in which all entities initially are part of one large group which is split into progressively smaller groups according to dissimilarity until ultimately each entity is in its own group or cluster. The outcome of both types of hierarchical clustering may be represented graphically as a dendrogram.

**hierarchical design** see hierarchically nested design.

**hierarchical linear model (HLM)** a statistical model that acknowledges different levels in the data, such that individuals or entities within each level have correlated scores. The model enables a researcher to test hypotheses about cross-level effects and partition the variance and covariance components among levels. For example, hierarchical linear models often are used in educational research since they can account for the fact that students within a classroom will behave similarly, as will classrooms within the same school, and so on up the hierarchy of levels. Also called multilevel model.

**hierarchically nested design** any research design that involves several levels of sampling, such that the entities on the lower levels of the design are nested or subsumed within higher order groups. For example, a hierarchically nested design for an educational study might involve students (A), who are nested within classrooms (B), which are nested within schools (C), which are further nested within school districts (D). Several statistical procedures (e.g., analysis of variance, regression analysis, hierarchical linear models) also incorporate a hierarchical aspect. Also called hierarchical design: nested design.

**hierarchical model** a statistical procedure that takes into account situations in which lower level variables or entities are part of a larger set or sets. For example, a hierarchical factor analysis model posits that relationships among a subset of lower level primary variables (e.g., verbal, mathematical, and social intelligence) can be explained by a higher order or general factor (e.g., general intelligence). Similarly, a hierarchical linear model is a particular type of hierarchical model that includes several levels of actual variables as components of a progressively larger overall set. Also called nested model.

**hierarchical model of personality** a model of either within-person dynamics or individual differences in personality in which some psychological constructs are viewed as high-level variables that organize or govern the functioning of other lower level variables. For example, a hierarchical model of personality traits might view the construct sociability as being at a lower level in a hierarchy than the construct extraversion; sociability would be seen as a form or example of the higher level trait of extraversion.

**hierarchical regression** a statistical procedure in which hypothesized predictors of a dependent variable are included in an analysis in several steps that illuminate the contribution of each set of variables. For example, a researcher interested in predicting career satisfaction could use hierarchical regression to assess the contribution of individual-level variables (e.g., career influence), institutional-level variables (e.g., work climate), and interactional-level variables (e.g., work respect). Also called hierarchical multiple regression; hierarchical regression analysis: sequential regression. See also multiple regression. Compare simultaneous regression.

**hierarchical theory of intelligence** any theory of intelligence postulating that the abilities constituting intelligence are arranged in a series of levels (of a hierarchy) ranging from general to specific. Many of these theories are based on recognizing three levels of factors, first proposed by U.S. psychologist Karl J. Holzinger (1892–1954): (a) the general factor; applying to all intellectual tasks; (b) group factors, which apply to some but not all intellectual tasks; and (c) specific factors, applying to individual tasks. Examples of such theories are the three-stratum model of intelligence and the Cattell–Horn theory of intelligence.

**hierarchization** n. in PRAEGETIAN THEORY, the process whereby each current cognitive structure can be traced to earlier, more primitive structures that were necessary for the attainment of the more advanced structure.

**hierarchy** n. 1. a clear ordering of individuals on some behavioral dimension, such as dominance-submission. A linear hierarchy occurs when all individuals can be arrayed in a strict transitive order along a continuum (see dominance hierarchy; organizational hierarchy),
Often, however, a hierarchy is more complex, with some individuals having equal status or acting in coalitions, or with ordering based on different factors (see animal dominance). In neuroscience, an organization of control systems such that one area of the brain controls another, which in turn may control neuromuscular action.

**Hierarchy-legitimizing myth** see social dominance theory.

**Hierarchy of motives (hierarchy of needs)** see maslow’s motivational hierarchy.

**Hierarchy of response** see response hierarchy.

**High** n. slang for the subjective feelings of intoxication experienced following ingestion of psychoactive drugs.

**High-altitude cerebral edema** see acute mountain sickness.

**High blood pressure** see hypertension.

**High chromaticity** see color purity.

**High brain center** loosely, any part of the cerebrum associated with cognitive processes, such as learning and memory.

**High level skill** a work method or ability that can be applied to many tasks rather than one particular task.

**Higher mental process** any of the more complex types of cognition, such as thinking, judgment, imagination, memory, and language.

**Higher order conditioning** in classical conditioning, a procedure in which the conditioned stimulus of one experiment acts as the unconditioned stimulus of another, for the purpose of conditioning a neutral stimulus. For example, after pairing a tone with food, and establishing the tone as a conditioned stimulus that elicits salivation, a light could be paired with the tone. If the light alone comes to elicit salivation, then higher order conditioning has occurred.

**Higher order consciousness** nonsensory conscious experiences, including abstract ideas, language-dependent thinking, and self-consciousness. Compare sensory consciousness. Proposed by U.S. neuroscientist Gerald M. Edelman (1929–2014) and others.

**Higher order construct** any large, coherent construct that is used to organize information and to integrate it into one’s general knowledge.

**Higher order correlation** see partial correlation.

**Higher order design** any research design that attempts to understand a phenomenon by assessing the separate and joint effects of several factors at once. For example, an experiment could be conducted to assess the effect of a treatment condition versus a control condition on cognitive functioning while simultaneously assessing the influence of gender; this would allow an assessment of the main effects for each factor (treatment condition and gender) as well as the interaction between them.

**Higher order interaction** in an analysis of variance, the joint effect of three or more independent variables on the dependent variable. For example, a researcher could conduct a study to assess the effect of a particular treatment (e.g., treatment vs. no treatment) as well as the effect of education level and socioeconomic status on cognitive functioning. This design would allow an examination of the main effects for treatment, education, and socioeconomic status individually; the two-way interaction between treatment and education, education and socioeconomic status, and treatment and socioeconomic status; and the higher order three-way interaction between treatment, education, and socioeconomic status.

**Higher order processes** see executive functions.

**Higher order thought** often, a synonym for conscious thought: any of the deliberate, complex cognitive processes of which one is explicitly aware and that are crucial to one’s intentional action and other self-referential activities. Higher order thought thus may be considered equivalent to executive functions and includes any of a variety of acts that involve the access and manipulation of self-knowledge, such as conceptualization, evaluation, introspection, and reflection. U.S. philosopher David M. Rosenthal has extended this idea into higher order thought theory, which specifies that a mental state is conscious only if one thinks deliberately about it such that one knows the state is being experienced and can report on it. Others (e.g., U.S. philosopher William G. Lycan [1945–]) advocate a higher order perception theory, in which consciousness arises from self-monitoring by a quasi-perceptual faculty; still others (e.g., U.S. philosopher Rocco J. Gennaro) propose a higher order global state theory, in which meta-activity is key.

**Higher response unit** a complex response or act consisting of multiple simple responses or acts.

**High-functioning autism (HFA)** a controversial, nonstandardized classification describing individuals who meet the DSM–IV–TR diagnostic criteria for autism but who have higher IQs and less severe impairment than seen in others with the disorder. Compare low-functioning autism. See also asperger’s disorder. [first described in 1943 by Austrian-born U.S. child psychiatrist Leo Kanner (1894–1981)]

**High-involvement management** an approach to managing organizations that attempts to tap the potential of employees by obtaining input from them on decisions, sharing information about the business with them, providing training to enhance their skills, and providing incentives for becoming skilled and committed. [described by U.S. management theorist Edward E. Lawler III (1938–)]

**High-pass filter** see filter.

**High-potency antipsychotic** any of various conventional antipsychotics that have either a relatively high degree of affinity for the dopamine D2 receptor or significant extrapyramidal symptoms. High-potency antipsychotics include fluphenazine, haloperidol, thiothixene (see thioxanthene), trifluoperazine, and pimozide.

**High resolution** the ability to distinguish as separate entities two stimuli that are very close to one another in some dimension.

**High risk** significantly heightened vulnerability to a disorder or disease. An individual’s risk status is influenced by genetic, physical, and behavioral factors or conditions. For example, children of a parent with bipolar disorder have a much greater risk of developing the disorder than other children, and individuals who engage in unprotected sex are at high risk of contracting HIV and other sexually transmitted diseases.

**High-risk design** a research design used to study individuals or groups in which there is thought to be a high probability of some disorder. For example, a high-risk design could be used to study families in which one or more
individuals have bipolar disorder so as to gauge the likelihood of additional family members subsequently experiencing the disorder.

**High School Personality Questionnaire (HSPQ)** a 142-item self-report inventory of 14 personality dimensions in adolescents ages 12 to 18. The dimensions include warmth, intelligence, emotional stability, excitability, dominance, cheerfulness, conformity, boldness, sensitivity, withdrawal, apprehension, self-sufficiency, self-discipline, and tension. [developed in 1958 by psychologists Raymond B. Cattell, Halla Beloff (1930– ), and Richard W. Coan (1928–)]

**high-technology assistive device** a device using complex electronics, such as a computerized communication system or a motorized wheelchair, to enhance the functional capabilities of individuals with disabilities. The device may require individualized adaptation and training. See ASSISTIVE TECHNOLOGY.

**high threshold** a threshold that is never exceeded unless a signal is present. Classical psychophysics assumes a high threshold, although some psychophysical models combine high thresholds with low thresholds, which can be exceeded by random noise.

**highway hypnosis** a colloquial name for accident proneness resulting from a state of drowsy inattention experienced during long-distance driving on monotonous roads.

**hilus** n. see DENTATE GYRUS.

**hindbrain** n. the posterior of three bulges that appear in the embryonic brain as it develops from the NEURAL TUBE. The bulge eventually becomes the MEDULLA OBLONGATA,pons,and CEREBELLM. Also called ROMBENCÉPHALON.

**hindsight bias** the tendency, after an event has occurred, to overestimate the extent to which the outcome could have been foreseen. Hindsight bias stems from (a) cognitive inputs—people selectively recall information consistent with what they now know to be true; (b) metacognitive inputs—people may misattribute their ease of understanding an outcome to its assumed prior likelihood; and (c) motivational inputs—people have a need to see the world as orderly and predictable.

**Hindu caste system** see CASTE.

**Hinduism** n. the name, invented by Europeans, for the religion of the majority of the inhabitants of the Indian subcontinent. Indians who are not followers of the distinct teachings of Islam, Jainism, or Sikhism are generally referred to as Hindus. In India, the religious complex of such people is called sanatana-dharma, “the eternal religion,” because it has incorporated all aspects of truth for many centuries. As a religion based on mythology, it has neither a founder nor a fixed canon. Myriad local cults and traditions of worship or belief can be distinguished. Common to all Hindus, however, is the teaching of the law of KARMA. The three most significant devotional movements in present-day Hinduism are Vaishnavism, devoted to the god Vishnu; Shaitism, devoted to the god Shiva; and Tantrism, or Shaktism, devoted to the goddess Shakti. Tantrism is of particular interest in psychology in that Shakti is the personification of the fundamental creative force whose primary expression is the sexual energy that unites the polarity of male and female and brings forth new life.

**hinge** n. in EXPLORATORY DATA ANALYSIS, either of the scores in a data set that divide the lower 25% of cases (the lower hinge) and the upper 25% of cases (the upper hinge) from the remainder of the cases.

**hippie (hippy)** n. a member of a 1960s and 1970s SUBCULTURE of mainly young people who rejected mainstream Western society and its values of work, consumerism, and material success in favor of an alternative lifestyle characterized by free love, communal living arrangements, and recreational drug use. The hippie philosophy was essentially one of pacifism and pleasure. See also COUNTERCULTURE; DRUG CULTURE; YOUTH CULTURE.

**hippocampal formation** a region of the brain located in the medial temporal lobe and concerned with the consolidation of long-term memory. It comprises the DENTATE GYRUS, HIPPOCAMPUS, and SUBICULUM and communicates with areas of neocortex via the ENTORHINAL CORTEX.

**hippocampal gyrus** see SUBICULUM.

**hippocampus** n. (pl. hippocampi) a seahorse-shaped part of the forebrain, in the basal medial region of the TEMPORAL LOBE, that is important for DECLARATIVE MEMORY and learning. Because of its resemblance to a ram’s horn, 19th-century neuroanatomists named it Ammon’s horn (cornu ammonis: CA) for the horn of the ram that represented the Egyptian deity Ammon. Parts of the hippocampus were then labeled CA1, CA2, CA3, and CA4; these designations are still used for the different regions of the hippocampus. See HIPPOCAMPAL FORMATION; PAPER CIRCUIT. —hippocampal adj.

**hippotherapy** n. the therapeutic use of horses to help people with physical and developmental disabilities improve their balance, coordination, posture, and mobility. During each 30-minute hippotherapy session, the client sits or lies on the horse, and a therapist evaluates and positively influences the client’s neuromuscular responses to the animal’s movement while an equine handler adjusts its gait, tempo, and direction. One or two sidewalkers next to the horse accompany the client for safety purposes. The therapists who conduct such sessions are specially trained physical, occupational, and speech and language therapists who offer hippotherapy as part of their broader, occupation-specific spectrum of activities. The handlers themselves are hippotherapy-certified. The therapy is most commonly used for people with autism, cerebral palsy, Down syndrome, multiple sclerosis, muscular dystrophy, spina bifida, spinal cord injury, stroke, and traumatic brain injury. In addition to its physical benefits, it often improves the client’s affect, self-confidence, communication skills, spatial awareness, SENSORY INTEGRATION, and social interaction. Hippotherapy is distinct from EQUINE-ASSISTED PSYCHOTHERAPY, which uses horses to help clients achieve personal and relational change. See also ANIMAL-ASSISTED THERAPY.

**HIPS** abbreviation for Harvey Impostor Phenomenon Scale. See IMPOSTOR PHENOMENON.

**hiricine** adj. in the ZWAARDEMAKER SMELL SYSTEM, denoting a quality that is smelled in goaty odors and rancid fat. See also CAPRYLIC.

**hired gun** a colloquial name for an expert witness who testifies in a manner that best suits his or her client, with little regard for any inaccuracies or misrepresentations of fact that might occur.

**HIS** abbreviation for healthcare information system. See INFORMATION SYSTEMS.

**Hispanic/Latino** adj. describing a person whose ances-
try, at least in part, can be traced to countries of Latin America or to Spain. The category Hispanic/Latino is racially diverse and thus is considered an ethnic category rather than a race.

**histamine** *n.* A compound that is synthesized from the amino acid histidine by the enzyme histidine decarboxylase. Most histamine in humans is localized in peripheral tissues, where it is involved in allergic reactions or the inflammatory response to injury, causing dilation of blood vessels. In the brain, histamine acts as a neurotransmitter to modulate such functions as arousal, appetite, and regulation of autonomic functions. [Histamine receptors](#) can be divided into three categories, designated H₁, H₂, and H₃ receptors. Many antidepressants and antipsychotics may block histamine receptors in the brain, causing sedation and other side effects.

**histamine antagonist** see [ANTIHISTAMINE](#).

**histamine headache** see [CLUSTER HEADACHE](#).

**histogenesis** *n.* The formation of body tissues.

**histogram** *n.* A graphical depiction of continuous data using bars of varying height, similar to a [BAR GRAPH](#) but with blocks on the x-axis adjoining one another so as to denote their continuous nature. For example, to show the average credit card debt of individuals, bars along the x-axis would represent amount of debt and would be connected to one another, while the heights of the bars would represent the number or frequency of individuals with each debt amount.

**histology** *n.* The scientific study of the microscopic structure and organization of body tissues. —histological adj. —histologist *n.*

**historical analysis** Research that examines past events to understand current or future events. For example, researchers could perform a historical analysis of an individual’s or a family’s substance use experiences to understand the present substance use behavior of that person or group.

**historical control group** A control group whose participants are selected to be similar to those in the treatment group on the basis of data collected sometime in the past.

**historical fallacy** An error of interpretation in which one reads into a process, either as a cause or an essential element, what only comes about as the result of the process. For example, a man has lost his wallet but can think of several places where he might have left it. When he finds it in the first place that he looks, he assumes falsely that he knew where the wallet was all along. His error is to suppose that a state of affairs arising from the process of looking (knowing where the wallet is) was in fact the cause of the process. The term was introduced by John Dewey in his classic paper, “The Reflex Arc Concept in Psychology” (1896), where he argued that psychology was committing this fallacy in its attempts to isolate one set of events termed responses from another set termed stimuli and to show that the former result from the latter. See also [VERSE CAUSALITY](#).

**historical linguistics** The study of how language evolves and changes over time. See also [COMPARATIVE LINGUISTICS](#); DIACHRONIC LINGUISTICS; GENETIC LINGUISTICS; [PHILOLOGY](#).

**historical method** The technique of analyzing, counseling, or otherwise offering therapy by focusing on a client’s personal history.

**historical prospective study** A research project that examines longitudinal data obtained in the past to track the incidence of a particular disorder over time and its association with various risk factors. For example, a researcher could examine the health records of smokers and nonsmokers to follow the path of an illness from before its manifestation through to its diagnosis and treatment. It is distinct from [PROSPECTIVE RESEARCH](#) generally, which begins with individuals who are apparently healthy in the present and moves forward to investigate whether a specific disorder will occur over time.

**historical psychoanalysis** See [PSYCHOHISTORY](#).

**historical trauma** See [INTERGENERATIONAL TRAUMA](#).

**historicism** *n.* 1. The belief that the study of history can reveal general laws governing historical events and social and cultural phenomena and that these laws may allow for predictions of the future. 2. The notion that beliefs, values, and cultural products are determined by their historical context and can only be understood in this context.

**history effect** The influence of events or circumstances outside an experiment on an outcome variable of interest. [Quasi-experimental research](#) often attempts to take history effects into account in order to rule out potential [CONFOUNDS](#) to a posited or apparent link between two variables. An example would be the occurrence of an actual earthquake during a field study of the effects of training in earthquake preparedness; this would likely increase news coverage of earthquakes, thereby resulting in greater knowledge dissemination outside of the training program.

**history taking** The process of compiling background information about a patient or research participant. Information can be obtained from the individual directly and from other sources, such as the individual’s family, hospitals or clinics, psychiatrists or psychologists, neurologists, social workers, and others who have direct knowledge of the individual. See [ANAANEMESIS](#).

**histrionic personality disorder** In [DSM–IV–TR](#) and [DSM–V](#), a personality disorder characterized by a pattern of long-term (rather than episodic) self-dramatization in which individuals draw attention to themselves, crave activity and excitement, overreact to minor events, experience angry outbursts, and are prone to manipulative suicide threats and gestures. Such individuals appear to others to be shallow, egocentric, inconsiderate, vain, demanding, dependent, and helpless. The disorder was formerly known as [HYSTERICAL PERSONALITY DISORDER](#).

**hit** *n.* The accurate identification of a signal in a signal detection task. Compare [MISS](#).

**HIIT** Acronym for [HOLTZMAN INKBLOT TECHNIQUE](#).

**hit rate** In signal detection tasks, the proportion of trials in which a signal is present and the participant correctly responds that it is.

**HIV** Human immunodeficiency virus: A parasitic agent in blood, semen, and vaginal fluid that destroys a class of lymphocytes with a crucial role in the immune response. HIV infection can occur by various routes—unprotected sexual intercourse, administration of contaminated blood.
products, sharing of contaminated needles and syringes by intravenous drug users, or transmission from an infected mother to her child in utero or through breast-feeding—and is characterized by a gradual deterioration of immune function that can progress to AIDS. The diagnosis of HIV infection remains stigmatizing in some cultures and can result in considerable emotional stress and social ostracism.

HIV/AIDS counseling see AIDS COUNSELING.

HIV dementia see AIDS DEMENTIA COMPLEX.

Hives n. a temporary inflammation of the skin marked by outbreaks of burning and itching swellings. The condition may be caused by psychogenic factors or by an allergy, such as to a food. Also called urticaria.

Hi-Wa itch a CULTURE-BOUND SYNDROME found in Mohave American Indian populations that includes symptoms such as depression, insomnia, loss of appetite, and sometimes suicide associated with unwanted separation from a loved one; it generally affects the young wife of an older Mohave male.

HLM abbreviation for HIERARCHICAL LINEAR MODEL.

HM the initials of a patient, Henry Molaison (1926–2008), who became amnesic after undergoing bilateral temporal lobectomy in 1953 for the relief of intractable seizures. The case of HM, who was a patient of U.S. neurologist William Beecher Scoville (1906–1984), demonstrated the critical role of the HIPPOCAMPUS and surrounding structures in the process of memory formation and storage.

hMG abbreviation for HUMAN MENOPAUSAL GONADOTROPIN.

HMO health maintenance organization: a health plan that offers a range of services through a specified network of health professionals and facilities to subscribing members for a fixed fee. Members select a primary care provider who coordinates all care and authorizes all services. Services may need further approval from the HMO utilization department, who coordinates all care and authorizes all services. The HMO is reimbursed through fixed, periodic prepayments (capitated rates) by, or on behalf of, each member for a specified period of time. HMOs may subcapsulate, or CARVE OUT, certain services, such as mental health, to other groups. See CAPITATION.

Hoarding n. 1. the carrying and storing of food or other items believed necessary for survival, which has been identified as either instinctive behavior, learned behavior, or both. For example, hoarding by rodents varies with the environmental temperature, increasing when the temperature falls and decreasing as the temperature rises. See FOOD CACHING, 2. a compulsion that involves the persistent collection of useless or trivial items (e.g., old newspapers, garbage, magazines) and an inability to organize or discard these. The accumulation of items (usually in piles) leads to the obstruction of living space, causing distress or impairing function. Any attempt or encouragement by others to discard hoards causes extreme anxiety. It is formally recognized as hoarding disorder in DSM-5, where it is listed in the same diagnostic category as OBSESSIVE-COMPULSIVE DISORDER and related disorders. See also CLUTTERING.

Hoarding orientation in the existential psychoanalysis of Erich Fromm, a character pattern in which the individual doubts that personal needs can ever be completely satisfied and bases his or her sense of security on what he or she can save and own. The character is thought to be rigid, stubborn, and obsessively orderly. Also called hoarding character. See also ANAL PERSONALITY. Compare EXPLOITATIVE ORIENTATION; MARKETING ORIENTATION.

Hoarseness n. an abnormally rough, harsh, or strained quality in the voice that may be produced by any interference with optimal adduction of the vocal cords, including that caused by overuse of the voice, damage to the larynx, or such disorders as gastric reflux and thyroid disease.

Hoffmann’s sign a sign of brain disease in individuals with HEMIPLEGIA: Flicking or nipping the nail of the second, third, or fourth finger will, if the reflex is present, cause a flexion in these fingers and the thumb. Also called Hoffmann’s reflex. [Johann Hoffmann (1857–1919), German neurologist]

hol- combining form see Holo-, hold functions cognitive abilities—such as those involved in vocabulary and verbal knowledge—that typically remain stable throughout much of the adult lifespan or improve with aging, as observed on intellectual or cognitive tests (e.g., the WECHSLER ADULT INTELLIGENCE SCALE). Compare DON’T-HOLD FUNCTIONS.

holding environment 1. in the OBJECT RELATIONS THEORY of British psychoanalyst Donald Winnicott (1896–1971), that aspect of the mother experienced by the infant as the environment that literally—and figuratively, by demonstrating highly focused attention and concern—holds him or her comfortably during calm states. This is in contrast to the mother who is experienced as the object of the infant’s excited states. 2. in psychoanalysis, any therapeutic space that allows an emotionally fragile or insecure person to deal with affects that might potentially be overwhelming.

Holdover effect see CARRYOVER EFFECT.

Holiday syndrome the sadness, anxiety, and pessimism that often occur during major holiday periods. Severe depression, serious injuries, suicides, and fatal accidents tend to increase during these periods. Also called holiday blues.

Holism n. any approach or theory holding that a system or organism is a coherent, unified whole that cannot be fully explained in terms of individual parts or characteristics. The system or organism may have properties as a complete entity or phenomenon in addition to those of its parts. Thus, an analysis or understanding of the parts does not provide an understanding of the whole. —Holistic adj.

Holistic education a form of psychotherapy, derived from the approach of HOLISTIC HEALTH, in which the therapist serves as a teacher and the client as student. The therapist aims to create conditions in which the student may choose to learn. For maximum growth, all aspects of the client’s physical, spiritual, emotional, and intellectual life are explored and developed. [developed by U.S. psychologist William C. Schutz (1925–2002)]

Holistic healing a health care concept based on the premise that body, mind, and spirit function as a harmonious unit and that an adverse effect on one also adversely affects the others, requiring treatment of the whole to restore the harmonious balance.

Holistic health a concept that medical practice, in the prevention and treatment of disease, should focus on the whole person—including physical, mental, spiritual, social, and environmental aspects—rather than on disease.
symptoms alone. Major features of holistic health include patient education about behavioral and attitudinal changes that promote and maintain good health and well-being, and patient self-help and participation in the healing process through diet, exercise, and other measures. It is often practiced in tandem with conventional medicine (e.g., medication, surgery) and with COMPLEMENTARY AND ALTERNATIVE MEDICINE. Also called holistic medicine.

holistic psychology an approach to psychology based on the view that psychological phenomena must be studied as wholes, or that individuals are biological, psychological, and sociocultural totalities that cannot be fully explained in terms of individual components or characteristics. Holistic psychology is not a specific school but a perspective that informs the theories, methodologies, and practice of certain approaches, such as HUMANISTIC PSYCHOLOGY and CLIENT-CENTERED THERAPY.

Hollingshead scales several measures of individual socioeconomic status based on education and occupation. They include the Hollingshead Four-Factor Index of Social Status and the earlier Hollingshead Two-Factor Index of Social Position. [August B. Hollingshead (1907–1980), U.S. sociologist]

hollow-square puzzle an exercise sometimes used in team-building interventions designed to enhance collaboration and communication. The task requires the group to assemble a model from various constituent pieces, some of which are shared among the group and some of which are held by individual group members.

Holmes’s phenomenon see REBOUND PHENOMENON. [Gordon M. Holmes (1876–1965), British neurologist]

Holmgren Test for Color Blindness one of the first standardized tests for color blindness, which required the participant to match skeins of colored yarns with standard skeins. [devised in 1879 by A. Frithiof Holmgren (1831–1897), Swedish physiologist]

holo- (hol-) combining form entire or complete.

hologram n. an interference pattern that appears as a three-dimensional image of an object.

holographic brain theory a model of brain function suggesting that neuronal processes operate by means of fieldlike states of wave interference similar to holograms. Also called holonomic brain theory. [originated by Karl H. Pribram]

holography n. a method of producing three-dimensional images by using interference patterns made by light waves. The technique is used in photography and has been suggested as an explanation for the process by which images may be formed in the mind. —holographic adj.

holonomic brain theory see HOLOGRAPHIC BRAIN THEORY.

holophrase n. one of the single-word utterances characteristic of children in the early stages of LANGUAGE ACQUISITION, such as da-da or yes. These are considered to involve a SPEECH ACT going beyond the literal meaning of the single word so that, for example, cookie means I want a cookie now. See RICH INTERPRETATION. —holophrastic adj.

holophrastic stage see ONE-WORD STAGE.

Holzman Inkblot Technique (HIT) a PROJECTIVE TECHNIQUE using two parallel forms of 45 inkblots that are scored based on 22 variables relating to perception and personality. Used in both personality research and clinical assessment, the technique is similar to the RORSCHACH INKBLOT TEST and was designed to overcome the psychometric limitations of that instrument. [developed in 1961 by U.S. psychologist Wayne H. Holzman (1923— ) and colleagues]

hom- combining form see HOMO-.

HOME acronym for HOME OBSERVATION FOR MEASUREMENT OF THE ENVIRONMENT.

home and community-based services (HCBS) care or services provided in a patient’s place of residence or in a noninstitutional setting located in the community. The aim is to help individuals of all ages with disabilities to live in the community, thereby avoiding more costly residential placements. In the United States, the primary means by which such services are funded is the Home and Community-Based Services Waiver (or Medicaid Waiver) program. Through this waiver, the federal government reimburses states for a percentage of their spending on designated community services, such as DAY HABILITATION, RESIDENTIAL HABILITATION, and service coordination. These services are defined in a flexible manner; they can be tailored to the specific needs of individuals enrolled in the waiver, allowing appropriate services to be provided to people with greatly varying requirements.

home-based reinforcement an intervention in which a teacher provides notes about a student’s inappropriate classroom behavior or poor academic performance to his or her parents, who in turn use rewards (e.g., tangible items, earned privileges, verbal praise) and sanctions (e.g., TIME OUT, loss of privileges) to encourage positive change. Research has shown that numerous benefits arise from parents and teachers working together in this way: Students tend to earn higher grades, perform better on tests, attend school more regularly, have better behavior, and show more positive attitudes toward themselves and toward school.

home cage a cage in which a nonhuman animal is housed when it is not engaged in an experimental session.

home care patient care in the home for people with physical or mental disabilities, including older adults with dementia or bodily weakness. Home care is an alternative to institutionalization, enabling the patient to live in familiar surroundings and preserve family ties. Services such as nursing care, administration of medication, therapeutic baths, physical therapy, and occupational therapy are provided by visiting professionals or paraprofessionals connected with clinics, hospitals, or health agencies. Also called home health care.

home health aide a specially trained person who works with a SOCIAL SERVICES agency or a local VISITING NURSE association to provide personal care services, such as bathing, light meal preparation, and dressing, to people with disabilities. See also HOMEMAKER HOME HEALTH AIDE.

home health care see HOME CARE.

homelessness n. the condition of being without a permanent residence due to economic inability or mental or physical incapacity to maintain a residence, housing shortages, barriers to accessing adequate, affordable housing, or any combination of these and other factors. Occurring in towns and smaller communities as well as major cities, homelessness is a complex social problem with no single explanation for its occurrence. Contributing factors tend to
be categorized as structural or individual. Structural causes relate to large-scale societal issues, such as unemployment and poverty, the housing market, and the general state of the economy. Individual causes are more personal or interpersonal, such as illness, recent incarceration, or family conflict. Research has shown that homeless people have higher rates of substance abuse, mental disorders (e.g., depression, anxiety, schizophrenia), cognitive deficits, and behavioral difficulties as well as poor self-esteem and poor self-efficacy. Disabilities and various medical conditions (e.g., cardiorespiratory disease, diabetes, sexually transmitted disease) are common as well. Some of these factors are also among the potential consequences of homelessness. Other effects include discrimination and social rejection, increased vulnerability to trauma or violent crime (e.g., assault), and greater likelihood of premature death.

**homemaker home health aide** A home health aide who assists people with disabilities in homemaking tasks, personal care, and rehabilitation routines in their own homes, through a private or public agency.

**homeo-** Combining form similar or like.

**Home Observation for Measurement of the Environment (HOME)** A measure of the quality and extent of stimulation available to a child in the home environment. It is available in four versions: infant/toddler (birth to 3 years), early childhood (3–6 years), middle childhood (6–10 years), and early adolescent (10–15 years). Each version contains both observational and parent-reported items that provide a detailed analysis of characteristics of the home (parental responsiveness, play materials, etc.) that are hypothesized to be associated with a child’s cognitive development. Originally published in 1967, the HOME was revised in 1984. [developed by U.S. childcare specialist Bettye M. Caldwell (1924–) and U.S. educational psychologist Robert H. Bradley (1946–)]

**homeopathy** n. A system of medicine based on the belief that “like cures like.” Small, highly diluted quantities of substances are given to cure symptoms when the same substances given at higher or more concentrated doses would actually cause those symptoms. Homeopathy is considered a form of complementary and alternative medicine. Compare allopathy. [first given practical application by German physician Christian Friedrich Samuel Hahnemann (1755–1843).] —homeopathic adj.

**homeostasis** n. 1. The regulation by an organism of all aspects of its internal environment, including body temperature, salt–water balance (see osmoregulation), acid–base balance (see hydrogen-ion concentration), and blood sugar level. This involves monitoring changes in the external and internal environments by means of receptors and adjusting bodily processes accordingly. Compare tension law. [first described by Walter B. Cannon.] 2. Maintenance of a stable balance, evenness, or symmetry. —homeostatic adj.

**homeostatic principle** In social psychology, the principle that individuals have a need to maintain or restore an optimal level of environmental, interpersonal, and psychological stimulation. Insufficient or excessive stimulation is theorized to cause tension that often prompts the behavior required to achieve optimal stimulation levels. For example, if an individual experiences excessive solitude, he or she will seek out others to restore the desired balance with his or her need for companionship. The principle is analogous to the biological concept of homeostasis.

**homeotherm** (homeoitherm) n. See endotherm. —homeothermic adj. —homeothermy n.

**home range** The entire space through which a nonhuman animal moves during its normal activities. The space may or may not be defended from other members of the same species. The part of the home range in which the greatest activity occurs is known as the core area. Home range (or secondary territory) differs from primary territory (see territoriality), which is an actively defended specific area, and from personal space, which is the defended space that moves with an individual.

**home schooling** 1. Formal instruction of a student in his or her home or other private setting, often by one or both parents or by a tutor. Instruction must meet the preset requirements of a school district, a state, or both. 2. Education in a home environment of one family’s children or a group of unrelated children.

**home-service agency** A group (e.g., a public health, social service, or voluntary organization) that provides home health aids or homemaker home health aids for people with mental or physical disabilities. The personnel generally are paraprofessionals who are recruited, trained, and supervised by another agency, such as a visiting nurse association or a hospital with a home-care unit.

**homesickness** n. A feeling of intense sadness and longing caused by absence from one's home or native land. See also nostalgia. —homesick adj.

**home visit** A visit to an individual at home by a professional or paraprofessional, such as a psychologist, physician, nurse, social worker, or rehabilitation therapist, for crisis intervention, aftercare, or other assistance in solving personal problems.

**homework** n. Tasks assigned to a client to be performed between sessions of therapy. Assignments may require reading, research, or practicing new behaviors (e.g., attending a lecture, speaking to a specific person).

**homicide** n. The killing of one person by another person. In a legal context, homicide is often subdivided into excusable homicide (as in self-defense or resulting from an accident), justifiable homicide (as in carrying out a death sentence), and felonious homicide (as in murder or manslaughter). —homicidal adj.

**homicidomania** n. A mental or emotional disturbance characterized by a desire to kill others, often including actual attempts to do so.

**homicidophilia** n. Sexual interest and arousal obtained from murder. In the extreme form, this paraphilia results in what are called lust murders, or cases of murder and rape. Less extreme cases may consist of the use of murder fantasies or murder-related pornographic materials during masturbation. Compare autoassassinophilia.

**homing** n. The ability of individuals to return to an original home after traveling or being transported to a point that is a considerable distance from the home and that lacks most visual clues as to its location. In an animal-homing experiment, banded Manx shearwaters were transported 3,050 miles from their native Isle of Man, off the west coast of England, to North America; released separately, they returned to their burrows on the island within 13 days. See also navigation.
hominin n. a primate of the family Hominidae, of which humans (Homo sapiens) are the only living species.
homo- (hom-) combining form 1. same or like. [from Greek homoios, “one and the same”] 2. human being. [from Latin homo, “man”]
homocystinuria n. a genetic metabolic disorder characterized by a deficiency of an enzyme needed to convert L-homocysteine to L-cystathionine. Intellectual disabilities often occur, along with a shuffling, ducklike gait and, in some instances, seizures or hemiplegia. Brain abnormalities are often due to arterial or venous thromboses. Also called cystathionine synthetase deficiency.
homoeroticism n. an erotic desire for people of one’s own sex. Also called homoerotism. Compare heteroeroticism. —homoerotic adj.
homogamic adj. referring to the sex that has two similar sex chromosomes, such as the female sex in mammals and the male sex in birds. Compare heterogamic.
homogamy n. a marriage between partners from similar ethnic, racial, religious, educational, or socioeconomic backgrounds. Compare heterogamy.
homogeneity n. 1. equality or near equality, particularly between two statistical quantities of interest. The term most often is used in connection with different populations. For example, homogeneity of means would be present in a one-way analysis of variance if the average values of the population groups being investigated were the same. Compare heterogeneity. 2. see linear system.
homogeneity of cognitive function in stage theories of cognitive development, such as Jean Piaget’s, the assumption that a child’s mental processes (e.g., problem solving) are relatively homogeneous, or similar, across different tasks and contexts.
homogeneity of covariance the condition in which multiple groups in an experimental design have the same covariance matrix. A basic assumption in a multivariate analysis of variance, it is the multivariate analog of homogeneity of variance.
homogeneity of variance the statistical assumption of equal variance, meaning that the average squared distance of a score from the mean is the same across all groups sampled in a study. This condition must be fulfilled in statistical methods that use a single term to represent how widely scores vary across groups, as with analysis of variance, multiple regression analysis, and other procedures. Also called equality of variance: homoscedasticity. Compare heterogeneity of variance.
homogeneous adj. having the same, or relatively similar, composition throughout. Compare heterogeneous.
homogeneous group an aggregate of individuals or other elements that are similar to one another in a number of significant respects. In a social context, for example, a homogeneous group might include members who are the same age or have the same socioeconomic background, values, work experience, education, and so on. In educational contexts, a homogeneous group may be an entire class or a smaller group formed within a class and based on similar ability in a specific area (e.g., mathematics). Compare heterogeneous group.
homogenitality n. an interest in the genitalia of one’s own sex.
homograph n. one of two or more words that are written in exactly the same way but have unrelated meanings. For example, row meaning linear arrangement and row meaning argument are homographs. Compare homonym; homophone. —homographic adj.
homolateral adj. on the same side of the body. —homolaterally adv.
homologous adj. 1. exhibiting resemblance based on common ancestry (see homology). 2. describing chromosomes that are identical in terms of their visible structure and location of gene segments, although they may carry different alleles. Diploid organisms, such as humans, possess homologous pairs of chromosomes (see autosomes) in the nuclei of their body cells. See also recombination. 3. describing any segment of a nucleic acid (DNA or RNA) or protein whose sequence of, respectively, bases or amino acids is similar to that of another segment.
homology n. a similarity of form in bodily structures of species that are descended from a common ancestor, such as the resemblance among forelimbs of vertebrates. Compare homoplasy. See also analogy. —homologous adj.
homonym n. one of two or more words that are written or pronounced (or both) in the same way but are unrelated in meaning. For example, cape meaning promontory and cape meaning garment are homonyms. Compare homograph; homophone.
homonymous hemianopia the loss of sight in the same half of the visual field of each eye (i.e., the left half of the visual field of both the left and right eyes, or vice versa) caused by injury to the postchiasmatic visual system (see postchiasmatic visual deficit). See also hemianopia.
homonymous paracentral scotoma see paracentral scotoma.
homonymous quadrantanopia see quadrantanopia.
homonymous reflex a reflex in which stimulation of a muscle produces a contraction of the same muscle. Compare heteronymous reflex.
homophile n. a person who loves others of his or her own sex—that is, a gay man or a lesbian.
homophily n. 1. the tendency for individuals who are socially connected in some way to display certain affinities, such as similarities in demographic background, attitudes, values, and so on. 2. the degree of similarity between individuals who share social ties. See also birds-of-a-feather phenomenon. Compare heterophily.
homophobia n. dread or fear of gay men and lesbians, associated with prejudice and anger toward them, that leads to discrimination in such areas as employment, housing, and legal rights and sometimes to violence (gay bashing). Extreme homophobia may lead to murder.
homophone n. one of two or more words that are pronounced in exactly the same way but have unrelated meanings and may have different spellings. For example, whole and hole are homophones. Compare homograph; homonym. —homophonic adj.
homoplasy n. a similarity of form in bodily structures of species that are not descended from a common ancestor (e.g., the body forms of a tuna and a dolphin). This superficial resemblance often arises through the process of convergent evolution because the species live in the
heteroscedasticity

same environment. Compare HOMOLOGY. See also ANALOGY. —homo- plast ic adj.

heteroscedasticity n. see HOMOGENEITY OF VARIANCE. —homo- plast ic adj.

heterosexual behavior sexual acts, such as mutual genital caressing, cunnilingus, fellatio, and anal intercourse, practiced between people of the same sex, whether or not they identify themselves as gay.

heterosexual community the gay and lesbian people in a particular country, region, or city, especially when regarded as having their own meeting places, customs, linguistic expressions, organizations, and so on. Use of this term is increasingly considered outdated, and the abbreviation LGT BQ is preferred instead.

heterosexuality n. sexual attraction or activity between members of the same sex. Although the term can refer to homosexual orientation in both men and women, current practice distinguishes between gay men and lesbians, and heterosexuality itself is now commonly referred to as same-sex sexual orientation or activity. —heterosexual adj., n.

heterosexual love a relationship with a member of one’s own sex involving the full range of erotic, emotional, and sexual feelings.

heterosexual marriage see SAME-SEX MARRIAGE.

heterosexual panic a sudden, acute anxiety attack precipitated by (a) the unconscious fear that one might be gay or lesbian or will act out gay or lesbian impulses, (b) the fear of being sexually attacked by a person of the same sex, or (c) loss of or separation from a same-sex partner. Also called Kempf’s disease. [first proposed in 1921 by U.S. psychiatrist Edward J. Kempf (1885–1971)]

heterosexual rights movement see GAY LIBERATION.

heterovarainic acid (HVA) the end product of the catecholism of the neurotransmitter dopamine, produced by the action either of catechol-O-methyltransferase (COMT) on 3,4-dihydroxyphenylacetic acid (DOPAC) or of aldehyde dehydrogenase on 3-methoxy-4-hydroxyphenylacetaldehyde (MHPA). Levels of homovanillic acid are typically reduced in individuals with Parkinson’s disease.

homozygous adj. possessing identical forms of a gene (i.e., identical ALLELES) at a given genetic locus on each of a pair of HOMOLOGOUS chromosomes. Either autosomal dominant (see DOMINANT ALLELE) or autosomal recessive (see RECESSIVE ALLELE) conditions are expressed when the individual is homozygous for that condition. Compare HETEROZYGOUS. —homozygote n.

homunculus n. (pl. homunculi) 1. a putative process or entity in the mind or the nervous system whose operations are invoked to explain some aspect of human behavior or experience. The problem with such theories is that the behavior or experience of the homunculus usually requires explanation in exactly the same way as that of the person as a whole. As a result, homunculus theories tend to end in CIRCULAR REASONING. For example, to explain its theory that certain ideas are kept from conscious awareness because they are threatening to the person, psychoanalysis must posit some specialized part of the person that is aware of the ideas and knows that they are threatening. Similarly, some information-processing theories invoke a “decision-making process” to explain the making of decisions. Both theories invoke a sophisticated level of inner awareness or processing in an attempt to explain another outward level of awareness or processing. For this reason, critics would say that they require homunculi, or that they commit the homunculus fallacy. 2. in neuroanatomy, a figurative representation, in distorted human form, of the relative sizes of motor and sensory areas in the brain that correspond to particular parts of the body. For example, the brain area devoted to the tongue is much larger than the area for the forearm, so the homunculus has a correspondingly larger tongue. See MOTOR HOMUNCULUS; SENSORY HOMUNCULUS. 3. a completely formed minute human figure (Latin, “little man”) thought by some 16th- and 17th-century theorists to exist in the spermatozoon and simply to expand in size during the transition from zygote to embryo to infant to adult. This idea is an example of PREFORMISM and is contrary to the epigenetic principle of cumulative development and successive differentiation. —homuncular adj.

honestly significant difference test see TUKEY’S HONESTLY SIGNIFICANT DIFFERENCE TEST.

honest signal among nonhuman animals, a signal that provides accurate information about an individual’s internal state or its intentions. Although some theorists argue that communication should be deceptive or manipulative to ensure survival, honest signals have value if they are highly correlated with a physical trait (e.g., body size) that might, for example, provide important information for mate selection or if they are used within a stable social group where dishonest signals can be detected and “liars” punished. See HANDICAP PRINCIPLE.

honesty n. 1. in general, truthfulness, uprightness, and integrity. 2. in psychotherapy, the ability of an individual to express true feelings and communicate immediate experiences, including conflicting, ambivalent, or guilt-ridden attitudes. —honest adj.

honesty test see INTEGRITY TESTING.

hookup n. a type of sexual encounter in which the participants have no expectation of continuing or developing their relationship beyond the sexual encounter. Hookups can involve strangers or individuals who are well acquainted with each other in a nonsexual way; a friend with whom a person is hooking up but not dating is often referred to as a friend with benefits. Hookups have become a popular means for satisfying sexual desires among many young adults, likely reflecting growing reluctance to enter committed relationships; however, they represent a risk factor for sexually transmitted diseases.

Hooper Visual Organization Test (VOT) a trade name for a test in which line drawings of familiar objects are cut up into pieces and then shown to a participant to mentally reorganize them and name the objects. The test was originally developed as a screening instrument for neurological dysfunction but subsequently has been used as a test of visuospatial skills. [developed by H. Elston Hooper, U.S. psychologist]

ho’oponopono n. in Hawaiian culture, a type of group process, similar to family therapy, in which the ‘OHANA or a similar group addresses its personal and family problems in order to restore harmony within the group.

Hoover’s sign a diagnostic test for neurological (as distinct from psychological) HEMIPLEGIA in which the individual in a reclining position attempts to raise the paralyzed leg. An individual with true hemiplegia reflexively presses down the heel of the healthy leg during the test.
hence the downward movement is a positive Hoover’s sign and suggests psychogenic paresis or malinger. [Charles Franklin Hoover (1865–1927), U.S. physician] **hope** *n.* the expectation that one will have positive experiences or that a potentially threatening or negative situation will not materialize or will ultimately result in a favorable state of affairs. Hope has been characterized in the psychological literature in various ways, including as a **character strength**: an emotion: a component of motivation that is critical to goal attainment; a mechanism that facilitates coping with loss, illness, and other significant stresses; or an integrated combination of these features. See also **optimism**. —**hopeful** adj.

**hopelessness** *n.* the feeling that one will not experience positive emotions or an improvement in one’s condition. Hopelessness is common in severe major depressive episodes and other depressive disorders and is often implicated in suicides and attempted suicides. —**hopeless** adj.

**Hopkins Symptom Checklist (HSC)** I A 58-item self-report inventory designed to identify symptom patterns along five dimensions—obessive-compulsive behavior, anxiety, depression, somatization, and interpersonal sensitivity—which are combined to yield a total distress score. See also **SYMPTOM CHECKLIST-90-REVISED**. [developed at The Johns Hopkins University in the 1950s]

**Hopkins Verbal Learning Test (HVLT)** I A standardized brief individual test used to assess verbal learning and memory (specifically, immediate recall, delayed recall, and delayed recognition) in individuals ages 16 years and older. The examiner reads aloud 12 nouns, and participants must first repeat them (both immediately and 25 minutes following their presentation) and then identify them from among a verbally presented list of distractors words. Originally published in 1991, the HVLT subsequently was revised in 2001 (HVLT-R). [developed by U.S. medical psychologist Jason Brandt (1954– ) and U.S. clinical psychologist Ralph H. B. Benedict (1960– ) at The Johns Hopkins University]

**horde** *n.* a large, usually mobile group, particularly a nomadic clan.

**horizontal career move** a career move involving a change in functional area or expertise but not a promotion to a higher level of authority.

**horizontal cell** see **retinal horizontal cell**.

**horizontal communication** the exchange of written or spoken messages among employees occupying positions at the same level of authority in an organization. Compare **downward communication**; **upward communication**.

**horizontal décalage** in Piagetian theory, the invariant order in which accomplishments occur within a particular stage of development. For example, an understanding of conservation of quantity is always achieved before understanding conservation of weight, which is achieved before understanding conservation of volume. Compare **vertical décalage**.

**horizontal group** a group composed of people from the same social class. Compare **vertical group**.

**horizontal job enlargement** see **job enlargement**.

**horizontal loading** see **job enlargement**.

**horizontal mobility** the movement of individuals or groups from one position or role to another within the same social class. Compare **vertical mobility**. See also **social mobility**.

**horizontal plane** an imaginary flat surface that divides the body or brain into upper and lower parts. Also called **transverse plane**.

**horizontal section** 1. in imaging, a theoretical “slice” of a body or an organ (e.g., the brain) in a plane perpendicular to the dorsal–ventral axis. 2. a thin slice of tissue for microscopic study that has been cut at an angle perpendicular to the dorsal–ventral axis of the organ. A horizontal section may also be taken of an entire organ for gross examination (e.g., a horizontal section of an entire brain).

**horizontal transmission** host-to-host transmission of infection, as contrasted with **vertical** (or **transplacental** transmission, in which the infection is passed from one generation to the next.

**horizontal–vertical illusion** the misperception that vertical lines are longer than horizontal lines when both are actually the same length. The vertical element of an upper case letter T, for example, looks longer than the cross bar, even when the lengths are identical. See also **foreshortening**; **helmholtz square illusion**.

**hormic psychology** a school of psychology originating in the 1920s that emphasizes goal seeking, striving, and foresight, with instincts serving as the primary motivation for behavior. It is particularly concerned with explaining social psychological phenomena in terms of instinctive behavior. See also **purposive psychology**; **sociobiology**; **teleology**. [introduced by William McDougall]

**hormone** *n.* a substance secreted into the bloodstream by an **endocrine gland** or other tissue or organ to regulate processes in distant target organs and tissues. These secretions include those from the anterior and posterior pituitary gland; the **cortisol**; and **epinephrine**, secreted by the adrenal glands; and the sex hormones released by the reproductive glands. Other organs that secrete hormones include the hypothalamus (see **hypothalamic hormone**); and the stomach, which emits at least five: **cholecystokinin**, **enterogastrone**, **gastrin**, **ghrelin**, and **secretin**. —**hormonal** adj.

**hormone feedback** a feedback system in which the output of hormones is regulated by other circulating hormones, which have positive or negative effects. During the follicular phase of the menstrual cycle, for example, estrogen has a positive effect on the hypothalamus, increasing the secretion of gonadotropin-releasing hormone and hence the secretion of pituitary gonadotropins, which stimulate ovulation.

**hormone replacement therapy (HRT)** 1. the administration of sex hormones either to relieve menopausal symptoms in women or to increase testosterone levels in men. For women, the use of HRT, usually with an estrogen (see **estrogen replacement therapy**), or a combined estrogen–progestin preparation, is controversial, since long-term use may increase the risk of breast cancer, cardiovascular disease, stroke, and other conditions associated with aging. For men, HRT with testosterone is used to treat hypogonadism. Its efficacy in increasing sex drive in men with lower testosterone levels due to normal aging or as a treatment for erectile dysfunction is inconclusive. 2. the administration of any other hormone to treat a hormone deficiency, such as thyroid hormone to treat hypothyroidism.
Horner effect

**Horner effect** see **FEAR OF SUCCESS.** [Matina Horner (1939–), U.S. psychologist]

**Horner’s law** the principle that red–green color blindness is a genetic disorder transmitted indirectly from male to male through a female. [Johann Friedrich Horner (1831–1886), Swiss ophthalmologist]

**Horner’s syndrome** a condition characterized by partial ptosis (drooping of the upper eyelid), miosis (excessive constriction of the pupil), and often anhidrosis (absence of sweating) on the same half of the face. Congenital or acquired, it is caused by damage to the PONS region of the brainstem. There may be lack of coordination in eye movements (SACCADES and SMOOTH-PURSUIT EYE MOVEMENTS). Also called **oculomotoric paralysis.** [Johann Horner]

**horopter** n. the location in space occupied by points that fall on corresponding locations on the two retinas. See also **PANUM’S FUSIONAL AREA; VIETH-MÜLLER CIRCLE.**

**horoscope** n. 1. in **ASTROLOGY,** a chart showing the relative position of the planets and the signs of the zodiac at the time of a person’s birth, used to infer that person’s character and to predict his or her future. 2. a short-term forecast of a person’s future based on the current position of the planets relative to his or her sign of the zodiac, especially as published in newspapers and magazines.

**horseradish peroxidase** (HRP) an enzyme found in horseradish and other plants that is used as a tracer, for example, to determine the neurons from which a particular set of axons originates.

**horseshoe crab** a marine arthropod with very large **COMPOUND EYES** useful for experimental investigations of the physiology of vision because its neurons are large and activity is easily recorded. Also called **limulidae.**

**horticultural therapy** the use of gardening as an auxiliary intervention for therapeutic or rehabilitational purposes. It is typically used for individuals with physical or mental illness or disability but may also be used to improve the social, educational, psychological, and physical well-being of older adults as well as those recovering from injury. Also called **horticulture therapy.**

**hospice** n. a place or a form of care for terminally ill individuals, often those with life expectancies of about half a year as determined by medical personnel. Instead of curing disease and prolonging life, the emphases of the hospice concept are patient comfort, psychological well-being, and pain management (see **PALLIATIVE CARE**). The approach is interdisciplinary, with care provided by medical, psychological, spiritual, volunteer, and family caregivers, either in special facilities or in the patient’s home. See also **TERMINAL CARE.** [pioneered by British nurse, social worker, and physician Cicely Saunders (1918–2005)]

**hospitalism** n. in infants, lack of psychomotor response or failure to gain weight or produce purposeful behavior, often thought to be a response to separation from mothers and subsequent institutionalization. See also **REACTIVE ATTACHMENT DISORDER.**

**hospitalitis** n. the state of mind of patients who are so dependent psychologically on hospital life that their symptoms suddenly recur when they are about to be discharged.

**hospitalization** n. 1. the placement of an individual in a hospital or mental health facility for treatment. 2. the period during which a patient is confined to a hospital or mental health facility. See also **INVoluntary HOSPITALIZATION; READMISSION.**

**hospital phobia** a persistent and involuntary fear of hospitals, classified in DSM-IV-TR and DSM-5 as a form of **SPECIFIC PHOBIA,** situational type.

**hostile aggression** see **AGGRESSION.**

**hostile attribution bias** a general tendency to ascribe harmful or otherwise adverse intent to the ambiguous behavior of others. For example, a child who insists that another child bumped into her on the school playground on purpose when the action in fact was accidental is demonstrating a hostile attribution bias, as is an employee who claims his name was deliberately left off the distribution list for a recent memo despite coworker assurances that the error was inadvertent. This cognitive distortion is associated with such phenomena as aggression, conduct disorders, narcissism, and **EXTERNALIZATION,** [first described in 1979 by personality psychologist William Nafcy: clinical psychologist Brian C. Hayden, and social psychologist Bella M. DePaulo]

**hostile-detached marriage** an unstable marriage in which there are short but malicious disagreements between the partners.

**hostile-engaged marriage** an unstable marriage in which the partners have long and frequent arguments without the balance of love and humor found in long-lasting **VOLATILE MARRIAGES.**

**hostile witness** an individual who is either unwilling to testify in court or exhibits hostility or bias against the party conducting the direct examination. If the court recognizes a person to be a hostile witness, the counsel conducting the examination is permitted to ask leading questions. See also **ADVERSE WITNESS.**

**hostile work environment** a situation in which the workplace is made intimidating, abusive, or offensive to an employee as a consequence of another’s conduct within it (e.g., inappropriate comments, remarks, or gestures; unwanted sexual attention) or because of characteristics of the setting (e.g., displays of distasteful, insulting, or otherwise inappropriate material). See also **MISSING ABBEY SAVINGS BANK V. VINSON; QUID PRO QUO SEXUAL HARASSMENT.**

**hostility** n. the overt expression of intense animosity or antagonism in action, feeling, or attitude. —**hostile** adj.

**hostility displacement** the direction of hostility or aggression to a target other than the agent responsible for provoking this behavior. Conventional accounts typically state that the target is selected because there is no anticipation of punishment for the attack. According to the classic analysis of Neal E. Miller, the strength of the urge to displace hostility is related to the target’s association with the perceived source of provocation. See **FRUSTRATION—AGGRESSION HYPOTHESIS.**

**hot-deck imputation** one of several methods of inserting values for missing data (see **IMPUTATION**) in which missing observations or data points are replaced by values from similar responses in the sample at hand. Suppose that a patient survey was conducted in two hospitals, A and B, and that five people from Hospital A failed to respond to an
item of the survey. Sampling five values from the respondents who did respond to that item at Hospital A and substituting these values for the missing observations is an example of a hot-deck imputation. Compare COLD-DECK IMPUTATION.

**Hotelling's T² test** a MULTIVARIATE ANALYSIS OF VARIANCE used to test the significance of the mean difference between two groups in their scores or outcomes on multiple dependent variables. An extension of the univariate T TEST, it is applicable to only two groups, rather than three or more groups. Also called Hotelling's T²: T-squared test. [Harold Hotelling (1895–1973), U.S. mathematician]

**hot flash** a typical menopausal symptom caused by decreased levels of estrogen and experienced as a sudden rush of heat to the neck, face, and sometimes other parts of the body that may last from 30 seconds to 5 minutes. It may begin with a sudden tingling in the fingers, toes, cheeks, or ears, and in some women it is followed by a sensation of cold. Fifty percent of women experience hot flashes around the time of menopause.

**hothousing** n. the acceleration of young children’s academic skills through instruction designed to increase academic achievement. Some theorists believe that hothousing is equivalent to hurrying children and that it is therefore maladaptive to normal development.

**hotline** n. a telephone line maintained by trained personnel for the purpose of providing a crisis intervention service. See TELEPHONE COUNSELING.

**hot plate** an apparatus used in studies of heat or pain sensitivity. A nonhuman animal (usually a rat or a mouse) is placed on top of an electrically heated plate, the temperature of which is controlled by the experimenter. The time that elapses before the animal raises its front paws off the plate at a given temperature is used as an index of sensitivity to heat or pain.

**hot-seat technique** a technique of GESTALT THERAPY in which a client sits in a chair next to the therapist, who encourages the client through direct prompting and questioning to relive stressful experiences and openly express feelings of discomfort, guilt, or resentment. The technique aims to generate a new, more vivid awareness, which leads the client to find his or her own solutions to problems or emotional difficulties. In a group therapy variation of the hot-seat technique, an individual member expresses to the therapist an interest in dealing with a particular issue, and the focus moves away from the group into an extended interaction between the group member and therapist for a limited period of time. During this one-on-one interaction, the other group members remain silent; afterward, they give feedback on how they were affected, what they observed, and how their own experiences are similar to those of the individual member discussed.

**houselight** n. a small light bulb or bulbs used to provide continuous low-level illumination of a CONDITIONING APPARATUS.

**Hovland model** see MESSAGE-LEARNING APPROACH.

**HPA** abbreviation for HYPERPHENYLALANINEMIA.

**HPA axis** abbreviated name for HYPOTHALAMIC–PITUITARY–ADRENAL AXIS.

**HR** abbreviation for HUMAN RESOURCES.

**HRNB** abbreviation for HALSTEAD–REITAN NEUROPSYCHOLOGICAL BATTERY.

**HRP** abbreviation for HORSEADISH PEROXIDASE.

**H–R–R plates** abbreviation for HARDY–RAND–RITTNER PSEUDOSCHROMATIC PLATES.

**HRSD** abbreviation for HAMILTON RATING SCALE FOR DEPRESSION.

**HRT** abbreviation for HORMONE REPLACEMENT THERAPY.

**HRTF** abbreviation for HEAD-RELATED TRANSFER FUNCTION.

**HSCL** abbreviation for HOPKINS SYMPTOM CHECKLIST.

**HSD test** abbreviation for honestly significant difference test. See T UKEY’S HONESLY SIGNIFICANT DIFFERENCE TEST.

**HSI** abbreviation for HUMAN SYSTEMS INTEGRATION.

**hsieh-ping** n. a CULTURE-BOUND SYNDROME observed in China and Taiwan, characterized by temporary trancelike states in which the individual supposedly becomes possessed by ancestral spirits. It is often accompanied by tremors, disorientation, delirium, and visual or auditory hallucinations.

**HSM** abbreviation for HEURISTIC-SYSTEMATICAL MODEL.

**HSPQ** abbreviation for HIGH SCHOOL PERSONALITY QUESTIONNAIRE.

**H spread** see INTERQUARTILE RANGE.

**5-HT** abbreviation for 5-hydroxytryptamine. See SEROTONIN.

**5-HTPP** abbreviation for 5-HYDROXYTRYPTOPHAN.

**5-HTTLPR** abbreviation for serotonin transporter–linked polymorphism region. See SEROTONIN TRANSPORTER.

**hubris** n. arrogant pride or presumption. In Greek tragedy, hubris is specifically the overweening pride that leads to the destruction of the protagonist. —hubristic adj.

**IUD** abbreviation for HEAD-UP DISPLAY.

**hue** n. the subjective quality of color, which is determined primarily by wavelength and secondarily by amplitude.

**Hull’s mathematico-deductive theory of learning** a mathematical system of learning based on classical and instrumental conditioning with numerous postulates and corollaries to explain various behaviors. There is major emphasis on NEED REDUCTION as a condition of learning, the building up of HABIT STRENGTH by contiguous reinforcement, EXTINCTION brought about by nonreinforced repetition of responses, and forgetting as a process of decay with the passage of time. [Clark L. HULL]

**human channel capacity** the limit on the amount of information that may be processed simultaneously by the human information-processing system.

**human chorionic gonadotropin** a hormone, produced by the human placenta, that maintains the activity of the CORPUS LUTEUM during pregnancy. Its presence or absence in the urine is used as a basis for pregnancy testing. See also GONADOTROPIN.

**human courtship** see COURTSHIP.

**human ecology** in sociology, the study of the relationship between human beings and their physical and social environments. See also ECOLOGICAL STUDY; ECOLOGICAL SYSTEMS THEORY; SOCIAL ECOLOGY; URBAN ECOLOGY.

**human engineering** the design of environments and equipment that promote optimum use of human capabili-
ties and optimum safety, efficiency, and comfort. See also ENGINEERING PSYCHOLOGY; HUMAN FACTORS ENGINEERING.

**human error** an error in the operation of a HUMAN–MACHINE SYSTEM resulting from human action or inaction (see ERROR OF COMMISSION; ERROR OF OMISSION), as opposed to mechanical failures or faults in product or system design. Although human error can never be entirely eradicated, good design will minimize both its occurrence and its consequences (see EXCLUSION DESIGN; FAIL-SAFE).

**human factors** 1. in ERGONOMICS, the impact of human beings, with their characteristic needs, abilities, and physical and mental limitations, on system function. 2. the considerations to be made when designing, evaluating, or optimizing systems for human use, especially with regard to safety, efficiency, and comfort. See also HUMAN SYSTEMS INTEGRATION. 3. particularly in the United States, a common synonym of ERGONOMICS.

**human factors engineering** an interdisciplinary field concerned with the design, maintenance, operation, and improvement of operating systems in which human beings are components, such as industrial equipment, automobiles, health care systems, transportation systems, recreational facilities, consumer products, and the general living environment. This term is often used synonymously with ENGINEERING PSYCHOLOGY. See also ENGINEERING ANTHROPOMETRY; ERGONOMICS; HUMAN ENGINEERING; SYSTEMS ENGINEERING.

**human factors psychology** a branch of psychology that studies the role of HUMAN FACTORS in operating systems, with the aim of redesigning environments, equipment, and processes to fit human abilities and characteristics. See HUMAN ENGINEERING. See also ERGONOMICS; SOCIOTECHNICAL SYSTEMS APPROACH.

**Human Genome Project** an international project to map each human gene and determine the complete sequence of base pairs in human DNA. The project began in 1990 and was completed in 2003. It has yielded vast amounts of valuable information about the genes responsible for various diseases, which may lead to the development of effective genetic screening tests and, possibly, treatments. However, controversy surrounds the attempts by some biotechnology companies to patent certain human DNA sequences with the potential for commercial exploitation. See also ELSI PROGRAM.

**human-growth movement** see HUMAN-POTENTIAL MOVEMENT.

**human immunodeficiency virus** see HIV.

**human information storage** the process in which the mind, conceived as being analogous to a computer, codes external information into a form that can be remembered, manipulated, and retrieved.

**humanism** n. 1. a perspective that begins with a presumption of the inherent dignity and worth of humankind and, as a scholarly or artistic discipline, focuses attention on the study and representation of human beings and human experiences. The roots of Western humanism lie in the Renaissance period, when those who studied the classical Greek and Roman languages and writings became known as humanists. 2. any position taken in opposition to religious belief or other forms of supernaturalism. See SECULAR HUMANISM. 3. in psychology, any perspective that seeks to uphold human values and to resist the reduction of human beings and behaviors to merely natural objects and events. In this spirit, HUMANISTIC PSYCHOLOGIES have resisted not only natural scientific psychology but also theories that emphasize the negative and pathological aspects of human nature. In psychology, the term humanism is often applied to theories and perspectives in the tradition of Carl Rogers and Abraham Maslow or to those inspired by PHENOMENOLOGY and EXISTENTIALISM. —humanist adj., n. —humanistic adj.

**humanistic communitarian socialism** an ideal political system proposed by Erich Fromm in which humane values would underlie the socioeconomic structure. The goal of humanistic communitarian socialism is a non-exploitative society, composed of small communities rather than large governmental or corporate entities, in which all members develop to their maximum ability, are self-regulating, and contribute fully as individuals and citizens.

**humanistic conscience** the type of conscience that is guided by individual standards and not by fear of external authority. Compare AUTHORITARIAN CONSCIENCE. [defined by Erich Fromm]

**humanistic–existential therapy** see EXISTENTIAL–HUMANISTIC THERAPY.

**humanistic perspective** the assumption in psychology that people are essentially good and constructive, that the tendency toward SELF-ACTUALIZATION is inherent, and that, given the proper environment, human beings will develop to their maximum potential. The humanistic perspective arose from the contributions of Gordon W. Allport, Abraham Maslow, and Carl Rogers, who advocated a personality theory based on the study of healthy individuals as opposed to people with mental disorders.

**humanistic psychology** an approach to psychology that flourished between the 1940s and the early 1970s and that is most visible today as a family of widely used approaches to psychotherapy and counseling. It derives largely from ideas associated with EXISTENTIALISM and PHENOMENOLOGY and focuses on individuals’ capacity to make their own choices, create their own style of life, and actualize themselves in their own way. Its approach is holistic, and its emphasis is on the development of human potential through experiential means rather than the analysis of the unconscious or the modification of behavior. Leading figures associated with this approach include Abraham Maslow, Carl Rogers, and Rollo May. Also called humanistic theory. See also FULFILLMENT MODEL; HUMAN-POTENTIAL MOVEMENT.

**humanistic therapy** any of a variety of psychotherapeutic approaches that reject psychoanalytic and behavioral approaches: seek to foster personal growth through direct experience; and focus on the development of human potential, the HERE AND NOW, concrete personality change, responsibility for oneself, and trust in natural processes and spontaneous feeling. Some examples of humanistic therapy are CLIENT-CENTERED THERAPY, GESTALT THERAPY, EXISTENTIAL PSYCHOTHERAPY, and EXPERIMENTAL PSYCHOTHERAPY.

**humanity** n. compassion in one’s personal relations with specific others, shown by kindness, nurturance, charity, and love.

**human–machine system** in ergonomics, any system with interdependencies between human operators, machines, and processes. Also called MAN–MACHINE SYSTEM; PERSON–MACHINE SYSTEM.
human menopausal gonadotropin (hMG) a mixture of follicle-stimulating hormone and luteinizing hormone extracted from the urine of postmenopausal women for stimulating ovulation in other women undergoing either assisted conception or treatment for infertility due to deficiency of pituitary gonadotropins. The concentrations of gonadotropins are high in postmenopausal women in response to decreased output of estrogens at menopause.

human nature the generally innate but flexible characteristics of humankind as a whole, comprising the set of behaviors, attitudes, and dispositions that typify the human race. The concept of human nature has been rejected by several schools of modern thought, notably Marxism, feminism, and postmodernism. See also essentialism; universalism.

humanoid adj., n. see android.

human operator modeling the practice of using qualitative or quantitative tools to illustrate the behavior, mental processes, or both of human operators when performing tasks. The use of physical or computer models for this purpose is known as human operator simulation. Physical simulations involve the use of robotic or remote-controlled operators in actual or realistic task environments. Computer simulations use a variety of parameters to test different scenarios and explore outcomes. Human operator modeling is used to describe, explain, or predict behavior under a variety of task and environmental conditions. See also model human processor.

human-potential model a psychological approach in education that emphasizes the importance of helping learners to achieve the maximum development of their potential in all aspects of their functioning. It is derived from the basic tenets of humanistic psychology. See also humanistic perspective.

human-potential movement an approach to psychotherapy and psychology that emphasizes personal growth, interpersonal sensitivity, and greater freedom and spontaneity in living. The ideas of German-born U.S. psychiatrist Frederick (Fritz) S. Perls (1893–1970) were an influential approach. Also called human-growth movement.

human relations see interpersonal relations.

human relations theory a general approach to management that emphasizes the importance of employee attitudes, interpersonal relationships, group dynamics, and leadership styles in achieving organizational effectiveness. In human relations theory, considerate, participative leaders who are skilled in communicating with employees are held to achieve better results than authoritarian leaders. See also Hawthorne effect.

human relations training techniques designed to promote awareness in an individual of the feelings and needs of others and to foster constructive interactions. See also sensitivity training; t-group.

human resources (HR) 1. the individuals and groups whose knowledge, skills, abilities, and other characteristics enable an organization to achieve its objectives. 2. the department of an organization concerned with recruiting, training, and appraising employees and with any issues relating to their welfare. Also called personnel.

human strength see character strength.

human–system coupling in ergonomics, the extent to which operator and system are interdependent. A highly automated system requires a lower degree of coupling than a manual system.

human systems integration (HSI) an area of research that investigates the means by which knowledge about the cognitive and physiological requirements for optimal human task performance (e.g., attention, decision making, biomechanics) can be translated into the effective design of complex technologies used to support that performance. The focus of research is primarily on advanced computer-based systems (e.g., those used in air traffic control) and specifically on their effects on the people using them and the efficacy of their design features (e.g., alarm signals, visual interfaces, automation) in supporting efficient, safe operations, particularly during high-risk situations. See ergonomics; human factors.

human trafficking see trafficking.

human–vehicle interface the junction between the human operator and the functions of a vehicle. It includes all components of the control panel.

humidity effects the effects of the amount of moisture in the air on one’s perception of ambient temperature. High humidity makes hot weather uncomfortable because it diminishes the cooling efficiency of air movement to evaporate heat from the body.

humiliation n. a feeling of shame as a result of being disgraced or deprecated. The feeling sometimes leads to severe depression and deterioration of the individual’s sense of self-esteem. Humiliation of a partner is frequently found in relationships characterized by sexual sadism and sexual masochism.

humility n. the quality of being humble, characterized by a low focus on the self, an accurate (not over- or underesti- mated) sense of one’s accomplishments and worth, and an acknowledgment of one’s limitations, imperfections, mistakes, gaps in knowledge, and so on.

humor n. 1. the capacity to perceive or express the amusing aspects of a situation. There is little agreement about the essence of humor and the reasons one laughs or smiles at jokes or anecdotes. Among philosophers, both Plato (c. 427–c. 347 BCE) and Thomas Hobbes claimed that individuals laugh at people and situations that make them feel superior, whereas Immanuel Kant emphasized surprise and anticlimax: “the sudden transformation of a strained expectation to nothing.” U.S. writer Max Eastman (1883–1969) saw humor as “playful pain,” a way of taking serious things lightly and thereby triumphing over them. Sigmund Freud called attention to the many jokes (spe- cially those having to do with sex and hostility) that enable individuals to give free expression to forbidden impulses and explained laughter in terms of a release of the energy normally employed in keeping them out of consciousness. See also incongruity theory of humor; release theory of humor. 2. the semifluid substance that occupies the spaces in the eyeball. See aqueous humor; vitreous humor. 3. in antiquity, one of four bodily fluids (blood, black bile, yellow bile, and phlegm) that were thought to be responsible for a person’s physical and psychological characteristics (see humoral theory). This belief accounts for
humoral immunity

the use of the word humor to mean mood, as in good humor, or whim, as in It is her humor. —humoral adj. —humorous adj.

humoral immunity see IMMUNE RESPONSE.

humoral reflex a reflex that involves secretion of a hormone.

humoral theory a former theory that explained physiological and psychological health or illness in terms of the state of balance or imbalance of various bodily fluids. According to Greek physician Hippocrates (5th century BCE), health was a function of the proper balance of four humors: blood, black bile, yellow bile, and phlegm (the classical humors or cardinal humors). This idea was also used to explain temperament: A predominance of blood was associated with a sanguine type; black bile with a melancholic type; yellow bile or choler with a choleric type; and phlegm with a phlegmatic type. Galen did much to preserve and promulgate this explanatory approach, which survived well into the 17th century. Humoral theory provides psychology with its earliest personality typology, as well as an early model of the relation between bodily and psychological states.

hunger n. the sensation caused by a need for food. Traditional conceptualizations viewed hunger as resulting from imbalances in homeostasis and food intake as necessary to maintain in the body an optimum balance of carbohydrates, fats, proteins, minerals, vitamins, and other nutrients. Contemporary theories, however, largely consider hunger to be initiated by the gradual disappearance of the inhibitory effects generated from the previous meal, such that hunger does not need to be stimulated but rather is always present and more or less masked depending on meal recency. See SATIETY. See also APPETITE; MALNUTRITION.

hunger center see FEEDING CENTER.

hunger drive an arousing state induced by food deprivation, precipitating food-seeking behavior. See also SPECIFIC HUNGER.

Hunger Winter see DUTCH HUNGER WINTER.

Hunter syndrome an X-linked recessive disease in which there is an excess of mucopolysaccharides in body tissues (see MUCOPOLYSACCHARIDOSIS). Almost exclusively affecting males, the disorder has two types, severe and attenuated. People with the severe type experience a decline in intellectual function and a rapid disease progression with elevated levels of polysaccharides and gargoylism. Mental development begins normally but slows after the early months and reaches a plateau around 2 years of age. The child may learn a few words but not sentences, and toilet training is seldom achieved. Also called Pfaundler–Hurler syndrome; mucopolysaccharidosis Type I. [Gertrud Hurler (1889–1965), Austrian pediatrician]

Huntington–Gilford progeria syndrome see AGING DISORDER. [Jonathan Hutchinson (1828–1913), British surgeon; Hastings Gilford (1861–1941), British physician]

HVA abbreviation for HOMOANILIC ACID.

HVLT abbreviation for HOPKINS VERBAL LEARNING TEST.

hwa-byung n. a CULTURE-BOUND SYNDROME specific to Korea and characterized by a range of symptoms that are attributed to the suppression of anger (Korean, literally: ‘anger disease’). Symptoms include a feeling of a mass in the throat, chest, or abdomen, a sensation of heat in the body, headaches, palpitations, indigestion, insomnia, fatigue, panic, dysphoria, fear of impending death, anorexia, generalized aches and pains, and poor concentration. Also called suppressed anger syndrome; wool-hwa-byung.

hyaline membrane disease see RESPIRATORY DISTRESS SYNDROME.

hyalophagia n. the eating of glass, typically a symptom of PICA.

hybrid n. 1. in genetics, the product of crossbreeding genetically dissimilar plants or animals. See HYBRIDIZATION. 2. in molecular biology, a double helix formed of NUCLEIC ACIDS from different sources.

hybridization n. the interbreeding of individuals with different genetic traits. Depending on the nature of the genes involved, HYBRIDIZATION might display traits of one or the other parent or some combination of parental traits. Hybridization is used in animal behavior studies as a method of evaluating the genetic transmission of behavior. —hybridize vb.

hybrid vigor increased vitality and other favorable qualities arising from crossbreeding genetically different plants or animals. Also called heterosis.

hybridophilia n. sexual interest in and attraction to those who commit crimes. In some cases, this may be directed toward people in prison for various types of criminal activities.

hydantoin n. any of a group of drugs developed primarily to control epileptic seizures. They were introduced in 1938 after careful studies of chemicals capable of suppressing electroshock convulsions without also causing adverse effects on the central nervous system. Hydantoin molecules are similar in structure to barbiturates but have turbances, and personality and behavioral changes. The age of onset is usually between 30 and 50, but there is a juvenile form of the disease in which symptoms first appear before the age of 20. Huntington’s disease is inherited as an autosomal dominant trait (see DOMINANT ALLELE); the single gene responsible is located on chromosome 4. Also called Huntington’s chorea. [George Huntington (1850–1916), U.S. physician]

Hurler syndrome an autosomal recessive disease marked by mucopolysaccharide levels in tissues more than 10 times normal (see MUCOPOLYSACCHARIDOSIS). Combined with elevated levels of polysaccharides and gargoylism, mental development begins normally but slows after the early months and reaches a plateau around 2 years of age. The child may learn a few words but not sentences, and toilet training is seldom achieved. Also called Pfaundler–Hurler syndrome; mucopolysaccharidosis Type I.

hunting behavior the pursuit of other animals for food or sport. Hunting behavior may include other forms of behavior, such as stalking, running after moving objects, or use of concealment or camouflage. In chimpanzees and social carnivores (e.g., wolves and lions), there is evidence of cooperative hunting behavior, which appears to be coordinated among several individuals.

Huntington’s disease (HD) a progressive hereditary disease associated with degeneration of nerve cells, particularly in the caudate nucleus of the basal ganglia and in the cerebral cortex. It is characterized by abnormalities of gait and posture, motor incoordination, and involuntary jerking motions (CHOREA) as well as DEMENTIA, mood dis-
the advantage of not altering the threshold for minimal seizures. The prototype of the hydantoin is PHENYTOIN (previously called diphenylhydantoin). Other hydantoin include methylenoxin (U.S. trade name: Mesantoin) and ethotoin (U.S. trade name: Pegauone), but these are rarely used.

**hydration n.** the act or process of accumulating or combining with water. For example, hydration occurs in body cells when sodium intake increases. Compare DEHYDRATION.

**hydraulic model** any physiological or psychological model based on the analogy of fluid flowing through a system under pressure, such that pressure may build up in the system and seek release. Sigmund FREUD’s model of the LIBEIO as an energy that can build pressure and seek release (CATHARSIS) is a notable example. A more literal use of the hydraulic model was the erroneous concept of the nervous system introduced in the early 17th century by René DESCARTES, who believed that nerves were tubes through which ANIMAL SPIRITS flowed from the brain to the muscles. According to this model, habits were formed when repeated use of the nerve tubes caused them to become distended and blocked.

**hydro-** (hydr-) combining form word or fluid.

**hydrocephalus n.** a condition caused by accumulation of cerebrospinal fluid in the ventricles of the brain, resulting in raised INTRACRANIAL PRESSURE, with symptoms such as headache, vomiting, nausea, poor coordination, gait imbalance, urinary incontinence, slowing or loss of development, lethargy, drowsiness, irritability, or changes in personality or cognition, including memory loss. Hydrocephalus commonly occurs as a congenital anomaly or due to obstruction of cerebrospinal fluid from head injury, brain tumor, or hemorrhage. The pressure can sometimes be relieved by surgery, in which the excess fluid is permanently shunted into the bloodstream. In infants, hydrocephalus often produces enlargement of the skull. Also called hydrocephaly. —hydro cephalic adj.

**hydrocodone n.** a mild to moderately potent orally administered OPIOID ANALGESIC used in the treatment of moderate to moderately severe pain. It is more effective when combined with ACETAMINOPHEN or an NSAID (e.g., aspirin) and is generally marketed in combination with such agents. It is also often marketed in combination with a cough suppressant for the symptomatic relief of cough due to colds or nasal congestion. U.S. trade names (among others): DETUSIN (in combination with pseudoephedrine); VICODIN (in combination with acetaminophen).

**hydrocortisone n.** see CORTISOL.

**hydrogen-ion concentration** a measure of the acidity or alkalinity of a substance. When acid and alkaline substances dissociate in water, hydrogen ions (H⁺) and hydroxyl ions (OH⁻) are released. Acidity and alkalinity are associated with the relative concentrations of H⁺. The hydrogen-ion concentration can be measured using the pH scale, on which values represent the negative logarithm of the H⁺ ion concentration. Thus, the greater the excess of H⁺ ions, the lower the pH value. A pH of 0 represents the greatest possible excess of H⁺ ions, or a “pure” acid. At the other extreme, a pH of 14 represents the maximum degree of alkalinity. A pH of 7 represents a neutral solution. Human body fluids have an average pH of about 7.4; that is, slightly alkaline. If the pH rises above 7.8 or falls below 6.8, enzymes and other biochemical substances in the body malfunction (see ACIDOSIS; ALKALOSIS). See also HOMEOSTASIS.

**hydrophobia n.** 1. a persistent and irrational fear of water, resulting in avoidance of activities involving water, such as swimming, drinking, or washing one’s hands. 2. a former name for RABIES. —hydrophobic adj.

**hydrotherapy n.** the therapeutic use of water to promote recovery from disease or injury. Hydrotherapy includes such treatments as baths, streams of water (douches), and aquatic sports or exercise.

**6-hydroxydopamine (6-OHDA) n.** a dopamine analog used in nonhuman animal studies for its ability to destroy catecholamine-containing nerve cell bodies. 6-OHDA does not cross the blood–brain barrier, but when administered into the central nervous system, it causes permanent degeneration of catecholamine-containing neurons. Destruction of dopamine-containing neurons in the NIGROSTRIAL TRACT with 6-OHDA results in symptoms that clinically resemble Parkinson’s disease.

**5-hydroxyindoleacetic acid (5-HIAA) n.** the main metabolic product of SEROTONIN. Some individuals with depression have low levels of 5-HIAA in the cerebrospinal fluid and exhibit a preferential response to CLOMIPRAMINE.

**5-hydroxytryptamine (5-HT) n.** see SEROTONIN.

**5-hydroxytryptophan (5-HTP) n.** a naturally occurring precursor of the neurotransmitter SEROTONIN. It is produced from the essential amino acid tryptophan (see TRYPTOPHAN HYDOXYLASE) and is converted in the brain to 5-hydroxytryptamine, or serotonin. Administration of 5-HTP increases the production of serotonin in the brain, and the agent is being investigated for potential use in the treatment of certain forms of MYOClonus (severe muscle spasms). 5-HTP is currently available as a dietary supplement for the relief of conditions including headache, depression, fibromyalgia, and CEREBELLAR ATAXIA (causing difficulty in standing and walking) and for appetite suppression. However, reports of a serious, potentially fatal reaction (cosinophilia-myalgia syndrome) have led to warnings regarding its use as a natural remedy.

**hydroxyzine n.** a sedating antihistamine of the DIPHE NYMETHANE class. It is used for the relief of pre- and postoperative pain, obstetric pain, anxiety, dermatitis, and vomiting. Although also appropriate for the management of alcohol withdrawal, it is rarely used for this purpose in modern clinical practice. Hydroxyzine has significant ANTI CHOLINERGIC EFFECTS. U.S. trade names: Atarax; Vistaril.

**hygiene n.** 1. the science of health and how to maintain it. 2. a condition or practice that promotes cleanliness and good health. —hygienic adj. —hygienist n.

**hygiene factors** in the TWO-FACTOR THEORY OF WORK MOTIVATION proposed by U.S. clinical psychologist Frederick Herzberg (1923–2000), certain aspects of the working situation that can produce discontent if they are poor or lacking but that cannot by themselves motivate employees to improve their job performance. These include pay, relations with peers and supervisors, working conditions, and benefits. Compare MOTIVATORS.

**hylozoism n.** the view that all material objects have some degree or quality of life. Some equate this view with PANPSYCHISM, which holds that all matter possesses some attributes of psyche. Others make the distinction that to possess the quality of life is not necessarily to be possessed of soul or sentience.
**hymen**

**hymen** *n.* a thin membrane that partly covers the opening to the vagina at birth. Although the hymen is sometimes not broken until the first experience of sexual intercourse, it may rupture at or before puberty; thus, its absence is not a reliable sign of loss of virginity. —**hymenal** adj.

**hyoscine** *n.* see SCOPOLAMINE.

**hyp-** *combining form* see HYPO-

**hypacusia** *n.* see HYPOACUSIA.

**hypalgesia** *n.* see HYPOALGESIA.

**hyper-** *prefix* 1. above or beyond (e.g., HYPERCOLUMN). 2. extreme or excessive (e.g., HYPERESTHESIA).

**hyperactivity** *n.* a condition characterized by spontaneous gross motor activity or restlessness that is excessive for the age of the individual. Although a prominent feature of ATTENTION-DEFICIT/HYPERACTIVITY DISORDER, it is not diagnostic of any particular disorder and must be correlated with other findings to identify the appropriate diagnosis. See also PURPOSELESS HYPERACTIVITY. —**hyperactive** adj.

**hyperaggressivity** *n.* an increased tendency to express anger and hostility in action, as in violent and assaultive behavior. See also EXPLOSIVE PERSONALITY.

**hyponadosteronism** *n.* see ALDOSTERONISM.

**hypercacisia** *n.* unusually acute hearing and a lowered tolerance for loud sounds. Also called **hyperacusia**.

**hyperaggressivity** *n.* an increased tendency to express anger and hostility in action, as in violent and assaultive behavior. See also EXPLOSIVE PERSONALITY.

**hyperaldosteronism** *n.* see ALDOSTERONISM.

**hyperactivity** *n.* a condition characterized by spontaneous gross motor activity or restlessness that is excessive for the age of the individual. Although a prominent feature of ATTENTION-DEFICIT/HYPERACTIVITY DISORDER, it is not diagnostic of any particular disorder and must be correlated with other findings to identify the appropriate diagnosis. See also PURPOSELESS HYPERACTIVITY. —**hyperactive** adj.

**hyperactivity** *n.* a condition characterized by spontaneous gross motor activity or restlessness that is excessive for the age of the individual. Although a prominent feature of ATTENTION-DEFICIT/HYPERACTIVITY DISORDER, it is not diagnostic of any particular disorder and must be correlated with other findings to identify the appropriate diagnosis. See also PURPOSELESS HYPERACTIVITY. —**hyperactive** adj.

**hyperarousal** *n.* 1. one of three sets of criteria used to diagnose POSTTRAUMATIC STRESS DISORDER and ACUTE STRESS DISORDER. Symptoms of hyperarousal include exaggerated startle response, disturbed sleep, difficulty in concentrating or remembering, and excessive vigilance. 2. a physiological response to stress. Also called **acute stress response.** See also FIGHT-OR-FLIGHT RESPONSE. [first described by Walter B. Cannon]

**hyperbilirubinemia** *n.* inordinate appetite and excessive intake of food. It is observed, for example, in certain psychological disorders and in patients with hypothalamic lesions. See also BILIRUBINEMIA; HYPERPHAGIA. —**hyperbilirubinemic** adj.

**hypercalcemia** *n.* high concentrations of calcium in the blood.

**hypercathechism** *n.* in psychoanalytic theory, an excess of psychic energy invested in an object. Compare HYPOCATECHISM. See CATHECHISM.

**hypercholesterolemic xanthomatosis** see XANTHOMATOSIS.

**hypercolumn** *n.* a repeating subdivision of striate cortex (primary visual cortex) that contains a full set of orientation columns and a pair of ocular dominance columns. Thus, the population of neurons in one hypercolumn includes those responsive to all orientations, as viewed through either eye. A hypercolumn occupies an area of about 1 mm² on the cortical surface.

**hypercomplex cell** a neuron in the visual cortex for which the optimal stimulus is a moving line of specific length or a moving corner. See also END-STOPPED CELL. [first described in 1965 by U.S. neurophysiologist David Hubel (1926–2013) and Swedish neurophysiologist Torsten Wiesel (1924–2013)]

**hypercorrection** *n.* in linguistics, the use of an incorrect form or pronunciation in a mistaken belief that this is more formal or correct than the one generally used. Hypercorrection usually arises from false analogy, half-remembered rules learned in childhood, or an exaggerated fear of using nonstandard or lower-class forms. Common examples in English are the incorrect use of whom rather than who in, for example, Whomever is responsible for this, and the use of I rather than me in, for example, She was referring to you and I.

**hypercritical** adj. having an excessive tendency to scrutinize and find fault.

**hyperemia** *n.* the presence of an increased amount of blood in a part of the body. In some parts, this condition causes a flushed appearance. See also BLUSHING.

**hyperesthesia** *n.* extreme sensitivity in any of the senses, especially abnormal sensitivity to touch. —**hyperesthetic** adj.

**hyperexcitability** *n.* a tendency to overreact to stimuli, often occurring during a MANIC EPISODE. —**hyperexcitable** adj.

**hyperfunction** *n.* excessive activity of a body function, part, or organ.

**hyperfunctionalism** *n.* excessive development of the genital system.

**hyperglycemia** *n.* a heightened sensitivity to taste. See SUGARFEARER. —**hypergeusic** adj.

**hyperglycemia** *n.* an excess of glucose in the blood. In diabetes mellitus, hyperglycemia results from a relative or absolute lack of the insulin needed to remove the excess glucose from the blood. Signs range from pain or sensory loss to failure of reflexes and coma. —**hyperglycemic** adj.

**hyperhedonia** *n.* a pathological increase in the feeling of pleasure derived from any act or event. Compare ANHEDONIA; HYPTIONDONIA.

**hyperhidrosis** *n.* excessive sweating, which may occur under various circumstances and is not necessarily related to environmental, physical, or psychological factors. In severe cases, the skin in the affected areas may become macerated and vulnerable to infections. Also called **hyperhidrosis**.

**hyperkinetics** *n.* a psychoactive compound that is thought to be the most pharmacologically active agent in ST. JOHN’S WORT.

**Hypericum perforatum** see ST. JOHN’S WORT.

**hyperinfection** *n.* excessive intake of food, fluid, or drugs through the mouth, particularly when intake is greater than the maximum safe level.

**hyperkinesia** *n.* 1. excessive involuntary movement. 2. restlessness or HYPERACTIVITY. Also called **hyperkinetic.** —**hyperkinetic** adj.

**hyperkinesis** *n.* a high level of sensitivity in the SOMATOSENSORY SYSTEM (e.g., to touch, weight, pressure, motion and position of the body). See also KINESIS; PROPRIOPCCEPTION. Compare HYPOKINESIA.

**hyperkinetic syndrome** an old name for ATTENTION-DEFICIT/HYPERACTIVITY DISORDER.
hyperlexia n. the development of extremely good reading skills at a very early age, well ahead of word comprehension or cognitive ability. Children with hyperlexia often start to recognize words without instruction and before any expressive language develops. Hyperlexia is usually found in the context of cognitive and language deficits or certain developmental disorders; some children with Autism, for example, may show hyperlexia. [first defined in 1967 by Norman E. Silberberg (1932–2007) and Margaret C. Silberberg] —hyperlexic adj.

hyperlipidemia n. the presence in the blood of excessive amounts of lipids (e.g., cholesterol, triglycerides), which may predispose a person to atherosclerosis.

hyperlordosis n. See LORDOSIS.

hypermania n. an extreme manic state marked by constant activity, erratic behavior, disposition, and incoherent speech. See also LETHAL CATATONIA. —hyper manic adj.

hypermetria n. overreaching an object during voluntary motor activity. This can be caused by impaired visual localization, defective visuomotor coordination, or a disorder that interferes with the execution of eye or hand movements. See also DYSMETRIA; OCULAR DYSMETRIA. Compare HYPOMETRIA.

hypersomnia n. 1. an extreme degree of retentiveness and recall, with unusual clarity of memory images. In forensic contexts, eyewitnesses have demonstrated increased recall after undergoing hypnotic induction to help retrieve memories, but such memories have been ruled inadmissible in some U.S. courts (see STATE V. MACK). 2. in memory testing, a net increase in the total number of items recalled from one test to another. Hypersomnia usually occurs when information is repeatedly tested in close succession. A net decrease in the total number of items recalled is called FORGETTING. See REMINISCENCE.

hypermobility testes testes that move between the scrotum and the abdominal cavity, usually because of an inguinal hernia that has not been corrected. The testes may descend into the scrotum when the environment is warm, or an inordinate desire for sexual activity, as seen after administration of some ANTICONVULSANT drugs. 2. an extreme responsiveness to sensory stimuli (e.g., sound, light, touch). 3. a tendency toward emotional overreaction to criticism, rejection, or other social judgment. See also SENSITIVITY.

hypersomnia n. excessive sleepiness during daytime hours or abnormally prolonged episodes of nighttime sleep. This can be a feature of certain DYSSOMNIAS (e.g., NARCOLEPSY) or other sleep or mental disorders, or it can be associated with neurological dysfunction or damage, a general medical condition, or substance use. However, hypersomnia may occur in the absence of any known cause or association with another condition (see PRIMARY HYPERSONMIA). See also DISORDERS OF EXCESSIVE SOMNOLENCE. Compare HYPOSOMNIA.

hypersonomolence disorder see DISORDERS OF EXCESSIVE SOMNOLENCE; PRIMARY HYPERSONMIA.
Hyperspecificty

**Hyperspecificity** *n.* a behavioral situation in which a learned association between two stimuli fails to generalize when the stimuli are presented in a novel combination. Although hyperspecificity is a common occurrence, it has been observed particularly in such disorders as amnesia and autism. One study, for example, described the case of a child with autism who would not use a friend’s toilet because it was not the specific one on which he was originally toilet trained.

**Hypersthenia** *n.* a condition of excessive muscle strength and tension. —**hypersthenic** *adj.*

**Hypertelorism** *n.* an abnormally large distance between two body organs or areas. *Ocular hypertelorism,* in which the eyes are further apart than normal, is a symptom associated with a variety of genetic disorders and neurological conditions involving cranial anomalies.

**Hypertension** *n.* high blood pressure: a circulatory disorder characterized by persistent arterial blood pressure that exceeds a standard, which usually is 140/90 mmHg. In the majority of cases, there is no obvious cause (see ESSENTIAL HYPERTENSION). In a few people, high blood pressure can be traced to a known cause, such as tumors of the adrenal gland, chronic kidney disease, hormone abnormalities, the use of oral contraceptives, or pregnancy. This is called secondary hypertension; it is usually cured if its cause is removed or is corrected. Malignant hypertension is a form of very high blood pressure that comes on quickly, usually accompanied by retinal hemorrhaging, and can result in organ damage if not immediately treated. Compare HYPOTENSION. —**hypertensive** *adj.*

**Hypertensive crisis** a sudden extreme rise in blood pressure.

**Hypertymia** *n.* an emotional response that is disproportionate to the stimulus, frequently occurring in MANIC EPISODES and HYPOMANIC EPISODES.

**Hypertropia** *n.* the condition of the eyes being farther apart than normal, is a symptom asso- ciated with a variety of genetic disorders and neurological conditions involving cranial anomalies.

**Hypertrophy** *n.* overgrowth of an organ or part due to an increase in the size of its constituent cells. —**hypertrophic** *adj.*

**Hypertropia** *n.* see STRABISMUS.

**Hyperventilation** *n.* abnormally rapid and deep breathing, usually due to anxiety or emotional stress. It lowers the carbon dioxide level of the blood and produces symptoms such as light-headedness, palpitation, numbness and tingling in the extremities, perspiration, and in some cases fainting (these features are known as hyperventilation syndrome). Also called overbreathing.

**Hypervigilance** *n.* a state of abnormally heightened alertness, particularly to threatening or potentially dangerous stimuli.

**Hypesthesia** *(hypeaesthesia)* *n.* severely diminished sensitivity in any of the senses, especially the touch sense. Also called hypoesthesia *(hypoesthesia).*

**Hypochondria** *(hypocondria)* *n.* a pathologically diminished in pleasure from experiences that normally would produce pleasure. Compare ANHEDONIA; HYPERHEDONIA.

**Hypophenophilia** *n.* sexual interest and arousal derived from touching skin, fur, hair, leather, or fabrics.

**Hypn-** combining form see HYPNO-.

**Hypnagogic** *adj.* describing or relating to the drowsy state that occurs in the transition from wakefulness to sleep. A transient, dreamlike image experienced while falling asleep is called a **hypnagogic hallucination**. Compare HYPNOPOMPYC.

**Hypnalgia** *n.* literally, sleep pain: pain experienced during sleep or in a dream.

**Hyno-** *(hyno-)* combining form sleep.

**Hypoanalysis** *n.* a modified and shortened form of psychoanalytic treatment, or a technique incorporated into full analysis, in which hypnosis is used (a) to help patients overcome RESISTANCES, (b) to enhance the TRANSFERRENCE process, and (c) to recover memories and release repressed material. The material so brought forth is meant to be incor- porated into the patient’s consciousness for exploration and, ultimately, for interpretation by the therapist. However, this form of therapy is controversial because many psychologists and psychoanalysts question the veracity of memories recovered during a hypnotic state.

**Hynodontics** *n.* the use of hypnotic suggestion in dentistry as a means of relaxing tense patients, relieving anxiety, reinforcing or replacing anesthesia, and correcting such habits as bruxism (grinding the teeth).

**Hypnodrama** *n.* a technique of PSYCHODRAMA in which a hypnotic state is induced and the client, or PROTAGONIST, is encouraged to act out his or her relationships and traumatic experiences with the aid of AUXILIARY EGOS. Hypno- drama might be used to overcome a client’s resistance to dramatizing his or her problems in conscious psychodrama and to stimulate the revival of past incidents and emotional scenes in their full intensity. The technique is rarely used now. [introduced in 1959 by Jacob L. MORENO]

**Hypnogenic** *adj.* 1. sleep producing. 2. hypnosis inducing. Historically, hypnosis was misidentified as a sleeplike state.

**Hypnogenic spot** a putative point on the body that, when touched, may induce hypnosis if the individual is suggestible.

**Hynoid state** 1. a state resembling hypnosis. 2. a state of light trance. 3. in medical usage, a sleeplike state. Also called hypnoidal state.

**Hypnophrenosis** *n.* any type of sleep disturbance. See also SLEEP DISORDER.

**Hypnogenic hallucination** *n.* a pathologically diminished in pleasure from experiences that normally would produce pleasure. Compare ANHEDONIA; HYPERHEDONIA.

**Hypnosis** *n.* (pl. hypnoses) the procedure, or the state induced by that procedure, in which suggestion is used to evoke changes in sensation, perception, cognition, emo- tion, or control over motor behavior. Subjects appear to be receptive, to varying degrees, to suggestions to act, feel, and behave differently than in an ordinary waking state. The exact nature of hypnotic suggestibility, and its possible
therapeutic uses, are still being studied and debated. As a specifically psychotherapeutic intervention, hypnosis is referred to as HYPNOTHERAPY. See also ALTERED STATE OF CONSCIOUSNESS; HETEROHYPNOSIS; POSTHYPNOTIC SUGGESTION; SELF-HYPNOSIS; WAKING HYPNOSIS.

**hypnotherapy n.** the use of hypnosis in psychological treatment, either in BRIEF PSYCHOTHERAPY directed toward alleviation of symptoms and modification of behavior patterns or in long-term RECONSTRUCTIVE PSYCHOTHERAPY aimed at personality adaptation or change. Hypnotherapy may use one or a combination of techniques, typically involving the administration by a properly trained professional of therapeutic suggestions to patients or clients who have been previously exposed to HYPNOSTIC INDUCTION. Although discussions of its clinical applications engender controversy, there is scientific evidence that hypnotherapy can be applied with some success to a wide range of health problems (e.g., hypertension, asthma, insomnia, bruxism), chronic and acute pain management, habit modification (e.g., overeating, smoking), mood and anxiety disorders (e.g., some phobias), and personality disorders. There is also some positive evidence demonstrating its effectiveness as an ADJUNCTIVE THERAPY. Also called clinical hypnosis. See also AUTOMATIC WRITING; DIRECT SUGGESTION; DREAM SUGGESTION; ERICKSONIAN PSYCHOTHERAPY; HYPNOANALYSIS; HYPNOTIC REGRESSION.

**hypnotic 1. n.** a drug that helps induce and sustain sleep by increasing drowsiness and reducing motor activity. In general, hypnotics differ from SEDATIVES only in terms of the dose administered, with higher doses used to produce sleep or anesthesia and lower doses to produce sedation or relieve anxiety. BENZODIAZEPINES are among the most widely prescribed hypnotics; antihistamines and other agents are used to lesser degrees. Newer, nonbenzodiazepine hypnotics, such as ESZOPICLONE, ZOLPIDEM, and ZALEPLON, are achieving clinical currency because of the relative infrequency of adverse side effects. 2. adj. pertaining to hypnosis or sleep.

**hypnotic amnesia** forgetfulness of certain specified events that is induced by hypnotic suggestion. See also POSTHYPNOTIC AMNESIA.

**hypnotic analgesia** reduced sensitivity to pain under hypnotic suggestion.

**hypnotic induction** a series of simple tasks, such as allowing one’s hand to fall upward, that leads an individual to enter a state of higher suggestibility during hypnosis. The process depends on the individual’s HYPNOTIC SUSCEPTIBILITY and often involves relaxation and a subtle shifting of perceived control to the hypnotist.

**hypnotic regression** a therapeutic technique in which an individual under hypnosis is induced to relive a previous experience that may be contributing to current emotional difficulties. There are two types of hypnotic regression: AGE REGRESSION and PAST-LIFE REGRESSION.

**hypnotic rigidity** a condition of apparent muscular rigidity induced by suggestion during hypnosis. For example, individuals told to hold out their arms in a rigid way may find themselves unable to bend the arm when asked to do so. See also CHALLENGE SUGGESTION; IDEOMOTOR SUGGESTION.

**hypnotic susceptibility** the degree to which an individual is able to enter into hypnosis. Although many individuals can enter at least a light trance, people vary greatly in their ability to achieve a moderate or DEEP TRANCE. Also called hypnotizability. See also STANFORD HYPNOTIC SUSCEPTIBILITY SCALE.

**hypnotic trance** see TRANCE.

**hypnotism n.** 1. the act of inducing hypnosis. 2. the practice of hypnosis. [usually credited to James BRAID, shortened from his word, neurohypnotism]

**hypnotizability n.** see HYPNOTIC SUSCEPTIBILITY. —hypnotizable adj.

**hypo- (hyp-) combining form** 1. under or below (e.g., HYPOGASTRAS). 2. less than normal: deficient (e.g., HYPOGLYCEMIA).

**hypoactive sexual desire disorder** in DSM–IV–TR, persistent and distressing deficiency or absence of sexual interest and desire to engage in sexual activity. This may be global, involving all forms of sexual activity, or situational, limited to one partner or one type of sexual activity. It also may be lifelong or result from some life event or relationship issue. In DSM–5, this term is tied exclusively to males and is called male hypoactive sexual desire disorder.

**hypoactivity n.** abnormally slowed or deficient motor or other activity. For example, functional neuroimaging studies have shown that depression is accompanied by a hypo-activity of brain regions involved in positively motivated behavior.

**hypoaucusia n.** a state of reduced hearing sensitivity. Also called hypacusia; hypacusia: hypacusia. —hypoaucitic adj.

**hypopagia n.** diminished sensitivity to pain. Also called hypalgia.

**hypobaropathy** n. see ALTITUDE SICKNESS.

**hypocathexis n.** in psychoanalytic theory, an abnormally low investment of PSYCHIC ENERGY in an OBJECT. Compare HYPERCATHEXIS. See CATHEXIS.

**hypochondriasis n.** morbid concern with the state of one’s health, including unfounded beliefs of ill health. The individual is often focused on having one type of illness at a time. When severe and disabling, this preoccupation is classified as a mental disorder and known as HYPOCHONDRIASIS. —hypochondriac or hypochondriacal adj. —hypochondriac n.

**hypochondriasis n.** in DSM–IV–TR, a SOMATOFORM DISORDER characterized by a preoccupation with the fear or belief that one has a serious physical disease based on the incorrect and unrealistic interpretation of bodily symptoms. This fear or belief persists for at least 6 months and interferes with social and occupational functioning in spite of medical reassurance that no physical disorder exists. DSM–5 eliminates this diagnosis, partly because of its perceived negative connotations (e.g., it has been perceived by patients as dismissing the validity of their concerns), and replaces it with two separate diagnoses that are each characterized by high health anxiety and health-related preoccupations but that occur either in the presence of significant somatic symptoms (see SOMATIC SYMPTOM DISORDER) or in the absence or with minimal evidence of such symptoms (see ILLNESS ANXIETY DISORDER).

**hypodermic injection** see SUBCUTANEOUS INJECTION.

**hypoeesthesia (hypoesthesia) n.** see HYPOSESTHESIA.

**hypofrontality n.** a condition of reduced activation or inadquate functioning of the cortex of the frontal lobes of
hypofunction

the brain. In theory, this is a factor in schizophrenia, but it is not well established either as a characteristic phenomenon or as a cause.

**hypofunction** n. reduced function or activity, especially of an organ, such as a gland.

**hypogastric nerve** a pair of single large nerves or sets of smaller parallel nerves that extend into the pelvic region and carry postganglionic fibers that innervate the bladder, rectum, and genitalia.

**hypoglosia** n. diminished sensitivity to taste. See also dysgeusia. —**hypogusic** adj.

**hypoglossal nerve** the 12th CRANIAL NERVE, a motor nerve that originates in a NUCLEUS on the floor of the fourth VENTRICLE within the brain and innervates the muscles of the tongue, lower jaw, and areas of the neck and chest. Also called cranial nerve XII.

**hypoglycemia** n. the condition of having a low blood-sugar level, due to interference with the formation of sugar in the blood or excessive utilization of sugar. In infants, the major symptoms are tremors, cyanosis, seizures, apathy, weakness, respiratory problems, and failure to develop intellectually; the infantile idiopathic form may be due to a single recessive gene. In adults, the major symptoms are weakness, profuse sweating, nervousness, and dizziness. The adult form may be a psychophysiological reaction (functional hyperinsulinism), or it may result from inadequate intake of carbohydrates or insulin overdose in those with diabetes mellitus. —**hypoglycemic** adj.

**hypogonadism** n. decreased functional activity of the gonads, with retardation of growth and sexual development.

**hypokinesis** n. abnormal slowness in the initiation of voluntary movement. Compare bradykinesia. Also called hypokinesia. —**hypokinetic** adj.

**hypokinesthesia** n. a diminished level of sensitivity in the somatosensory system (e.g., to touch, weight, pressure, and motion and position of the body). See also kinesesthesia; proprioception. Compare hyperkinesesthesia.

**hypoplasia** n. an abnormally low level of lipids in the blood.

**hypomania** n. 1. generally, a state of enhanced mood and increased energy and activity that resembles MANIA but is milder. 2. more specifically, a HYPOMANIC EPISODE. —**hypomanic** adj.

**hypomanic episode** a period of elevated, expansive, or irritable mood accompanied by various combinations of inflated self-esteem, a decreased need for sleep, increased speech, racing thoughts, distractibility, increased activity or PSYCHOMOTOR AGITATION, and increased involvement in risky activities (e.g., buying sprees, sexual indiscretions). One or more hypomanic episodes are characteristic of bipolar II disorder (see bipolar disorder), and hypomanic symptoms are a feature of CYCLOTHYMIC DISORDER. Also called hypomania. Compare manic episode.

**hypomenorrhea** n. a condition of diminished menstrual flow or menstruation of abnormally short duration.

**hypometria** n. underreaching an object during voluntary motor activity. This can be caused by impaired visual localization, defective visuomotor coordination, or a disorder that interferes with the execution of eye or hand movements. See also dysmetria; ocular dysmetria. Compare hypermetria.

**hypomotility** n. abnormally decreased or deficient activity or movement.

**hyponasality** n. lack of nasal resonance as a result of partial or complete obstruction in the nasal tract. Also called denasality.

**hypophagia** n. pathologically reduced food intake. Compare hyperphagia.

**hypophoria** n. deviation of one eye in a downward direction. See also phoria.

**hypophyseal cachexia** a disease caused by total failure of the pituitary gland, resulting in secondary atrophy of the adrenal cortex, thyroid gland, and gonads. Sexual glands and breasts atrophy, teeth and hair fall out, and anorexia, diabetes insipidus, hypoglycemia, and mental changes develop. The disease occurs in two forms: Sheehan's syndrome, which affects women after childbirth; and SIMMONDS' disease, which affects both sexes. Also called pituitary cachexia.

**hypophyseal fossa** see fossa.

**hypophysectomy** n. surgical removal of the pituitary gland (hypophysis). Also called pituitectomy.

**hypophysis (hypophysis cerebri)** n. see pituitary gland.

**hypoplasia** n. underdevelopment of an organ or tissue, usually due to an inadequate number of cells or a diminished size of structural cells. —**hypoplastic** adj.

**hypoprosxia** n. an abnormal lack of attentive ability. Also called hypoprospsia.

**hyporexia** n. a pathologically decreased appetite. See also anorexia. Compare hyperorexia.

**hyposexual nature** n. an abnormally low level of sexual behavior. Hyposexual individuals may show no sex drive or interest in sexual activity. —**hyposexual** adj.

**hyposmia** n. decreased sensitivity to some or all odors. Individuals with this condition are described as hyposmic. Also called microsmia. Compare hyperosmia.

**hyposomnia** n. a reduction in a person's sleep time, often as a result of insomnia or some other sleep disturbance. See also sleep disorder. Compare hypersomnia.

**hypospadias** n. a congenital anomaly in which the urethra opens below its normal anatomical position. In males, hypospadias is usually manifested by a urethral opening on the underside of the penis. In females, the urethra may open into the vagina.

**hypotension** n. abnormally low blood pressure, causing dizziness and fainting. Compare hypertension. See also orthostatic hypotension. —**hypotensive** adj.
**hypothalamic hormone** any hormone secreted by neurons of the HYPOTHALAMUS. Neuroendocrine cells in the hypothalamus produce the hormones oxytocin and vasopressin. The axons of these cells pass through the pituitary stalk (infundibulum) to the posterior pituitary, where they are released into the bloodstream. Other neuroendocrine cells in the hypothalamus produce either releasing hormones, which stimulate secretion of anterior pituitary hormones, or inhibiting hormones, which prevent secretion of anterior pituitary hormones. These hormones travel to the anterior pituitary through the hypothalamic–pituitary portal system.

**hypothalamic hyperphagia** see ventromedial hypothalamic syndrome.

**hypothalamic–hypophyseal portal system** see hypothalamic–pituitary portal system.

**hypothalamic–pituitary–adrenal axis** (HPA axis) a major mammalian system maintaining homeostasis by regulating the neuroendocrine and sympathetic nervous systems as well as modulating immune function. Consisting of the hypothalamus in the center of the brain, the pituitary gland directly underneath, and the adrenal glands on top of the kidneys, the HPA axis helps regulate such widely varied processes as food consumption, digestion, energy usage (in the form of glucose metabolism), reproduction and sexual behavior, cardiovascular functioning, memory acquisition and retrieval, and emotion, and it also forms the core of the physiological response to stress. Outputs from the amygdala stimulate the paraventricular nucleus of the hypothalamus to secrete arginine vasopressin (AVP) and corticotropin-releasing factor (CRF) into the hypothalamic–pituitary portal system. The pattern of release follows a circadian rhythm in which the highest levels of circulating vasopressin and CRF occur in the early morning and gradually fall throughout the day to a nighttime low. In the presence of stressors, however, this circadian rhythm disappears and secretions remain elevated to enable the body to properly mobilize to confront or avoid these stressors as part of the general adaptation syndrome. AVP and CRF then synergistically stimulate the formation and release from the anterior pituitary of corticotropin, which in turn regulates the production and release of cortisol, and other glucocorticoids from the outer layer (cortex) of the adrenal gland into the bloodstream. Cortisol indirectly inhibits the production and release of additional AVP and CRF through its influence upon the hippocampus and other brain areas, thus forming a self-regulating negative feedback loop. Dysfunction of the HPA axis has been implicated in the pathophysiology of numerous conditions, such as mood disorders, anxiety disorders, eating disorders, obesity, alcohol dependence, insomnia, gastrointestinal disorders, cardiovascular disease, chronic fatigue syndrome, fibromyalgia, cancer, and rheumatoid arthritis and other autoimmune diseases. Also called hypothalamic–pituitary–adrenocortical system (HPA system). See also sympathetically-adrenergic axis.

**hypothalamic–pituitary portal system** a system of blood capillaries that transports releasing hormones from the hypothalamus to the anterior pituitary. Also called hypothalamic–hypophyseal portal system. See also hypothalamic–pituitary–adrenal axis.

**hypothalamic syndrome** any of various disorders arising from injuries to the hypothalamus. These may involve disturbances of eating, drinking, sleep, water balance, and temperature or development of secondary sexual characteristics. See lateral hypothalamic syndrome; ventromedial hypothalamic syndrome.

**hypothalamic theory of Cannon** see cannon–bard theory. [Walter B. Cannon]

**hypothalamus** n. (pl. hypothalami) part of the diencephalon of the brain, lying ventral to the thalamus, that contains nuclei with primary control of the autonomic (involuntary) functions of the body. It also helps integrate autonomic activity into appropriate responses to internal and external stimuli. Additionally, it is involved in appetite, thirst, sleep, and sexuality. See also hypothalamic hormone; lateral hypothalamus; ventromedial hypothalamus. —hypothalamic adj.

**hypothermia** n. the state of having an abnormally low body temperature. It can be caused by absence of normal reflexes such as shivering, sometimes associated with disease or a disorder of the brain, or by exposure to extreme cold. Accidental hypothermia is most likely to affect older people, who are less able to cope with the cooling effect of environmental temperatures in the winter months. Symptoms include listlessness, drowsiness, apathy, and indifference to progressive frostbite, progressing (if untreated) to coma and death. See also induced hypothermia. —hypothermic adj.

**hypothesis** n. (pl. hypotheses) an empirically testable proposition about some fact, behavior, relationship, or the like, usually based on theory, that states an expected outcome resulting from specific conditions or assumptions.

**hypothesis testing** a statistical inference procedure for determining whether a given proposition about a population parameter should be rejected on the basis of observed sample data. See also significance testing.

**hypothetical construct** see construct.

**hypothetical imperative** in the moral teaching of Immanuel Kant, a maxim of the type “If you would achieve X, take action Y.” Such maxims of skill or prudence differ from the categorical imperative of morality in that (a) they are aimed at particular material ends rather than absolute and unconditional ends and (b) they cannot be defended as a universal and transhistorical law. See also universalizability.

**hypothetico-deductive method** a method of scientific inquiry in which the credibility or explanatory power of a falsifiable hypothesis is tested by making predictions on the basis of this hypothesis and determining whether these predictions are consistent with empirical observations. It is one of the most widely used scientific methods for disproving hypotheses and building corroborations for those that remain. Also called mathematico-deductive method.

**hypothetico-deductive reasoning** the abstract logical reasoning that, according to the piagetian theory of cognitive development, emerges in early adolescence and marks the formal operational stage. Hypothetico-deductive reasoning is distinguished by the capacity for abstract thinking and hypothesis testing, which frees the adolescent from total reliance on concrete thinking and immediate perception.

**hypothymia** n. an obsolescent name for a restricted range of affect, occurring in severe cases of major depressive episode.
hypothyroidism n. underactivity of the thyroid gland, resulting in underproduction of thyroid hormones and a consequent decrease in metabolic rate. Manifestations include fatigue, weakness, and weight gain and other physical problems. Dysphoria, depression, and psychosis can be seen in more severe forms. Compare HYPERTHYROIDISM. See also CONGENITAL HYPOTHYROIDISM.

hypotonia n. decreased muscle tone or strength. Compare HYPERTONIA. —hypotonic adj.

hypotropia n. see STRABISMUS.

hypovolemic thirst thirst caused by depletion of the volume of extracellular fluid, as, for example, by blood loss (i.e., hypovolemia) or vomiting. Also called volumetric thirst. Compare OSMOMETRIC THIRST.

hypoxanthine–guanine phosphoribosyltransferase (HGPRT) an enzyme whose deficiency in the human body leads to symptoms of Lesch–Nyhan syndrome. It was the first enzyme found to be associated with an inherited disorder involving maladaptive behavior and intellectual disability. Also called hypoxanthine phosphoribosyltransferase.

hypoxia n. a deficiency of oxygen in the blood. The most reliable method for measuring the degree of hypoxia is blood gas analysis to determine the partial pressure of oxygen in the arterial blood. Insufficient oxygenation of the blood may lead to HYPOXIA. Compare ANOXEMIA.

hypoxia n. reduced oxygen in the body tissues, including the brain. This can result in widespread brain injury depending on the degree of oxygen deficiency and its duration. Signs and symptoms of hypoxia vary according to its cause but generally include shortness of breath, rapid pulse, fainting, and mental disturbances (e.g., delirium, euphoria). See also ANOXIA. —hypoxic adj.

hypoxic hypoxia hypoxia due to insufficient oxygen reaching the blood, as at the decreased barometric pressures of high altitudes. See ALTITUDE SICKNESS.

hypoxophilia n. sexual fantasy involving arousal obtained by reduction of oxygen flow to the brain. It is a PARAPHILIA usually involving one person alone (i.e., AUTOEROTIC ASPHYXIA) but occasionally involving sexual partners (i.e., ASPHYXPHILIA). Methods and tools used to achieve arousal include, among others, strangulation by rope, smothering by means of a plastic bag over the head, hanging, and breathing in an anesthetic. Highly dangerous, hypoxophilia results in numerous fatalities.

hysterectomy n. the surgical removal of the uterus. It may be total hysterectomy, including excision of the cervix; subtotal hysterectomy, in which only the uterus above the cervix is removed; or radical hysterectomy, with excision of a part of the vagina with the uterus and cervix.

hysterectomy n. 1. an effect in which the perception of a stimulus is influenced by one’s immediately preceding perceptions. It can be demonstrated in experiments that involve making successive changes to a stimulus that varies along some dimension and asking a participant to describe his or her perception. When values along the dimension are steadily increased, there comes a point at which the participant will begin to place the percept in a different category (e.g., a sound is loud rather than quiet). However, when values along the dimension are decreased, the crossover point will occur at a different point along the dimension. 2. in vision, the tendency for a perceptual state to persist under gradually changing conditions. For example, stereoscopic fusion can persist, producing the appearance of depth even when BINOCULAR DISPARITY between the two images becomes so great that they would normally not be able to be fused. —hysteretic adj.

hysteria n. the historical name for the condition now largely classified as CONVERSION DISORDER but with symptoms dispersed across other formal diagnoses as well (e.g., HISTRIONIC PERSONALITY DISORDER). Although technically outdated, it is often used as a lay term for any psychogenic disorder characterized by symptoms such as paralysis, blindness, loss of sensation, and hallucinations and often accompanied by suggestibility, emotional outbursts, and histrionic behavior. Sigmund Freud interpreted hysterical symptoms as defenses against guilty sexual impulses (e.g., a paralyzed hand cannot masturbate), but other conflicts are now recognized. Freud also included dissociative conditions in his concept of hysteria, but these are now regarded as separate disorders. The name derives ultimately from the Greek hystera, “uterus,” based on the early and erroneous belief that such disorders were unique to women and originated in uterine disorders. —hysterical adj.

hysterical amnesia an older name, now rarely encountered, for a disorder characterized by inability to recall traumatic or anxiety-provoking events, such as experiences associated with guilt, failure, or rejection. See DISSO-CIATIVE AMNESIA.

hysterical blindness see FUNCTIONAL BLINDNESS.

hysterical disorder an outdated name for any disorder characterized by involuntary psychogenic dysfunction of the sensory, motor, or visceral activities of the body. See CONVERSION DISORDER; SOMATIZATION DISORDER.

hysterical paralysis a former name for CONVERSION PARALYSIS.

hysterical personality disorder see HISTRIONIC PERSONALITY DISORDER.

hysterical psychosis an old name for a condition in which psychotc symptoms (e.g., hallucinations, delusions, and bizarre and sometimes violent behavior) appear suddenly in a person with HISTRIONIC PERSONALITY DISORDER, usually in response to a stressful precipitating life event. Symptoms are of short duration, lasting 2 weeks or less, and there is a full return to the previous level of functioning. Currently, however, hysterical psychosis is not widely considered a distinct clinical entity. Also called dissociative psychosis.

hysteriform adj. characterized by symptoms that resemble those associated with HYSTERTIA. The term is not in current usage.

hystero- (hyster-) combining form uterus.

Hz symbol for HERTZ.
The iatrochemical school provided the impetus for the development of modern pharmaceutical laboratories and physiological processes. This concept, at least in its early stages, included the development of the thermometer as an instrument for physical or psychological disorders. The process of developing a pathological condition that is inadvertently induced or aggravated in a patient is called iatrogenesis (or iatrogeny).

Iatrogenia adj denoting or relating to a pathological condition that is inadvertently induced or aggravated in a patient by a health care provider. It may be due to the behavior of the provider (e.g., the manner in which he or she examined the patient) or be a result of the treatment he or she prescribed. For example, an iatrogenic addiction is a dependence on a substance, most often a painkiller or minor tranquilizer, originally prescribed by a physician to treat a physical or psychological disorder. The process of developing an iatrogenic condition is called iatrogenesis (or iatrogeny).

Iatrophysical school of thought a 17th-century school of thought that sought to apply the principles of mathematics and mechanics to medicine. Early examples include the development of the thermometer as an instrument of medical diagnosis and the invention of other mechanical and measurement devices to impart knowledge of physiological processes. This concept, at least in its early development, was based on the Cartesian view that the physical body is essentially a machine (see CARTESIAN DUAlISM). Many early proponents of this school also practiced iatrochemistry (see IATROCHEMICAL SCHOOL OF THOUGHT). Also called iatromathematics: iatromechanism.

Ibogaine n a hallucinogenic agent found in the root of the African forest plant Tabernanthe iboga. It is used mainly by adherents of the Bwiti (or Bouiti) religion in rituals or as a stimulant, although data suggest that ibogaine may have potential clinical use in the treatment of substance dependence and management of withdrawal symptoms; it blocks serotonin reuptake and is also an agonist at kappa opioid receptors.

Ibotenic acid an agent that enhances the action of the excitatory neurotransmitter GLUTAMATE. It is an agonist at NMDA RECEPTORS. Ibotenic acid and its metabolic product, muscimol (a GABA AGONIST), are found in some mushrooms of the genus Amanita (see MUSHROOMS).

IBS abbreviation for IRRITABLE BOWEL SYNDROME.

ICC 1. abbreviation for INTRACLASS CORRELATION COEFFICIENT. 2. abbreviation for ITEM CHARACTERISTIC CURVE.

ICD abbreviation for INTERNATIONAL CLASSIFICATION OF DISEASES.

Ice n. slang for illicitly manufactured METHAMPHETAMINE, a common drug of abuse, especially the free-base, concentrated, smokable form of methamphetamine. It has an intense, persistent action; chronic use may lead to serious psychiatric, metabolic, cardiovascular, and neuromuscular changes.

Iceberg metaphor the notion that conscious events, like the proverbial tip of the iceberg, represent only a small and accessible aspect of a larger domain of unconscious psychological functioning. Although this metaphor is commonly attributed to Sigmund Freud, it appears nowhere in his published works.

Iceberg principle the principle that the more obvious reasons for a behavior or opinion are almost never a complete explanation: Much of the real explanation lies below the surface, requiring extensive interviews or other research techniques to uncover.

Iceberg profile a pattern of response to the profile of mood states questionnaire in which vigor scores are above the 50th T SCORE and all other scales (tension, depression, anger, fatigue, and confusion) are below that level. Successful ELITE ATHLETES have been shown to exhibit this mental health profile.
**iconic memory**

which a resemblance between two objects, images, or events allows one to be a sign or symbol for the other.

**iconic memory** the brief retention of an image of a visual stimulus beyond cessation of the stimulus. This iconic image usually lasts less than a second. In a **MULTISTORE MODEL OF MEMORY**, iconic memory precedes **SHORT-TERM MEMORY**. Also called **VISUAL MEMORY**.

**iconic representation** 1. the **MENTAL REPRESENTATION** of visual stimuli in raw, unprocessed form. 2. in Jerome Seymour Bruner’s theory of cognitive development, the representation of objects and experiences as images based on sensory impressions. The process underlying this form of knowledge acquisition, which begins to develop in early infancy and is dominant in the preschool years, is called the **ICONIC MODE** (or **ICONIC STAGE**). Compare **INACTIVE REPRESENTATION**; **SYMBOLIC REPRESENTATION**.

**iconic symbol** a linguistic sign (written or spoken word) that has a physical resemblance, rather than an arbitrary relation, to its referent. Examples include onomatopoeic coinages, such as *choo-choo* (train), and the signs used in pictographic languages. With these few exceptions, linguistic signs are held to be arbitrary in modern thinking on language. The contrary view, which holds that there is a general if hidden correspondence between the sounds of words and their referents, is known as the theory of **PHONETIC SYMBOLISM**. Compare **ARBITRARY SYMBOL**.

**iconoclast** n. 1. one who challenges or seeks to overthrow established ideas, traditions, or practices. 2. in religion, one who opposes iconolatry or, more generally, the use of physical images in worship. —**ICONOCLASTIC adj**.

**iconolatry** n. the veneration of certain holy images as channels of the divine, as practiced by the Orthodox and Eastern Catholic (Uniate) Churches. This is distinguished from worship of the images themselves, which would be idolatry.

**iconomania** n. a pathological impulse to collect and worship images.

**ICP** abbreviation for **INTRACRANIAL PRESSURE**.

**ICS** abbreviation for **INTRACRANIAL STIMULATION**.

**ICSH** abbreviation for interstitial cell-stimulating hormone. See **LUTINIZING HORMONE**.

**icterus** n. see **JAUNDICE**.

**ictus** n. a sudden event, particularly a seizure.

**ICU** abbreviation for **INTENSIVE CARE UNIT**.

**id** 1. *n.* in psychoanalytic theory, the component of the personality that contains the instinctual, biological drives that supply the psyche with its basic energy or *lust*. Sigmund Freud conceived of the id as the most primitive component of the personality, located in the deepest level of the unconscious; it has no inner organization and operates in obedience to the **PLEASURE PRINCIPLE**. Thus, the infant’s life is dominated by the desire for immediate gratification of instincts, such as hunger and sex, until the ego begins to develop and operate in accordance with reality. See also **PRIMARY PROCESS**; **STRUCTURAL MODEL**. 2. abbreviation for **intraabdominal**.

**IDA** abbreviation for **INITIAL DATA ANALYSIS**.

**id anxiety** in psychoanalytic theory, anxiety deriving from instinctual drives. This is the main cause of **PRIMARY ANXIETY**. Compare **EGO ANXIETY**; **SUPEREGO ANXIETY**.

**IDD** abbreviation for insulin-dependent DIABETES MELLITUS.

**idea** n. 1. in cognitive psychology, a mental image or cognition that is ultimately derived from experience but that may occur without direct reference to perception or sensory processes. 2. in the writings of René Descartes and the British empiricist philosophers (see **EMPIRICISM**), a mental event that may correspond to something outside the mind but that is itself the immediate object of thought or perception. Descartes made a celebrated and much disputed distinction between **DERIVED IDEAS** and **INNATE IDEAS**. See also **ASSOCIATION OF IDEAS**. 3. in the thought of Greek philosopher Plato, the abstract or intellectual form of something regarded as its true reality. See **PLATONIC IDEALISM**; **THEORY OF FORMS**.

**IDEA** abbreviation for INDIVIDUALS WITH DISABILITIES EDUCATION ACT.

**idealism** n. 1. in philosophy, the position that reality, including the natural world, is not made up of separate objects. Positions range from strong forms, holding that mind constitutes the things of reality, to weaker forms, holding that reality is correlated with the workings of the mind. There is also a range of positions as to the nature of mind, from those holding that mind must be conceived of as absolute, universal, and apart from nature itself to those holding that mind may be conceived of as individual minds. See **ABSOLUTE IDEALISM**; **IDEALISTIC MONISM**; **SUBJECTIVE IDEALISM**. See also **MIND–BODY PROBLEM**. 2. commitment to moral, political, or religious ideals. 3. see **PLATONIC IDEALISM**. Compare **MATREALISM**. —**IDEALIST** n. —**IDEALISTIC** adj.

**idealistic monism** the position that all reality consists of a single substance, that substance being mind or spirit. See **IDEOISM**; **MONISM**. Compare **NATURAL MONISM**. See also **MIND–BODY PROBLEM**.

**idealization** n. 1. the exaggeration of the positive attributes and minimization of the imperfections or failings associated with a person, place, thing, or situation, so that it is viewed as perfect or nearly perfect. 2. in psychoanalytic theory, a **DEFENSE MECHANISM** that protects the individual from conscious feelings of ambivalence toward the idealized object. Idealization of parents and other important figures plays a role in the development of the **EGO–IDEAL**. —idealize vb.

**idealizing transference** in **SELF PSYCHOLOGY**, a **NARCISSISTIC TRANSFERENCE** that, when activated in treatment, results in the patient experiencing the analyst or therapist as a powerful and benevolent parental figure. When engaged in this form of transference, the patient feels protected and able to share in the power and capabilities of the therapist, much as a young child idealizes his or her parents and feels protected by them. Compare **MIRROR TRANSFERENCE**; **TWINSHIP TRANSFERENCE**. [first described by Austrian-born U.S. psychoanalyst Heinz Kohut (1913–1981)]

**ideal observer** a hypothetical person whose sensory and perceptual systems operate without error or bias. The concept of the ideal observer is used most commonly in the context of psychophysical testing, particularly **SIGNAL DETECTION THEORY**. Performance of the ideal observer can be simulated and compared with actual human performance.

**ideal performance state** (IPS) the state of cognitive and physiological activation that permits optimal perfor-
mance for an individual. See ZONE OF OPTIMAL FUNCTIONING.

ideal self in models of self-concept, a mental representation of an exemplary set of psychological attributes that one strives or wishes to possess.

idea of influence see DELUSION OF INFLUENCE.

idea of reference the sense that events or the actions of others (e.g., talking, whispering, smiling) relate particularly to oneself. In an extreme degree, it is a DELUSION OF REFERENCE.

ideation n. the process of forming ideas and images.

—ideate vb. —ideational adj.

ideational agnosia a form of AGNOSIA characterized by an inability to form an association between the idea or purpose of an object and the object itself. This inability cannot be attributed to impairment of a primary sensory modality.

ideational apraxia see APAXIA.

idee fixe 1. a firmly held, irrational idea or belief that is maintained despite evidence to the contrary. It may take the form of a delusion and become an obsession. Also called fixed belief: fixed idea. 2. a subconscious unit of mental processing (see AUTOMATISM) that has become split off or dissociated from consciousness and, as a result, interferes with the normal processing of information. In some theories, this is considered a primary mechanism for the symptoms of HYSTERIA. [proposed by Pierre JANET]

identical elements theory the concept that the ability to learn a new task is enhanced to the extent that it contains elements of previously mastered tasks. Also called identical components theory.

identical points points on the retinas of the left and right eyes that receive identical images from the same object at a specified distance.

identical twins see MONOZYGOTIC TWINS.

identifiable neuron a large neuron that is similar from one individual to the next, enabling investigators to recognize it and give it a code name. Identifiable neurons are common in invertebrates but uncommon in vertebrates.

identification n. 1. the process of associating the self closely with other individuals and their characteristics or views. This process takes many forms: The infant feels part of his or her mother; the child gradually adopts the attitudes, standards, and personality traits of the parents; the adolescent takes on the characteristics of the peer group; the adult identifies with a particular profession or political party. Identification operates largely on a nonconscious or preconscious level. 2. in psychoanalytic theory, a DEFENSE MECHANISM in which the individual incorporates aspects of his or her OBJECTS inside the ego to alleviate the anxiety associated with OBJECT LOSS or to reduce hostility between himself or herself and the object. 3. in CONFIRMATORY FACTOR ANALYSIS and STRUCTURAL EQUATION MODELING, a situation in which the model contains a sufficient number of both fixed and free PARAMETERS to result in unique estimates from the observed data. A model is said to be identified or identifiable if a unique set of its parameter values can be determined from observations. OVERIDENTIFICATION occurs when there are more knowns than free parameters, and UNDERIDENTIFICATION occurs when it is not possible to estimate all of the model’s parameters.

identification–production distinction a hypothesis about PRIMING that amends the distinction commonly made for tests of implicit memory—that is, between PERCEPTUAL TESTS that tap perceptual processing of the surface features of a stimulus and CONCEPTUAL TESTS that tap conceptual processing of meaning or semantic information. Instead, it proposes a distinction that emphasizes different processing demands between tests that require the production of a response and those that require identification or verification regarding some property of an item. For example, WORD-STEM COMPLETION (a perceptual test) and the CATEGORY PRODUCTION TEST (a conceptual test) require, respectively, that participants produce a whole word (e.g., strong) from a word stem (e.g., str_) or produce an item (e.g., strawberry) that belongs to a given category (e.g., types of fruit). In contrast, perceptual identification (a perceptual test) and category verification (a conceptual test) require, respectively, that participants identify a physical property of a stimulus or verify whether items are members of a given category. Also called identification–production hypothesis. See IMPLICIT MEMORY TEST. [proposed by U.S. psychologist John D. E. Gabrieli and colleagues]

identification test a verbal intelligence test in which the participant identifies objects or parts of objects in a picture.

identification transference in GROUP THERAPY, the client’s identification with other members of the group and desire to emulate them. [first described by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981)]

identification with the aggressor an unconscious mechanism in which an individual identifies with someone who poses a threat or with an opponent who cannot be mastered. The identification may involve adopting the aggression or emulating other characteristics of the aggressor. This has been observed in cases of hostage taking and in other extreme situations such as concentration camps. In psychoanalytic theory, it occurs on a developmental level when the child identifies with a rival, the father or mother, toward the end of the OEDIPAL PHASE. It was first described by Anna FREUD in 1936. See also DEFENSIVE IDENTIFICATION; STOCKHOLM SYNDROME.

identified patient a member of a structured group (especially a family) who exhibits the symptoms of a mental disorder and for whom treatment may be sought by the other group members. Clinical investigation may reveal that there is a complex and seriously maladaptive behavioral pattern among members of the group as a whole but that the psychological stigma has fallen primarily on one person, the identified patient. Also called symptom bearer. See also DYSFUNCTIONAL FAMILY.

identity n. 1. an individual’s sense of self defined by (a) a set of physical, psychological, and interpersonal characteristics that is not wholly shared with any other person and (b) a range of affiliations (e.g., ethnicity) and social roles. Identity involves a sense of continuity, or the feeling that one is the same person today that one was yesterday or last year (despite physical or other changes). Such a sense is derived from one’s body sensations; one’s body image; and the feeling that one’s memories, goals, values, expectations, and beliefs belong to the self. Also called personal identity. 2. in cognitive development, awareness that an object is the same even though it may undergo transformations. For example, a coffee cup remains the same object
identity achievement status

despite differences in distance, size, color, lighting, orientation, and even shape. Also called object identity.

identity achievement status see IDENTITY STATUS MODEL.

identity confusion uncertainty regarding one’s identity, which often occurs during adolescence but may also occur at a later stage of life. See IDENTITY VERSUS IDENTITY CONFUSION.

identity crisis a phase of life marked by experimentation; changing, conflicting, or newly emerging values; and a lack of commitment to one’s usual roles in society (especially in work and family relationships). Erik ERIKSON claimed that it is natural and desirable for adolescents to go through a period of identity crisis and that greater maturity results from the experience. The concept has been expanded to refer to adult MIDLIFE CRISISes and other periods marked by change or uncertainty about the self. See ego identity.

identity diffusion 1. lack of stability or focus in the view of the self or in any of the elements of an individual’s identity. It is common especially in BORDERLINE PERSONALITY DISORDER. 2. in the ego psychology of Erik ERIKSON, a possible outcome of the IDENTITY VERSUS IDENTITY CONFUSION stage, whereby the individual emerges with an uncertain sense of identity and confusion about his or her wishes, attitudes, and goals. See also identity status model.

identity disorder see dissociative identity disorder; gender identity disorder.

identity foreclosure premature commitment to an identity: the unquestioning acceptance by individuals (usually adolescents) of the role, values, and goals that others (e.g., parents, close friends, teachers, athletic coaches) have chosen for them. The individual’s commitment to the foreclosed identity—for example, that of an athlete—occurs without exploring its value or contemplating alternative roles that might be more appropriate for him or her. See also identity status model; separation-individuation.

identity matrix (symbol: I) a square matrix with values of 1 along its main diagonal and 0s elsewhere. Identity matrices are used in factor analysis solutions and matrix algebra.

identity need in the theory of Erich FROMM, the need to achieve a sense of uniqueness, individuality, and selfhood. Psychological autonomy and the severing of incestuous ties are considered essential for healthy individuality. Unhealthy, spurious individuality is expressed in conformity, a manifestation of the escape from freedom. Compare rootedness.

identity, negation, reciprocal, and correlative operations (INRC group) in piagetian theory, a group of four logical operations developed during the formal operational stage that are applied to new pieces of information before they become knowledge. These operations can be illustrated by considering a dime and a penny both showing heads. The identity (I) operation leaves the situation unchanged: Both coins remain heads up. The negation (N) operation negates the situation: If the dime has been turned over once, an N operation would be turning the dime back over. The reciprocal (R) operation reciprocates an earlier operation: If the previous operation was turning the penny over, the R operation would be turning the dime over. The correlative (C) operation is the inverse of the reciprocal operation: If the R operation was turning the dime over, the C operation would be turning both the dime and penny over. Piaget asserted that these logical operations were in fact cognitive operations that formal operational thinkers apply to solve problems.

identity politics 1. political activity or theorizing that derives from individuals’ sense of belonging to particular ethnic, sexual, or other identity-based groups, rather than from traditional party or ideological commitments. 2. the interpersonal processes involved in establishing, maintaining, and negotiating both one’s own personal and social identity and the identities of others in the social setting.

identity principle 1. in logic, the principle that where X is known to be identical to Y, any statement about X (or Y) will have the same meaning and truth value as the same statement about Y (or X). So, for example, any statement made about Paris will have the same meaning, and be equally true or false, as the same statement made about the capital of France. See also laws of thought. 2. in the theory of Jean PIAGET, the principle underlying a child’s awareness of the conservation of physical quantities.

identity status model an expansion of identity versus identity confusion, the fifth stage in Erik ERIKSON’s EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT. The model posits four possible identity statuses that an individual might assume, particularly during adolescence, each characterized by a different level of exploration of and commitment to a specific identity. Ideally, development moves toward identity achievement status, characterized by evidence of both identity exploration and commitment; this status is related to stable self-esteem and healthy psychological functioning. The other three identity statuses are moratorium status, which (as in Erikson’s Moratorium period) is characterized by evidence of identity exploration but a lack of commitment; foreclosure status, depicted by commitment to an identity that adults have set forth for an individual but by failure to explore different options before that commitment is made; and diffusion status, characterized by the lack of both identity exploration and commitment (compare Erikson’s identity diffusion). [first proposed in 1966 by Canadian psychologist James E. Marcia]

identity style an adolescent’s characteristic mode of approaching problems and decisions that are relevant to his or her personal identity or sense of self. Differences in style reflect differences in the social-cognitive processes that individuals use to construct a sense of identity. Three basic identity styles are recognized: informational, normative, and diffuse-avoidant. Information-oriented individuals actively seek out, evaluate, and use self-relevant information. They are skeptical about their self-constructions and willing to test and revise aspects of their self-identity when confronted with discrepant feedback. Normative individuals deal with identity questions and decisional situations by conforming to the prescriptions and expectations of significant others. Diffuse-avoidant-oriented individuals are reluctant to face up to and confront personal problems and decisions. [introduced in 1988 by U.S. psychologist Michael David Berzonsky (1943—)]

identity theory the theory that mental states are identical with brain states. In token identity theory, identical mental and brain states occur within the individual. Type identity theory extends this to theorize that when two or more people share a mental state (e.g., the belief that ice is
cold) they also have the same brain state. Also called central state theory: identity theory of the mind. See also eliminationism; ephiphenomenalism; materialism; mind-body problem; physicalism; reductionism.

identity versus identity confusion the fifth of Erikson’s eight stages of psychosocial development, marked by an identity crisis that occurs during adolescence. During this stage, the individual may experience a psychosocial moratorium, a period of time that permits experimentation with social roles. The individual may “try on” different roles and identify with different groups before forming a cohesive, positive identity that allows him or her to contribute to society; alternatively, the individual may identify with outgroups to form a negative identity or may remain confused about his or her sense of identity. A state Erikson calls identity diffusion. See also identity status model.

ideogram n. a picture or symbol used to represent an object or idea. For example, ideograms are often used in computer interfaces to represent actions that can be selected by pointing to and clicking on them with a mouse. In this context, they are usually referred to as icons. Also called ideograph. See also logographic.

ideology n. 1. a more or less systematic ordering of ideas with associated doctrines, attitudes, beliefs, and symbols that together form a more or less coherent philosophy or weltanschauung for a person, group, or sociopolitical movement. 2. in marxism, any philosophy or set of ideas regarded as false and distorting, usually because it ignores or tries to disguise the material basis of society. —ideological adj.

ideomotor activity movement, in some cases elaborate, related to ongoing thoughts but produced without volition. Ideomotor activity explains a variety of phenomena, including gestures during conversations. Also called ideomotor action. [first identified in 1852 by British physiologist and physician William Benjamin Carpenter (1813–1885)]

ideomotor apraxia see apraxia.

ideomotor compatibility the extent to which stimuli resemble the sensory feedback from their assigned responses. For example, if the stimulus is the speech sound [a] and the response is to say the letter aloud, stimulus and response have high ideomotor compatibility. Ideomotor compatibility minimizes the difficulty of response selection.

ideomotor principle see psychoneuromuscular theory.

ideomotor suggestion an idea suggested by a hypnotist that brings about an apparently automatic muscular response in the hypnotized individual. The cue is usually a simple statement or command, such as Your arm is becoming lighter or Your head feels tired. See ideomotor theory. See also challenge suggestion; hypnotic rigidity.

ideomotor theory the hypothesis that actions are evoked impulsively by mental representations and are carried out spontaneously in the absence of inhibition. Ideomotor theory is the basis of most early theories of hypnotic suggestion. [introduced by British physiologist William Benjamin Carpenter (1813–1885)]

idi- combining form distinct or private.

idiocentric 1. adj. denoting interest in or focus on one’s self rather than on other objects or people. 2. n. an individual who is dispositionally predisposed to put his or her personal interests and motivations before the interests and goals of other people and other groups. Idiocentrics are more likely to describe themselves in terms of personal qualities and traits rather than memberships and roles. See also allocentricism; individualism. Compare allocentric. —idiocentricism n.

idiocy n. an obsolete name for profound mental retardation.

idiodynamics n. 1. the concept that the individual is primarily responsible for selecting stimuli and organizing responses. Individuals attend to those aspects of the environment they deem relevant, rather than responding to whatever stimuli are present and detectable. 2. a personality theory that emphasizes one’s unique life experiences (one’s idioverse), the relevance of psychodynamic factors, and the role of creativity in one’s search for personal integration. [proposed by Saul Rosenzweig]

idiogamist n. a person who is capable of full sexual response only with his or her spouse and is sexually incapable or inadequate with other partners. An idogamist is usually a man who cannot obtain or maintain penile erection with any partner other than his wife (or, sometimes, women who resemble his wife).

idiogenesis n. origin without evident cause, particularly the origin of an idiosyncratic disease.

idioglottia n. 1. a synonym for cryptophasia. 2. the omission, substitution, and distortion of so many sounds that speech is rendered unintelligible. Also called idiolalia.

idiographic adj. relating to the description and understanding of an individual case, as opposed to the formulation of nomothetic general laws describing the average case that can then be applied to the single case. U.S. psychologists Kenneth MacCorquadale (1919–1986) and Paul Everett Meehl identified these as two contrasting traditions in explaining psychological phenomena. An idiographic approach involves the thorough, intensive study of a single person or case in order to obtain an in-depth understanding of that person or case, as contrasted with a study of the universal aspects of groups of people or cases. In those areas of psychology in which the individual person is the unit of analysis (e.g., in personality, developmental, or clinical psychology), the idiographic approach has appeal because it seeks to characterize a particular individual, emphasizing that individual’s characteristic traits (i.e., idiographic traits or unique traits) and the uniqueness of the individual’s behavior and adjustment, rather than to produce a universal set of psychological constructs that might be applicable to a population.

idiolalia n. see idioglottia.

idiolact n. a dialect spoken at the level of an individual. In one sense, all speakers have an idiolect because no two people use their native language in the same way. In another, the term is reserved for the most idiosyncratic forms of personal language use, especially those involving eccentricities of construction or vocabulary. An idiolect of this kind may be developed by a person who acquires a second language unsystematically, especially if this occurs in an unusual or isolated learning environment (see interlanguage: fossilization). Some poets and writers also develop distinctive idiolects in their writings. —idiolctal adj.

idiom n. a fixed phrase established by usage whose mean-
idiopathic

idiopathic adj. without known cause or of spontaneous origin. The term usually denotes diseases whose etiologies are obscure, such as some forms of epilepsy.

idiopathic epilepsy see EPILEPSY.

idiopathic adj. denoting a mental disorder that is caused by a disease of the brain.

idioretinal light an illusion of shades of gray observed in a dark environment. The effect is caused by chemical changes in the retina or brain cells rather than by the wavelength of visible light.

idiopath n. 1. a habit or quality of body or mind peculiar to an individual. 2. an abnormal response to an agent (e.g., a drug) that is peculiar to an individual. —idiopathic adj.

idiopathic classification in classification tasks, the grouping of items that do not appear to share physical or conceptual characteristics. Also called random classification. Compare COMPLEMENTARY CLASSIFICATION; CONCEPTUAL CLASSIFICATION; PERCEPTUAL CLASSIFICATION.

 idiopathic intoxication a condition characterized by sudden and extreme changes in personality, mood, and behavior following the ingestion of an amount of alcohol usually considered to be too little to account for the degree of the changes. It may include extreme excitement, impulsive and aggressive behavior (at times to the point of extreme violence), persecutory ideas, disorientation, and hallucinations. The episode ends when the individual falls into a deep sleep, after which there is often complete loss of memory for it. Some researchers believe that the condition may be related to stress or may be due in part to a psychomotor seizure triggered by alcohol. Also called mania a potu: pathological intoxication. See also FUROR.

idiopathic adj. an unexpected reaction to a drug, resulting in effects that may be contrary to the anticipated results. The term generally refers to an extreme sensitivity or an extreme insensitivity to a particular agent. Such reactions may be genetically mediated.

idiocracy n. an obsolete name for a person with profound mental retardation. —idiotic adj.

idiocracy n. pl. idiots savants or, less often, idiot savants see SAVANT. [French, “learned idiot”]

idiverse n. in postmodern discourse (see POSTMODERNISM), the totality of a person’s unique sensations, perceptions, and understandings; that is, a person’s unique lived world.

id psychology in psychoanalysis, an approach that focuses on the organized, instinctual impulses contained in the id that seek immediate pleasurable gratification of primitive needs. The id is believed to dominate the lives of infants and is frequently described as primitive and irrational until it is disciplined by the other two major components of the personality: the ego and the superego. Compare EGO PSYCHOLOGY.

IDS abbreviation for INTEGRATED DELIVERY SYSTEM.

IEP abbreviation for INDIVIDUALIZED EDUCATION PROGRAM.

I/E ratio abbreviation for INSPIRATION—EXPIRATION RATIO.

IFSP abbreviation for INDIVIDUAL FAMILY SERVICE PLAN.

if . . . then profiles a methodology for describing personal dispositions in which within-person variations across social contexts are charted in terms of the behaviors evoked by particular situations. [developed by Austrian-born U.S. personality psychologist Walter Mischel (1930–) and Japanese-born U.S. psychologist Yuichi Shoda]

IGT abbreviation for IOWA GAMBLING TASK.

IHS abbreviation for INDIAN HEALTH SERVICE.

ich’aa n. a CULTURE-BOUND SYNDROME found in Navaho communities, with symptoms similar to those of AMOK.

I–It adj. describing a relationship in which a subject (“I”) treats something or someone else exclusively as an impersonal object (“It”) to be used or controlled. German Jewish philosopher Martin Buber (1878–1965), who originated the term, maintained that this type of relationship between people stands in the way of human warmth, mutuality, trust, and group cohesiveness. Compare I–THOU.

IKBS abbreviation for INTELLIGENCE KNOWLEDGE-BASED SYSTEM.

ikota n. see MYRIAChIT.

ILD abbreviation for interaural level differences. See BIN-auralcue.

iliohypogastric nerve one of the nerves that extend from the spinal cord in the lumbar region, with branches that innervate the skin of the gluteal and lower abdominal regions.

ilioinguinal nerve a nerve with branches that extend into the genitalia. In the male, the ilioinguinal nerve follows the spermatic cord through the inguinal ring and sends branches into the penis and scrotum. In the female, this nerve extends to the mons pubis and the labia majora.

illegitimacy n. 1. the status of a child whose parents were unmarried at the time of birth. In Western societies, the term has fallen into virtual disuse with changing family structures (e.g., cohabiting but unmarried parents, SINGLE MOTHERS BY CHOICE), the fading of the stigma formerly attached to illegitimacy, and the disappearance of most legal distinctions between legitimate and illegitimate children. 2. the state of being unlawful, improper, or contrary to reason and logic. —illegitimate adj.
 illicit adj. illegal: particularly referring to psychoactive drugs that have few or no legitimate medical uses or that are not legally available to the person using them. The term may also refer to substance use and other behavior that is contrary to social convention or custom or is otherwise prohibited or disapproved of, as in an illicit sexual relationship.

Illinois Test of Psycholinguistic Abilities (ITPA) a norm-referenced test for children ages 5 to 13 years and designed to measure spoken and written linguistic abilities considered important in communication and learning disorders. It currently consists of 12 subtests: spoken analogies, spoken vocabulary, morphological closure, syntactic sentences, sound deletion, rhyming sequences, sentence sequencing, written vocabulary, sight decoding, sound decoding, sight spelling, and sound spelling. First published in 1961 as an experimental edition, the ITPA is now in its third edition (published in 2001). [originally developed by U.S. psychologists Samuel Alexander Kirk (1904–1996) and James Jerome McCarthy (1927–2012) at the University of Illinois]

illiteracy n. 1. an inability to read, write, or both. Functional illiteracy is a reading and writing skill level that is inadequate for performing normal tasks of daily living. 2. a lack of education or knowledge in a particular field of education or, more generally, evidence of social and educational ineptitude. —illiterate adj.

illness n. the experience of sickness or lack of well-being of body or mind.

illness anxiety disorder in DSM–5, a disorder characterized by high anxiety about one’s health, by excessive preoccupation with having an illness or acquiring it, and by behaviors associated with the presumed or feared condition (e.g., repeatedly checking oneself for possible signs of illness), yet with no significant somatic symptoms that warrant such concern. One of two replacement diagnoses for hypochondriasis, illness anxiety disorder is determined based only on this set of criteria and does not also apply to the presence of both high health anxiety and significant somatic symptoms. See somatic symptom disorder.

illness behavior behaviors, attitudes, and emotions exhibited by individuals during the course of a physical or mental illness. It includes the perception of feeling ill, the expression of illness-related concerns to others, changes in functioning, and utilization of health care services.

illocutionary act in the theory of speech acts, the act that is performed by saying something (e.g., asking, ordering, threatening), as opposed to the act of speaking itself (the locutionary act) or the act of causing a particular effect on others (e.g., persuading, amusing, inspiring) as a result of speech (the perlocutionary act). In practice, most utterances involve the performance of all three acts simultaneously. See also performative. [first described by British philosopher John Longshaw Austin (1911–1960)]

illogicality n. a tendency to make unwarranted or faulty inferences, often characteristic of delusional thinking and speech. —illogical adj.

illuminance n. (symbol: E) the light (luminous flux) falling on a unit area of a surface. The standard unit of illuminance is the lux.

illuminating adj. —illuminating n. the act of lighting or casting light or the state of being lighted. 2. a moment of insight, such as about the nature and processes of an interpersonal relationship, the solution to a problem, or the understanding of an event. See also AHA EXPERIENCE; EPYPHANY.

illumination conditions the types of illumination (taking into account such factors as intensity and absence of glare) available within an environment, particularly as related to suitability for certain tasks and the comfort of those performing them.

illumination standards the amounts of illumination recommended for effective performance of certain tasks, as determined by the Illuminating Engineering Society of North America. The illumination standards were formerly expressed in foot-candles but are now expressed in lux.

illumination unit formerly, the amount of light produced by one foot-candle; now replaced by the lux.

illuminism n. an exalted hallucinatory state in which the person carries on conversations with imaginary, often supernatural, beings.

illusion n. 1. a false sensory perception. Illusions of the senses, such as visual illusions, result from the misinterpretation of sensory stimuli. For example, parallel railroad tracks appear to meet in the distance (see ALLEY PROBLEM; LINEAR PERSPECTIVE). Other examples of visual illusions are APPARENT MOVEMENT, CONTRAST ILLUSIONS, distortion illusions (such as the HERING ILLUSION, MÜLLER-LYER ILLUSION, POGGENDORF ILLUSION, PONZO ILLUSION, and ZÖLLNER ILLUSION), and the PANUN PHENOMENON. Illusions involving other senses include ARISTOTLE’S ILLUSION. All of these illusions occur under ordinary conditions. The distorted perceptions that may accompany abnormal conditions, such as delirium and schizophrenia, or that occur in those taking mind-altering drugs are more properly called hallucinations. 2. a distortion in memory (see MEMORY ILLUSION), such as déjà vu. 3. more generally, any false belief or mistaken idea. —illusory adj.

illusion of agency the illusion of controlling an event that is not actually under one’s control. Also called illusion of will. [defined by U.S. psychologist Daniel M. Wegner (1948– )]

illusion of control a false belief that external events result from or are governed by one’s own actions or choices. A sports fan who wears the same “lucky” shirt for each home game in order to give his or her team an edge provides an example. See positive illusion. [coined in 1975 by U.S. social and clinical psychologist Ellen Langer (1947– )]

illusion of doubles see CAPGRAS SYNDROME.

illusion of orientation misidentification of environmental or other stimuli, such as confusion about one’s location or the identity of people, due to impaired consciousness (e.g., during delirium).

illusion of unique invulnerability the false belief that one is somehow safeguarded from the dangers and misfortunes that afflict other people. The illusion may cause people to disregard such safety measures as seat belts or condoms. [coined in 1983 by U.S. social psychologist Linda Perloff (1955– )]

illusion of will see ILLUSION OF AGENCY.

illusory conjunction the attribution of a characteristic of one stimulus to another stimulus when the stimuli are presented only briefly. Illusory conjunctions are most common with visual stimuli when, for example, the color
of one form can be attributed to a different form. However, illusory conjunctions can also occur for other sensory stimuli.

**illusory contour** see subjective contour.

**illusory correlation** 1. the appearance of a relationship that in reality does not exist, 2. an overestimation of the degree of relationship (i.e., correlation) between two variables. For example, if an unusual action occurred at the same time that an adolescent was present in a group of adults, the assumption that the action was carried out by the adolescent would be an illusory correlation.

**illusory covariation** an apparent predictable or systematic correlation between two phenomena (objects or events) that in fact does not exist. See co-occurrence; covariation.

**illusory memory** see false memory.

**illusory movement** see apparent movement.

**illy (illie)** n. see Fry.

**iloperidone n.** an atypical antipsychotic agent of the benzisoxazole class that is active at a range of receptors. Its efficacy is thought to result particularly from its dopamine D2 and serotonin 5-HT2 receptor antagonism. Its wide-ranging receptor activity is thought to confer antipsychotic activity with fewer extrapyramidal symptoms and with a somewhat more favorable metabolic profile than is seen with other atypical antipsychotics. U.S. trade name: Fanapt.

**im** abbreviation for intramuscular.

**image** n. 1. a likeness or cognitive representation of an earlier sensory experience recalled without external stimulation. For example, remembering the shape of a horse or the sound of a jet airplane brings to mind an image derived from earlier experiences with these stimuli. 2. a representation of an object produced by an optical system. See also retinal image.

**imageless thought** thinking that occurs without the aid of images or sensory content. The Würzburg school upheld the existence of imageless thought on the basis of introspective reports, such as experiential participants’ stated ability to name a piece of fruit without picturing it. Edward Bradford Titchener and others in the structuralist school opposed this view (see structuralism). See Bewusstseinslage.

**imagery** n. 1. cognitive generation of sensory input from the five senses, individually or collectively, which is recalled from experience or self-generated in a nonexperienced form. 2. mental images considered collectively, or the particular type of imagery characteristic of an individual, such as visual imagery. See imagery code; imagery training; kinesthetic imagery.

**imagery code** the encoding of an object, idea, or impression in terms of its visual imagery. For example, the item “typewriter” might be remembered as a mental picture of a typewriter, rather than as the word typewriter. Compare semantic code.

**imagery cue** a cognitively created signal used to direct behavior. Examples are mental images of a stop sign when one has negative thoughts or of a butterfly when one wants to exhibit delicate, free-flowing motion in a skating routine. See also thought stopping.

**imagery effect** the finding that imagining the referent of a word (e.g., envisioning an airplane when asked to study the word airplane) produces better memory for the word than does simply reading it.

**imagery rehearsal therapy** a short-term cognitive behavior intervention for individuals experiencing chronic nightmares (particularly veterans with trauma-related sleep problems) in which participants write about their recurring nightmares, edit these stories (or scripts) to include more positive images, and then rehearse the images from the new, more positive scripts. Rehearsal is both self-guided (e.g., 5–20 minutes daily) and therapist-guided, and the new script eventually replaces or transforms the nightmare. Imagery rehearsal therapy typically is conducted in a small-group format over two 3-hour sessions, but variations in the number of sessions and duration of treatment are common. Use of the technique is associated with reduced nightmare frequency and intensity, decreased distress and anxiety, and enhanced sleep quality. [developed in 2001 by U.S. physician and sleep disorders specialist Barry Krakow]

**imagery technique** the use of imagined scenes as a therapeutic technique, often in hypnotherapy but also in therapies that use breathing and relaxation techniques to reduce stress or anxiety. For example, an anxious client may be directed to imagine a placid scene recalled from memory, such as sitting, relaxed and calm, on a beach. The technique may be used by an individual in stressful situations, such as a nervous passenger in an aircraft. See also guided imagery; guided affective imagery.

**imagery training** a series of exercises to improve the clarity, vividness, and controllability of the images from the five senses, first individually, then in combination.

**imaginal exposure** a type of exposure therapy used for treating individuals with anxiety disorders (e.g., phobias, obsessive-compulsive disorder, posttraumatic stress disorder). Vivid imagery evoked through speech is used by the therapist to expose the client mentally to an anxiety-evoking stimulus. Compare in vivo exposure.

**Imaginary** n. the realm of images: one of three aspects of the psychoanalytic field defined by French psychoanalyst Jacques Lacan (1901–1981). The Imaginary is that state of being in which the infant has no sense of being a subject distinct from other people or the external world and no sense of his or her place in human culture. After the infant’s entry into the symbolic (the world of language, culture, and morality), he or she can return to the wholeness of the Imaginary only in fantasy. See also real.

**imaginary audience** the belief of an adolescent that others are constantly focusing attention on him or her, scrutinizing behaviors, appearance, and the like. The adolescent feels as though he or she is continually the central topic of interest to a group of spectators (i.e., an audience) when in fact this is not the case (i.e., an imaginary audience). It is an early adolescent construct reflective of acute self-consciousness and is considered an expression of adolescent egocentrism. [first described by U.S. developmental psychologist David Elkind (1931– )]

**imaginary companion** a fictitious person, animal, or object created by a child or adolescent. The individual gives the imaginary companion a name, talks to it, shares feelings, pretends to play with it, and may use it as a scapegoat for his or her misdeeds. The phenomenon is considered an elaborate but common form of symbolic play. Also called invisible playmate.
imagination *n.* the faculty that produces ideas and images in the absence of direct sensory data, often by combining fragments of previous sensory experiences into new syntheses. See also CREATIVE IMAGINATION. —imaginary adj. —imagine vb.

imagination inflation the increased likelihood that a person will judge an event as having actually occurred (e.g., during childhood) when he or she imagines the event before making such a judgment.

imaging *n.* 1. the process of scanning the brain or other organs or tissues to obtain an optical image that can be used for medical and research purposes, such as locating abnormalities or studying anatomy and function. Techniques used include COMPUTED TOMOGRAPHY, POSITION EMISSION TOMOGRAPHY (PET), ANATOMICAL MAGNETIC RESONANCE IMAGING (aMRI), and FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI). The imaging may be either static or dynamic. See also BRAIN IMAGING; NUCLEAR IMAGING. 2. in therapy, the use of suggested mental images to control body function, including the easing of pain. See also IMAGERY TECHNIQUE; VISUALIZATION.

imago *n.* an unconscious mental image of another person, especially the mother or father, that influences the way in which an individual relates to others. The imago is typically formed in infancy and childhood and is generally an idealized or otherwise not completely accurate representation. The term was originally used by Sigmund Freud and the early psychoanalysts, and its meaning has carried over into other schools of psychology and psychotherapy.

imago therapy a type of therapy for relationship problems based on the theory that people carry unconscious composite images (see IMAGO) of the character traits and behaviors of their primary childhood caretakers that impel them to select certain partners and to behave in ways that are meant to heal earlier emotional wounds but that actually create relationship problems. Structured exercises, either in groups or in COUPLES THERAPY, reveal the imago and help individuals learn to become less defensive and more compassionate toward partners as well as themselves.

imbecility *n.* formerly, a moderate to severe level of intellectual disability characterized by an IQ between 25 and 50 to 55 and social and practical skills similar to those of 2- to 7-year-olds.

imipramine *n.* a TRICYCLIC ANTIDEPRESSANT (TCA) with a tertiary amine molecular structure. It was originally synthesized in the hope of creating an effective antidepressive but was observed to be ineffective in reducing psychotic symptoms. It did, however, seem to help individuals with severe depression and was subsequently marketed as an antidepressant. It is considered the prototype TCA, and like all tricyclic agents, its use as an antidepressant has been largely supplanted by less toxic drugs. It retains a therapeutic role as a sedative and adjunct in the management of neuromuscular or musculoskeletal pain. U.S. trade name: Tofranil.

imitation *n.* the process of copying the behavior of another person, group, or object, intentionally or unintentionally. It is a basic form of learning that accounts for many human skills, gestures, interests, attitudes, role behaviors, social customs, and verbal expressions, but it can also take pathological form, as in ECHOLALIA and ECHOPRAXIA. Some theorists propose that true imitation requires that an observer be able to take the perspective of the model. This contrasts with other forms of SOCIAL LEARNING, such as EMULATION, LOCAL ENHANCEMENT, and MIMICRY. There is controversy concerning whether true imitation occurs in nonhuman animals or whether they either merely emulate the actions of others or are attracted to the location of others and by chance appear to show imitation. —imitate vb.

imitation game see TURING TEST.

imitative learning the first stage of CULTURAL LEARNING, which occurs when the learner internalizes aspects of the model’s behavioral strategies and intentions for executing the behavior. According to cultural learning theory, imitative learning is followed by INSTRUCTED LEARNING and COLLABORATIVE LEARNING. [proposed by U.S. psychologist Michael Tomasello (1950–), and colleagues]

immanent justice the belief that rules are fixed and immutable and that punishment automatically follows misdeeds regardless of extenuating circumstances. Children up to the age of 8 equate the morality of an act only with its consequences; not until later do they develop the capacity to judge motive and subjective considerations. See MORAL ABSOLUTISM; MORAL REALISM. Compare DISTRIBUTIVE JUSTICE. [postulated by Jean PIaget]

immaterialism *n.* the philosophical position that denies the independent existence of matter as a substance in which qualities (see PRIMARY QUALITY; SECONDARY QUALITY) might inhere. Sensible objects are held to exist as the sum of the qualities they produce in the perceiving mind, with no material substratum. The best known philosophy of this kind is that of George BERKELEY. It is difficult to distinguish such a position from IDEALISM, which holds that mind is essential to all reality and that things and qualities exist only as perceived. Compare MATERIALISM.

immature science a science that has not advanced to the stage of development characteristic of a PREPARADIGMATIC SCIENCE or a NORMAL SCIENCE. [proposed by U.S. philosopher of science Thomas Kuhn (1922–1996)]

immaturity *n.* a state of incomplete growth or development (e.g., neural immaturity). The term, however, is often used to describe childish, maladaptive, or otherwise inappropriate behaviors, particularly when indicative of a lack of age-relevant skills.

immediacy behavior any action, movement, or physical stance that indicates comfort, intimacy, or a close relationship between two people, for example, EYE CONTACT or touching.

immediate experience see MEDIATE EXPERIENCE.

immediate gratification the experience of satisfaction or receipt of reward as soon as a response is made. See also PLEASURE PRINCIPLE. Compare DELAY OF GRATIFICATION.

immediate memory a type or stage of memory in which an individual recalls information recently presented, such as a street address or telephone number, although this information may be forgotten after its immediate use. Immediate memory is frequently tested in assessing intelligence or neurological impairment. See also SHORT-TERM MEMORY.

immediate recall test a test in which the participant is tested for recall (reproduction) of stimuli immediately after the stimuli are presented.

immobility *n.* a condition in which an organism shows
I

immune response

no signs of motion, as in DEATH FEIGNING or FREEZING BEHAVIOR. This may occur in response to sudden stimuli that might be associated with a predator, or it may be elicited in a fear-conditioning study as a learned response to an aver-sively conditioned signal. —immobile adj.

immune response the response of the IMMUNE SYSTEM to invasion of the body by foreign substances (ANTIGENS). Nonspecific immune responses include inflammation (with the release of HISTAMINE) and PHAGOCYTOSIS of invading microbes, tissues, and so forth by LEUKOCYTES (white blood cells). The two types of specific immune response are hu-
moral immunity, in which B Lymphocytes produce Anti-
body that either destroy antigens or enhance the de-
truction of antigens by other cells; and cell-mediated
immunity, mediated by T lymphocytes, which attack anti-
gens directly and specifically. See also ANTIGEN—ANTIBODY
REACTION.

immune system a complex system in vertebrates that
helps protect the body against pathological effects of for-

gien substances (ANTIGENS), such as viruses and bacteria.
The organs involved include the bone marrow and THY-

mus, in which Lymphocytes—the principal agents respon-
sible for specific IMMUNE RESPONSES—are produced.

Together with the spleen, lymph nodes, and other lymphoid
tissues and various chemicals (e.g., CYTOKINES) that medi-

ate the immune response. The immune system interacts

both with the nervous system and the endocrine system.

See also PSYCHONEUROIMMUNOLOGY.

immunity n. the ability of the body to resist infection

based on the actions of the IMMUNE SYSTEM in mount-

ing IMMUNE RESPONSES. Active immunity arises when immune
cells (see LYMPHOCYTE) produce, and remain able to pro-
duce, appropriate antibodies following infection or deliber-
ate stimulation (IMMUNIZATION). Passive immunity
is conferred by the introduction of antibodies from another
organism (e.g., via COLOSTRUM). Innate immunity does not
require prior contact with invading microorganisms or tis-

sues and involves nonspecific immune responses. See also

ANTIGEN—ANTIBODY REACTION.

immunization n. the process of conferring immunity by

other than natural means. Active immunity is acquired by

inoculation or vaccination, which involves the injection of a

specific, prepared antigen to induce the production of natu-
ral antibodies by the body’s immune system. Passive

immunity, which is short-lived (1–6 months), is acquired

by the injection of prepared antibodies obtained from an

animal or human already immune to the disease in ques-

tion.

immunocytochemistry n. techniques that use labeled

antibodies specific to particular proteins to localize those

proteins in cells or tissues. The label creates a visible mark,

thus enabling visualization and localization of the compo-

nent. Also called immunohistochemistry.

immunology n. the branch of medicine that specializes

in the study of IMMUNITY and immune reactions (e.g.,
allergies and hypersensitivities). —immunological adj.

—immunologist n.

Imodium n. a trade name for LOPERAMIDE.

impact analysis a quantitative analytic procedure used to

assess the net success or failure of a program, usually

through controlled experimentation. It is appropriate only
if the program’s objectives are specifiable and measurable.

The program is well implemented for its intended partici-

pants, and the outcome measures are reliable and valid.

Also called IMPACT ASSESSMENT. See also OUTCOME EVALU-
ATION: SUMMATIVE EVALUATION.

impaired judgment difficulty in forming evaluative

opinions or reaching conclusions concerning available evi-
dence, often about people and courses of action. Impaired
judgment may lead to seemingly irrational actions and
risk-taking behaviors. It has been thought of as both a di-
agnostic and a predictive criterion for delirium, dementia,
and substance-related disorders, but its diagnosis and mea-
surement are hindered by the lack of an agreed operational
definition. Various fields have contributed research on this
issue, including developmental and industrial psychology,
experimental psychology (perception), medicine, and legal
decision making.

impairment n. a decrement in the body’s typical physio-

logical or psychological functioning.

impairment index a measure of impairment on a se-

ries of cognitive tests. The best known such index is the

Halstead–Reitan Impairment Index, which reflects the per-
centage of tests in the impaired range; the higher the per-
centage, the greater the likelihood of brain damage or
dysfunction. This index may also be affected by poor effort,
dissimulation, or psychogenic states.

impeachment evidence evidence used to attack or
discredit testimony given by an individual in court.

imperative n. 1. any demand that is critical or pressing. See
CATHERGICAL IMPERATIVE; ETHICAL IMPERATIVE. 2. in
psychoanalytic theory, a demand of the SUPEREGO that re-

presents the commanding voice of parental or social rule
and operates on an unconscious level to direct the behavior
of the individual. 3. in linguistics, the MOOD of a verb used
to issue commands or make requests, as in Get off! or Please
come back. Compare INDICATIVE; INTERROGATIVE; SUBJUNC-
TIVE.

imperceptible adj. below THRESHOLD. For example, an
imperceptible difference is a physical difference between

two stimulus events that is below an observer’s DIFFERENCE
THRESHOLD. This results in the two events being judged as

the same psychologically when they are not the same physi-

cally.

impersonation n. 1. the deliberate assumption of an-
other person’s identity, usually as a means of gaining sta-
tus or other advantage. See also IMPACTOR SYNDROME. 2.
the imitation of another person’s behavior or mannerisms,
which is sometimes done for its corrective or therapeutic
effect on one’s own behavior (e.g., to gain insight).

impingement n. 1. in the OBJECT RELATIONS THEORY of
British psychoanalyst Donald Winnicott (1896–1971), an
experience in the infant’s maternal environment that is felt
to be disturbing. Such experiences are postulated to lead to
the development of a FALSE SELF because the infant may de-
velop through a series of reactions to impingements rather
than becoming aware of his or her true tendencies and ca-

cpacities by discovering the environment on his or her own

terms. 2. in perception, impact or contact with a sensory
receptor. —impinge vb.

implantation n. 1. the attachment of a fertilized ovum
to the uterine wall at the BLASTOCYST stage of development,
6 to 8 days after ovulation. 2. the placing of a drug (e.g., a
subcutaneous implant) or an object (e.g., an artificial pace-
maker) within the tissues of the body.

implanted memory a person’s apparent recollection of
an event that never occurred but that someone else has convinced the person did occur. See FALSE MEMORY.

implemental mind-set see MIND-SET.

implementation evaluation an evaluation approach that focuses on the way a program was delivered and whether it reached its intended recipients.

implicate n. in linguistics, a proposition that is not stated explicitly in an utterance and is not a condition for its truth but can nevertheless be inferred from it. The types of implicature recognized in PRAGMATICS and DISCOURSE ANALYSIS go beyond those recognized as valid in formal logic. For example, the statement Mary is my dad’s wife would imply in most contexts Mary is not my mother, even though the first proposition cannot be said to entail the second. Compare PRESUPPOSITION. See also CONVERSATIONAL INFERENCE; INDIRECT SPEECH ACT. —implicative adj.

Implicit Association Test (IAT) an IMPLICIT ATTITUDE MEASURE introduced in 1998 in which participants perform a series of categorization tasks on a computer for a set of words representing an ATTITUDE OBJECT (e.g., words such as ant, fly, and grasshopper representing the attitude object of insects). Attitudes are assessed by having participants perform a joint categorization task in which they must judge whether the target words are members of a specified category (e.g., insects) as well as whether a second set of intermixed words, selected to be highly evaluative in nature, are positive or negative. In one phase of the test, the computer response key used to indicate membership in the specified category is the same as that used to indicate a positive word. In a different phase, the key used to indicate membership in the specified category is the same as that used to indicate a negative word. If attitudes are positive, judging the target words should be faster when the same response key is used for category membership and positive words than when the same response key is used for category membership and negative words. Negative attitudes produce the opposite pattern. [originally developed by U.S. psychologist Anthony G. Greenwald (1939– ) and his colleagues]

implicit attitude a relatively enduring and general evaluative response of which a person has little or no conscious awareness. Compare EXPLICIT ATTITUDE.

implicit attitude measure any procedure for evaluating attitudes in which a person is not consciously aware of the fact that his or her attitude toward something or someone is being assessed. Measures of this type are generally INDIRECT ATTITUDE MEASURES. Compare EXPLICIT ATTITUDE MEASURE.

implicit behavior 1. behavior that cannot be observed directly, such as a cognitive process or emotional reaction. 2. behavior that cannot be observed without the aid of instruments, such as subtle physiological responses. 3. behavior of which the individual is not consciously aware.

implicit causality the property of VERBS such that causality is implicit either in the AGENT or the PATIENT of the verb.

implicit cognition any knowledge or information processing of which an individual is not explicitly aware.

implicit emotion regulation see EMOTION REGULATION.

implicit knowledge see TACIT KNOWLEDGE.

implicit leadership theories perceivers’ general as-

implicit learning learning of a cognitive or behavioral task that occurs without intention to learn or awareness of what has been learned. Implicit learning is evidenced by improved task performance rather than as a response to an explicit request to remember. See also IMPLICIT MEMORY.

implicit measure a measurement of a psychological construct that is obtained while the individual being assessed is unaware that the measurement is taking place, often used to assess attitudes, stereotypes, and emotions in social cognition research. Typically, an implicit measure is assessed as a response outcome of an experimental procedure in which the participant is engaged in a cognitive task. For example, a word-stem completion task might be employed to assess emotion implicitly such that if a person could be completed to form a positive emotional word (e.g., joy) or a neutral word (e.g., joy).

implicit memory memory for a previous event or experience that is produced indirectly, without an explicit request to recall the event and without awareness that memory is involved. For instance, after seeing the word store in one context, a person would complete the word fragment st_ as store rather than stare, even without remembering that store had been recently encountered. Implicit memory can exist when conscious or EXPLICIT MEMORY fails, as occurs in amnesia and brain disease. This term, proposed in 1985 by Canadian psychologist Peter Graf and U.S. psychologist Daniel L. Schacter (1952– ), is used interchangeably with NONDECLARATIVE MEMORY.

implicit memory test a memory test that elicits nonconscious memories by instructing participants to respond with whatever first comes to mind. Despite the participants’ lack of conscious recollection of prior events, the tests show the effects of these events in terms of the speed of participant response or the content of the memories they retrieve. The tests are often organized into three categories: perceptual, conceptual, and procedural. They can also be verbal or nonverbal. Examples of implicit memory tests include WORD-STEM COMPLETION (perceptual, verbal); picture-fragment identification (perceptual, nonverbal); GENERAL KNOWLEDGE TESTS and CATEGORY PRODUCTION TESTS (conceptual, verbal); object categorization (conceptual, nonverbal); reading inverted text (procedural, verbal); and MIRROR DRAWING (procedural, nonverbal). Also called INDIRECT MEMORY TEST. Compare EXPLICIT MEMORY TEST. See also CONCEPTUAL TEST; IDENTIFICATION–PRODUCTION DISTINCTION; PERCEPTUAL TEST.

implicit personality theories see NAIVE PERSONALITY THEORIES.

implicit prejudice a negative attitude, of which one is not consciously aware, against a specific social group. Compare EXPLICIT PREJUDICE.

implicit process a COGNITIVE PROCESS that is not available to introspection and cannot be described accurately, even under optimal conditions. Compare EXPLICIT PROCESS.
**implicit response** see COVERT RESPONSE.

**implicit self theory** the proposal that people hold a self-belief that psychological attributes (e.g., personality, emotion, intelligence) are either fixed, essential qualities that are impossible to control (entity theory) or are more malleable, controllable, and able to be developed gradually (incremental theory). These self-beliefs imply certain expectations, which in turn guide behavior. In particular, beliefs about controllability guide the way people construe their reality and influence their motivation to engage in self-regulation. [formulated by U.S. personality psychologist Carol S. Dweck (1946– ) in her analysis of cognition, personality, and motivation]

**implosive therapy** a technique in behavior therapy that is similar to flooding but distinct in generally involving imagined stimuli and in attempting to enhance anxiety arousal by adding imaginary exposure cues believed by the therapist to be relevant to the client’s fear. Also called implosion therapy. [developed by U.S. psychologists Thomas G. Stampfl (1923–2005) and Donald J. Levis (1936– )]

**importance of an attitude** the extent to which an individual personally cares about an attitude object or attaches psychological significance to it. Importance is related to ATTITUDE STRENGTH. See also CENTRALITY OF AN ATTITUDE, EGO INVOLVEMENT.

**impossible figure** a shape or form in which different components produce conflicting and mutually exclusive interpretations.

**impostor phenomenon** the situation in which highly accomplished, successful individuals paradoxically believe they are frauds who ultimately will fail and be unmasked—although their achievements had somehow been the most or all of their achievements had somehow been the case. In psychological contexts and ERECTILE DYSFUNCTION in other clinical contexts. Impotence may also denote premature ejaculation, limited interest in sex, orgasm without pleasure, or coitus without ejaculation. —impotent adj.

**imporved** adj. 1. describing a stimulus that is lacking in complexity or information value. 2. deficient in or deprived of certain qualities or lacking in richness because something essential is missing. For example, an impoverished environment offers few opportunities to engage in activity and does not provide adequate sensory and intellectual stimulation. See also INTELLUCTUAL IMPOVERISHMENT. —impoveryishment n.

**impression** n. 1. the presumed effect of stimulation on the brain. 2. a vague or unanalyzed judgment or reaction.

**impression formation** the process in which an individual develops a schema of some object, person, or group. Early research on impression formation demonstrated that impressions were often influenced by the primary effect; more recent studies have focused on the roles played in the process by such factors as the perceivers’ cognitive processes (e.g., how readily some types of ideas come to mind) and feelings (e.g., anger can predispose the perceiver to stereotype an individual).

**impressionism factor** in psychological aesthetics, a dimension of artistic style characterized by an emphasis on surface qualities and textures, such as effects of light or color. In studies of perceptions of art by Daniel E. Berlyne, the impressionism factor is reflected in evaluative ratings that are highly positive for surface qualities and highly negative for beliefs, imagination, and lines.

**impression management** behaviors intended to control how others perceive oneself, especially by guiding them to attribute desirable traits to oneself. Typically, it is assumed that people attempt to present favorable images of themselves as a means of obtaining social rewards and enhancing self-esteem. Impression management has been offered as an alternative explanation for some phenomena that traditionally have been interpreted in terms of cognitive dissonance theory. Some psychologists distinguish impression management from self-presentation by proposing that impression management involves only deliberate, conscious strategies. [first described in 1959 by Canadian-born U.S. sociologist Erving Goffman (1922–1982)]

**imprinting** n. a simple yet profound and highly effective learning process that occurs during a critical period in the life of some animals. It was first described in 1873 by British naturalist Douglas A. Spalding (1840–1877) when he observed that newly hatched chicks tended to follow the first moving object, human or animal, that caught their attention. The term itself was introduced by Konrad Lorenz in 1937. Some investigators believe that such processes are instinctual; others regard them as a form of preparedness.

**improvement rate** see DISCHARGE RATE.

**improvisation** n. in psychodrama, the spontaneous acting out of problems and situations without prior preparation.

**IMPS** abbreviation for INPATIENT MULTIDIMENSIONAL PSYCHIATRIC SCALE.

**impuberism** n. a state of not having reached puberty because of age or delayed development. 2. the continua-
tion of childhood characteristics into adolescence or adulthood. Also called impuberty.

impulse n. 1. a sudden and compelling urge to act, often resulting in action without deliberation. Also called impulsion. See also IMPULSE-CONTROL DISORDER; IMPULSIVE. 2. see NERVE IMPULSE. 3. in psychoanalytic theory, the expression of psychic energy from instinctual drives, such as sex and hunger.

impulse control the ability to resist an impulse, desire, or temptation and to regulate its translation into action.

impulse-control disorder a disorder characterized by a failure to resist impulses, drives, or temptations to commit acts that are harmful to oneself or to others. Examples include INTERMITTENT EXPLOSIVE DISORDER, KLEPTOMANIA, PATHOLOGICAL GAMBLING, PYROMANIA, and TRICHOTILLOMANIA. Other disorders that may involve problems of impulse control include substance use disorders, paraphilias, conduct disorders, and mood disorders.

impulse-timing model a model for the organization of a motor program in which the movement trajectory is determined by the amplitude and timing of force impulses produced by the agonist and antagonist muscles. See also EQUILIBRIUM-POINT MODEL.

impulsion n. see IMPULSE.

impulsive adj. describing or displaying behavior characterized by little or no forethought, reflection, or consideration of the consequences of an action, particularly one that involves taking risks. Compare REFLECTIVE. See also REFLECTION–IMPULSIVITY; SELF-CONTROL. —impulsiveness or impulsivity n.

impulsive character a personality pattern marked by a tendency to act hastily and without adequate reflection on the possible consequences.

imputation n. a procedure for filling in missing values in a data set before analyzing the resultant completed data set. There are several methods of imputation, including COLD-DECK IMPUTATION, HOT-DECK IMPUTATION, and MULTIPLE IMPUTATION.

Imuran n. a trade name for azathioprine.

in absentia referring to legal proceedings against people conducted in their absence. [Latin, “in the absence”]

inaccessibility n. 1. the state of being impossible to reach, approach, or use; 2. unresponsiveness to external stimuli, most commonly associated with the state of withdrawal sometimes seen in autism and schizophrenia. —inaccessible adj.

inadvertent plagiarism see CRYPTOMNESIA.

inanimate noun see ANIMATE NOUN.

inappetence n. impaired appetite or desire, which is a frequent symptom of depression.

inappropriate affect emotional responses that are not in keeping with the situation or are incompatible with expressed thoughts or wishes, such as smiling when told about the death of a friend. Extreme inappropriate affect is a defining characteristic of DISORGANIZED SCHIZOPHRENIA.

inappropriate stimulus a stimulus or condition that elicits a response not normally triggered by that stimulus. For example, pressing against one’s closed eyelid elicits perception of lights; that is, a mechanical stimulus elicits a response in photoreceptors that typically respond to light.

Inaspine n. a trade name for droperidol.

inattention n. a state in which there is a lack of concentrated or focused attention or in which attention drifts back and forth. See also SELECTIVE INATTENTION; PERCEPTUAL EXTINCTION.

inattentional blindness a failure to notice unexpected but perceptible stimuli in a visual scene while one’s attention is focused on something else in the scene. This phenomenon occurs even when items are visible for several seconds. In two classic experiments, many participants focusing on judging the line lengths of a cross failed to notice a simultaneously presented square, and many focusing on counting the number of passes made by a basketball team failed to notice a person dressed in a gorilla suit walk by. Real-world examples are also common, such as magic tricks in which observers fail to see the magician’s sleight of hand in front of them and accidents in which drivers fail to see others on the road. Various factors affect the rate of inattentional blindness, including the visual relationship of the unexpected item to other items, the meaningfulness of the unexpected item, and—most significantly—the observer’s attentional set and cognitive load: inattentive blindness is especially pronounced for task-irrelevant stimuli and in situations with high task-processing demands. Some researchers have suggested that inattentive blindness is in fact a kind of inattentional amnesia, in which people consciously perceive unattended objects but quickly forget them. In this view, attention is critical not for engaging the perceptual processes but rather for encoding the products of those processes into short-term memory. See also ATTENTIONAL BLINDNESS; CHANGE BLINDNESS; REPEITION BLINDNESS; SELECTIVE PERCEPTION. [term coined in 1998 by U.S. psychologists Arien Mack (1931- ) and Irvin Rock (1922–1995)]

in-basket test a WORK-SAMPLE TEST used in management training and selection. The participant is given an assortment of items (letters, memos, reports) that might be found in a typical office in-basket and must take action on them as if he or she were on the job.

inborn adj. see INNATE.

inborn error of metabolism any biochemical disorder caused by a genetic defect. It may be expressed as a defect or deficiency in the structure or enzymatic function of a protein molecule or in the transport of a vital substance across a cell membrane. Examples of such errors include diabetes mellitus, gout, phenylketonuria, and Tay–Sachs disease. Also called METABOLIC ANOMALY.

inbreeding n. the mating of individuals that are closely related. Inbreeding increases the risk of perpetuating certain genetic defects in the family, as in consanguineous marriages. Inbreeding within small populations, such as geographically isolated populations, leads to increased frequency of particular mutations within such groups. This fact has been used to demonstrate the FOUNDER EFFECT for certain cancers and other disorders. Inbreeding studies have contributed to efforts to identify and test for muta-
inbreeding avoidance

tions predisposing to disease in some groups of people. Compare OUTBREEDING.

inbreeding avoidance the avoidance of breeding with close relatives in order to maintain genetic diversity. Several mechanisms that promote inbreeding avoidance have been identified. In some species, olfactory or vocal signals may provide information about genetic relatedness, but most often individuals simply avoid breeding with those who are most familiar. Some studies of MATE SELECTION provide evidence of optimal outbreeding. Neither closely related individuals nor those that differ greatly are chosen; those that are different enough to avoid inbreeding but not too different are regarded as optimal mates.

incantation n. ritualistic chanting, singing, or speaking. The incantation of certain prescribed phrases forms an important part of many religious and magical RITUALS. —in
cant vb.

incendiary n. an older name for PYROMANIA.

incentive n. an external stimulus, such as a condition or an object, that enhances or serves as a motive for behavior.

incentive motivation 1. in HULL’S MATHEMATICOC-DEDUCTIVE THEORY OF LEARNING, an inducement, such as the expectation of a reward or punishment, that serves as an intervening variable or MEDiator to influence response strength. See also STIMULUS-INTENSITY DYNAMISM. 2. more generally, any motivation induced by a positive reinforcer.

incentive system in organizational settings, a set of rewards and rules for their disbursement that is designed to influence future performance. Incentives vary in motivating power from group to group. As well as increased pay, common incentives include pensions, GAINSHARING schemes, performance-related bonuses, employee stock shares, gym memberships, and corporate entertainment (e.g., tickets for sports events). See also DISINCENTIVE; WORK MOTIVATION.

incentive theory the theory that motivation arousal depends on the interaction between environmental incentives (i.e., stimulus objects)—both positive and negative—and an organism’s psychological and physiological states (e.g., drive states).

incentive value the perceived value of a motivating stimulus or condition, which varies among individuals.

incest n. sexual activity between family members, whether related by blood or not. Some form of incest taboo, or prohibition in custom or law against incest between first-degree relatives (e.g., father—daughter, mother—son, brother—sister), is found in nearly every society. In some societies, sexual intercourse between cousins, uncles and nieces, or aunts and nephews is also prohibited: in others, it is permitted. —incestuous adj.

incest barrier in psychoanalytic theory, an EGO DEFENSE against incestuous impulses and fantasies. The barrier is the result of the INTROJECTION of social laws and customs. These internal and external prohibitions free the LIBIDO to make an external OBJECT CHOICE.

incestuous ties in psychoanalytic theory, the condition in which an individual remains psychologically dependent on the mother, family, or symbolic substitute to the extent that healthy involvement with others and with society is inhibited or precluded. According to Erich FROMM, who introduced the term, incestuous ties represent the negative resolution of the search for ROOTEDNESS. See also IDENTITY NEED.

incidence n. the rate of occurrence of new cases of a given event or condition (e.g., a disorder, disease, symptom, or injury) in a particular population in a given period. An incidence rate is normally expressed as the number of cases per some standard proportion (1,000 or 100,000 are commonly used) of the entire population at risk per year. See also PREVALENCE.

incidental learning learning that is not premeditated, deliberate, or intentional and that is acquired as a result of some other, possibly unrelated, mental activity. Some theorists believe that much learning takes place without any intention to learn, occurring incidentally to other cognitive processing of information. Also called nonintentional learning. See also LATENT LEARNING. Compare INTEN
tIONAL LEARNING.

incidental memory a memory that is acquired without conscious effort or intention to remember.

incident process 1. a systematic sequence of actions or steps that is approved for use in a potentially dangerous situation, such as a fire, severe weather, or the presence of bombs or guns. In a school setting, these measures are often practiced as a drill to familiarize students with the appropriate procedure. 2. a system in which learners begin with inadequate data and ask questions to gain additional information. The instructor has all the data and reveals a limited amount at the beginning, then discloses more in response to specific questions so that the group can reach decisions. The system is designed to teach the skills of analysis, synthesis, and interrogation that are relevant to problem solving and investigative techniques.

inclusion n. the practice of teaching students with disabilities in the same classroom as other students to the fullest extent possible, via the provision of appropriate supportive services. See also FULL INCLUSION.

inclusion–exclusion criteria in clinical research, criteria used to determine which individuals are eligible to participate in a particular study. Inclusion criteria might specify, for example, age range, whereas exclusion criteria might specify, for example, the existence of more than one illness or psychological disorder.

inclusion/exclusion model a theory of judgment postulating that ASSIMILATION EFFECTS occur when features of the context are included in the temporary representation of the target and that CONTRAST EFFECTS occur when extreme features of the context are excluded from that representation. See also FLEXIBLE CORRECTION MODEL; SET/RESET MODEL. [proposed by the U.S. psychologists Norbert Schwarz (1953– ) and Herbert Bless]

inclusive fitness the REPRODUCTIVE SUCCESS not only of an individual but also of all of that individual’s relatives in proportion to their COEFFICIENT OF RELATEDNESS. In calculating estimates of reproductive success, it is assumed that parents, offspring, and siblings have an average of 50% of their genes in common; that grandparents and grand-offspring, as well as uncles or aunts and nieces or nephews, share 25% of genes; and that first cousins share 12.5% of genes.

inclusiveness n. one of the GESTALT PRINCIPLES OF ORGANIZATION. It states that there is a tendency to perceive only the larger figure when a smaller figure is completely
incremental learning

encompassed within it. Also called law (or principle) of inclusiveness.

incoherence n. inability to express oneself in a clear and orderly manner, most commonly manifested as disjointed and unintelligible speech. This may be an expression of disorganized and impaired thinking. —incoherent adj.

incompatibility n. 1. the state in which two or more people are unable to interact harmoniously with each other. Compare COMPATIBILITY. 2. in philosophy, the position that FREE WILL and DETERMINISM are incompatible and cannot coexist in any form or sense. Compare COMPATIBILITY. See also HARD DETERMINISM. —incompatible adj.

incompatible response a response or action that conflicts with another or occurs simultaneously with another. For example, a state of anxiety is incompatible with a state of relaxation.

incompatible response method a technique used to break bad habits in which an undesirable response is replaced by a more acceptable one that cannot coexist with the undesirable response.

incompetence n. 1. the inability to carry out a required task or activity adequately. 2. in law, the inability of a defendant to participate meaningfully in criminal proceedings, which include all elements of the criminal justice system, from initial interrogation to sentencing. Defendants who do not have the ability to communicate with attorneys or understand the proceedings may be ruled incompetent to stand trial (see COMPETENCY TO STAND TRIAL). See also DUSKY STANDARD. 3. in law, the inability to make sound judgments regarding one’s transactions or personal affairs. See LEGAL CAPACITY. Also called incompetence. Compare COMPETENCE. —incompetent adj.

incompetency plea the plea, in a court of law, that the defendant, because of mental illness, mental defect, or other reasons, does not understand the nature and objective of the proceedings; cannot appreciate or comprehend his or her own condition in relation to the proceedings; or is unable, for some other reason, to assist the attorney in his or her own defense. See also COMPETENCY TO STAND TRIAL.

incompetent reservoir see DILUTION EFFECT.

incomplete block design an experimental design in which treatments are grouped into sets or “blocks,” not all of which include every treatment, and each block is administered to a different group of participants. Incomplete block designs often are employed to avoid administering too many treatment conditions to the same group of participants. Incomplete block designs are used when the researcher wishes to avoid carrying out all possible combinations of treatments. For example, in a study comparing the effectiveness of three different drugs, the researcher might arrange the treatments in a block design so that each patient received one drug in each of the three blocks. Compare COMPLETE BLOCK DESIGN. See BLOCK DESIGN.

incomplete counterbalancing an experimental design that controls for ORDER EFFECTS by using a limited number of possible sequences of treatments administered in such a way that each treatment appears equally often in each position. For instance, the following arrangement of sequences of three treatments (A, B, C), each assigned to a different subgroup of participants, demonstrates incomplete counterbalancing: A-B-C to Subgroup 1, B-C-A to Subgroup 2, and C-A-B to Subgroup 3. Compare COMPLETE COUNTERBALANCING. See also LATIN SQUARE.

incomplete factorial design see FRACTIONAL FACTORIAL DESIGN.

incomplete-pictures test a test of visual recognition and interpretation in which drawings in varying degrees of completion are presented, and the participant attempts to identify the object as early in the series as possible. See also PICTURE-COMPLETION TEST.

incomplete-sentence test see SENTENCE-COMPLETION TEST.

incomplete spinal cord injury damage to the spinal cord that results in partial loss of motor or sensory function below the site of the injury. See also SPINAL CORD INJURY.

incongruence n. 1. lack of consistency or appropriateness, as in INAPPROPRIATE AFFECT or as when one’s subjective evaluation of a situation is at odds with reality. 2. as defined by Carl ROGERS, a lack of alignment between the real self and the ideal self. See REAL–IDEAL SELF CONGRUENCE. 3. in Rogerian CLIENT-CENTERED THERAPY, a lack of genuineness, honesty, or open expression on the part of the therapist in his or her interactions with a client. —incongruent adj.

incongruity n. the quality of being inconsistent, incompatible, not harmonious, or otherwise in disagreement with an accepted mode or standard. Perception experiments may include tests of incongruity in which, for example, a deck of playing cards may contain incongruous colors and suits, such as black hearts or purple spades.

incongruity theory of humor an explanation of the ability of humor to elicit laughter that emphasizes the juxtaposition of incompatible or contradictory elements. For example, British-born U.S. comedian Bob Hope (1903–2003) once quipped in regard to a place he was visiting: “The mosquitoes here are huge. Last night I shot one in my pajamas. They were tight on him too.” Such theories have roots in the work of Immanuel KANT, Arthur SCHOENHAUER, Herbert SPENCER, and Sigmund FREUD. See also RELEASE THEORY OF HUMOR.

incontinence n. 1. an inability to control basic body functions, such as urination and defecation (see FECAL INCONTINENCE; URINARY INCONTINENCE). Incontinence is often caused by bodily and neurological injury or damage or physical abnormalities and changes. 2. an inability to restrain sexual impulses. —incontinent adj.

incoordination n. a lack of harmony or organization of movement.

incorporation n. in psychoanalytic theory, the fantasy that one has ingested an external object, which is felt to be physically present inside the body. According to the theory, it first occurs in the ORAL STAGE, when the infant fantasizes that he or she has ingested the mother’s breast. Incorporation is thought to be an early form of, and is often confused with, IDENTIFICATION and INTRODUCTION. —incorporate v.

incorporation dream see DREAM INCORPORATION.

incremental adj. describing or relating to changes that take place in small, cumulative steps rather than in large jumps.

incremental learning see ALL-OR-NONE LEARNING.
incremental theory see IMPLICIT SELF THEORY.

incremental validity the improvement obtained by adding a particular procedure or technique to an existing combination of assessment methods. In other words, incremental validity reflects the value of each measure or piece of information to the process and outcome of assessment. The standards for evaluating incremental validity depend on the goal of the assessment, such as whether one wishes to gather unique information, predict a criterion, make a diagnosis, or choose a treatment. For example, teacher observations of the daily frequency of a child’s vocal tic may not add critical information in diagnosing a tic disorder but may contribute significantly when the purpose of the assessment is to monitor treatment progress.

incubation n. 1. the provision of warmth and protection for eggs that develop outside the female’s body. In birds, incubation can be undertaken by either or both parents and is essential for hatching of the eggs. 2. the gradual generation of a solution to a problem at a nonconscious or semi-conscious level, often after an attempt at a conscious, deliberate solution has failed. 3. in microbiology, the growth of cultures in a controlled environment. 4. the maintenance of an artificial environment for a premature or hypoxic infant. 5. the asymptomatic stage of development of an infection. —incubate vb. —incubator n.

incubation of anxiety the increase in a conditioned anxiety response that occurs with repeated unreinforced presentation of a CONDITIONED STIMULUS. For example, a person with a spider phobia might become more afraid of spiders each time he or she encounters one, even if no encounter is paired with a traumatic event, such as the spider biting. [First proposed by Hans Eysenck as the basis of his conditioning theory of neurosis]

incubus n. 1. a demon or evil spirit in male form believed to have sexual intercourse with sleeping women. Compare succubus. 2. a person or thing that is oppressive or an encumbrance. incus n. see OSSICLES.

indecency n. behavior considered offensive, obscene, improper, or immoral according to the norms of a particular culture, especially in relation to sexual matters. —indecent adj.

indefinite article in linguistics, an ARTICLE (a or an in English) used with a noun phrase to indicate a nonspecific entity or one not previously defined, as in A day is a wonderful companion or A dog started barking. Compare DEFINITE ARTICLE.

indemnity plan a system of HEALTH INSURANCE in which the insurer pays for the costs of covered services after care has been given. Such plans are typically based on FEE-FOR-SERVICE and offer participants considerable freedom to choose their own health care providers.

independence n. 1. freedom from the influence or control of other individuals or groups. 2. complete lack of relationship between two or more events, sampling units, or variables, such that none is influenced by any other and that changes in one have no implication for changes in any other. For example, a standard assumption in ANALYSIS OF VARIANCE, MULTIPLE REGRESSION, and many other statistical analyses is INDEPENDENCE OF OBSERVATIONS, or the fact that the occurrence of one observation does not influence the occurrence of any others. See also STATISTICAL INDEPENDENCE. —independent adj., n.

independent events the situation in which observing one event does not provide any additional information about the occurrence or outcome of another event. For example, the outcome of a coin flip and the Dow Jones Industrial Average are independent events, whereas the temperatures of two consecutive days are not necessarily independent. Formally, two events, A and B, are independent if the probability of event A is the same as the conditional probability of event A given event B, that is, \( P(A) = P(A|B) \), or equivalently, \( P(B) = P(B|A) \). Compare DEPENDENT EVENTS.

independent groups see INDEPENDENT SAMPLES.

independent-groups design see BETWEEN-SUBJECTS DESIGN.

independent living 1. the ability of an individual to perform—without assistance from others—all or most of the daily functions typically required to be self-sufficient, including those tasks essential to personal care (see ACTIVITIES OF DAILY LIVING) and to maintaining a home and job. 2. a philosophy and civil reform movement promoting the rights of people with disabilities to determine the course of their lives and be full, productive members of society with access to the same social and political freedoms and opportunities as individuals without disabilities. Central to the philosophy are the concepts of self-determination and self-worth, peer support, consumer-controlled assistance and support services, and political and social reform. Centers for Independent Living (CILs), nonresidential, nonprofit organizations that are staffed and operated by individuals with disabilities, encourage self-sufficiency and self-determination in all aspects of life for individuals with disabilities by providing information and referral services, peer counseling, and independent living support (e.g., help with ASSISTIVE TECHNOLOGY, budgeting, meal preparation, transportation arrangements, employment searches, and gaining access to housing and health care). CILs also advocate for legislative and social change aimed at benefiting individuals with disabilities.

independent-living aid see ASSISTIVE TECHNOLOGY.

independent-living program 1. a system of community-based services and support designed to help individuals with disabilities achieve their highest level of personal functioning without the need to depend on others. Independent-living programs are administered by state vocational rehabilitation agencies. See also INDEPENDENT LIVING. 2. a federally funded, state-administered program to prepare foster care youth who are 16 to 21 years old for the transition to independence.

independent phenomena any phenomena that appear to occur independently of a human AGENT. In parapsychology, the term refers to apparently paranormal phenomena that cannot be ascribed to TELEPATHY or PSI-COKINESIS. These might include video or audio recordings of POLTERGEIST activity made in an empty house.

independent practice association (IPA) an organized form of prepaid medical practice in which a group of private physicians join together in an association and are reimbursed on a FEE-FOR-SERVICE basis or a CAPITATION basis.

independent random sampling see SIMPLE RANDOM SAMPLING.

independent random variables RANDOM VARIABLES that exhibit a complete lack of relationship, such that no
information about one variable, \( x \), conveys any information about another variable, \( y \). Any events related to these variables are INDEPENDENT EVENTS.

**independent samples** groups of individuals or sets of data that are unrelated to one another. For example, experimental groups consisting of different and unrelated participants are independent samples, as are the data sets obtained from these groups. Also called independent groups. Compare DEPENDENT SAMPLES.

**independent-samples \( t \) test** a \( T \) TEST used to analyze data from a BETWEEN-SUBJECTS DESIGN, in which the different groups of individuals or other entities measured are not associated with one another. In the independent-samples \( t \) test, one calculates the value of the \( T \) TEST STATISTIC from the means, standard deviations, and sizes of the two groups of interest, then compares its value to a \( T \) DISTRIBUTION for a given DEGREE OF FREEDOM under the assumptions of normality and INDEPENDENCE of observations, among others. Also called independent-measures \( t \) test. Compare DEPENDENT-SAMPLES \( T \) TEST.

**independent sampling** a process for selecting a sample of study participants from a larger potential group of individuals such that the probability of each person being selected for inclusion is not influenced by which people have been chosen already. The resulting samples will be INDEPENDENT SAMPLES.

**independent self-construal** a view of the self (SELF-CONSTRUAL) that emphasizes one’s separateness and unique traits and accomplishments and that downplays one’s embeddedness in a network of social relationships. Compare INTERDEPENDENT SELF-CONSTRUAL.

**independent variable** (IV) the variable in an experiment that is specifically manipulated or is observed to occur before the dependent, or outcome, variable, in order to assess its effect or influence. Independent variables may or may not be causally related to the DEPENDENT VARIABLE. In statistical analyses—such as PATH ANALYSIS, REGRESSION ANALYSIS, and STRUCTURAL EQUATION MODELING—an independent variable is likely to be referred to as a causal variable, explanatory variable, or PREDICTOR VARIABLE. See also EXOGENOUS VARIABLE; TREATMENT.

**Inderal** n. a trade name for PROPRANOLOL.

**indeterminacy** n. 1. the inability to uniquely determine the form or magnitude of a relationship. 2. the inability to arrive at a unique solution to a problem or mathematical form. 3. IN FACTOR ANALYSIS, the inability to form a unique representation of the factor structure.

**indeterminacy principle** see UNCERTAINTY PRINCIPLE.

**indeterminate sentencing** a punishment in which the judge mandates confinement of an offender over a time range (e.g., between 5 and 10 years) rather than a fixed period (e.g., 7 years). This practice allows greater discretion of the parole board to establish the specific time of release.

**indeterminism** n. 1. in psychology, the doctrine that humans have FREE WILL and are able to act independently of antecedent or current situations, as in making choices. Compare DETERMINISM. See also HARD DETERMINISM; SOFT DETERMINISM. 2. in philosophy, the position that events do not have necessary and sufficient causes. —indeterminist adj.

**index** 1. n. a reference point, standard, or indicator. 2. n. a variable that is employed to indicate the presence of another phenomenon or event. 3. n. a number formed from a combination of other measures to represent another, more general entity. For example, an index of a person’s graduate school potential might be formed from his or her undergraduate grade-point average and score on an admissions test. 4. vb. to act as an index of.

**index adoptees** see CROSS-FOSTERING.

**index case** see PROBAND.

**index of discrimination** the degree to which a test or test item differentiates between individuals of different performance levels, often given as the percentage difference between high-performing and low-performing individuals who answer a target item correctly. Also called discrimination index.

**index of reliability** see RELIABILITY COEFFICIENT.

**index of validity** see VALIDITY COEFFICIENT.

**index of variability** see DISPERSION MEASURE.

**Indian Health Service (IHS)** the principal federal health care provider and health advocate for Native Americans, providing services to approximately 1.9 million American Indians and Alaska Natives belonging to more than 564 federally recognized peoples in 35 states. It is an agency within the U.S. Department of Health and Human Services.

**indicative** n. in linguistics, the MOOD of a verb used to make ordinary DECLARATIVE statements, rather than commands, questions, and so on. Compare IMPERATIVE; INTERROGATIVE; SUBJUNCTIVE.

**indicator variable** 1. see DUMMY VARIABLE. 2. see MANIFEST VARIABLE.

**indictment** n. a formal accusation of criminal wrongdoing brought before the court by a grand jury; the group responsible for reviewing complaints of wrongdoing, to determine whether a trial is warranted. —indict vb.

**indifference of indicator** the observation that, although items on tests of intelligence differ widely in appearance, almost all of them seem to measure GENERAL ABILITY to a greater or lesser extent. The term indifference is used to signify that the items measure the same thing without regard to their specific appearance.

**indigenous researcher** in ergonomics, a researcher who originates from the same environment or community as the target users for a specific system or product design. Indigenous researchers are employed in TASK ANALYSIS and USABILITY ENGINEERING among different ethnic and cultural groups. See also CULTURAL ERGONOMICS; POPULATION STEREOTYPE.

**indirect agonist** a substance that acts to increase the activity of an AGONIST at a receptor in ways other than direct action at the receptor site. Indirect agonists may exert their effect by increasing the metabolism or release of agonist compounds or by displacing other substances that impair full binding of an agonist to its receptor site.

**indirect associations** a symptom of schizophrenia in which the association between ideas is not apparent and not expressed, such that the person’s statements seem bizarre and incoherent to others. See also LOOSENING OF ASSOCIATIONS.

**indirect attitude measure** any procedure for assessing attitudes that does not require a person to provide a re-
port of his or her attitude. Nontraditional approaches to attitude measurement, such as the lost letter procedure and the error-choice technique, are examples. See also explicit attitude measure; implicit attitude measure. Compare direct attitude measure.

indirect measurement a method in which a researcher gathers data about one variable (or a combination of variables) as a means of representing a second variable of interest that cannot be assessed in a more straightforward manner. See proxy variable.

indirect memory test see implicit memory test.

indirect method of therapy a method of conducting therapy, particularly exemplified by client-centered therapy, in which the therapist does not attempt to direct the client's communication or evaluate the client's remarks, although he or she may refer back to the client's remarks or restate them (see restatement).

indirect object see object.

indirect odor effect see direct odor effect.

indirect relationship in structural equation modeling, a correlation between two variables that involves an intervening variable or mediator. For example, age may affect rate of pay, which in turn may affect job satisfaction: This being so, the correlation between age and job satisfaction would be an indirect relationship. The term is often used incorrectly to denote a negative relationship. Compare direct relationship.

indirect scaling see direct scaling.

indirect speech act a speech act whose purpose is not explicit from the form or content of the utterance but must be inferred. For example, it's so cold in here! may well be intended as a request that someone close the window. See conversational inference; form–function distinction; implicature.

indirect suggestibility see secondary suggestibility.

individual accuracy see social relations model.

individual differences traits or other characteristics by which individuals may be distinguished from one another. This is the focus of differential psychology, for which the term individual differences psychology increasingly is used.

individual-differences scaling (INDSCAL) a method of studying how personal attributes influence judgments about the similarity among members of or items in a category. A form of multidimensional scaling, it assumes that people may differ on both the characteristics they use to define a category and the importance they place on each characteristic. Also called weighted multidimensional scaling.

Individual Family Service Plan (IFSP) a plan of services and supports for children up to 3 years of age and their families. Under the U.S. requirements for early intervention programs, the IFSP content must address the child's developmental status and the concerns of parents, define services to be provided and their desired outcomes, and (if appropriate) contain transition steps to preschool services. Also called Individualized Family Service Plan.

individualism n. 1. a social or cultural tradition, ideology, or personal outlook that emphasizes the individual and his or her rights, independence, and relationships with other individuals. Compare collectivism. 2. in ethical and political theory, the view that individuals have intrinsic value. This implies that the unique values, desires, and perspectives of individuals should also be valued in their own right. Thus, individualism often manifests itself as an approach to life that emphasizes the essential right to be oneself and to seek fulfillment of one's own needs and desires. —individualist n. —individualistic adj.

individualist feminism a perspective within feminist thought that is closely related to individualism. The position values female autonomy, emphasizes individual rights and freedom of action, and upholds diversity as an inherent good. See feminism.

individualistic reward structure a performance setting structured in such a way that rewards are assigned on the basis of individual achievement and the success or failure of each person is independent of the success or failure of any other individual. Compare competitive reward structure; cooperative reward structure.

individuality n. the uniqueness of each individual's personality.

individualization n. any process in which an individual becomes distinguishable, in one of multiple ways, from one or more other members of the same species, sex, or other category. —individualize vb.

individualized education program (IEP) a plan describing the special education and related services specifically designed to meet the unique educational needs of a student with a disability. Each IEP must be documented in writing, tailored to a particular child, and implemented in accordance with the requirements of U.S. federal law. The IEP must be created by a team of individuals that includes, but is not restricted to, parents, teachers, a representative of the school system, and an individual who will evaluate the child's needs and monitor progress. See also free and appropriate public education.

individualized instruction a method of instruction characterized by one-to-one teaching and self-paced learning directed toward progressive goals that reflect course or curriculum objectives. Teachers assist students in identifying skills that need development or knowledge that needs to be acquired. Group projects are also incorporated in the program.

individualized reading a method of teaching reading that makes use of the child's interests and of a variety of books specifically focused on the child's level of skills.

individual program an instructional method in which students are responsible for developing and carrying out their own program. This method is most often used for children who possess a high level of motivation and cognitive development. Compare command style.

individual psychology 1. the psychological theory of Alfred Adler, which is based on the idea that throughout life individuals strive for a sense of mastery, completeness, and belonging and are governed by a conscious drive to overcome their sense of inferiority by developing to their fullest potential, obtaining their life goals, and creating their own styles of life. This is opposed to the view that human beings are dominated by “blind,” irrational instincts operating on an unconscious level. Also called Adlerian psychology. 2. historically, a synonym for differential psychology.

individual psychotherapy see individual therapy.
individual response stereotypy see AUTONOMIC REACTIVITY.

individual selection an aspect of NATURAL SELECTION in which those traits of an individual that lead to increased REPRODUCTIVE SUCCESS are more likely to appear in subsequent generations. The focus of individual selection is on the direct benefits to the individual; this contrasts with kin selection, in which those who assist their relatives receive indirect benefits.

Individual Service Plan (ISP) the core plan of services and supports for a person with a developmental disability, constructed by professionals, paraprofessionals, the focal person (depending on his or her abilities), and other concerned parties (e.g., parents, advocates). The ISP incorporates relevant comprehensive functional assessment findings, stipulates desired and preferred outcomes, and identifies the full range of services and supports to be provided in order to achieve each outcome. In certain instances, ISPs may be drawn up for individuals with psychiatric conditions, emotional disturbances, or behavior disorders.

Individuals With Disabilities Education Act (IDEA) legislation passed by the U.S. Congress in 1990 and amended in 1997 and 2004 that provides public funding for special educational services and mandates that such services be provided in the LEAST RESTRICTIVE ENVIRONMENT. It consolidated and replaced the EDUCATION FOR ALL HANDICAPPED CHILDREN ACT.

individual therapy treatment of psychological problems that is conducted on a one-to-one basis. One therapist sees one client at a time. Tailoring the process to his or her unique needs in the exploration of contributory factors and alleviation of symptoms. Also called dyadic therapy, individual psychotherapy. Compare GROUP THERAPY.

individuation 1. generally, the physiological, psychological, and sociocultural processes by which a person attains status as an individual being and exerts himself or herself as such in the world. 2. in the psychoanalytic theory of Carl JUNG, the gradual development of a unified, integrated personality that incorporates greater and greater amounts of the unconscious, both personal and collective, and resolves any conflicts that exist, such as those between introverted and extraverted tendencies. 3. a phase of development, occurring between the 18th and 36th months, in which infants become less dependent on their mothers and begin to satisfy their own wishes and fend for themselves. [postulated by Hungarian-born U.S. child psychoanalyst Margaret Schönberger Mahler (1897–1985)].

indoctrination n. the social inculcation of beliefs, especially by individuals in positions of power or authority. —indoctrinate vb.

indole n. a compound that is the basis of LSD (lysergic acid diethylamide) and many substances involved in nervous system activity, including serotonin, melatonin, and tryptophan.

indolealkylamine n. see HALLUCINOGEN.

indoleamine n. any of a class of BIOGENIC AMINES formed by an indole molecule, which is produced as a breakdown metabolite of tryptophan, and an amine group. Indoleamines include the neurotransmitter serotonin and the hormone melatonin.

INDSCAL abbreviation for INDIVIDUAL-DIFFERENCES SCALING.

induced abortion the deliberate, premature removal of the fetus from the uterus prior to the stage of viability (ability to live outside the uterus) by artificial means, such as drugs or mechanical devices. See also ABORTION: THERAPEUTIC ABORTION.

induced aggression a state of violence or hostile behavior caused by drugs, electrical stimulation of a brain area, or aversive stimuli.

induced color a color change in a visual field resulting from stimulation of a neighboring area, rather than from stimulation of the part of the field in which the change appears.

induced compliance effect see FORCED COMPLIANCE EFFECT.

induced hallucination a hallucination evoked by hypnotic suggestion in susceptible individuals.

induced hypothermia the gradual reduction of body temperature by artificial means, usually for medical reasons. It is used, for example, in some surgical procedures (especially those involving the heart) to decrease the body’s need for oxygen and in the treatment of neurological diseases causing a fever.

induced movement an illusion of movement that occurs when a small stationary stimulus is surrounded by a large moving stimulus. The small object appears to move, while the large object appears to be still. An example is the HAUNTED SWING ILLUSION. Also called vection.

induced psychotic disorder see SHARED PSYCHOTIC DISORDER.

induced tonus sustained muscle tension brought about by a movement of another body part.

induction n. 1. a general conclusion, principle, or explanation derived by reasoning from particular instances or observations. See INDUCTIVE REASONING. Compare DEDUCTION. 2. the process of inductive reasoning itself. 3. in conditioning, the phenomenon in which reinforcement of some forms of behavior results in an increased probability not only of those forms but also of similar but nonreinforced forms. For example, if lever presses with forces between 0.2 and 0.3 N are reinforced, presses with forces less than 0.2 N or greater than 0.3 N will increase in frequency although they are never explicitly reinforced. Also called response generalization. 4. in developmental biology, the process by which one set of cells influences the fate of neighboring cells, usually by secreting a chemical factor that changes gene expression in the target cells. 5. the act or process of producing or causing to occur. —inductive adj.

induction test a series of test items in which the participant must apply INDUCTIVE REASONING to derive or formulate a general law, rule, or principle based on several relevant facts or cases.

inductive problem solving a learning technique in which the student is asked to identify relevant relationships between given facts and events and explain the general principles that underlie these relationships.

inductive reasoning the form of reasoning in which inferences and general principles are drawn from specific observations and cases. Inductive reasoning is a corner-
inductive statistics

stone of the scientific method (see BACONIAN METHOD) in that it underlies the process of developing hypotheses from particular facts and observations. Compare DEDUCTIVE REASONING. See also GENERALIZATION.

inductive statistics see INFERENTIAL STATISTICS.

inductive teaching model an approach in education that strongly emphasizes the role of inductive reasoning and INDUCTIVE PROBLEM SOLVING in cognitive development. Also called INQUIRY TRAINING MODEL.

industrial and organizational psychology (I/O psychology) the branch of psychology that studies human behavior in the work environment and applies general psychological principles to work-related issues and problems, notably in such areas as PERSONNEL SELECTION, PERSONNEL TRAINING, EMPLOYEE EVALUATION, working conditions, ACCIDENT PREVENTION, JOB ANALYSIS, JOB SATISFACTION, leadership, team effectiveness, and WORK MOTIVATION. I/O psychologists conduct empirical research aimed at understanding individual and group behavior within organizations and use their findings to improve ORGANIZATIONAL EFFECTIVENESS and the welfare of employees. Also called BUSINESS PSYCHOLOGY: EMPLOYMENT PSYCHOLOGY: INDUSTRIAL PSYCHOLOGY: MANAGEMENT PSYCHOLOGY: OCCUPATIONAL PSYCHOLOGY: ORGANIZATIONAL PSYCHOLOGY: WORK PSYCHOLOGY. See also OCCUPATIONAL HEALTH PSYCHOLOGY; PERSONNEL PSYCHOLOGY.

industrial democracy a system of managing an organization in which employees participate in important decisions. An example would be the use of autonomous work groups in which employees determine their work procedures and assignments and are responsible for evaluating and rewarding performance. See also PARTICIPATIVE DECISION MAKING; QUALITY CIRCLE; SCANLON PLAN.

industrial efficiency see EFFICIENCY.

industrial ergonomics a specialty area of ERGONOMICS that applies knowledge of human physical capabilities and limitations to the design of industrial WORK SYSTEMS, including work processes.

industrial psychology see INDUSTRIAL AND ORGANIZATIONAL PSYCHOLOGY.

industrial psychopath an individual in a work setting who displays a pattern of behavior regarded as typical of ANTISOCIAL PERSONALITY DISORDER. Such individuals act without regard for others and use manipulation to effectively manage both supporters and detractors, often resulting in career advancement. This type of individual is most likely to find success in organizations undergoing rapid changes.

industrial relations see LABOR RELATIONS.

industriousness n. see CONSCIENTIOUSNESS.

industry versus inferiority the fourth of ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, occurring from ages 6 to 11 years, during which the child learns to be productive and to accept evaluation of his or her efforts or becomes discouraged and feels inferior or incompetent.

ineffability n. the quality of certain experiences that makes them indescribable. This quality is often associated with spiritual, aesthetic, or emotional experiences. See also QUALIA. —ineffable adj.

infancy n. the earliest period of postnatal life, in humans generally denoting the time from birth through the first year. —infant n.

infant and preschool tests individually administered tests designed to assess the development of infants (from birth to 18 months) and preschool children (from 18 to 60 months). Important tests include the BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT, the MCCARTHY SCALES OF CHILDREN’S ABILITIES, and the WECHSLER PRESCHOOL AND PRIMARY SCALE OF INTELLIGENCE.

infant at risk an infant whose development may be threatened by complications at the time of birth, such as conditions that reduce the supply of oxygen to brain tissue, or by conditions after birth, such as malnutrition during the first months of life.

Infant Behavior Record the former name for the Behavior Rating scale. See BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT.

infant consciousness sensory awareness, volitional action, and other aspects of phenomenal experience in newborns and older infants. Investigations of infant consciousness suggest that it begins in early gestation with the formation of anatomical, physiological, and neural structures that will serve an individual’s conscious experience in postnatal life: develops in late gestation into a fetus’s latent engagement with sensed surroundings in and ex utero; becomes nascently experienced in early postnatal life, as a newborn begins to explore the world outside his or her own body; and emerges increasingly as a distinct experience with the achievement of DEVELOPMENTAL MILESTONES in later infancy and childhood.

infant-directed speech the specialized style of speech that adults and older children use when talking specifically to infants, which usually includes much inflection and repetition. See also CHILD-DIRECTED SPEECH.

infanticide n. the killing of an infant or child. Although now predominantly considered both immoral and criminal, in the past infanticide was an accepted practice in some societies, often as a response to scarcity or overpopulation or as a means of eliminating offspring deemed unfit. Infants (particularly female infants) are still at risk in some cultures. Infanticide has been observed in many nonhuman animal species. It is thought to be advantageous for a new male taking over a group, who thus avoids the need to care for unrelated young; moreover, females that lose offspring will stop lactation and be able to reproduce sooner. Infanticide has also been observed in COOPERATIVE-BREEDING species when two females give birth at around the same time and there is competition for helpers to provide care for the young. —infanticidal adj.

infantile amnesia see CHILDHOOD AMNESIA.

infantile autism see AUTISM.

infantile myxedema see BRUSSAID’S INFANTILISM.

infantile paralysis see POLIOMYELITIS.

infantile sexuality in psychoanalytic theory, the concept that PSYCHIC ENERGY or LIBIDO concentrated in various organs of the body throughout infancy gives rise to erotic pleasure. This is manifested in sucking the mother’s breast during the ORAL STAGE of psychosexual development, in defecating during the ANAL STAGE, and in self-stimulating activities during the early GENITAL STAGE. The term and concept, first enunciated by Sigmund FREUD, proved highly controversial from the start, and it is more in line with sub-
sequent thought to emphasize the sensual nature of breast-feeding, defecation, and discovery of the body in childhood and the role of the pleasurable feelings so obtained in the origin and development of sexual feelings.

infantile speech speech or verbalizations using the sounds and forms characteristic of infants or very young children beyond the stage when such speech is normal.

infantilism n. behavior, physical characteristics, or mental functioning in older children or adults that is characteristic of that of infants or young children. See REGRESSION.

infantilization n. the encouragement of infantile or childish behavior in a more mature individual. —infanti-lize vb.

infant massage therapy the systematic gentle touching, stroking, and kneading of the body of a baby. Therapeutic benefits include helping the baby relax and inducing sounder, longer sleep.

infant reflex see PRIMITIVE REFLEX.

infant states of arousal the behavioral states experienced by infants in fairly even alternation, including (a) regular, periodic, and irregular sleep; (b) crying; (c) waking activity; and (d) ALERT INACTIVITY.

infant test see INFANT AND PRESCHOOL TESTS.

infarction n. 1. an area of dead tissue resulting from obstruction of a supplying artery. Infarction of brain tissue can have effects ranging from mild to severe, depending on the extent of the dead tissue and its location in the brain (see CEREBRAL INFARCTION). A myocardial infarction (heart attack) involves death of a segment of the heart muscle, usually due to obstruction of a coronary artery, and is a common cause of death. 2. a sudden shortfall in the blood supply to a particular tissue, organ, or part resulting from obstruction of a supplying artery, due, for example, to THROMBOSIS or EMBOLISM. Also called infarct. See STROKE.

infecundity n. inability to produce offspring.

inference n. 1. a CONCLUSION deduced from an earlier premise or premises according to valid RULES OF INFERENCE, or the process of drawing such a conclusion. Some hold that an inference, as contrasted with a mere conclusion, requires that the person making it actually believe that the inference and the premises from which it is drawn are true. Also called logical inference. 2. in statistical analysis, a conclusion about a population based on logical reasoning from data gathered about a smaller sample (see INFERENTIAL STATISTICS). The most common example of this type of inference is statistical hypothesis testing (see INFERENTIAL TEST). —inferential adj.

inferential validity the extent to which causal inferences made in a laboratory setting are applicable to the real-life experiences they are meant to represent. See also EXTERNAL VALIDITY.

inferior adj. in anatomy, lower, below, or toward the feet. Compare SUPERIOR.

inferior colliculus either of the caudal pair of colli-culi. They receive and process auditory nerve impulses and relay these to the MEDIAL GENICULATE NUCLEI.

inferior frontal gyrus an anatomically poorly defined region of the frontal lobe that includes BROCA’S AREA and is involved in language production, risk aversion, and empathetic response to facial expressions.

inferior function in the ANALYTIC PSYCHOLOGY of Carl Jung, one of the three nondominant, unconscious functions of the personality that are dominated by the SUPERIOR FUNCTION in a particular FUNCTIONAL TYPE.

inferiority n. in ERIKSON’S EIGHT STAGES OF PSYCHO-SOCIAL DEVELOPMENT, see INDUSTRY VERSUS INFERIORITY.

inferiority complex a basic feeling of inadequacy and insecurity, deriving from actual or imagined physical or psychological deficiency, that may result in behavioral expression ranging from the withdrawal of immobilizing timidity to the overcompensation of excessive competition and aggression. Compare SUPERIORITY COMPLEX. [introduced in 1907 by Alfred Adler]

inferior longitudinal fasciculus a bundle of association fibers that extends from the occipital to the temporal pole of each CEREBRAL HEMISPHERE.

inferior oblique the extrinsic EYE MUSCLE that rotates the eyeball upward if it contracts when the eye is pointing toward the nose and contributes to upward motion (together with the INFERIOR RECTUS) if it contracts when the eye is pointing straight ahead.

inferior olivary complex (inferior olivary nucleus; inferior olive) see OLIVARY NUCLEUS.

inferior rectus the extrinsic EYE MUSCLE that rotates the eyeball upward if it contracts when the eye is pointing toward the side of the head and contributes to upward motion (together with the INFERIOR OBLIQUE) if it contracts when the eye is pointing straight ahead.

inferior temporal gyrus a ridge (gyrus) that extends along the lower surface of the TEMPORAL LOBE of the brain, bounded above by the middle temporal sulcus. It has a role in language, semantic memory, visual processing, and sensory integration.

inferotemporal cortex (IT cortex) a region of the brain on the inferior (lower) portion of the outer layer (cor-tex) of the temporal lobe that is particularly involved in the perception of form. This VISUAL ASSOCIATION CORTEX contains neurons with very complicated stimulus requirements; lesions in this area impair form and object perception even though visual discrimination thresholds are unchanged (see VISUAL AGNOSIA). See also GRAND-MOTHER CELL.

infertility n. inability to produce offspring due to a low FERTILITY level in the male partner, the female partner, or both. Infertility is caused by physical problems. No evidence clearly shows a psychological cause, although maternal stress has been suggested as a factor. See also ARTIFICIAL IN-SEMINATION; IN VITRO FERTILIZATION. —infertile adj.
inflibulation n. the removal of the entire clitoris and most of the labia and sewing together the remaining tissue, leaving a small opening for menstruation and urination. It is practiced in some cultures as the most severe form of female genital mutilation, usually done during early childhood or the prepubertal years.

infidelity n. 1. the situation in which one partner in a marriage or intimate relationship becomes sexually or emotionally involved with a person other than the partner's spouse or girlfriend or boyfriend. The infidelity, also called cheating, usually transpires in secrecy between those in the extradyadic relationship; however, online infidelity, in which the extradyadic intimacy occurs on social networks and other Internet-based sites that may be only marginally private, is becoming widespread. Regardless of its method of pursuit, its effects can be harmful: Infidelity has been linked to significant adverse emotional and behavioral consequences, especially for the individual who is cheated on, including decreased self-esteem and increased risk of depression and suicide. Additionally, it is cited as a common cause of divorce or relationship dissolution. See also ADULTERY. 2. more generally, any disloyalty or lack of faith.

infinite-valued logic a system of logic that differs from classical logic, which permits only two truth categories to be assigned to a proposition (true or false), by allowing for multiple categories or degrees of truthfulness. For example, whereas the statement Smith is a professor is either true or false, the statement Smith is depressed might have varying degrees of truthfulness. Thus, the intersection of the categories “Smith” and “depressed” has “fuzzy” as opposed to “crisp” boundaries. Infinite-valued logic is related to FUZZY LOGIC. See also BIVALENCE.

infixed n. an element inserted medially within a word to modify the word’s meaning. The only known examples in English are swear words, as in fan-fucking-tastic. Compare PREFIX; SUFFIX.

inflation n. in linguistics, a modification in the form of a word, often by the addition of a SUFFIX, that signals a change in tense, person, number, or case. Common inflections in English are the addition of -ed or -ing to signal the past tense or present participle of a verb and the addition of -s or -’s to signal the plural or possessive form of a noun. See MORPHOLOGY.—inflactive adj.

influence analysis a set of techniques that allows one to determine the degree to which specific data points affect the overall result of a statistical procedure. For example, in REGRESSION ANALYSIS it is used to examine which observations have a disproportionate influence on the proposed REGRESSION EQUATION.

influence tactics the specific actions taken by one person to change the behavior or attitudes of another.

influencing machine the subject of a DELUSION OF PERSECUTION in which the individual feels controlled by a machine that serves as the instrument of persecution.

informal communications in organizational settings, communications among employees that do not occur through the formally prescribed CHANNELS OF COMMUNICATION. Informal communications often serve important functions that are instrumental in achieving organizational objectives, such as fostering innovation and problem solving.

informal fallacy see FALLACY.

informant n. an expert who is consulted in ethnographic and related research. The researcher obtains information from the informant regarding the individual, group, and cultural characteristics and behaviors of the unit (e.g., group, tribe, society) about which the informant has knowledge.

informatics n. the science of using technology to collect, process, analyze, utilize, classify, store, and generally manage data and knowledge. Informatics is used in computer design, databases, and human interface design. See BIOMATHEMATICS.

information n. 1. knowledge about facts or ideas gained through investigation, experience, or practice. 2. in INFORMATION THEORY, a message that reduces uncertainty; that is, information tells us something we do not already know. The BIT is the common unit of information in information theory.

informational cascade in decision making and risk management, the tendency for individuals to ignore their private knowledge and act as others do, assuming that these others must have better information; the result is an ever-increasing uniformity of behavior. Stock market bubbles and bank panics are examples.

informational influence 1. those interpersonal processes that challenge the correctness of an individual's beliefs or the appropriateness of his or her behavior, thereby promoting change. Such influence may occur directly, as a result of communication and persuasion, or indirectly, through exposure to information and comparison of oneself with others (see SOCIAL COMPARISON THEORY). Also called informational social influence. Compare INTERPERSONAL INFLUENCE; NORMATIVE INFLUENCE. 2. the degree to which a person's judgments or opinions about an unclear situation are accepted by others as correct.

informational power a capacity to influence others that is based on one's knowledge of facts relevant to the situation.

information-error technique see ERROR-CHOICE TECHNIQUE.

information feedback responses that inform an individual about the correctness, physical effect, or social or emotional impact of his or her behavior or thinking. The concept is similar to the principle behind KNOWLEDGE OF RESULTS, namely, that immediate feedback is beneficial to learning. In interpersonal relations and psychotherapy, information feedback gives an individual insight into other people's experience of him or her. In BEHAVIOR THERAPY, information feedback is intended to help change and shape behavior directly.

information hypothesis the claim that conscious sensory processes may be modeled and explained by reference to the formal concepts of INFORMATION THEORY.

information overload the state that occurs when the amount or intensity of information exceeds the individual's processing capacity, leading to anxiety, poor decision making, and other undesirable consequences. Different people respond differently to information overload, and individuals with conditions such as autism can be especially sensitive to it. Thus, the subjective condition of the person is as important as the absolute amount of informational stimulation he or she encounters. See also COGNITIVE OVERLOAD; COMMUNICATION OVERLOAD; SENSORY OVERLOAD; STIMULUS OVERLOAD.
Ingratiation

Information processing (IP) 1. the manipulation of data by computers to accomplish some goal, such as problem solving or communication. 2. in cognitive psychology, the flow of information through the human nervous system, involving the operation of perceptual systems, memory stores, decision processes, and response mechanisms. Information processing psychology is the approach that concentrates on understanding these operations. See also INFORMATION THEORY.

Information-processing model any conceptualization of memory as involving the progressive transfer of information through a system, much as a computer manipulates information in order to store, retrieve, and generate responses to it. The most popular model is that proposed in 1968 by U.S. cognitive psychologists Richard C. Atkinson and Richard M. Shiffrin (1942– ). Sometimes also referred to as the multistore model or the three-stage model, their theory views memory as a system with three distinct components—SENSORY MEMORY, which collects and transforms material; SHORT-TERM MEMORY, which temporarily holds material; and LONG-TERM MEMORY, which more permanently retains material and recalls it as needed—that sequentially process information through the stages of ENCODING, STORAGE, and RETRIEVAL. Each component differs in how much material it can hold and for how long, as well as the mechanisms by which it operates. CONTROL PROCESSES govern informational flow, memory search, output of responses, and so forth. Compare CONNECTIONIST MODEL.

Information science the field of study concerned with the representation, storage, retrieval, and transmission of information. Information science usually includes computer science and communication science. See INFORMATION THEORY.

Information systems technology used to collect, manage, store, and report data. An example of such technology is a healthcare information system (HIS) designed to integrate the management of all aspects of a patient’s medical records with a hospital’s administrative and financial processes. Reports generated from the combined data collected by the system’s database can serve to document and account for many program services, costs, and outcomes.

Information technology (IT) the application of INFORMATION SCIENCE to practical objectives. Information technology subsumes computer and communication technologies.

Information test a test that measures a person’s general knowledge in different areas and at different levels of complexity.

Information theory the principles relating to the communication or transmission of INFORMATION, which is defined as any message that reduces uncertainty. These principles deal with such areas as the encoding and decoding of messages, types of CHANNELS OF COMMUNICATION and their capacity to throughput information, the application of mathematical methods to the problem, the problem of noise (distortion), and the relative effectiveness of various kinds of FEEDBACK.

Informed consent a person’s voluntary agreement to participate in a procedure on the basis of his or her understanding of its nature, its potential benefits and possible risks, and available alternatives. Informed consent is a fundamental requirement of research with humans and typically involves having participants sign documents, prior to the start of a study, that describe specifically what their involvement would entail and noting that they are free to decline participation or to withdraw from the research at any time. In therapeutic contexts, the principle of informed consent has provided a foundation for do not resuscitate (DNR) orders and other ADVANCE DIRECTIVES and for the natural-death acts that have been passed into law throughout the United States. See also INSTITUTIONAL REVIEW BOARD.

Infradian rhythm any periodic variation in physiological or psychological function (see BIOLOGICAL RHYTHM) recurring in a cycle of less than 24 hours, such as the breathing rhythm. Compare CIRCADIAN RHYTHM; ULTRADIAN RHYTHM.

Infrahuman adj. an obsolete term describing all species “below” humans (i.e., nonhumans). This reflects the earlier concept of a “chain of being” that culminates in humans.

Infrared n. that part of the electromagnetic spectrum with wavelengths between about 0.8 µm and 1 mm. The near-infrared part of the range (0.8–3 µm) is experienced as heat. Infrared cameras are sensitive to thermal emissions from objects and can therefore produce photography in the dark.

Infrared theory of smell a theory that the olfactory sense organ functions as an infrared spectrometer. It assumes that ODORANTS each have a unique infrared absorption spectrum, which produces transient cooling of the cilia in the OLFACTORY EPITHELIUM. The theory is called into question by the fact that isomers of some odorants have identical infrared absorption spectrums but produce different odors.

Infrasonic communication among some nonhuman animals, the use of sound frequencies below the range of human hearing (i.e., below 20 Hz) for communication. Both elephants and whales use infrasonic communication extensively. The low frequencies have very long wavelengths that are transmitted for very long distances: They have been shown to coordinate activity between individuals over distances of several kilometers. Compare ULTRASONIC COMMUNICATION. [discovered in the 1980s by Cornell University researcher Katharine Boynton Payne (1937– )]

Infrasound n. sound whose frequency is too low to be detected by human hearing, generally encompassing the range of 20 Hz to .001 Hz. The scientific study of infrasound is known as infrasonics. Able to cover long distances and circumvent or penetrate obstacles without dispersing, infrasonic waves are used by many nonhuman animals to communicate (see INFRASONIC COMMUNICATION) and have a variety of applications in geological monitoring (e.g., prediction of volcanic eruptions, detection of earthquakes). Compare ULTRASONIC.

Infundibulum n. (pl. infundibula) a funnel-shaped anatomical structure, in particular the stalk of the PITUITARY GLAND, situated just below the THIRD VENTRICLE of the brain and above the sphenoid sinus at the base of the skull.

Ingenious adj. cleverness at solving routine problems of daily life (at work, home, etc.): everyday CREATIVITY.

Ingratiation n. efforts to win the liking and approval of other people, especially by deliberate IMPRESSION MANAGE-
Ingroup. Ingratiation is usually regarded as strategic, insincere, and manipulative. —ingratiate vb.

Ingroup n. 1. in general, any group to which one belongs or with which one identifies, but particularly a group judged to be different from other groups (outgroups). 2. a group characterized by intense bonds of affiliation such that each member feels a sense of kinship and some degree of loyalty to other members by virtue of their common group membership. Also called we-group. [defined in 1906 by U.S. sociologist William G. Sumner (1840–1910)]

Ingroup bias the tendency to favor one’s own group, its members, its characteristics, and its products, particularly in reference to other groups. The favoring of the ingroup tends to be more pronounced than the rejection of the outgroup, but both tendencies become more pronounced during periods of intergroup contact. At the regional, cultural, or national level, this bias is often termed ethnocentrism. Also called ingroup favoritism. See also GROUP-SERVING BIAS.

Ingroup extremity effect the tendency to describe and evaluate ingroup members, their actions, and their products in exaggeratedly positive ways. Compare outgroup extremity effect. See also INGROUP BIAS; LINGUISTIC INTERGROUP BIAS.

Inguinal adj. referring to the groin (inguen).

INH abbreviation for isonicotinic acid hydrazide. See ISO- NIAZID.

Inhabitance n. the idea that ghosts or spirits can occupy particular locations, as in hauntings, or take control of people, animals, or things, as in cases of alleged possession. See EXORCISM.

Inhalant n. any of a variety of volatile substances that can be inhaled to produce intoxicating effects. Anesthetic gases (e.g., ether, chloroform, NITROUS OXIDE), industrial solvents (e.g., TOLUENE, gasoline, trichloroethylene, various aerosol propellants), and organic nitriles (e.g., AMYL NITRITE) are common inhalants. Anesthetic gases may cause asphyxiation, and chloroform has been associated with damage to the liver and kidneys. Industrial solvents are generally toxic, associated with damage to the kidneys, liver, and both central and peripheral nervous systems. Organic nitriles are less toxic but may cause ARRHYTHMIAS in individuals with heart conditions. Household products, such as model airplane glue, nail polish remover, spray paint, fabric protector, cooking spray, and correction fluid, are also used as inhalants, especially by adolescents. See also INHALATION OF DRUGS.

Inhalant abuse in DSM–IV–TR, a pattern of inhalant use marked by recurrent significant adverse consequences related to the repeated ingestion of these substances. This diagnosis is preempted by the diagnosis of INHALANT DEPENDENCE: If the criteria for inhalant abuse and inhalant dependence are both met, only the latter diagnosis is given. In DSM–5, however, both have been subsumed into the category INHALANT USE DISORDER and are no longer considered distinct diagnoses. See also SUBSTANCE ABUSE.

Inhalant dependence in DSM–IV–TR, a pattern of repeated or compulsive use of inhalants despite significant inhalant-related behavioral, physiological, and psychological problems and tolerance and characteristic withdrawal symptoms if use is suspended. In DSM–5, inhalant dependence and INHALANT ABUSE have been subsumed into in-
inhibitory aftereffect see INHIBITION OF RETURN.

inhibitory conditioning CLASSICAL CONDITIONING in which the presence of a conditioned stimulus denotes the absence of an unconditioned stimulus that has a preexisting excitatory context. That is, the unconditioned stimulus must be one to which the organism has been exposed previously; otherwise, its absence would have no importance. Compare EXCITATORY CONDITIONING.

inhibitory gradient (inhibition gradient) see GENERALIZATION GRADIENT.

inhibitory neurotransmitter see NEUROTRANSMITTER.

inhibitory postsynaptic potential (IPSP) a brief increase in the difference in electrical charge across the membrane of a neuron that is caused by the transmission of a signal from a neighboring neuron across the synapse (specialized junction) separating them. IPSPs decrease the probability that the postsynaptic neuron will initiate an ACTION POTENTIAL and hence fire a nerve impulse. Compare EXCITATORY POSTSYNAPTIC POTENTIAL.

inhibitory potential a hypothesized temporary state in which REACTIVE INHIBITION and CONDITIONED INHIBITION result from responding to a stimulus, causing a reduction in the potential of recurrence of that response. [proposed by Clark L. Hull]

inhibitory process 1. any phenomenon in human or nonhuman animal behavior that prevents or blocks actions that are problematic for the individual. See EXCITATORY-INHIBITORY PROCESSES. 2. in memory, a mechanism that acts on situations requiring voluntary control to avoid intrusions from unwanted information (e.g., DIRECTED FORGETTING). 3. in neurorecognition, an automatic mechanism triggered whenever irrelevant information is activated and competes with relevant information. See RETRIEVAL BLOCK.

inhibitory synapse a specialized type of junction at which activity from one neuron (in the form of an ACTION POTENTIAL) reduces the probability of activity in an adjacent neuron by initiating an INHIBITORY POSTSYNAPTIC POTENTIAL. Compare EXCITATORY SYNAPSE.

in-home respite see RESpite CARE.

in-house evaluation an organization’s internal program assessments, conducted by an INTERNAL EVALUATOR, as opposed to evaluation conducted by an EXTERNAL EVALUATOR.

initial cry see EPILEPTIC CRY.

initial data analysis (IDA) an examination of the quality of a data set that is undertaken before beginning more complex statistical tests of hypotheses. It often involves calculating DESCRIPTIVE STATISTICS such as the mean and STANDARD DEVIATION, identifying minimum and maximum values, and graphing the data points to determine whether their arrangement follows a known or expected distribution. IDA is important for ensuring that data conform to assumptions of the statistical models that will be used for subsequent formal analysis.

initial insomnia difficulty in falling asleep. Some people with initial insomnia become so worried about being unable to fall asleep or about the effects of loss of sleep that they cannot relax sufficiently to induce sleep. Initial insomnia may be a symptom of a MAJOR DEPRESSIVE EPISODE. Also called ONSET INSOMNIA: SLEEP-ONSET INSOMNIA. Compare MIDDLE INSOMNIA: TERMINAL INSOMNIA.

initial interview in psychotherapy, the first interview with a client, which has some or all of the following goals: to establish a positive relationship, to listen to the client’s problem described in his or her own words, to make a tentative diagnosis, to set treatment goals, and to formulate a plan for diagnostic tests, possible treatment, or referral.

initial link see CONCURRENT-CHAINS PROCEDURE.

initial spurt the high productivity or performance frequently noted at the start of a job, task, or series of trials. The initial spurt is more common with new tasks than tasks already familiar to the individual. Compare END SPURT.

Initial Teaching Alphabet (ITA) a near-phonetic alphabet of 44 characters, each with a single sound. It has been used since the early 1960s, with varying success, in teaching English-speaking children to read. [devised by British educator and publisher James Pitman (1901–1985)]

initial value dependency see LAW OF INITIAL VALUES.

initial values law see LAW OF INITIAL VALUES.

initiating structure a function of effective leadership that involves organizing the group for its work, typically by setting standards and objectives, identifying roles and positioning members in those roles, developing standard operating procedures, criticizing poor work, and defining the relationship between leaders and subordinates. Compare CONSIDERATION.

initiation deficit see ABulia.

initiative versus guilt the third of ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, which occurs during the child’s 3rd through 5th years. In planning, launching, and initiating fantasy, play, and other activity, the child learns to believe in his or her ability to successfully pursue goals. However, if these pursuits often fail or are criticized, the child may develop instead a feeling of self-doubt and guilt.

injunctive norm any of various socially determined consensual standards (SOCIAL NORMS) that describe how people should act, feel, and think in a given situation, irrespective of how people typically respond in the setting. Individuals who violate these standards are often judged negatively. Also called PRESCRIPTIVE NORM. Compare DESCRIPTIVE NORM.

injury deceitfulness in sport, failure to disclose the presence of an injury in order to join or retain one’s position on a team, to exercise, or to avoid benching or some other consequence.

injury denial failure to acknowledge the existence or severity of an injury.

injury feigning behavior used by some birds to fool potential predators and lure them away from a nest. The bird pretends to have an injury (e.g., a broken wing) at some distance from the nest, thus distracting the attention of an approaching predator by presenting itself as easy prey.

inkblot test see BORSCHACH INKBLOT TEST.

INL abbreviation for INNER NUCLEAR LAYER.

inlier n. an incorrect value in a data set. Inliers may arise from SYSTEMATIC ERROR, respondent error, or processing error. For example, a researcher may inadvertently report a
innate

value in the wrong unit, such as including a READ SCORE in a distribution of STANDARDIZED SCORES.

innate adj. 1. denoting a capability or characteristic existing in an organism from birth, belonging to the original or essential constitution of the body or mind. In innate processes should be distinguished from those that develop later in infancy and childhood under maturational control. 2. in philosophy, denoting an idea that is knowable by reason alone and that does not need to be established or confirmed by experience. Also called inborn; native.

innate behavior behavior that appears to be developed and expressed with no specific training or experience and thus has a strong genetic basis. It is generally accepted that most behavior is neither purely innate nor purely due to learning or experience. See EP IgEnEsis; NATURE—NURTURE.

innate ideas ideas that are held to be present in the mind prior to any experience. Innate ideas are usually taken to be those ideas that are so intuitively obvious as to require no proof, such as the Axioms of geometry or the “contradiction principle” (X is not non-X) in logic. For René Descartes, who is often cited as the originator of the concept, innate ideas referred not so much to particular ideas as to the capacities and processes of rationality that allow such ideas to be immediately intuited as true. The notion of innate ideas later came under attack from John Locke and other thinkers in the empiricist tradition (see Empiricism). Compare derived ideas.

innate releasing mechanism (IRM) in ethology, the hypothesized neurological means by which organisms exhibit a fixed action pattern given a particular releaser, suggesting that there is a direct correspondence between a specific elicitor and a specific behavioral event. For example, the zigzag dance is performed by a male three-spined stickleback fish only when it sees another fish with a swollen abdomen.

inner audience an imagined listener to one’s own silent, inner speech, often associated in psychoanalytic and psychodynamic theory with an authority figure. The sense of an inner audience may be important in the early development of self-regulation.

inner conflict see intrapsychic conflict.

inner dialogue a mental debate that an individual may engage in about any issue. In some systems of psychotherapy, clients are encouraged to express their inner dialogue aloud in words during sessions.

inner-directed adj. describing or relating to an individual who is self-motivated and not easily influenced by the opinions, values, or pressures of other people. Compare other-directed; tradition-directed. [introduced by U.S. sociologist David Riesman (1909—2002)]

inner ear the part of the ear that comprises the bony and membranous labyrinths and contains the sense organs responsible for hearing and balance. For hearing, the major structure is the COCHLEA (see also LABYRINTH). For the sense of balance, the major structures are the SEMICIRCULAR CANALS, SACRILE, and UTRICLE (see also VESTIBULAR APPARATUS).

inner estrangement the feeling that external objects are unfamiliar and unreal. [defined by Austrian psychoanalyst Paul Federn (1871—1950)]

inner hair cells see hair cell.

inner language 1. the visual, auditory, and kinesthetic mental imagery of words and concepts. 2. speech spoken to oneself without vocalization. According to Lev Vygotsky, inner language follows egocentric speech and represents the child’s recruitment of language in his or her reasoning efforts. Also called inner speech. See also IN- TERNALIZED SPEECH; VERBAL THOUGHT.

inner nuclear layer (INL) the layer of retinal cell bodies interposed between the photoreceptors and the RETINAL GANGLION CELLS. The inner nuclear layer contains AMACRINE CELLS, RETINAL HORIZONTAL CELLS, RETINAL BIPOLAR CELLS, and Müller cells.

inner psychophysics a systematic attempt to relate experience in the mind to states of excitation in the sensory apparatus. Compare outer psychophysics. See psycho - physical law. [introduced by Gustav Theodor Fechner]

inner scribe see VISUOSPATIAL SKETCHPAD.

inner speech see INNER LANGUAGE.

innervation n. the supply of nerves to an organ (e.g., muscle or gland) or a body region. —innervate vb.

innervation ratio the ratio expressing the number of muscle fibers innervated by a single motor axon. It may vary from 3 muscle fibers per axon for small muscles in the fingers to 150 muscle fibers per axon for large muscle bundles of the arms and legs. The lower the ratio, the finer is the control of movements.

innovation diffusion the gradual spread of a new technology to populations or population segments. Rates of diffusion are determined by the adoption and successful use of the technology. Innovation includes both tangible technologies, such as computer-based systems, and intangible technologies, such as processes or ways of thinking. See also product champion.

innovative therapies loosely, psychological treatments or techniques that are new and different from traditional therapies and often have not yet been empirically validated.

inoculation theory a theory postulating that resistance to persuasion can be created by exposing people to weak persuasive attacks that are easily refuted. This helps people practice defending their attitudes as well as make them aware that their attitudes can be challenged, which thereby creates resistance to subsequent stronger messages, [originally proposed by William J. McGuire] inocye n. a genus of mushrooms, some species of which are poisonous because they contain the toxic alkaloid muscarine. Symptoms of poisoning include salivation, perspiration, and lacrimation (tears); at higher doses, these symptoms may be followed by abdominal pains, severe nausea and vomiting, diarrhea, visual disturbances, labored breathing, and bradycardia (slowed heart rate), which may potentially result in death from cardiac or respiratory failure. Treatment is with atropine.

inositol n. a compound similar to glucose that occurs in many foods and is sometimes classed as a vitamin. It is a component of cell-membrane phospholipids and plasma lipoproteins, and phosphorylated derivatives (see inositol phosphates) function as second messengers in cells.

inositol phosphates derivatives of inositol that con-
tain one or more phosphate groups, some of which are second messengers in cells, serving to relay signals from receptors at the cell surface to other parts of the cell. The most studied of these second messengers is inositol 1,4,5-trisphosphate (IP$_3$). The action of LITHIUM salts, used to treat bipolar disorders, may be linked to their inhibition of the enzyme inositol monophosphatase, which is involved in the recycling of inositol from the inositol phosphates. It has been hypothesized that this inhibition thus leads to a deficiency of inositol and a corresponding excess of inositol phosphates.

inpatient $n.$ a person who has been formally admitted to a hospital for a period of at least 24 hours for observation, diagnosis, or treatment, as distinguished from an outpatient or an emergency-room patient.

Inpatient Multidimensional Psychiatric Scale (IMPS) an interview-based rating instrument used to assess attitudes and behaviors of individuals with psychoses, typically administered on admission to mental institutions. It yields information on symptom severity and is used to classify patients into psychotic types, such as hostile–paranoid, excited–hostile, excited–grandiose, and so forth. The scale was originally published in 1962 as a revision of the 1953 Multidimensional Scale for Rating Psychiatric Patients. [developed by U.S. psychometrician Maurice Lorr (1910–1998) and U.S. psychologists C. James Klett (1926–), Douglas M. McNair (1927–2008), and Julian J. Lasky (1918–2012)]

inpatient services diagnostic and treatment services available to hospitalized patients and usually unavailable or only partially available in outpatient facilities. Examples are continuous supervision; medical treatment and nursing care; specialized treatment techniques, such as rehabilitational, occupational, movement, or recreation therapy; and social work services.

input $n.$ the signals fed into a communication channel together with the energy put into a system. In the context of the interaction between a person and a computer, input usually refers to data or instructions fed into the computer. Compare output.

input–output mechanism a simple model of information processing in which a given input automatically produces a given output. An input–output mechanism is a closed system in which information is subjected to a fixed sequence of preset operations and there is no interaction with the environment during throughput. Some behaviorist theories have been criticized as reducing the human organism to an input–output mechanism.

input-process-output model (IPO model) an analysis of performance and processing systems that assumes raw materials (inputs) are transformed by internal system processes to generate results (output). Applied to human information processing, for example, an IPO model assumes that perceptual mechanisms encode information, which then is transformed by cognitive processes to result in psychological and behavioral responses. Similarly, IPO models of group productivity assume that group-level processes mediate the relationship between individual, group, and situational input variables and the resulting performance outcomes.

inquiry training model see inductive teaching model.

inquistorial system see adversarial system.

INRC group abbreviation for IDENTITY, NEGATION, RECIPROCAL, AND CORRELATIVE OPERATIONS.

in re Gault a 1967 U.S. Supreme Court decision that fundamentally changed the rights of juveniles in legal proceedings by establishing that MINORS have many of the same due process rights as adults.

insane asylum a former (19th-century) name for a residential institution for the treatment of people with severe mental illness. Also called lunatic asylum. See asylum.

insanity $n.$ in law, a condition of the mind that renders a person incapable of being responsible for his or her criminal acts. Defendants who are found to be not guilty by reason of insanity therefore lack CRIMINAL RESPONSIBILITY for their conduct. Whether a person is insane, in this legal sense, is determined by judges and juries, not psychologists or psychiatrists. Numerical legal standards for determining criminal responsibility, the central issue in an INSANITY DEFENSE, have been used at various times in many jurisdictions. These include the DURHAM RULE, the AMERICAN LAW INSTITUTE MODEL PENAL CODE INSANITY TEST, and the M’NAUGHTEN RULE. See also PARTIAL INSANITY. —insane adj.

insanity defense in criminal law, the defense plea that an individual lacks CRIMINAL RESPONSIBILITY for his or her conduct. See also DIMINISHED RESPONSIBILITY.

Insanity Defense Reform Act (IDRA) legislation passed by the U.S. Congress in 1984 that modified existing laws relating to INSANITY DEFENSE cases. One modification involved removing the volitional component of the AMERICAN LAW INSTITUTE MODEL PENAL CODE INSANITY TEST, so that the inability to "conform one’s conduct to the requirements of the law" was no longer a factor in judging insanity. Another modification involved shifting the burden of proof (responsibility for convincing the court beyond a reasonable doubt of the truth of an allegation) in such cases from the prosecution to the defense.

insect phobia see animal phobia: specific phobia.

insecure attachment in the STRANGE SITUATION, one of several patterns of a generally negative parent–child relationship in which the child fails to display confidence when the parent is present, sometimes shows distress when the parent leaves, and reacts to the returning parent by avoidance (see AVOIDANT ATTACHMENT) or with ambivalence (see AMBIVALENT ATTACHMENT). See also ANXIOUS–AVOIDANT ATTACHMENT; ANXIOUS–RESISTANT ATTACHMENT; DISORGANIZED ATTACHMENT. Compare secure attachment.

insecurity $n.$ a feeling of inadequacy, lack of self-confidence, and inability to cope, accompanied by general uncertainty and anxiety about one’s goals, abilities, or relationships with others. —insecure adj.

insemination $n.$ the deposition of semen within the vagina, either during coitus or by other means (see ARTIFICIAL INSEMINATION).

insensible $adj.$ 1. without sensation or consciousness. 2. lacking emotional responsiveness. —insensibility $n.$

insert headphone a device for presenting sound in a sealed ear canal. Typically, the transducer is located remotely and sound is routed via a thin tube, which is embedded at its terminus in a soft foam plug; the earplug and tube are inserted in the ear canal. Such a system provides better acoustic isolation than do typical headphones and
perhaps better control of the sound impinging on the tympanic membrane.

**insight** n. 1. the clear and often sudden discernment of a solution to a problem by means that are not obvious and may never become so, even after one has tried hard to work out how one has arrived at the solution. There are many different theories of how insights are formed and of the kinds of insights that exist. For example, in the 1990s, U.S. psychologists Robert J. Sternberg (1949— ) and Janet Davidson proposed a theory in which there are three main kinds of insights: (a) selective encoding insights, which are used to distinguish relevant from irrelevant information; (b) selective comparison insights, which are used to distinguish what information already stored in long-term memory is relevant for one’s purposes; and (c) selective combination insights, which are used to put together the available information so as to formulate a solution to a given problem. 2. in psychotherapy, an awareness of underlying sources of emotional, cognitive, or behavioral responses and difficulties in oneself or another person. See also AHA EXPERIENCE: EPIPHANY.

**insight learning** a cognitive form of learning involving the mental rearrangement or restructuring of the elements in a problem to achieve a sudden understanding of the problem and arrive at a solution. Insight learning was described by Wolfgang Köhler in the 1920s, based on his observations of apes stacking boxes or using sticks to retrieve food, and was offered as an alternative to TRIAL-AND-ERROR LEARNING.

**insight therapy** any form of psychotherapy based on the theory that a client’s problems cannot be resolved without his or her gaining self-understanding and thus becoming aware of their origins. This approach—characteristic, for example, of PSYCHOANALYSIS and PSYCHODYNAMIC PSYCHOTHERAPY—contrasts with therapies directed toward removal of symptoms or behavior modification.

**in situ hybridization** a method for detecting particular nuclotide sequences within DNA or RNA in tissue sections by providing a labeled nucleotide probe that is complementary to, and will therefore hybridize with, the sequence of interest.

**insomnia** n. difficulty in initiating or maintaining a restorative sleep, which results in fatigue, the severity or persistence of which causes clinically significant distress or impairment in functioning. Such sleeplessness may be caused by a transient or chronic physical condition or psychological disturbance. Also called agrypnia; ahypnia. See DISORDERS OF INITIATING AND MAINTAINING SLEEP; FATAL FAMILIAL INSOMNIA; INITIAL INSOMNIA; INTERMITTENT INSOMNIA; MIDDLE INSOMNIA; PRIMARY INSOMNIA; PSUEDOINSOMNIA; TERMINAL INSOMNIA. 

**insomnia disorder** see DISORDERS OF INITIATING AND MAINTAINING SLEEP; PRIMARY INSOMNIA.

**inspectionalism** n. see VOYEURISM.

**inspection time (IT)** in DISCRIMINATION LEARNING, the amount of time it takes an individual to make simple visual discriminations, such as determining which of two lines is longer. Under specific experimental conditions, inspection time is found to be correlated with IQ.

**inspective exploration** EXPLORATORY BEHAVIOR used as a means of reducing anxiety, fear, or uncertainty associated with novel stimuli and thus decreasing arousal. Also called specific exploration. Compare DIVERSIVE EXPLORATION, [defined by Daniel E. BERLIN]

**inspiration** n. 1. the act of drawing air into the lungs. 2. in cognitive psychology, a sudden insight or leap in understanding that produces new, creative ideas or approaches to a problem. See AHA EXPERIENCE: DISCONTINUITY HYPOTHESIS. 3. the process of being aroused or stimulated to do something, or the quality of being so aroused, as in Her speech gave us the inspiration we needed. —inspirational adj. —inspire vb. —inspired adj.

**inspirational motivation** a goal-directed state aroused by exposure to high-performing, successful, or admired models.

**inspiration–expiration ratio (I/E ratio)** the ratio of the duration of the inspiration phase of the respiratory cycle to the duration of the exhalation phase; that is, the time taken to breathe in divided by the time taken to breathe out. This ratio is typically used in studies of emotion: Fearful states have high I/E ratios, whereas nonfearful attentive states have low I/E ratios.

**instability** n. in psychology, a tendency toward lack of self-control, erratic behavior, shifting attitudes and beliefs, and rapidly changing or excessive emotions. —unstable adj.

**instance theory** see EXEMPLAR THEORY.

**instant gratification** the meeting or satisfying of one’s needs or wishes without delay. Therapy may be important to help reduce the desire for instant gratification when postponing needs and tolerating delays would be realistic or in the best interests of the client.

**instigation therapy** BEHAVIOR THERAPY in which the therapist provides a positive model and reinforces the client’s progress toward self-regulation and self-evaluation.

**instinct** n. 1. an innate, species-specific biological force that impels an organism to do something, particularly to perform a certain act or respond in a certain manner to specific stimuli. See also HORMIC PSYCHOLOGY. 2. in classical psychoanalytic theory, a basic biological drive (e.g., hunger, thirst, sex, aggression) that must be fulfilled in order to maintain physical and psychological equilibrium. Sigmund FREUD classified instincts into two types: those derived from the LIFE INSTINCT and those derived from the DEATH INSTINCT. See also COMPONENT INSTINCT; EROTIC INSTINCT; LIBIDO; SATISFACTION OF INSTINCTS; SEXUAL INSTINCT. 3. in popular usage, any inherent or unlearned predisposition (behavioral or otherwise) or motivational force. —instinctive or instincual adj.

**instinctive behavior** stereotyped, unlearned, largely stimulus-bound adaptive behavior limited in its expression by the inherent properties of the nervous system and genetic factors. It is species specific and involves complex activity patterns rather than simple reflexes. See FIXED ACTION PATTERN; INNATE RELEASING MECHANISM; MODAL ACTION PATTERN; RELEASER.

**instinctive drift** the tendency of learned, reinforced behavior to gradually return to a more innate behavior. For example, raccoons trained to drop coins into a container will eventually begin to dip the coins into the container, pull them back out, rub them together, and dip them in again. The learned behavior of dropping coins becomes more representative of the innate behavior of food washing. Also called instincual drift. [proposed in 1961 by
intrinsic knowledge unlearned and generally unalterable behavior, observable when a new stimulus (i.e., one not previously encountered) elicits an affective response indicative of genetic influences. An example is fear of and flight from certain predators in the absence of previous exposure to these animals.

instructed behavior

instructor n. 1. an established practice, tradition, behavior, or system of roles and relationships, such as marriage, that is considered a normative structure or arrangement within a society. Sociologists usually distinguish between four main types of institutions: political (e.g., monarchy), economic (e.g., capitalism), cultural (e.g., media, education, religion), and social (e.g., family organization, race, gender). 2. a large, often publicly funded organization, such as a university, museum, or charitable foundation, or the building that houses such an organization. 3. a building or building complex in which individuals are cared for or confined for extended periods of time, especially a psychiatric hospital or a prison. —institutional ad.

Institutional Animal Care and Use Committee (IACUC) a committee responsible for overseeing an institute’s program and research protocols involving nonhuman animals. The primary responsibility of the IACUC is to ensure the humane treatment of the animals and compliance of the research program and procedures with established regulations. U.S. federal law mandates that any institution conducting research with laboratory animals must establish an IACUC, and any member of the institution who plans to conduct an experiment or undertake activities that involve animals must submit a proposal to the IACUC for review. See also ANIMAL CARE AND USE. institutional care medical or mental health care services received by an inpatient in a hospital, nursing home, or other residential institution.

institutionalization n. 1. placement of an individual in an institution for therapeutic or correctional purposes or when he or she is incapable of living independently, often as a result of a physical or mental condition. 2. an individual’s gradual adaptation to institutional life over a long period, especially when this is seen as rendering him or her passive, dependent, and generally unsuited to life outside the institution. —institutionalize vb.

institutionalized racism differential treatment of individuals on the basis of their racial group by religious organizations, governments, businesses, the media, educational institutions, and other large social entities. Examples include discrimination in hiring, promotion, and advancement at work; restrictive housing regulations that promote segregation; unfair portrayal of minority members in newspapers and magazines; and legal statutes that restrict the civil liberties of the members of specific racial categories. A parallel phenomenon exists for sexism. Also called institutional racism.

institutional neurosis see SOCIAL BREAKDOWN SYNDROME.

institutional release see RELEASE.

institutional research a study conducted to obtain information about an academic setting. For example, a university may research its faculty, staff, students, finances, technology, campus climate, and other characteristics so as to facilitate better decision making.

institutional review board (IRB) a committee named by an agency or institution to review research proposals originating within that agency for ethical acceptability and compliance with the organization’s codes of conduct. IRBs help protect research participants and are mandatory at any U.S. institution receiving federal funds for research.

instructed learning the second stage of CULTURAL LEARNING, in which a more accomplished person instructs a less accomplished person. The process requires that learners grasp the instructor’s understanding of the task and then compare it with their own understanding. See also COLLABORATIVE LEARNING; Imitative learning. [proposed by U.S. psychologist Michael Tomasello (1950– ) and colleagues]

instructional set the attitude toward a task or test that is communicated (intentionally or unintentionally) by the experimenter to the participants. It conveys information on how they should approach the task or test, such as whether speed is more (or less) important than accuracy.

instructional theory of development the theory that the development of unorganized neural elements into differentiated neural structures is shaped by environmental factors.

institutional treatment any educational intervention designed, implemented, and evaluated by an instructor to increase learning or enhance various kinds of performance.

instrument n. 1. any tool, device, or other means by which researchers assess or gather data about study participants. Examples include tests, INTERVIEWS, QUESTIONNAIRES, SURVEYS, RATING SCALES, and reaction-time apparatus. See also ASSESSMENT INSTRUMENT. 2. in general, an implement used in performing specific operations, such as cutting or writing.

instrumental n. in some languages, such as Sanskrit, a case of nouns, pronouns, and noun phrases identifying entities that are used by the AGENT to perform the action of a verb. The instrumental is also used as a category in CASE GRAMMAR; in The crowbar pried open the door, for example, the inanimate noun crowbar is said to be the instrumental rather than the agent (here unidentified). See also EXPERIENER; PATIENT.

instrumental activities of daily living (IADLs) activities essential to an individual’s ability to function autonomously, including cooking, doing laundry, using the telephone, managing money, shopping, getting to places beyond walking distance, and the like. See also ACTIVITIES OF DAILY LIVING.

instrumental aggression see AGGRESSION.

instrumental behavior 1. behavior that is learned and elicited via positive or negative reinforcement of target (rather than instinctive) responses. The term is used synonymously with OPERANT BEHAVIOR, usually for describing
instrumental conditioning

behavior during conditioning procedures that involves long sequences of activity, such as solving a puzzle box. 2. actions that directly affect or manage the behavior of others. Among nonhuman animals, for example, a subordinate adult may engage in infantile behavior to inhibit others' threatening or aggressive actions. Some animals use alarm calls to distract other group members so they can make use of a valued resource without interference.

instrumental conditioning any form of conditioning in which the correct response is essential for reinforcement. Instrumental conditioning is similar to operant conditioning and usually involves complex activities in order to reach a goal, such as when a rat is trained to navigate a maze to obtain food. It contrasts with classical conditioning, in which reinforcement is given regardless of the response. Also called instrumental learning: Type II conditioning, Type R conditioning.

instrumental dependence the tendency to rely on others for accomplishing tasks.

Instrumental Enrichment a program for helping people improve their intellectual performance by developing the metacognitive and cognitive skills essential to successful performance of intellectual tasks. First used for pupils with intellectual disabilities, Instrumental Enrichment was later applied to performers at all ages and intellectual levels. The program involves solving puzzles, some of which are similar to the kinds of problems found on conventional intelligence tests, as well as bridging, which involves relating performance on these puzzles to the solution of real-world problems. Results of evaluations are mixed but suggest at least some benefits for performers with intellectual disabilities (who tend to be weak in metacognitive skills). [formulated in the 1970s by Romanian-born Israeli psychologist Reuven Feuerstein (1921–2014) and his collaborators]

instrumentalism n. 1. in the philosophy of science, the position that theories are not to be considered as either true or false but as instruments of explanation that allow observations of the world to be meaningfully ordered. This view is related to Machian positivism. 2. a theory of knowledge that emphasizes the pragmatic value, rather than the truth value, of ideas. In this view, the value of an idea, concept, or judgment lies in its ability to explain, predict, and control one's concrete functional interactions with the experienced world. This view is related to pragmatism. [developed by John Dewey] 3. the view or attitude that the primary motivation for social interaction is the attainment of some positive advantage or good for the self, so that others are regarded and used as instruments in acquiring such advantage. —instrumentalist adj., n.

instrumentality theory the theory that a person’s attitude toward an event will depend on his or her perception of its function as an instrument in bringing about desirable or undesirable consequences. See also valence–instrumentality–expectancy theory.

instrumental learning see instrumental conditioning.

instrumental orientation the tendency of an individual or group to focus on assigned tasks and goals and the tangible benefits of achieving them (e.g., increased pay) rather than on the interpersonal relationships involved in achieving them. See also task-motivated; task-oriented group.

instrumental relativist orientation see preconventional level.

instrumental response any response that achieves a goal or contributes to its achievement, such as a response that is effective in gaining a reward or avoiding pain (e.g., a rat pressing a bar to obtain food).

instrumentation n. the creation and use of equipment and devices (including psychological tests) for the measurement of some attribute or the control of experiments (e.g., automation of stimulus presentation and data collection). It is important that a measurement instrument not only be trustworthy and reliable but also properly maintained and consistently administered so as to ensure internal validity.

instrumentation effect any change in the dependent variable in a study that arises from changes in the measuring instrument used. For example, an experimenter may subtly but unintentionally alter his or her testing method across sessions, such that a pretest and a posttest are administered differently. Instrumentation effects pose a threat to internal validity.

instrument drift changes in an instrument, usually gradual and often predictable, that can threaten the validity of conclusions drawn from the data obtained with that instrument. An example would be the stretching of spring scales. Periodic recalibration of the measuring device helps minimize or rectify instrument drift. Also called instrument decay. See also observer drift.

insufficient justification effect the finding that in some situations people are more likely to undertake a task that goes against their character or personal beliefs when offered a small reward versus a larger reward, and similarly more likely to decline a desired activity when presented with a mild threat versus a more serious threat. For example, in a classic 1959 study by psychologists Leon Festinger and James M. Carlsmith, participants were offered money to lie about their interest in a particular task: Those who received $1 were more motivated to lie than those who received $20. The theory is that when extrinsic motivation is low, people are motivated to reduce the cognitive dissonance they experience by finding an intrinsic motivation for their behavior (e.g., by telling themselves they had no wish to break that particular rule anyway). Compare overjustification effect.

insufflation n. 1. the act of breathing or blowing into something. 2. the nasal inhalation of a drug, as in snorting cocaine. —insufflate vb.

insula n. (pl. insulae) a region of the cerebral cortex of primate brains that is buried in a cleft near the lower end of the lateral sulcus. It is thought to play a major role in emotion (particularly negative emotions, such as disgust), taste, self-awareness, and motor control of functions such as swallowing and speech articulation. It may also be involved in addictive cravings and the regulation of procedural memory. Also called central lobe: insular cortex.

island of Reil. [from Latin, “island”]. first described by German physician Johann Reil (1759–1813).

insulin n. a hormone, secreted by the B cells of the islets of Langerhans in the pancreas, that facilitates the transfer of glucose molecules through cell membranes. Together with glucagon, it plays a key role in regulating blood sugar and carbohydrate metabolism. In the absence of sufficient concentrations of insulin, glucose accumulates in
the blood and is excreted, as in DIABETES MELLITUS (see also HYPERGLYCEMIA). Excessive concentrations of insulin (resulting, e.g., from insulin overdose or an insulin-secret ing tumor) give rise to HYPOGLYCEMIA.

insulin-dependent diabetes mellitus (IDDM) see DIABETES MELLITUS.

insulin lipodystrophy see LIPODYSTROPHY.

insulin-shock therapy a treatment for schizophrenia, rarely used after 1960, in which hypoglycemia was induced by intramuscular injection of insulin to produce a temporary coma. Inductions might last for 15 to 60 minutes, and a full course of treatment typically involved numerous coma inductions over a given period. Also called coma therapy: insulin-coma therapy. [introduced in 1927 by Austrian-born U.S. psychiatrist Manfred J. Sakel (1900–1957)]

intake interview 1. the initial interview with a client by a therapist or counselor to obtain both information regarding the issues or problems that have brought the client into therapy or counseling and preliminary information regarding personal and family history. 2. the initial interview with a patient who is being admitted into a psychiatric hospital, day treatment program, or inpatient substance abuse facility. Intake interviews are also common in government-funded mental health services, such as those provided at community mental health centers, in determining eligibility and appropriateness of the client for services offered. An intake interview may be carried out by a specialist who may not necessarily treat the patient, with the information obtained used to determine the best course of treatment and the appropriate therapist to provide it.

integral n. 1. a whole number (e.g., 2, 9, 11), as opposed to numbers that are fractions (e.g., 1/4, 1.5). 2. the area underneath a curve plotted on an x-axis and y-axis between two points, a and b. It is one of two main concepts—the other being the DERIVATIVE—applied within calculus to the study of change and area.

integrated care a consistent, systematic, and coordinated set of HEALTH CARE services that are developed, managed, and delivered to individual patients over a range of organizations and by a variety of associated professionals and other care providers. The approach seeks to reduce fragmented care (i.e., diagnosis and treatment by multiple unconnected and minimally communicating doctors and caregivers); to improve clinical outcomes, quality of life, patient satisfaction, effectiveness, and efficiency (ideally using EVIDENCE-BASED PRACTICE guidelines); and to reduce costs. The complexities underlying development of such approaches include establishing a common philosophy of assessment and treatment, developing partnership relationships, linking and planning information systems, coordinating patient flow among providers, and so forth. The efficacy of integrated care is often viewed and measured from two perspectives: that of the patient and that of the organizations and individual service providers. Although primarily associated with medicine proper, services may include mental health components (e.g., psychosocial assessment and treatment). Also called integrated medicine.

integrated delivery system (IDS) a health care provider organization that is completely integrated operationally and clinically and that offers a full range of health care services, including physician, hospital, and adjunct services. IDSs began to develop in the early 1980s and multiplied rapidly in the 1990s. They are found in varying formats, one of the more typical being an alliance between hospitals and individual physicians or GROUP MEDICAL PRACTICES. An IDS is a MANAGED CARE organization.

integrated display in ergonomics, a machine display designed on the principle that similar categories of information should be grouped together. Compare SEPARATED DISPLAY.

integrated model in evaluation research, an administrative relationship (used in FORMATIVE EVALUATION) between a program director and multiple production units made up of writers, designers, and evaluators who are all involved in program development as well as program evaluation. Members of these units do not necessarily share equal importance or equal access to the program director. Also called dependent model. Compare SEGREGATED MODEL.

integrated system a program allowing individuals with disabilities to manage computer functions, their environments, telephone communication, and powered mobility through a central control.

integration n. 1. the coordination or unification of parts into a totality. This general meaning has been incorporated into a wide variety of psychological contexts and topics. For example, the integration of personality denotes the gradual bringing together of constituent traits, behavioral patterns, motives, and so forth to form an organized whole that functions effectively and with minimal effort or without conflict. 2. see ACCELEuration STRATEGIES. 3. in attitude research, see COMPLEXITY OF AN ATTITUDE.

integrative agnosia a form of VISUAL AGNOSIA in which individuals are able to perceive the elements of an object but find it difficult to combine them into a perceptual whole. Typically, symptoms of both apperceptive and associative agnosia are present. Individuals affected by this kind of agnosia can usually draw an object accurately but only through a laborious process.

integrated bargaining a form of BARGAINING in which the parties work together to achieve outcomes that benefit both sides. Compare DISTRIBUTIVE BARGAINING.

integrated behavioral couples therapy a form of BEHAVIORAL COUPLES THERAPY that specifically focuses on helping partners to develop acceptance and greater emotional understanding of one another and to integrate that understanding with an effort to identify, address, and change problematic patterns in their relationship that bother them both. The therapy also helps couples to explore how experiences in their respective pasts may inform their relationship in the present. Compare COGNITIVE BEHAVIORAL COUPLES THERAPY. [developed in the 1990s by U.S. psychologists Andrew Christensen and Neil Jacobson (1949–1999)]

integrated complexity the extent to which an ATTITUDE OBJECT is considered to have both positive and negative features and the extent to which these features are seen as related to one another. Low integrative complexity occurs when an attitude object is seen exclusively in positive or negative terms. Moderate integrative complexity occurs when the object is seen as having both positive and negative features, but these features are seen as having little relation to one another. High integrative complexity occurs when the positive and negative features are seen as related to one another.

integrated learning the process of learning tasks that
integrative medicine

involve simultaneous or successive functioning of several modalities, as in reading and writing.

integrative medicine the combination of conventional medical treatments and complementary therapies that have demonstrated scientific merit with regard to safety and efficacy. See also COMPLEMENTARY AND ALTERNATIVE MEDICINE.

integrative psychotherapy psychotherapy that selects theoretical models or techniques from various therapeutic schools to suit the client’s particular problems. For example, PSYCHOANALYTIC PSYCHOTHERAPY and GESTALT THERAPY may be combined through the practice of INTERPRETATION of material in the HERE AND NOW. The Society for the Exploration of Psychotherapy Integration (SEPI), founded in 1983, reflects the growing interest in, and the rapid development and use of, such combined therapeutic techniques. Also called psychotherapy integration. See also ECLIPSE PSYCHOTHERAPY.

integrity n. the quality of moral consistency, honesty, and truthfulness with oneself and others.

integrity group psychotherapy a type of GROUP THERAPY in which openness and honesty are expected from all participants, and experienced members of the group serve as models of sincerity and involvement. [developed by O. Hobart Mower]

integrity testing procedures used to determine whether employees or applicants for employment are likely to engage in COUNTERPRODUCTIVE WORK BEHAVIOR. Overt integrity tests are inventories that directly ask people about their past behaviors and their attitudes toward unethical, illegal, and counterproductive behavior. Personality-based integrity tests are inventories measuring the character traits thought to be related to unethical, illegal, and counterproductive behavior. Integrity tests are sometimes called honesty tests.

integrity versus despair the eighth and final stage of ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, which occurs during old age. In this stage, the individual reflects on the life he or she has lived and may develop either integrity—a sense of satisfaction in having lived a good life and the ability to approach death with equanimity—or despair—a feeling of bitterness about opportunities missed and time wasted, and a dread of approaching death. Also called ego integrity versus despair.

intellect n. 1. the INTELLECTUAL FUNCTIONS of the mind considered collectively. 2. an individual’s capacity for abstract, objective reasoning, especially as contrasted with his or her capacity for feeling, imagining, or acting. —intellectual adj.

intellectual detachment see DETACHMENT.

intellectual disability a DEVELOPMENTAL DISABILITY characterized by mild to profound limitations in cognitive function (e.g., learning, problem solving, reasoning, planning) and in ADAPTIVE BEHAVIOR, impairing one’s ability to acquire skills typical for one’s age group as a child or necessary for one’s later independent functioning as an adult. It is now the preferred term for MENTAL RETARDATION. In DSM–5, a diagnosis of intellectual disability, including its degree of severity, requires clinical assessment of an individual’s level of difficulty with conceptual skills (e.g., reading, writing, arithmetic), social skills (e.g., communication, emotion regulation), and practical skills (e.g., self-care, ability to manage ACTIVITIES OF DAILY LIVING). Deficits in cognitive function may be assessed with standardized intelligence tests, but an individual’s IQ as measured by such tests is less emphasized in the diagnostic criteria for intellectual disability than in the traditional criteria for mental retardation. Also called intellectual development disorder.

intellectual function any of the mental functions involved in acquiring, developing, and relating ideas, concepts, and hypotheses. Memory, imagination, and judgment can also be considered intellectual functions. Also called intellectual operation. See also HIGHER MENTAL PROCESS.

intellectual impoverishment diminished intellectual capacity, such as problem-solving ability and concentration. This condition is observed in many people with schizophrenia, dementia, or depression and in individuals living in a deprived, unstimulating environment. See also POVERTY OF IDEAS.

intellectual insight in psychotherapy, an objective, rational awareness of experiences or relationships. Some theorists posit that intellectual insight by itself does not advance the therapeutic process and may even impede it because little or no feeling (i.e., emotional content) is involved.

intellectualism n. 1. in philosophy, a position consistent with IDEALISM or RATIONALISM that emphasizes the preeminence of mind or idea. 2. in psychology, the doctrine that cognitive functions are preeminent, so that emotive and motivational experiential states can be explained by, or originate from, more fundamental cognitive states. —intellectualist adj.

intellectualization n. in psychoanalysis, a DEFENSE MECHANISM in which conflicts or emotional problems are dealt with abstractly or concealed by excessive intellectual activity. —intellectualize vb.

intellectual maturity the adult stage of intellectual development, in which the individual typically has a high level of good judgment, often combined with WISDOM.

intellectual operation see INTELLIGENCE FUNCTION.

intellectual plasticity the extent to which an individual’s intellectual abilities are modifiable and thus subject to various kinds of change.

intellectual stimulation 1. the pleasurable sense of being challenged and provoked that can arise from an encounter with new, difficult, or interesting ideas. 2. the enhancement of cognitive processing—including creativity, discernment, and insight—that occurs when individuals exchange ideas and opinions during interpersonal or group discussion.

intellectual subaverage functioning an IQ more than two standard deviations below the mean obtained on an intelligence test.

intelligence n. the ability to derive information, learn from experience, adapt to the environment, understand, and correctly utilize thought and reason. See also IQ; MEASURES OF INTELLIGENCE. —intelligent adj.

intelligence knowledge-based system (IKBS) a system used in the United Kingdom for reasoning and decision making. It was developed from ARTIFICIAL INTELLIGENCE, using a KNOWLEDGE REPRESENTATION system (symbolic, quantitative, or both) to provide either a solution to some problem or an aid to decision making.
interaction analysis

intelligence measure see INTELLIGENCE TEST; MEASURES OF INTELLIGENCE.

intelligence quotient see IQ.

intelligence test an individually administered test used to determine a person’s level of intelligence by measuring his or her ability to solve problems, form concepts, reason, acquire detail, and perform other intellectual tasks. It comprises mental, verbal, and performance tasks of graded difficulty that have been standardized by use on a representative sample of the population. Examples of intelligence tests include the STANFORD–BINET INTELLIGENCE SCALE and the WISC R ADULT INTELLIGENCE SCALE. Also called intelligence scale. See IQ.

intelligent design a theoretical position, in opposition to the theory of EVOLUTION, that the universe with all its diversity is so ingeniously and complexly constructed and interrelated that it could only have been created by some intelligent force and that complex biological organisms could not have emerged through NATURAL SELECTION. In some contexts, the term has become synonymous with CREATIONISM.

intensional meaning the meaning of a word or phrase as defined by listing the essential or salient properties of the thing or concept referred to. For example, the intensional meaning of sister is “female sibling.” Compare EXTENSIONAL MEANING.

intensity n. 1. the quantitative value of a stimulus or sensation. 2. the strength of any behavior, such as an impulse or emotion. 3. the strength of an individual’s performance in some activity or field with reference to one or more of the following attributes: arousal, commitment, effort, assertiveness, and attentional focus. Also called performance intensity. —intense adj.

intensive care syndrome a type of psychotic condition observed in some individuals in intensive care who are immobilized in an isolated, unfamiliar environment that may have the effect of sensory deprivation. Variable factors may include the mental and physical condition of the individual prior to the need for intensive care, the age of the individual, medical or surgical complications, and behavioral effects of drugs administered.

intensive care unit (ICU) a hospital unit in which critically ill patients receive intensive and continuous nursing, medical care, and supervision that includes the use of sophisticated monitoring and resuscitative equipment. ICUs are often organized for the care of specific groups of patients, such as neonatal ICUs or pulmonary ICUs. Also called critical care unit (CCU). Compare CONTINUING CARE UNIT.

intensive psychotherapy broad, thorough, and prolonged psychological treatment of an individual’s concerns and problems. The qualifier intensive indicates both the nature of the discussions, which typically involve extensive examination of the individual’s life history and conflicts, and the duration of the therapy. Compare BRIEF PSYCHOTHERAPY.

intent analysis analysis of social interaction in which verbal content is classified according to intent (providing support, seeking approval, etc.).

intention n. 1. a prior conscious decision to perform a behavior. In experiments, intention is often equated with the goals defined by the task instructions. 2. more generally, any directedness in one’s thoughts or behaviors, whether or not this involves conscious decision making. —intentional adj.

intentional accident see PURPOSIVE ACCIDENT.

intentional agent an individual whose behavior is based on what he or she knows and wants and who acts deliberately to achieve goals. In infants, the ability to distinguish intentional agents from inanimate objects begins by 9 months of age.

intentional behavior goal-oriented behavior in which an individual uses strategies to achieve various ends or effects. According to the PIAGETIAN THEORY of cognitive development, intentional behavior emerges in human infants between 8 and 12 months of age.

intentional forgetting inaccessibility of a memory that is due to repression or to an unconscious wish to forget.

intentional inexistence in ACT PSYCHOLOGY and PHENOMENOLOGY, the principle that the object of perception or thought (the intentional object) exists within the act of perceiving or thinking. See INTENTIONALITY. [developed by Franz BRENTANO]

intentionality n. a characteristic of an individual’s acts that requires the individual (a) to have goals, desires, and standards; (b) to select behaviors that are in the service of attaining the goal (e.g., means to an end); and (c) to call into conscious awareness a desired future state. Investigators differ as to whether (a) alone, (a) and (b) but not (c), or (a), (b), and (c) are required for intentionality to be attributable to an individual. The concept of intentionality, as developed by Franz BRENTANO, has been very influential in ACT PSYCHOLOGY, PHENOMENOLOGY, and related approaches in HERMENEUTICS.

intentional learning learning that is planned or deliberate and therefore consciously employs MNEMONICS or other strategies. Compare INCIDENTAL LEARNING.

intentional stance a strategy for interpreting and predicting behavior that views organisms as rational beings acting in a reasonable manner according to their beliefs and desires (i.e., their intentions). [proposed by U.S. philosopher Daniel C. Dennett (1942— )]

intention movement a physical behavior that precipitates another physical response, so that the first behavior may signal the second. For example, when two people are talking, one may exhibit certain postural behaviors (e.g., changing stance, shifting weight) predictive of terminating the interaction before actually ending the conversation and walking away.

intention tremor see ACTION TREMOR.

interaction n. 1. a relationship between two or more systems, people, or groups that results in mutual or reciprocal influence. See also SOCIAL INTERACTION. 2. see INTERACTION EFFECT. —interact v.

interactional model of anxiety a model proposing that STATE ANXIETY is determined by the interaction of factors relating to a situation and factors relating to an individual. See also DIATHESIS–STRESS MODEL.

interactional synchrony see SYNCHRONY.

interactional territory see GROUP SPACE.

interaction analysis a variety of methods used to describe, categorize, and evaluate instances of person–person
interaction effect

interaction, person–system interaction, or team and group interaction. Interaction analysis is used in specialties such as HUMAN FACTORS ENGINEERING, human–computer interaction, cultural studies, and communication studies.

**interaction effect** in a FACTORIAL DESIGN, the joint effect of two or more independent variables on a dependent variable above and beyond the sum of their individual effects: The independent variables combine to have a different (and multiplicative) effect, such that the value of one is contingent on the value of another. This indicates that the relationship between the independent variables changes as their values change. For example, if a researcher is studying how gender (female vs. male) and dieting (Diet A vs. Diet B) influence weight loss, an interaction effect would occur if women using Diet A lost more weight than men using Diet A. Interaction effects contrast with—and may obscure—MAIN EFFECTS. See also HIGHER ORDER INTERACTION. Compare ADDITIVE EFFECT.

**interactionism** n. 1. the position that mind and body are distinct, incompatible substances that nevertheless interact, so that each has a causal influence on the other. This position is particularly associated with René DESCARTES. See CARTESIAN DUALISM: MIND–BODY PROBLEM. 2. a set of approaches, particularly in personality psychology, in which behavior is explained not in terms of personality attributes or situational influences but by references to interactions that typify the behavior of a certain type of person in a certain type of setting. —interactionist adj.

**interactionist view of intelligence** the view that intelligence always develops as an interaction between biological dispositions and environmental conditions and that it is difficult or impossible to separate the contributions of these two factors. Interactionists point out that genes always express themselves (manifest their effects in an individual) through a given set of environments and that the expression of the genes may be different as a function of the environment in which they are expressed.

**interaction process analysis (IPA)** a technique used to study the emotional, intellectual, and behavioral interactions among members of a group. It requires observers to classify every behavior displayed by each group member into one of 12 mutually exclusive categories, such as "asks for information" or "shows tension." See also CATEGORY-SYSTEM METHOD: STRUCTURED OBSERVATION. [developed by U.S. social psychologist Robert Freed Bales (1916–2004)]

**interactive advertising** in Internet marketing, a promotional technique in which consumers are encouraged to interact with a website by entering information, such as by answering questions.

**interactive group psychotherapy** see INTERPERSONAL GROUP PSYCHOTHERAPY.

**interactive sport** a sport that requires the participants to integrate and coordinate their actions with those of other players. Football and basketball are examples of interactive sports. Compare COACTIVE SPORT.

**Interamerican Society of Psychology** Sociedad Interamericana de Psicología (SIP): a professional organization founded in 1951 to promote communication and research among psychologists in North, Central, and South America and the Caribbean.

**interattitudinal consistency** the extent to which attitudes in an ATTITUDE SYSTEM are evaullatively consistent with one another. High consistency occurs when each attitude implies the other attitudes in the system. Low consistency occurs when some attitudes in the system imply the opposite of others.

**interaural difference** see BINAURAL CUE.

**interaural rivalry** the competition within the auditory system to comprehend conflicting inputs received simultaneously in both ears. Interaural rivalry has been employed in the study of temporal lobe lesions: Patients typically recall less of the information heard in the left ear if a lesion is on the right side, and vice versa. See also DICHOTIC LISTENING.

**interbehavioral psychology** a system of psychology concerned with interactions between an organism and its environment. The focus is on the interaction of stimulus functions (the use or role of a stimulus) and response functions (the purpose served by a response) and how context and experience shape those interactions. Also called INTERBEHAVIORISM. [proposed by Jacob Robert KANTOR]

**interblobs** pl. n. the regions of striate cortex that exist between the CYTOCHROME OXIDASE BLOBS. Neurons in the interblobs are less sensitive to wavelength than are neurons in the blobs.

**intercept** n. the point at which either axis of a graph is intersected by a line plotted on the graph. For example, it is the value of y when x = 0 in an equation of the form y = a + bx, or the value of x where a REGRESSION LINE crosses the y-AXIS. See also X-INTERCEPT; Y-INTERCEPT.

**interclass correlation** the degree of bivariate relationship between two variables from different measurement classes (i.e., the variables have distinct metrics and variances). For example, one may use an interclass correlation to determine the relation of IQ points (a class of measurement representing aptitude) to grade-point averages (a class of measurement representing achievement), or the relation of length (e.g., inches) to weight (e.g., pounds). Currently, the only interclass correlation in common use is the Pearson PRODUCT-MOMENT CORRELATION COEFFICIENT. Compare INTRACLASS CORRELATION.

**intercoder reliability** see INTRATER RELIABILITY.

**intercorrelation** n. the CORRELATION between each variable and every other variable in a group of variables.

**intercourse** n. see COITUS.

**interdecile range** the difference between the ninth and first DECILES of a distribution (i.e., the number obtained by subtracting the 10th PERCENTILE score from the 90th percentile score). The interdecile range provides a measure of DISPERSION in a data set that is minimally affected by OUTLIERS (extreme values). See also INTERQUARTILE RANGE.

**interdental** 1. adj. denoting a speech sound made with the tongue placed between the upper and lower front teeth (e.g., [θ]). 2. n. an interdental speech sound.

**interdental lisp** see LISPB.

**interdependence** n. a state in which two or more people, situations, variables, or other entities rely on or react with one another such that one cannot change without affecting the other. OUTCOME INTERDEPENDENCE is an example. Also called interdependency.—interdependent adj., n.

**interdependence theory** an approach to analyzing social interactions and relationships that focuses on how each person’s outcomes depend on the actions of others.
More specifically, interdependence theory identifies the most important characteristics of social situations and describes their implications for understanding how individuals make choices and take action. A central element of the theory is the proposition that people have standards against which they compare their current outcomes. When people's actual experiences are inconsistent with their standards, they may act to alter the situation. See OUTCOME INTERDEPENDENCE. [introduced in 1959 by John W. THIBAUT and Harold H. KELLEY]

interdependent self-construal a view of the self (SELF-CONSTRUAL) that emphasizes one's embeddedness in a network of social relationships and that downplays one's separateness and unique traits or accomplishments. Compare INDEPENDENT SELF-CONSTRUAL.

interdisciplinary approach a manner of dealing with psychological, medical, or other scientific questions in which individuals from different disciplines or professions collaborate to obtain a more thorough, detailed understanding of the nature of the questions and consequently develop more comprehensive answers. For example, an interdisciplinary approach to the treatment or rehabilitation of an individual who is ill, disabled, or experiencing distress or pain uses the talents and experiences of therapists from a number of appropriate medical and psychological specialties. Also called multidisciplinary approach.

interest n. an attitude characterized by a need or desire to give selective attention to something that is significant to the individual, such as an activity, goal, or research area.

interest factors in VOCATIONAL GUIDANCE and PERSONNEL SELECTION, an individual's interests or preferences regarded as indicators of personality traits and therefore of suitability for a particular job or type of employment. Interest factors can be derived from INTEREST TESTS and other SELF-REPORT INVENTORIES or from hobbies, leisure-time activities, and previous jobs.

interestingness n. in psychological aesthetics, that quality in a work of art that arouses interest rather than pleasure. Interestingness tends to increase with the levels of complexity and uncertainty in the work.

interest test a SELF-REPORT INVENTORY in which the participant is required to express likes or dislikes for a range of activities and attitudes. These are then compared with the interest patterns of successful members of different occupations as a means of assessing the participant's suitability for different types of work. Important examples are the KUDER PREFERENCE RECORD and the STRONG INTEREST INVENTORY. Also called interest inventory: occupational interest measure.

interferential sex coitus in which one places the penis between the thighs of another person. Heterosexual couples may do this as an attempted form of birth control or to maintain the woman's virginity. It may also be part of male homosexual intercourse. Also called coitus inter femora.

interference n. 1. the blocking of learning or of memory RETRIEVAL by the learning or remembering of other conflicting material. Interference has many sources, including prior learning (see PROACTIVE INTERFERENCE), subsequent learning (see RETROACTIVE INTERFERENCE), competition during recall (see OUTPUT INTERFERENCE), and presentation of other material (see interpulated task). 2. the mutual effect on meeting of two or more light, sound, or other waves, the overlap of which produces a new pattern of waves. The term is used most frequently with reference to waves of the same or similar frequency, whose interference may be either constructive or destructive. In the former, the waves are in phase and the wave motions are reinforced, which results in alternating areas of increased and decreased wave amplitude (e.g., as light and dark lines or louder and softer sound); in the latter, the waves are out of phase and the wave motions are decreased or cancelled. 3. the distortion of a signal due to the presence of NOISE.

interference sensitivity see RESISTANCE TO INTERFERENCE.

interference theory the hypothesis that forgetting is due to competition from other learning or other memories.

intergenerational trauma a phenomenon in which the descendants of a person who has experienced a terrifying event show adverse emotional and behavioral reactions to the event that are similar to those of the person himself or herself. These reactions vary by generation but often include shame, increased anxiety and guilt, a heightened sense of vulnerability and helplessness, low self-esteem, depression, suicidality, substance abuse, dissociation, hypervigilance, intrusive thoughts, difficulty with relationships and attachment to others, difficulty in regulating aggression, and extreme reactivity to stress. The exact mechanisms of the phenomenon remain unknown but are believed to involve effects on relationship skills, personal behavior, and attitudes and beliefs that affect subsequent generations. The role of parental communication about the event and the nature of family functioning appear to be particularly important in trauma transmission. Research on intergenerational trauma concentrated initially on the children, grandchildren, and great-grandchildren of survivors of the Holocaust and Japanese American internment camps, but it has now broadened to include American Indian tribes, the families of Vietnam War veterans, and others. Also called historical trauma: multigenerational trauma: secondary traumatization.

inguinal sex coitus in which the penis is placed between the cheeks of the buttocks, without entry into the vagina or anus.

intergroup competition see COMPETITION.

intergroup conflict disagreement or confrontation between two or more groups and their members, such as between work departments, entire companies, political parties, or nations. This may involve interpersonal discord, psychological tension, or physical violence. In many social species, intergroup conflict is a major factor affecting group-level movement patterns and space use and ultimately in shaping the evolution of group living and complex sociality. See also CONFLICT RESOLUTION. Compare INTRAGROUP CONFLICT.

intergroup-contact hypothesis see CONTACT HYPOTHESIS.

intergroup dynamics the processes that influence the shifting relationships between groups, including intergroup stereotyping, competition, conflict, and INGROUP BIAS. See also GROUP DYNAMICS.

interhemispheric fissure see LATERAL FISSURE.

interhemispheric interaction any neurophysiological, electrophysiological, or neurochemical exchange occurring between the cerebral hemispheres.
interhemispheric transfer

interhemispheric transfer the transfer of memory traces or learning experiences from one cerebral hemisphere to the other. Interhemispheric transfer can be demonstrated with experiments using laboratory animals and can be observed in humans who transfer handedness from the right to the left hand, or vice versa, following an injury or loss of a hand.

interim behavior behavior that occurs generally midway in time between successive stimuli. Compare ADJUNCTIVE BEHAVIOR; COLLATERAL BEHAVIOR; MEDIATING BEHAVIOR.

interindividual differences the variations between individuals in one or more traits, behaviors, or characteristics (e.g., variations in intelligence). See also INDIVIDUAL DIFFERENCES.

interitem correlation the degree of correlation between each test item in a set, used as a measure of the INTERNAL CONSISTENCY of a test and thus of its RELIABILITY. For example, if a participant’s responses to each item on a 10-item test could be correlated with his or her responses to every other item on the test to determine the extent to which the items reflect the same construct.

interitem interval the time interval between the presentation of items in a sequence. For instance, in a memory experiment, words in a list may be presented five seconds apart. See also INTERSTIMULUS INTERVAL.

interjudge reliability see INTERRATER RELIABILITY.

interlanguage n. in second-language acquisition, a state in which the learner has developed an internally consistent grammatical system with properties of both the native language and the target language. See FOSILIZATION; IDIOLICT; LANGUAGE TRANSFER.

interlocking pathologies nonconscious and dysfunctional ways of acting that are present in a couple or other intimate dyad or in a family or other close social unit.

interlocking reinforcement schedule a schedule of INTERMITTENT REINFORCEMENT in which the requirements of one schedule change depending on progress in another schedule. For example, in an interlocking fixed-interval, fixed-ratio schedule, reinforcement is given after a fixed number of responses and a fixed time, but this could be changed so that the number of responses required for reinforcement decreases as the interval between responses and reinforcement increases.

intermale aggression among nonhuman animals, aggression occurring between males, usually to develop, maintain, or challenge their dominance relationship. See also INTERNAL CONFLICT.

intermarriage n. 1. marriage between two individuals belonging to different racial, ethnic, or religious groups. See ENDOGAMY; MISCEGENATION; OUTBREEDING. 2. marriage between two closely related individuals, as in a consanguineous marriage. See INBREEDING. —intermarry vb.

intermediary variable see MEDIATOR.

intermediate care facility (ICF) a facility providing an appropriate level of nursing and other medical care to individuals who do not require the degree of care and treatment provided by a hospital or SKILLED NURSING FACILITY but need more than room and board.

intermediate cell see TYPE III CELL.

intermediate need in MASLOW’S MOTIVATIONAL HIER-
or homogeneity among the items on a test, such that they are consistent with one another and measuring the same thing. Internal consistency is an index of the RELIABILITY of a test. Also called internal consistency reliability; internal reliability. See also INTERITEM CORRELATION.

**internal control** see LOCUS OF CONTROL.

**internal culture conflict** see CULTURE CONFLICT.

**internal environment** the conditions within the body, including temperature, blood pressure, blood-sugar level, and acid–base balance, as opposed to those in the external environment. The internal environment is maintained in a constant state, as required for the normal functioning of the body’s tissues and organs, by mechanisms of HOMEOSTASIS. [proposed by Claude BERNARD]

**internal evaluator** an individual who conducts an evaluation of a service delivery program and is also a regular full-time staff member of the program being evaluated. Compare EXTERNAL EVALUATOR.

**internal fertilization** see FERTILIZATION.

**internal frustration** in classical psychoanalytic theory, denial of gratification of instinctual impulses due to internal factors (e.g., the superego), as opposed to external factors.

**internal granular layer** see CORtical LAYERS.

**internal inequity** the situation in which employers compensate certain employees at levels that are unfair relative to other employees in the same organization. Compare EXTERNAL INEQUITY. See EQUITY THEORY.

**internalization** n. 1. the nonconscious mental process by which the characteristics, beliefs, feelings, or attitudes of other individuals or groups are assimilated into the self and adopted as one’s own, 2. in psychoanalytic theory, the process of incorporating an object relationship inside the psyche, which reproduces the external relationship as an intrapsychic phenomenon. For example, through internalization the relationship between father and child is reproduced in the relationship between superego and ego or, in relational theory, between self and other. Internalization is often mistakenly used as a synonym for introjection. —internalize vb.

**internalized speech** silent speech in which one argues with oneself over a course of action, rehearses what one is going to do, or reassures oneself when feeling threatened. See also INNER LANGUAGE; SELF-TALK.

**internalizing behavior** see EXTERNALIZING–INTERNALIZING.

**internal locus of control** see LOCUS OF CONTROL.

**internal object** an image or representation of a person (particularly someone significant to the individual, such as a parent) that is experienced as an internalized “presence” within the mind. In her development of object relations theory, Melanie KLEIN saw the psyche as being made up of internal objects whose relations to each other and to the individual determine his or her personality and symptoms. See also PART-OBJECT.

**internal pyramidal layer** see CORtical LAYERS.

**internal rhythm** see RESPIRATION.

**internal saboteur** see BIOLOGICAL RHYTHM.

**internal-state ratings** one of several methods of evaluating a person’s reactions to a work of art. Internal-state ratings are based on the person’s mood while exposed to a pattern. Other types of rating scales include descriptive ratings and EVALUATIVE RATINGS. See STYLISTIC RATINGS.

**internal validity** the degree to which a study or experiment is free from flaws in its internal structure and its results can therefore be taken to represent the true nature of the phenomenon. In other words, internal validity pertains to the soundness of results obtained within the controlled conditions of a particular study, specifically with respect to whether one can draw reasonable conclusions about cause-and-effect relationships among variables. Compare EXTERNAL VALIDITY.

**internal working model of attachment** a cognitive construction or set of assumptions about the workings of relationships, such as expectations of support or affection. The earliest relationships may form the template for this internal model, which may be positive or negative. See also ATTACHMENT THEORY. [originally proposed by John BOWLBY]

**International Association of Applied Psychology (IAAP)** the oldest international association of professional psychologists, founded in 1920 to promote the science and practice of applied psychology and to facilitate interaction and communication among those who work in applied psychology around the world.

**International Classification of Diseases (ICD)** the global standard for diagnostic classification of all health conditions as compiled by the World Health Organization (WHO) for clinical, health management, and epidemiological purposes. At the national level, WHO’s member countries use the ICD in morbidity and mortality statistics, whereas individual practitioners use its codes for reimbursement for services; in the United States, under the Health Insurance Portability and Accountability Act (HIPPA), all health care providers are to use the ICD diagnosis code sets for billing. Based on a formal classification system originally developed in 1893, the ICD has since undergone numerous revisions. The current version, ICD–10, published in 1992 as the International Statistical Classification of Diseases and Related Health Problems, uses a four-character alphanumeric coding system to classify diseases and disorders and their subtypes, including those relating to mental and behavioral disorders. Another revision, ICD–11, is expected in 2017, with the goal of improving usability by ensuring that its diagnostic categories align with actual clinical practice. It will be available both in printed form and as an electronic database that will allow interactive data sharing. Eventually, data will be integrated into health informatics systems, accessible worldwide and aggregated at the clinic, health system, and country levels for use in a variety of ways, such as to help determine treatments, outcomes, reimbursement, and even health policy. See also DSM–IV–TR; DSM–5.

**International Council of Psychologists** a professional organization founded in 1941 to advance psychology and its applications by facilitating communication and strengthening bonds between psychologists worldwide. In 1981, the council was recognized as a nongovernmental organization in consultative status with the United Nations Economic and Social Council.

**International Military Testing Association** an organization that, since its founding in 1959, has held
conferences on the job proficiency evaluation of enlisted military personnel and increasingly on research relevant to behavioral science as applied to the military (e.g., occupational analysis, leadership, organizational behavior, human factors, manpower analysis). Originally called the Military Testing Association, the organization changed its name in 1993 to reflect the increasing involvement of countries around the world. Participants include civilian as well as uniformed researchers and practitioners.

International Phonetic Alphabet (IPA) a system of written symbols devised by the International Phonetic Association to enable the phonetic transcription of any spoken language. It is based on the Roman alphabet, with various additional symbols.

International Pilot Study of Schizophrenia (IPSS) a 1973 diagnostic study sponsored by the World Health Organization, involving psychiatrists in nine countries and a total of 1,119 patients assigned to a schizophrenic or nonschizophrenic category. The most discriminating of 13 symptoms were lack of insight, auditory hallucinations, verbal hallucinations, ideas of reference, and delusions of reference. The project used the present state examination. See also first-rank symptoms.

International Positive Psychology Association (IPPA) a professional organization, founded in 2007, whose mission is to promote positive psychology as a science, encourage and facilitate its responsible and effective application across disciplines and professions, and disseminate the findings of its research. The division of IPPA devoted to students is the Students of the International Positive Psychology Association (SIPPA).

International Society for Sport Psychology (ISSP) formed in 1965, an international and multidisciplinary organization of researchers, psychologists, educators, coaches, administrators, and national organizations devoted to the promotion of research, practice, and development in sport and exercise psychology.

International Union of Psychological Science (IUPsyS) an affiliation of professional psychological organizations, founded in 1951 to develop the exchange of ideas and scientific information between psychologists of different countries and, in particular, to organize international congresses and other meetings on subjects of general or special interest in psychology. The union evolved from the International Congress of Psychology, first held in Paris in 1889.

Internet addiction a behavioral pattern characterized by excessive or obsessive online and offline computer use that leads to distress and impairment. The condition, though controversial, has attracted increasing attention in the popular media and among health care professionals. Expanding research has identified various subtypes, including those involving excessive gaming, sexual preoccupations, and e-mail and text messaging.

Internet meme see meme.

interneuron n. any neuron that is neither sensory nor motor but connects other neurons within the central nervous system. Also called connector neuron.

interobserver reliability see interrater reliability.

interoception n. sensitivity to stimuli inside the body, resulting from the response of specialized sensory cells called interoceptors to occurrences within the body (e.g., from the viscera). Compare exteroception.

interoceptive conditioning classical conditioning that requires direct access to internal organs, through fistulas, balloons inserted into the digestive tract, or implanted electrical devices, to present the conditioned stimulus.

interoceptive stimulus any stimulus arising from inside an organism. Examples include headaches, stomachaches, and hunger pangs. Compare exteroceptive stimulus; proprioceptive stimulus.

interoceptive system the totality of sensory receptors and nerves that gather information from within the body.

interoceptor n. see interoception. —interoceptive adj.

interocular distance the distance between the pupils of the left and right eyes when the eyes are in normal fixation.

interocular transfer the ability of an aftereffect to be produced by stimulation through only one eye but to be experienced by looking only through the other eye. The presence of interocular transfer implies that the afterimage is mediated by a postretinal structure, such as the cerebral cortex, since the two eyes have no direct communication prior to the activation of binocular cells in the striate cortex.

interpersonal adj. pertaining to actions, events, and feelings between two or more individuals. For example, interpersonal skill is an aptitude enabling a person to carry on effective interactions and relationships with others, such as the ability to communicate thought and feeling or to assume appropriate social responsibilities.

interpersonal accommodation the “give-and-take” process involved in developing satisfactory relationships, in which one must put aside personal preferences to maintain good relations with others.

interpersonal attraction see attraction.

interpersonal competition see competition.

interpersonal concordance orientation see conventional level.

interpersonal conflict disagreement or discord between people with respect to goals, values, or attitudes.

interpersonal distance the physical distance that individuals choose to maintain between themselves and others while interacting. Studies show that most individuals maintain a smaller interpersonal distance for friends than for strangers. The comfortable or optimal distance also varies with the type of interaction and setting as well as with differences in nationality, culture, personality, and other characteristics. See body buffer zone; bubble concept of personal space. See also proxemics.

interpersonal gap in communication, the difference between what a speaker intends to convey and the impact of the message on a listener. Many factors contribute to this gap, some related to the speaker’s encoding of the message and others to the listener’s decoding of it. Research has shown that speakers often assume that their intent is more transparent to listeners than it actually is, a tendency called the signal amplification bias, which may lead speakers to perceive that their listeners are less responsive than they would like them to be.
Interpersonal group psychotherapy a group approach to the treatment of psychological, behavioral, and emotional problems that emphasizes the curative influence of exploring the interactions of group members, including the analysis of group events, experiences, and relationships. In this approach, the group serves as a social microcosm that provides corrective emotional experiences in the here and now via a therapist who acts as both a participant and an observer. The goal of the approach is to enable group members to gain valuable insights while learning to relate to each other and then to apply those insights in their everyday lives outside of the group setting. Also called interactive group psychotherapy. See also interpersonal theory.

Interpersonal influence direct social pressure exerted on a person or group by another person or group in the form of demands or threats on the one hand or promises of rewards or social approval on the other. Compare informational influence, normative influence.

Interpersonal intelligence in the multiple-intelligences theory, the intelligence involved in understanding and relating to other people. Interpersonal intelligence is alleged to be relatively independent of other intelligences posited by the theory.

Interpersonal learning group any group formed to help individuals extend their self-understanding and improve their relationships with others, such as an experiential group, T-group, or growth group. See also structured learning group.

Interpersonal perception see social perception.

Interpersonal process recall (IPR) a method used for understanding the processes of psychotherapy and for the training of counselors and therapists. It involves videotaping or audiotaping counseling or psychotherapy sessions, which are later reexperienced and analyzed by the counselor or therapist in the presence of a supervisor, who questions and discusses the thoughts and feelings of the counselor or therapist and client. [developed by U.S. counseling psychologist Norman I. Kagan (1931–1994)]

Interpersonal psychotherapy (IPT) a time-limited form of psychotherapy, originally based on the interpersonal theory of Harry Stack Sullivan, positing that relations with others constitute the primary force motivating human behavior. A central feature of IPT is the clarification of the client’s interpersonal interactions with significant others, including the therapist. The therapist helps the client explore current and past experiences in detail, relating not only to interpersonal reaction but also to general environmental influences on personal adaptive and maladaptive thinking and behavior.

Interpersonal reconstructive psychotherapy an integrative psychotherapy and method of symptom analysis that applies psychodynamic and cognitive behavior techniques to the treatment of individuals with personality disorders, specifically to their presenting problems and symptoms that relate to long-term interpersonal difficulties. Interventions are active and focused on attachment-based factors that maintain current dysfunction, with the goal of helping such individuals understand the source of and then modify their chronically self-destructive thoughts and maladaptive behavior. [developed by U.S. clinical psychologist Lorna Smith Benjamin (1934–)]

Interpersonal relations 1. the connections and interactions, especially ones that are socially and emotionally significant, between two or more people. 2. the pattern or patterns observable in an individual’s dealings with other people.

Interpersonal theory the theory of personality developed by Harry Stack Sullivan, which is based on the belief that people’s interactions with other people, especially significant others, determine their sense of security, sense of self, and the dynamisms that motivate their behavior. For Sullivan, personality is the product of a long series of stages in which the individual gradually develops a “good feeling” toward others and a sense of a good me toward himself or herself. The individual also learns how to ward off anxiety and correct distorted perceptions of other people, learns to verify his or her ideas through consensual validation, and above all seeks to achieve effective interpersonal relationships on a mature level.

Interpersonal zone see distance zone.

Interphase n. the interval between cell divisions, when the nucleus has finished dividing, particularly in rapidly dividing tissues or during embryonic growth.

Interpolated task an activity that is presented between two experimental tasks to fill time or to disguise the connection between the two critical tasks. For instance, an interpolated arithmetic task might be given between the study phase and test phase of a memory experiment. See also interference.

Interpolation n. a strategy for determining an unknown value given knowledge of surrounding data points. For example, if the average score on a test is 70 for a group of beginner students and the average score on the same test is 90 for an advanced group of students, one might use interpolation to estimate an average score of 80 on the test for an intermediate group of students.

Interposition n. a monocular depth cue occurring when two objects are in the same line of vision and the closer object, which is fully in view, partly conceals the farther object. Also called relative position.

Interpret vb. 1. to translate orally from one language into another. A distinction is sometimes made between interpreting, in which it is sufficient to convey the sense of the original, and translation, in which some attempt to replicate form and style will also usually be made. 2. in psychotherapy, to provide an interpretation. —interpret n.

Interpretation n. 1. in psychotherapy, explanation by the therapist in terms that are meaningful to the client of the client’s issues, behaviors, or feelings. Interpretation typically is made along the lines of the conceptual framework or dynamic model of the particular therapy. In psychoanalysis, for example, the analyst uses the constructs of psychoanalytic theory to interpret the patient’s early experiences, dreams, character defenses, and resistance. Although interpretation exists to some extent in almost any form of therapy, it is a critical procedural step in psychoanalysis and in other forms of psychodynamic psychotherapy. 2. an oral translation (see interpret).

Interpretive phenomenological analysis (IPA) a qualitative approach in which a researcher explores how a participant understands his or her personal and social worlds and gives meaning to particular experiences, events, and states. For example, the strategy might be used to understand how a person comes to terms with the death of a spouse. IPA uses structured interviews to gather ver-
interpretive response

bal and nonverbal information, which is then analyzed to uncover and describe underlying themes.

interpretive response a reply by a therapist intended to summarize or illuminate the essential meaning of or motive underlying a statement made by a client during therapy. See also INTERPRETATION.

interpretive therapy any form of psychotherapy in which the therapist elicits the client’s conflicts, repressions, dreams, and resistances, which are then interpreted or explained to the client in the light of his or her experiences. See also INTERPRETATION.

interpretivism n. in EPistemology, the assertion that knowledge is deeply tied to the act of interpretation; there are multiple apprehendable and equally valid realities as opposed to a single objective reality. Interpretivism thus represents a form of RELATIVISM. See also CONSTRUCTIVISM.

interquartile range (IQR) an index of the DISPERSION within a data set: the difference between the 75th and 25th PERCENTILE scores (also known as the upper and lower HINGS) within a distribution. Also called SPREAD: MID-SPREAD.

interrater reliability the extent to which independent evaluators produce similar ratings in judging the same abilities or characteristics in the same target person or object. It often is expressed as a CORRELATION COEFFICIENT. If consistency is high, a researcher can be confident that similarly trained individuals would likely produce similar scores on targets of the same kind. If consistency is low, there is little confidence that the obtained scores could be reproduced with a different set of raters. Also called INTER-RATER RELIABILITY: INTER-RATER RELIABILITY: INTER-OBSERVER RELIABILITY: INTER-RATER RELIABILITY.

interresponse time (IRT) the time between successive responses, especially between successive responses of the same type.

interrogative n. in linguistics, the form of a sentence used to pose a question rather than to make a statement, issue a command, and so on, or the MOOD of the verb used in such constructions. In English there are two main types of interrogative: yes/no questions (e.g., Are you going?) and wh-questions using what, when, where, who, and how (e.g., Where are you going?). Both types require the use of an AUXILIARY VERB (usually be, have, or do). The structural relationships between the DEclarATIVE and interrogative forms of a sentence are of major interest in GENERATIVE GRAMMAR and PSYCHOLINGUISTICS (see AUXILIARY INVERSION). Compare IMPERATIVE: INDICATIVE: SUBJUNCTIVE.

interrogative suggestibility the degree to which an individual is susceptible to suggestive questioning. The level of suggestibility may be assessed in two ways: (a) yield, or the degree to which an individual will respond affirmatively to leading questions, and (b) shift, or the tendency to alter previous responses when receiving negative feedback.

interrogatories pl. n. formal written questions prepared for an official pretrial questioning of an individual who possesses information relevant to a case or used in the judicial examination of an individual or party.

interrole conflict the form of ROLE CONFLICT that occurs when individuals have multiple roles and the expectations and behaviors associated with one role are not consistent with the expectations and behaviors associated with another. In organizational settings, for example, a common interrole conflict is that between work and family, whereby the role pressures from each domain may be mutually incompatible. Compare INTRA-ROLE CONFLICT.

interrupted time-series design a QUASI-EXPERIMENTAL DESIGN in which the effects of an intervention are evaluated by comparing outcome measures obtained at several time intervals before and several time intervals after the intervention was introduced. Unlike traditional TIME-SERIES DESIGNS, which make use of a continuous predictor variable, an interrupted time-series design uses a categorical predictor—the absence or presence of an intervention.

interscorer reliability see INTRARATER RELIABILITY.

intersegmental arc reflex a REFLEX ARC formed by fibers of sensory neurons or interneurons that travel from one spinal segment to another to communicate with motor neurons.

intersegmental reflex see SPINAL REFLEX.

intersegmental tract see GROUND BUNDLE.

intersensory perception the coordination of information presented through separate modalities into an integrated experience. Information from one sensory source is transmitted to the ASSOCIATION CORTEX, where it can be integrated with information from another sensory source. Intersensory perception is required in tasks that coordinate two or more sensorimotor activities, such as playing a musical instrument according to the pattern of notes on a page of sheet music. Also called CROSS-MODAL PERCEPTION. See PERCEPTUAL SYNTHESIS: SENSORY INTERACTION.

intersex n. 1. a modern and evolving term for HERMAPHRODITISM and pseudohermaphroditism, the condition of possessing the sexual characteristics of both sexes. Sometimes called INTERSEXUALISM: INTERSEXUALITY. 2. an individual who exhibits sexual characteristics of both sexes. However, using phrases such as “an intersex individual” or “a person with intersex conditions” is considered preferable. —INTERSEX adj.

interspecies interaction all forms of interaction between species. Long-term interactions include PARASITISM, in which one species lives on or in another at a cost to the host; MUTUALISM, in which both species benefit from the interaction; and COMMENSALISM, in which the species coexist with neither cost nor benefit. Short-term interspecies interactions include predator–prey relationships and the mixed flocking of birds to feed and give ALARM CALLS together.

interstimulus interval (ISI) the time between stimulus presentations, usually timed from the end of one stimulus presentation to the beginning of the next. See also INTERITEM INTERVAL.

interstitial cell any of the cells that fill the spaces between other tissues and structures. The interstitial cells of the TESTIS surround the seminiferous tubules and secrete testosterone when stimulated by LUTEINIZING HORMONE.

interstitial cell-stimulating hormone (ICSH) see LUTEINIZING HORMONE.

interstripes pl. n. regions of PERSISTENT ISH see LUTENIZING HORMONE.

intersubjectivity n. the sharing of subjective experience between two or more people. Intersubjectivity is seen as essential to language and the production of social
meaning. The term is often applied to the relationship between a therapist and a client.—intersubjective adj.

interthalamic adhesion n. a mass of gray matter that extends in most individuals across the midline of the third ventricle of the brain from the medial surfaces of the two halves of the thalamus. Although sometimes called the middle commissure, the interthalamic adhesion has no particular commissural (i.e., connecting) function. Also called massa intermedia.

interval n. a range of scores or values, such as a CLASS INTERVAL or CONFIDENCE INTERVAL.

interval data numerical values that indicate magnitude but lack a “natural” zero point. Interval data represent exact quantities of the variables under consideration, and when arranged consecutively they have equal differences among adjacent values (regardless of the specific values selected) that correspond to genuine differences between the physical quantities being measured. Temperature is an example of interval data: the difference between 50°F and 49°F is the same as the difference between 40°F and 39°F; but a temperature of 0°F does not indicate that there is no temperature. Compare RATIO DATA. See also INTERVAL SCALE.

interval estimate an estimated range of likely values for a given population PARAMETER. For example, a researcher might use data from a sample to determine that the average score on a particular variable in the larger population falls between 20 and 25. Compare POINT ESTIMATE.

interval of uncertainty the interval between the upper threshold (a just noticeable stimulus) and the lower threshold (a just imperceptible stimulus) when finding a DIFFERENCE THRESHOLD.

interval reinforcement the reinforcement of the first response to a stimulus after a predetermined interval has elapsed. Reinforcement may be given at uniform or variable intervals; the number of responses during the interval is irrelevant. Also called interval-reinforcement schedule. See also FIXED-INTERVAL SCHEDULE; RANDOM-INTERVAL SCHEDULE; VARIABLE-INTERVAL SCHEDULE. Compare RATIO REINFORCEMENT.

interval sampling a form of RANDOM SAMPLING in which participants at uniformly separated points are selected for study and the starting point for selection is arbitrary. An example is choosing every 10th name from a list of candidates.

interval scale a scale marked in equal intervals so that the difference between any two consecutive values on the scale is equivalent regardless of the two values selected. Interval scales lack a true, meaningful zero point, which is what distinguishes them from RATIO SCALES. For example, Fahrenheit temperature uses an interval scale: The difference between 50°F and 49°F is the same as the difference between 40°F and 39°F, but a temperature of 0°F does not indicate that there is no temperature. See also INTERVAL DATA.

interval variable a variable that is measured using an INTERVAL SCALE. Because values on such a scale are equally spaced, the differences between values of an interval variable are meaningful. Compare ORDINAL VARIABLE.

intervening variable see MEDIATOR.

intervention n. 1. generally, any action intended to interfere with and stop or modify a process, as in treatment undertaken to halt, manage, or alter the course of the pathological process of a disease or disorder. 2. action on the part of a psychotherapist to deal with the issues and problems of a client. The selection of the intervention is guided by the nature of the problem, the orientation of the therapist, the setting, and the willingness and ability of the client to proceed with the treatment. Also called psychological intervention. 3. a technique in addictions counseling in which significant individuals in a client’s life meet with him or her, in the presence of a trained counselor, to express their observations and feelings about the client’s addiction and related problems. The session, typically a surprise to the client, may last several hours, after which the client has a choice of seeking a recommended treatment immediately (e.g., as an inpatient) or ignoring the intervention. If the client chooses not to seek treatment, participants state the interpersonal consequences; for example, a spouse may request that the client move out, or the client’s employment may be terminated. 4. a similar confrontation between an individual and family and friends but outside of the formal structure of counseling or therapy; usually over similar issues and with the goal of urging the confronted individual to seek help with an attitudinal or behavioral problem. Also called family intervention. 5. in research design, an experimental manipulation.—intervene vb.

interventionist n. a physician, behavioral scientist, therapist, or other professional who modifies the conditions or symptoms of a patient.

intervention program for children any of a number of types of program intended to provide intellectual, emotional, nutritional, or medical benefits to children believed to be at risk for inadequate development. Target children are usually preschoolers and are often from homes judged to be economically or culturally disadvantaged.

intervention research strategies and processes designed to measure the change in a situation or individual after a systematic modification (diet, therapeutic technique, etc.) has been imposed or to measure the effects of one type of intervention program as compared to those of another program. Experimentation is the most common type of intervention research, but CLINICAL TRIALS and qualitative studies may also be used. Also called intervention study.

interventricular foramen an opening that connects the third ventricle of the brain with either lateral ventricle. It permits the flow of cerebrospinal fluid through the ventricles. Also called foramen of Monro.

interview n. a directed conversation in which a researcher, therapist, clinician, employer, or the like (the interviewer) intends to elicit specific information from an individual (the interviewee) for purposes of research, diagnosis, treatment, or employment. Conducted face to face, by telephone, or online, interviews may be either standardized, including set questions, or open ended, varying with material introduced in responses by the interviewee. Their RELIABILITY is of particular concern, and interviewers must be careful to minimize or eliminate personal judgment and biases in evaluating responses. See STRUCTURED INTERVIEW; UNSTRUCTURED INTERVIEW. See also CLINICAL INTERVIEW; EMPLOYMENT INTERVIEW.

interviewer effect the influence of the characteristics of an interviewer upon the responses provided by an interviewee. The interviewer’s age, gender, and level of experi-
interviewer stereotype

ence may affect the manner in which the interviewee responds, as may his or her general demeanor and nonverbal cues. For example, a person might discuss sensitive topics, such as sexual or drinking behavior, more openly and truthfully with an interviewer who is of the same gender. The term interviewer bias refers more specifically to an interviewer’s expectations, beliefs, and prejudices as they influence the interview process and the interpretation of the data it provides.

interviewer stereotype in PERSONNEL PSYCHOLOGY, an interviewer’s concept of the “ideal” job candidate, which becomes the standard against which actual job applicants are compared. Such a stereotype may obscure the genuine merits of applicants who deviate from it in some way. See also PROFILE MATCHING SYSTEM.

interviewer training instructional methods employed in training individuals to be effective interviewers. These may include group discussions, role play, and the use of recordings of real or simulated interviews, in addition to instruction in the basic principles of interviewing.

interview group psychotherapy a form of ANALYTIC GROUP PSYCHOTHERAPY for adolescents and adults that focuses on fixations and difficulties of the LIBIDO and relies primarily upon catharsis, insight, and reality testing to effect personality change. A balanced therapeutic group is selected on the basis of common problems and personal characteristics, and participants are encouraged to reveal their attitudes, symptoms, and feelings. [developed by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981)]

interview schedule a script containing the questions an interviewer will ask.

intestinal lipodystrophy see LIPODYSTROPHY.

intimacy n. an interpersonal state of extreme emotional closeness such that each party’s PERSONAL SPACE can be entered by any of the other parties without causing discomfort to that person. Intimacy characterizes close, familiar, and usually affectionate or loving personal relationships and requires the parties to have a detailed knowledge or deep understanding of each other. —intimate adj.

intimacy problem difficulty in forming close relationships and becoming intimate with others, whether physically or psychologically. The problem might involve difficulties with sexual contact, self-disclosure, trust, or commitment to a lasting relationship. See also FEAR OF COMMITMENT.

intimacy versus isolation the sixth of ERIKSON’S EIGHT STAGES OF PSYCHOSOCIAL DEVELOPMENT, which extends from late adolescence through courtship and early family life to early middle age. During this period, individuals must learn to share and care without losing themselves: if they fail, they will feel alone and isolated. The development of a cohesive identity in the previous stage (see IDENTITY VERSUS IDENTITY CONFUSION) provides the opportunity to achieve true intimacy; but the development of IDENTITY DIFFUSION makes it harder for individuals to achieve a positive outcome at this stage.

intimate partner violence physical, psychological, or sexual abuse of one person by another in a close relationship. The couple may be heterosexual or same sex, and they may be (or have been) dating, married, or living together. Apart from violence and threats of abuse, control is a hallmark of the abusive intimate partner relationship, with the aggressor controlling the partner’s access to family and friends, taking control of shared finances, and constantly monitoring the partner’s activities. If rejected, the perpetrator may also stalk the partner. Victims of intimate partner violence are at greater risk for developing depression, substance abuse, and other disorders. See also RAB-TED WOMEN: DOMESTIC VIOLENCE.

intimate zone the small DISTANCE ZONE adopted by those in very close relationships, such as that of lovers or of mother and infant. Compare PERSONAL DISTANCE ZONE; PUBLIC DISTANCE ZONE; SOCIAL ZONE. See also PROXEMICS.

intonation n. see TONE.

intoxicant n. a substance capable of producing transient alterations in mental function. The nature of the intoxication depends on the psychoactive properties of the intoxicant. In general, mild intoxication is marked by minor perceptual changes or a sense of euphoria or well-being; more pronounced intoxication involves such changes as behavioral disinhibition, perceptual distortions, hallucinations, or delirium; and severe intoxication is marked by loss of motor control and cognitive and autonomic function, possibly progressing to coma or death.

intoxication n. see SUBSTANCE INTOXICATION.

intoxication defense a defense that a crime was committed by a person who was intoxicated, which has been used to challenge a charge of CRIMINAL RESPONSIBILITY. If the intoxicant was taken involuntarily, it can negate criminal responsibility altogether. If the intoxicant was taken voluntarily, it may serve as a MITIGATING FACTOR in reducing the penalty imposed, or it may be used to argue against PREMEDITATION in a first-degree murder charge. See DIMINISHED CAPACITY.

intra-attitudinal consistency the extent to which evaluative responses underlying a single attitude are consistent with one another. Uniformly positive responses or uniformly negative responses constitute high consistency. The existence of both positive and negative responses reflects low consistency. See also AMBIVALENCE OF AN ATTITUDE.

intracarotid amobarbital procedure see WADA TEST.

intracarotid sodium Amytal test (ISA) see WADA TEST.

intracellular fluid the fluid within the plasma membrane of an organism’s cells. Also called cellular fluid.

intracellular thirst see OSMOMETRIC THIRST.

intracerebral hemorrhage see CEREBRAL HEMORRHAGE.

intraclass correlation the degree of homogeneity among unordered members (people, items, etc.) of a group. For example, it may reflect the level of agreement among different judges rating a specific attribute. It is indexed by the intraclass correlation coefficient (ICC), which ranges from 0 to 1 in value. A larger ICC indicates more homogeneity and thus that a correspondingly smaller proportion of the total variance in a dependent variable is attributable to individual differences within the group. Compare INTERCLASS CORRELATION.

intraconscious personality a phenomenon of DISSO-CIATIVE IDENTITY DISORDER in which one personality functioning on an unconscious level is aware of the thoughts
intracranial adj. within the skull or CRANIUM.
intracranial hemorrhage bleeding within the skull. Hemorrhages of this type include CEREBRAL HEMORRHAGES and SUBARACHNOID HEMORRHAGES.
intracranial pressure (ICP) the pressure within the skull. Excessive intracranial pressure can cause brain damage and impede blood flow within the brain, with a range of effects that may include memory loss, balance problems, dementia, coma, and death. Causes of raised ICP include hydrocephalus, hemorrhage, hematomas, brain tumors, and head injuries.
intracranial stimulation (ICS) stimulation of a brain region by direct application of an electric current through implanted electrodes. When this stimulation is controlled by the individual being stimulated, it is called INTRACRANIAL SELF-STIMULATION; it also may be called BRAIN SELF-STIMULATION or ELECTRICAL SELF-STIMULATION OF THE BRAIN (ESSB). In nonhuman animal experiments, this is achieved by the animal performing an OPERANT RESPONSE, such as lever pressing. When the electrodes are placed in certain areas of the brain, animals will press the lever quite frequently, indicating that stimulation of these brain areas is rewarding. [originated in 1954 by U.S. psychologist James OLIS and Canadian psychologist Peter M. Milner]
intradimensional discrimination distinguishing between stimuli that are identical except for one aspect, such as size, color, or loudness. This is a form of EXPERT PERFORMANCE.
intrafamilial dynamics the processes by which family members influence each other’s thoughts, feelings, and behaviors and the changes in the family relationships that these processes bring. Also called FAMILY DYNAMICS.
intracarpal fiber a small muscle fiber, 2 to 12 of which are located within each MUSCLE SPINDLE. Intracarpal fibers are sensitive to stretching and muscle tension and are connected to the STRETCH RECEPTORS. Compare EXTRAFOSSAL FIBER.
intragroup competition see COMPETITION.
intragroup conflict disagreement or confrontation between two or more members of a single group, as when people on a work team have different opinions about how best to accomplish a specified goal. Intragroup conflict poses a significant challenge to effective team functioning and has been divided into three primary types. PROCESS CONFLICT pertains to the logistics of task accomplishment. RELATIONSHIP CONFLICT involves interpersonal incompatibilities, and TASK CONFLICT concerns disagreement about the content of the task itself. Compare INTERGROUP CONFLICT.
intragroup territorial behavior see GROUP TERRITORIAL BEHAVIOR.
intraindividual differences the variations between two or more traits, behaviors, or characteristics of a single person. For example, certain aptitude tests measure a testee’s strengths in mathematical, verbal, and analytic abilities; differences among the three standardized scores represent intraindividual differences. See also INDIVIDUAL DIFFERENCES.
intralaminar nucleus any of certain NUCLEI located in the internal medullary lamina, a nearly vertical layer of white matter in the thalamus. The largest of these nuclei is the CENTER MEDIAN.
intralaminar system a diffuse system of thalamic nerve cells associated with sleep and wakefulness and believed to be a part of the RETICULAR FORMATION.
intramaze cue a CUE that is within a maze, such as floor texture, wall color, or a scent.
intramuscular injection (IM injection) the injection of a substance into a muscle by means of a hypodermic syringe, usually into the muscle of the upper arm, thigh, or buttock. The choice of muscle area is important in avoiding damage to a nerve or blood vessel. See ADMINISTRATION.
intransitivity n. the quality of a relationship among elements such that relationships do not transfer across the elements (i.e., that relationships do not exhibit TRANSITIVITY). For example, a transitive relationship would be the following: given that a > b and that b > c, it must be the case that a > c. An intransitive relationship would be one in which such a conclusion did not necessarily follow. Such relationships appear to be illogical and inconsistent but are often found in matters of personal preference or other subjective judgments. For example, a person might prefer the color blue over red and red over green, but when given a choice, he or she might prefer green over blue.
—intransitive adj.
intraocular pressure (IOP) the pressure inside the eye, as measured by TONOMETRY. Increased IOP may indicate glaucoma, a disease in which the pressure inside the eye increases to the point at which it causes impaired vision and eventually blindness if untreated. The use of drugs with anticholinergic effects (e.g., tricyclic antidepressants, antihistamines, sympathomimetics) may raise IOP in patients with acute glaucoma, potentially requiring immediate medical intervention to preserve sight.
intrapersonal adj. describing factors operating or constructs occurring within the person, such as attitudes, decisions, self-concept, self-esteem, or self-regulation.
intrapersonal conflict see INTRAPSYCHIC CONFLICT.
intrapersonal intelligence in the MULTIPLE-INTELLIGENCES THEORY, the intelligence involved in self-understanding and in reflecting upon oneself, one’s skills, one’s motives, and so forth. Intrapersonal intelligence is alleged to be relatively independent of other intelligences posited by the theory.
intrapsyhic adj. pertaining to impulses, ideas, conflicts, or other psychological phenomena that arise or occur within the psyche or mind. Compare EXTRAPSYCHIC.
intrapsyhic ataxia lack of coordination of feelings, thoughts, and volition (e.g., laughing when depressed). The concept was introduced in 1904 by Austrian psychiatrist Erwin Stransky (1878–1962) in association with schizophrenia, but it has subsequently been seen in other disorders as well. Also called MENTAL ATAXIA. See also INAPPROPRIATE AFFECT.
intrapsyhic conflict in psychoanalytic theory, the clash of opposing forces within the psyche, such as conflicting drives, wishes, or agencies. Also called INNER CONFLICT; INTERNAL CONFLICT; INTRAPERSONAL CONFLICT; PSYCHIC CONFLICT.
inrarole conflict the form of ROLE CONFLICT caused by incompatibility among the behaviors and expectations as-
intrauterine device

associated with a single role. These inconsistencies may result from the inherent complexity of the role itself, the ambiguity of the role, or a lack of consensus in defining the role and its demands. Compare INTERROLE CONFLICT.

intrauterine device (IUD) a device made of plastic or other material (e.g., copper, rubber) that is inserted into the cervix as a contraceptive device. Usually having a coil design or the shape of a T, Y or other configuration, it interferes with implantation of an embryo in the wall of the uterus.

intravenous drug use a form of drug use in which the substance is injected directly into a vein with a hypodermic needle and syringe to speed up and maximize the effect. This typically involves self-administration of a psychoactive drug, often an opioid and especially heroin. Sharing or reusing needles or syringes increases the risk of acquiring and transmitting serious blood-borne infections, including hepatitis and HIV. See also NEEDLE EXCHANGE PROGRAM.

intravenous injection (iv injection) the injection of a substance into a vein by means of a hypodermic syringe. This technique is used when rapid absorption of a drug is needed, when the substance would be irritating to the skin or to muscle tissue, or when it cannot be administered through the digestive tract. It is a dangerous route of administration because of its rapid onset of pharmacological action, which may cause a potentially fatal reaction. Slow intravenous injection, called intravenous (iv) infusion, is used for blood transfusions, parenteral administration of nutrients (i.e., directly into the bloodstream, bypassing the digestive tract), or continuous administration of drugs. See also ADMINISTRATION.

intraverbal n. a verbal response occasioned by a preceding verbal stimulus. It illustrates CHAINING in the domain of VERBAL BEHAVIOR.

intrinsic activity 1. the magnitude of a response to a drug regardless of dosage. 2. a measure of the efficacy of a drug-receptor complex in producing a pharmacological effect. Also called intrinsic efficacy. 3. the inborn readiness of babies to be inquisitive and to make contact with their environment. According to Jean Piaget, cognitive structures, by their very nature, seek to be active, predisposing the child to learn from experience with the environment.

intrinsic behavior 1. a type of behavior expressed through a specific organ (e.g., smiling, the knee-jerk reflex). 2. behavior that is inherently rewarding. For example, reading a book is pleasurable for some individuals and so is intrinsically rewarding.

intrinsic eye muscles see EYE MUSCLES.

intrinsic motivation an incentive to engage in a specific activity that derives from pleasure in the activity itself (e.g., a genuine interest in a subject studied) rather than because of any external benefits that might be obtained (e.g., money, course credits). Compare EXTRINSIC MOTIVATION.

intrinsic reinforcement the attainment of a positively valued outcome from the performance of an action. The outcome itself is inherent to the activity and called an intrinsic reinforcer. For example, blowing on a harmonica naturally produces sounds. If the sounds serve to reinforce blowing on the harmonica, then the sounds provide intrinsic reinforcement. Compare EXTRINSIC REINFORCEMENT.

intrinsic religion a religious orientation in which religious practice is an end itself, rather than a means to other ends. Compare EXTRINSIC RELIGION. [introduced by Gordon W. Allport]

intrinsic reward a positively valued outcome that is implicit in an activity, such as the pleasure or satisfaction gained from developing a special skill. Intrinsic rewards originate directly from the task performance and do not originate from other people. Compare EXTRINSIC REWARD.

introduction n. a personality trait reflecting the extent to which a person is attentive to understanding the needs, motives, and experiences of himself or herself and others. —introceptive adj.

introitus n. an opening or entrance to a hollow organ or tube. For example, the anus is the introitus of the rectum, and the introitus vaginae is the entrance of the vagina.

introduction n. 1. a process in which an individual unconsciously incorporates aspects of external reality into the self, particularly the attitudes, values, and qualities of another person or a part of another person's personality. Introjection may occur, for example, in the mourning process for a loved one. 2. in psychoanalytic theory, the process of absorbing the qualities of an external OBJECT into the psyche in the form of an internal object or mental REPRESENTATION (i.e., an introject), which then has an influence on behavior. This process is posited to be a normal part of development, as when introjection of parental values and attitudes forms the SUPEREGO, but it may also be used as a DEFENSE MECHANISM in situations that arouse anxiety. Compare IDENTIFICATION; INCORPORATION. —introject vb. —introjective adj.

introjective depression self-critical depression: intense sadness and DYSPHORIA involving punitive, relentless feelings of self-doubt, self-criticism, and self-loathing. The individual with introjective depression becomes involved in numerous activities in an attempt to compensate for his or her excessively high standards, constant drive to perform and achieve, and feelings of guilt and shame over not having lived up to expectations. See also AUTONOMOUS DEPRESSION. Compare ANALYTIC DEPRESSION.

introjective personality according to some psychoanalytic theories, a line of personality development that is focused on achievement and evaluation and—if the personality fails to develop properly—may result in feelings of worthlessness, failure, and psychopathological self-criticism. Compare ANALYTIC PERSONALITY.

intromission n. the act of putting one thing into something else, especially the insertion of the penis into the vagina. See also PENETRATION. —intromissive adj.

intrropunitive adj. referring to the punishment of oneself: tending to turn anger, blame, or hostility internally, against the self, in response to frustration. Compare EXTRA- PUNITIVE. —intrropunitiveness n.

introspection n. 1. the process of attempting to directly access one's own internal psychological processes, judgments, perceptions, or states. 2. in the literature on attitudes, the process in which a person attempts to explain the reasons for holding a particular attitude, reaching
a specific decision, or engaging in a particular behavior. —introspective adj.

**introspectionism** n. the doctrine that the basic method of psychological investigation is or should be INTROSPECTION. Historically, such an approach is associated with the school of psychological STRUCTURALISM. —introspection-ist adj.

**introspective method** an approach to research in which participants describe their conscious experiences.

**introversion** n. orientation toward the internal private world of one’s self and one’s inner thoughts and feelings, rather than toward the outer world of people and things. Introversion is a broad personality trait and, like extraversion, exists on a continuum of attitudes and behaviors. Introverts are relatively more withdrawn, retiring, reserved, quiet, and deliberate; they may tend to mute or guard expression of positive affect, adopt more skeptical views or positions, and prefer to work independently. [concept originated by Carl JUNG for the study of personality types] —introversive adj. —introvert n. —introverted adj.

**introversion–extraversion** n. the range, or continuum, of self-orientation from introversion, characterized by inward and self-directed concerns and behaviors, to extraversion, characterized by outward and social-directed concerns and behaviors. See also EYSENCK’S DIMENSIONS: FIVE-FACTOR PERSONALITY MODEL. [concept originated by Carl Jung for the study of personality types]

**intrusion error** in a memory test, the recall of an item that was not among the material presented for remembering. Intrusion errors can be informative about the nature of forgetting, as when the intrusion is a synonym, rhyme, or associate of a correct item.

**intrusive thoughts** mental events that interrupt the flow of task-related thoughts in spite of efforts to avoid them. Minor intrusions are normal and widespread (see MIND WANDERING). Upsetting intrusions are common after trauma and in obsessive-compulsive disorder.

**intuition** n. immediate insight or perception, as contrasted with conscious reasoning or reflection. Intuitions have been characterized alternatively as quasi-mystical experiences or as the products of instinct, feeling, minimal sense impressions, or unconscious forces. —intuit vb. —intuitive adj.

**intuitionism** n. 1. the belief that knowledge is obtained primarily by means of intuition. 2. the tendency of people to prefer to think, reason, and remember by processing inexact memory representations rather than by working logically from exact representations. See FUZZY TRACE THEORY. [proposed by U.S. psychologists Charles Brainerd (1944– ) and Valerie Reyna (1955– )]

**intuitive judgment** a decision reached on the basis of subjective feelings that cannot easily be articulated and may not be fully conscious. See INTUITION; SYSTEM 1.

**intuitive knowledge** knowledge that appears to be based on subjective judgment or gut feeling rather than on specific learning. Intuitive knowledge is probably based on nonconsciously recalled information, such as IMPLICIT MEMORY or PROCEDURAL MEMORY, both of which are forms of knowing that are not necessarily accompanied by verbal awareness of knowing.

**intuitive stage** in PIAGETIAN THEORY, the period during the PREOPERATIONAL STAGE, from about 4 to 7 years, in which children are able to think in terms of classes and to deal with number concepts, although their thinking is dominated by perception.

**intuitive type** in Carl Jung’s Analytic Psychology, a FUNCTIONAL TYPE characterized by an ability to adapt “by means of unconscious indications” and “a fine and sharpened perception and interpretation of faintly conscious stimuli.” The intuitive type is one of Jung’s two IRATIONAL TYPES; the other is the SENSATION TYPE. See also FEELING TYPE; THINKING TYPE.

**Intuniv** n. a trade name for GUAFCININE.

**in utero** in the uterus; that is, before birth.

**invalid** 1. n. a person with a chronic illness or disability who is confined to the home or another environment. 2. adj. lacking VALIDITY.

**invariance** n. 1. in the theory of ECOLOGICAL PERCEPTION, any property of an object that remains constant despite changes in the point of observation or surrounding conditions. 2. the property of being unchanged by a TRANSFORMATION. For example, after adding a constant value to each of a set of scores on a test, the degrees of difference among the scores will demonstrate invariance, being the same for the original and transformed set. —invariant adj.

**invariant feature** a characteristic of an object that does not change when the object is viewed under different circumstances. Because invariant features are unaffected by manipulations of the object or the observer, they are powerful cues for object recognition by humans or machines. For example, when solid objects of different orientation are compared, the volume of the objects is an invariant feature.

**invariant sequence** in stage theories of development, such as PIAGETIAN THEORY, the unchanging order in which the stages of development occur. Children must progress sequentially through these stages, none of which can be skipped.

**invasive adj.** 1. denoting procedures or tests that require puncture or incision of the skin or insertion of an instrument or foreign material into the body. 2. able to spread from one tissue to another, or having the capacity to spread, as in the case of an infection or a malignant tumor. Compare NONINVASIVE.

**invention of new means through mental combination** see MENTAL COMBINATION.

**inventory** n. a list of items, often in question form, used in describing and studying behavior, interests, and attitudes.

**inverse agonist** see AGONIST.

**inverse correlation** see NEGATIVE CORRELATION.

**inverse derivation** see BACK-FORMATION.

**inverse dynamics** see INVERSE KINEMATICS.

**inverse factor analysis** see Q-TECHNIQUE FACTOR ANALYSIS.

**inverse kinematics** the transformation necessary to go from movement goals, typically specified in terms of positions or trajectories in space, to the means of achieving those goals, described in terms of joint angles. Inverse dynamics expresses this transformation in terms of the forces exerted by muscles. Because of the DEGREES OF FREE-
inverse relationship

DOM PROBLEM. Each of these transformations has many possible solutions for any particular movement.

inverse relationship see NEGATIVE RELATIONSHIP.

inverse-square law any law of physics stating that one variable decreases or increases in proportion to the reciprocal of the square of another variable. For example, the intensity of a sound is inversely proportional to the square of the distance from the source.

inverse transformation see RECIPROCAL TRANSFORMATION.

Inversine n. a trade name for MECAMYLAMINE.

inversion n. 1. In PIAGETIAN THEORY, see NEGATION. 2. in vision, a reversed image formed on the retina. 3. an old name for same-sex behavior or orientation or the assumption of the role of the opposite sex.

inversion of affect see REVERSAL OF AFFECT.

inverted retina the vertebrate retina, with reference to the fact that light must pass through all the cell layers of the retina before it reaches the photosensitive region of the PHOTORECEPTORS, which is at the very back of the eye.

inverted-U hypothesis a proposed correlation between motivation (or AROUSAL) and performance such that performance is poorest when motivation or arousal is at very low or very high states. This function is typically referred to as the YERKES–DOODSON LAW. Emotional intensity (motivation) increases from a zero point to an optimal point, increasing the quality of performance; increase in intensity after this optimal point leads to performance deterioration and disorganization, forming an inverted U-shaped curve. The optimal point is reached sooner (i.e., at lower intensities) the less well learned or more complex the performance; increases in emotional intensity supposedly affect finer skills, finer discriminations, complex reasoning tasks, and recently acquired skills more readily than routine activities. However, the correlation is considered weak; at best, the inverted U-function represents an entire family of curves in which the peak of performance takes place at different levels of arousal.

inverted U-shaped distribution see U-SHAPED DISTRIBUTION.

investigatory behavior exploration of a new object or other aspect of the environment. Among nonhuman animals, investigatory behavior can be important in locating new food resources, detecting cryptic predators, extending HOME RANGE, or finding shelter. In laboratory studies, investigatory behavior is often observed independent of any external rewards. See also CURIOSITY.

investment n. see CATHEXIS. —invest vb.

investment model a theory explaining commitment to a relationship in terms of one’s satisfaction with, alternatives to, and investments in the relationship. According to the model, commitment is a function of not only a comparison of the relationship to the individual’s expectations but also the quality of the best available alternative and the magnitude of the individual’s investment in the relationship; the investment of resources serves to increase commitment by increasing the costs of leaving the relationship. Although originally developed in the context of romantic associations and friendships and used to explain why people stay in abusive relationships, the investment model has since been extended to a variety of other areas, including employment and education. [proposed in 1980 by U.S. social psychologist Caryl E. Rusbult (1952–2010)]

invincibility fable see PERSONAL FABLE.

invisible displacement see OBJECT PERMANENCE.

invisible playmate see IMAGINARY COMPANION.

invisible support any kind of assistance given by one person to another person that the recipient does not notice and is generally unaware of receiving. Invisible support can involve any of the typical forms of SOCIAL SUPPORT, such as material assistance, advice, or love and esteem. Although controversial, studies show that under certain circumstances, invisible support may be more effective than visible support, likely because visible support implies personal inadequacy for dealing with the circumstances at hand and may also create indebtedness to the helper. [coined by psychologist Niall Bolger (1958– )]

in vitro referring to biological conditions or processes that occur or are made to occur outside of a living body, usually in a laboratory test tube; an example is IN VITRO FERTILIZATION. Compare EX Vivo; IN Vivo. [Latin, literally: “in glass”]

in vitro fertilization (IVF) a procedure in which an ovum (egg) is removed from a woman’s body, fertilized externally with sperm, and then returned to the uterus. It is used to treat the most difficult cases of INFERTILITY, but success rates for the procedure are not high.

in vivo 1. referring to biological conditions or processes that occur or are observed within the living organism. Compare EX Vivo; IN VITRO. 2. denoting a condition or process that approximates a real-life environment, often created for an experiment or research study. [Latin, literally: “in life”]

in vivo desensitization a technique used in BEHAVIOR THERAPY, usually to reduce or eliminate phobias, in which the client is exposed to stimuli that induce anxiety. The therapist, in discussion with the client, produces a hierarchy of anxiety-invoking events or items relating to the anxiety-producing stimulus or phobia. The client is then exposed to the actual stimuli in the hierarchy, rather than asked simply to imagine them. Success depends on the client overcoming anxiety as the events or items are encountered. Compare COVERT DESENSITIZATION. See also SYSTEMATIC DESENSITIZATION. [first developed by Mary Cover JONES]

in vivo exposure a type of EXPOSURE THERAPY, generally used for treating individuals with phobias, obsessive-compulsive disorder, and other anxiety disorders, in which the client directly experiences anxiety-provoking situations or stimuli in real-world conditions. For example, a client who fears flying could be accompanied by a therapist to the airport to simulate boarding a plane while practicing anxiety-decreasing techniques, such as deep breathing. Compare IMAGINAL EXPOSURE.

involuntary adj. describing activity, movement, behavior, or other processes (e.g., REFLEXES) that occur without intention or volition, as opposed to those that are intentionally initiated. Compare VOLUNTARY.

involuntary attention attention that is captured by a prominent or salient stimulus—for example, in the peripheral visual field—rather than deliberately applied or focused by the individual. Also called EXOGENOUS ATTENTION.
involuntary civil commitment  COMMITMENT of an individual to a mental facility against his or her wishes. For individuals to be committed in this way, it must be established in court that the individuals pose a threat to themselves or others.

involuntary hospitalization the confinement of a person with a serious mental illness to a mental hospital by medical authorization and legal direction (as in INVOLUNTARY CIVIL COMMITMENT). Individuals so hospitalized may be considered dangerous to themselves or others, may fail to recognize the severity of their illness and the need for treatment, or may be unable to have their daily living and treatment needs otherwise met in the community or to survive without medical attention. Compare VOLUNTARY ADMISSION.

involuntary muscle  see SMOOTH MUSCLE.

involuntary nervous system  a less common name for the AUTONOMIC NERVOUS SYSTEM; that is, the neural circuits and pathways involved in involuntary bodily functions.

involuntary response  a response that is not under conscious control, such as the reflex contraction of the pupils in response to bright light.

involuntary retrieval  the spontaneous retrieval of a memory into consciousness that occurs without an intention to retrieve it, in contrast to voluntary retrieval, which involves a deliberate search to retrieve a specific memory. Sometimes an AUTOBIOGRAPHICAL MEMORY is involuntarily retrieved, as in the PROUST PHENOMENON.

involuntary treatment  see FORCED TREATMENT.

involuntary turnover  the number of employees who leave an organization or unit involuntarily during a given period. A distinction is usually made between uncontrollable involuntary turnover, as by death, retirement, or reductions in the workforce, and controllable involuntary turnover, as by work-related accidents or illness or by dismissal for poor performance or disciplinary violations. A high rate of controllable involuntary turnover is almost always a sign of serious organizational problems. Compare VOLUNTARY TURNOVER. See TURNOVER.

involuntary sexual behavior  see SEXUAL ABUSE.

involutional  adj. describing the decline of the body or any of its parts from an optimal level of functioning as a result of increasing age. —involution n.

involved grandparent  the type of grandparent who has a warm, loving relationship with his or her grandchildren and takes on some of the day-to-day responsibilities for them, such as after-school care or financial assistance. Compare COMPANIONATE GRANDPARENT; REMOTE GRANDPARENT.

iodopsin  n. any one of three PHOTOPIGMENTS found in the RETINAL CONES. Each consists of 11-cis-retinal combined with one of three different OPSINS, each of which confers a different wavelength sensitivity on the iodopsin. Also called CONE OPSIN. See also RHODOPSIN.

ion  n. an atom or molecule that has acquired an electrical charge by gaining or losing one or more electrons. —ionic adj.

Ionamin  n. a trade name for PHENTERMINE.

ion channel  a group of proteins forming a channel that spans a cell membrane, allowing the passage of ions between the extracellular environment and the cytoplasm of the cell. Ion channels are selective; allow passage of ions of a particular chemical nature, size, or electrostatic charge; and may be un gated (i.e., always open) or gated, opening and closing in response to chemical, electrical, or mechanical signals (see GATED ION CHANNEL). Ion channels are important in the transmission of neural signals between neurons at a SYNAPSE. The opening of sodi um channels in the membrane of a postsynaptic neuron permits an influx of sodium ions (Na+) into the neuron, which produces an EXCITATORY POSTSYNAPTIC POTENTIAL. The opening of potassium channels or chloride channels allows potassium ions (K+) to leave the postsynaptic neuron or chloride ions (Cl–) to enter it, either of which produces an INHIBITORY POSTSYNAPTIC POTENTIAL. See also CALCIUM CHANNEL.

ionotropic receptor  a RECEPTOR protein that includes an ION CHANNEL that is opened when the receptor is activated. See GLUTAMATE RECEPTOR. Compare METABOTROPIC RECEPTOR.

ion pump 1. a protein molecule that carries out ACTIVE TRANSPORT of ions across a cell membrane. See also SODIUM PUMP. 2. a type of vacuum pump that turns gases into solids to remove them from an environment.

IOP  abbreviation for INTRAOCULAR PRESSURE.

I/O psychology  abbreviation for INDUSTRIAL AND ORGANIZATIONAL PSYCHOLOGY.

IOR  abbreviation for INHIBITION OF RETURN.

Iowa Gambling Task (IGT)  a computerized measure of decision-making abilities in which participants attempt to win as much play money as possible by selecting cards from four decks. Two of the decks yield large immediate monetary gains but long-term losses, and the other two yield small immediate gains but long-term rewards. Each deck consists of 40 cards, and participants play until they have chosen 100 cards. The IGT is used in a broad range of clinical investigations (e.g., mood disorders, pathological gambling, substance abuse) and other research activities to examine people’s EXECUTIVE FUNCTIONS via their capacity to account for the long-term implications of their choices. Also called Bechara Gambling Task. (originally developed in 1994 by neuroscientist Antoine Bechara, Portuguese-born U.S. neuroscientists Antonio R. Damasio (1944–) and Hanna B. C. Damasio, and U.S. neuropsychologist Steven W. Anderson to identify individuals with PREFRONTAL CORTEX damage)

Iowa Tests of Basic Skills (ITBS)  an ACHIEVEMENT BATTERY providing tests for reading, language, mathematics, social studies, science, and sources of information for students in kindergarten through Grade 8. It is divided into 10 skill levels (numbered 5 through 14) according to grade, with norms for the beginning, middle, and end of each academic year. The numerical label of each level reflects the approximate age of the children for which it is intended (e.g., Level 9 is administered to students in Grade 3, who are typically 9 years old). The various subtests of the ITBS are designed to measure the higher level cognitive functions considered basic to succeeding in school, such as interpretation, classification, comparison, and analysis. The ITBS, originally developed at the University of Iowa in 1935 as the Iowa Every Pupil Test of Basic Skills, was revised most recently in 2001, 2003, and 2007.
ip abbreviation for intraperitoneal.

IP abbreviation for INFORMATION PROCESSING.

IPA 1. abbreviation for INDEPENDENT PRACTICE ASSOCIA

IPD abbreviation for interaural phase differences. See BINAURAL CUE.

IPL abbreviation for INNER PLEXIFORM LAYER.

IPO model abbreviation for INPUT-PROCESS-OUTPUT MODEL.

IPPA abbreviation for INTERNATIONAL POSITIVE PSYCHOLOGY ASSOCIATION.

IPR abbreviation for INTERPERSONAL PROCESS RECALL.

iproniazid n. a MONOAMINE OXIDASE INHIBITOR developed in the 1950s for the treatment of tuberculosis and later found to have therapeutic value in the treatment of mood disorders. Iproniazid was found to elevate the mood of tuberculosis patients, and clinical trials led to its widespread use as an antidepressant. However, it has now been replaced by other less toxic antidepressant drugs.

IPSS abbreviation for INTERNATIONAL PILOT STUDY OF SCHIZOPHRENIA.

IPT abbreviation for INTERPERSONAL PSYCHOTHERAPY.

IQ intelligence quotient: a standard measure of an individual's intelligence level based on psychological tests. In the early years of intelligence testing, IQ was calculated by dividing the MENTAL AGE by the CHRONOLOGICAL AGE and multiplying by 100 to produce a ratio IQ. This concept has now mostly been replaced by the DEVIATION IQ, computed as a function of the discrepancy of an individual score from the mean (ange). The mean IQ is customarily 100, with slightly more than two thirds of all scores falling within plus or minus 15 points of the mean (usually one standard deviation). More than 95% of all scores fall between 70 (two standard deviations below the mean) and 130 (two standard deviations above the mean). Some tests yield more specific IQ scores, such as a VERBAL IQ, which measures VERBAL INTELLIGENCE, and a performance IQ, which measures NONVERBAL INTELLIGENCE. Discrepancies between the two can be used diagnostically to detect learning disabilities or specific cognitive deficiencies. Additional data are often derived from IQ tests, such as performance speed, freedom from distractibility, verbal comprehension, and PERCEPTUAL ORGANIZATION indices. There are critics who consider the concept of IQ (and other intelligence scales) to be flawed. They point out that the IQ test is more a measure of previously learned skills and knowledge than of underlying native ability and that many participants are simply not accustomed to sitting still and following orders (conditions that such tests require), although they function well in the real world. Critics also refer to cases of misrepresentation of facts in the history of IQ research. Nevertheless, these problems seem to apply to the interpretation of IQ scores rather than the validity of the scores themselves.

IRB abbreviation for INSTITUTIONAL REVIEW BOARD.

IRIDOCYCLITIS n. inflammation of the iris and ciliary body of the eye. Heterochromic iridocyclitis is a form of the disorder that results in a loss of pigment in the iris.

IRIDODYSTROPHIA n. a highly controversial method of assessing health by examining the irises of an individual's eyes. Patterns, color variations, and other characteristics of the connective tissue of the iris are thought to be related to specific body parts and indicate health, disorder, or disease. This method lacks sufficient supporting evidence and is not widely accepted among medical professionals.

Iris n. a muscular disk that surrounds the pupil of the eye and controls the amount of light entering the eye by contraction or relaxation. The stroma of the iris, which faces the cornea, contains a pigment that gives the eye its coloration; the back of the iris is lined with a dark pigment that restricts light entry to the pupil, regardless of the apparent color of the iris.

Iris coloboma a congenital defect of the iris that shows as a cleft or fissure (coloboma) extending outward from the edge of the pupil. A coloboma usually occurs in the lower
portion of the iris. The defect may be one of several signs of a chromosomal anomaly.

irkunii n. see MYRIACHET.

IRM abbreviation for INNATE RELEASING MECHANISM.

ironic mental control the phenomenon whereby the attempt to suppress unwanted thoughts results in an unexpectedly high level of awareness of them. Also called ironic monitoring process. [defined by U.S. psychologist Daniel M. Wegner (1948– )]

irradiation n. 1. exposure of the body to RADIATION, usually ionizing radiation. See RADIATION THERAPY. 2. any outward diffusion of energy. 3. an outmoded concept of Ivan PAVLOV that neural processes tend to spread across the cerebral cortex from one functional region to another. —irradiate vb.

irradiation effects the results of exposure to ionizing radiation. Examples of conditions that may be related to irradiation effects include anencephaly, microcephaly, Down syndrome, cerebral atrophy, and intellectual disability. Irradiation effects on cells of the testes appear as abnormal cell divisions within 2 hours of exposure to radioactivity.

irradiation theory of learning the theory that each stimulus activates a specific set of cells in the brain, and this activation spreads (irradiates). Two stimuli become associated when their areas of activation overlap. Irradiation was hypothesized by Ivan PAVLOV to be the neural basis for classical conditioning.

irrational adj. 1. lacking in reason or sound judgment: illogical or unreasonable. 2. lacking in usual mental clarity.

irrational belief an illogical, erroneous, or distorted idea, firmly held despite objective contradictory evidence. See NONRATIONAL. See also COGNITIVE DISTORTION. [attributed to Albert ELLIS]

irrationality n. the state, condition, or quality of lacking rational thought. The term is typically used in relation to cognitive behavior (e.g., thinking, decision making) that is illogical or delusional.

irrational type in Carl JUNG’s ANALYTIC PSYCHOLOGY, one of the two major categories of FUNCTIONAL TYPE. It comprises the INTUITIVE TYPE and the SENSATION TYPE. Compare RATIONAL TYPE.

irregular adj. in linguistics, denoting a word or a form of a word that does not follow the usual patterns of INFLECTION in a language. For example, go has the irregular past tense went (not go-ed) and sheep has the irregular plural sheep (not sheeps). Compare REGULAR.

irrelevant language a language composed of sounds, phrases, or words that are usually understood only by the speaker, as observed in some individuals with schizophrenia or autism.

irresistible impulse rule formerly, a rule commonly used in U.S. courts of law for determining INSANITY, according to which defendants were judged to be insane and therefore absolved of CRIMINAL RESPONSIBILITY if they were unable to control their conduct, even if they were aware that it was wrong. This rule is no longer used.

irreversible coma see BRAIN DEATH.

irreversible MAOI see MONOAMINE OXIDASE INHIBITOR.

irritability n. 1. a state of excessive, easily provoked anger, annoyance, or impatience. 2. in physiology, the ability of a cell or tissue to respond to stimuli (e.g., NEURAL IRRITABILITY). —irritable adj.

irritable aggression see AGGRESSION.

irritable bowel syndrome (IBS) a common functional disorder of the intestines characterized by abdominal pain or discomfort (e.g., bloating) and changes in bowel habits, with some people experiencing increased diarrhea, others increased constipation, and others alternating between the two. As yet there is no known cause (psychological or physiological), though stress and emotional factors are currently thought to play a role. Also called mucous colitis: spastic colitis.

IRT 1. abbreviation for INTERRESPONSE TIME. 2. abbreviation for ITEM RESPONSE THEORY.

ISA abbreviation for intracarotid sodium Amytal test. See WADA TEST.

ischemia n. deficiency of blood in an organ or tissue, due to functional constriction or actual obstruction of a blood vessel. See CEREBRAL ISCHEMIA. —ischemic adj.

ischemic penumbra an area of moderate tissue damage surrounding a focus of primary damage due to inadequate blood supply (see ISCHEMIA). Tissues in the penumbra may be partially preserved due to collateral (alternative) blood flow from neighboring normal areas.

Ishihara Test for Color Blindness a COLOR-BLINDNESS TEST using a series of plates (Ishihara plates) in which numbers or letters are formed by dots of a given color against a background of dots of varying degrees of brightness and saturation. A modification of the earlier STILLING COLOR VISION TEST, the Ishihara test was devised in 1916 for use by the Japanese army. It first became available commercially in late 1917 and reportedly is now the most widely used color-blindness test. [Shinobu Ishihara (1879–1963), Japanese ophthalmologist]

ISI abbreviation for INTERSTIMULUS INTERVAL.

island deafness see TONAL GAP.

island of Reil see INSULA. [Johann Reil (1759–1813), German physician]

islands of knowledge separate, small domains of highly specialized knowledge. Such organization of knowledge is typically found in such fields as medicine and psychology, where there are numerous subspecialties.

islets of Langerhans clusters of ENDOCRINE cells within the pancreas. The A (or alpha) cells secrete GLUCAGON, the B (or beta) cells secrete INSULIN, and the D (or delta) cells secrete SOMATOSTATIN. Together these hormones play a key role in regulating blood sugar and carbohydrate metabolism. [Paul Langerhans (1847–1888), German anatomist]

ISO- combining form equal or alike.

isocarboxazid n. an irreversible MONOAMINE OXIDASE INHIBITOR used as a second-line agent for treatment-resistant depression. Its use is limited by its potentially dangerous interactions with serotonergic and noradrenergic agents and with tyramine-containing foodstuffs (e.g., cheese). U.S. trade name: Marplan.

isochrony n. an observed regularity in which the components of continuous, complex movements (e.g., drawing, speaking, handwriting, typing) are often produced at equal
time intervals, even though the tasks being performed do not require this regularity. —isochnal adj. —isochnous adj.

**Isohedonic trap** the flaw in Daniel E. Berlyne’s theory of aesthetic preference (see AROUSAL POTENTIAL) that stimuli producing equal amounts of arousal should be equally preferred. Given that equal amounts of arousal can be produced by pleasing or displeasing stimuli, this cannot be the case.

**Isolate** 1. n. an individual who remains apart from others, either as a result of choosing to minimize his or her contact with others or through rejection and ostracism by other individuals or groups. For example, a person who is part of a work group but has no, very few, or very superficial social and personal relations with other group members would be an isolate. 2. n. in SOCIOMETRY, any individual who is infrequently or never mentioned when group members report whom they like in their group. In measures of peer acceptance among children, an isolate typically is called a neglected child. See Sociometric Status. 3. vb. see Isolation.

**Isolated brain** see CEREBEAL ISOLE; ENCéPHALE ISOLÉ.

**Isolated explosive disorder** an impulse-control disorder characterized by a single, discrete episode in which the individual commits a violent, catastrophic act, such as shooting strangers during a sudden fit of rage. The episode is out of all proportion to any precipitating stress, is not due to any other mental disorder or to a general medical condition, and is not substance induced. Also called cataclysmic crisis. Compare INTERMITTENT EXPLOSIVE DISORDER.

**Isolate monkey** a monkey that is separated from its mother at birth or at a very early age and raised in complete isolation.

**Isolating language** a language in which each MORPHEME is typically a separate word, as in, for example, classical (but not modern) Chinese. Compare AGGLUTINATIVE LANGUAGE; FUSIONAL LANGUAGE.

**Isolating mechanism** in evolution, a mechanism that prevents two populations from interbreeding and thus enables the populations to diverge to allow separate species to evolve. Isolating mechanisms may also prevent interbreeding between overlapping species. Geographic separation, behavioral differences, differences in physical features, and different seasons for reproduction all serve as isolating mechanisms.

**Isolation** 1. the condition of being separated, such as in SOCIAL ISOLATION. 2. in psychoanalytic theory, a defense mechanism that relies on keeping unwelcome thoughts and feelings from forming associative links with other thoughts and feelings, with the result that the unwelcome thought is rarely activated. See also COMPARTMENTALIZATION. 3. in Erikson’s Eight Stages of Psychosocial Development, see intimacy versus isolation. —isolate vb.

**Isolation effect** see DISTINCTIVENESS EFFECT.

**Isolation experiment** the removal of a nonhuman animal from social or other contact with other members of its species in order to observe behavioral or other effects.

**Isolation of affect** in psychoanalytic theory, a defense mechanism in which the individual screen out painful feelings by recalling a traumatic or painful event without experiencing the emotion associated with it.

**Isolation syndrome** see MIXED TRANSCORTICAL APHASIA.

**Isolation tank** see FLOTATION TANK.

**Isomerization** n. a change in the structural arrangement of a molecule without any change in its constituent atoms, which may alter the properties of the molecule. When photons are absorbed by the photopigment RHODOPSIN, for example, the 1-Lcis retinal component undergoes isomerization and triggers a biochemical cascade that ultimately results in a visual signal.

**Isomers** pl. n. forms of molecules that are identical in chemical composition but differ in the spatial orientation of their atoms (i.e., they are stereoisomers). Enantiomers are stereoisomers that exist in pairs as mirror images. The two enantiomers of a pair rotate the plane of polarized light in opposite directions: I forms produce leftward or counterclockwise rotation (levorotation), whereas D forms produce rightward or clockwise rotation (dextrorotation). In general, I forms tend to have biological activity.

**Isometric contraction** a type of muscle contraction in which tension develops but the muscle does not shorten, as when a weightlifter grasps a barbell. Compare ISOTONIC CONTRACTION.

**Isometric control** in ergonomics, a control device, such as a lever or handle, that incorporates a degree of resistance, so that it can be activated only by the application of a certain level of force. Compare ISOTONIC CONTROL.

**Isometric tremor** see ACTION TREMOR.

**Isomorphism** n. 1. a one-to-one structural correspondence between two or more different entities or their constituent parts. 2. the concept, especially in gestalt psychology, that there is a structural correspondence between perceptual experience and neural activity in the brain. —isomorph n. —isomorphic adj.

**Isoniazid** n. a drug of choice for the treatment of tuberculosis. Use of the drug can cause a form of neuritis by blocking the function of pyridoxine (vitamin B6) in metabolizing glutamic acid to form the neurotransmitter GAMMA-AMINOBUTYRIC ACID. Isoniazid is structurally related to a known monoamine oxidase inhibitor (MAOI), IPRONIAZID, and was reputed to have some antidepressant activity, although it is not clinically used in this role and is not an MAOI. Also called isonicotinic acid hydrazide (INH).

**Isophilia** n. feelings of affection or affectionate behavior toward members of one’s own sex, but without the genital component characteristic of same-sex sexual behavior.[first described by Harry Stack SULLIVAN]

**Isopropyl alcohol** an isomer of propyl alcohol used as a solvent, antiseptic, and cleaning fluid and as an ingredient in some cosmetics, disinfectants, and topical medications. If ingested, it has initial effects similar to those of ETHANOL, but it is extremely toxic.

**Isopto Carpine** a trade name for PILOCARPINE.

**Isopto Eserine** a trade name for PHYSOSTIGMINE.

**Isosensitivity function** see RECEIVER-OPERATING CHARACTERISTIC CURVE.

**Isotonic contraction** a type of muscle contraction in which the muscle shortens and thickens, as when a person flexes the biceps muscle. Compare ISOMETRIC CONTRACTION.

**Isotonic control** in ergonomics, a control device, such
as a button or switch, that is activated by displacement of the control from a neutral point. Isotonic controls have no resistance and their activation is not dependent on the level of force applied. Compare ISOMETRIC CONTROL.

**isotretinoin** n. an analog of vitamin A used in the treatment of severe acne that is resistant to other therapies. It is highly teratogenic (see TERAogenous) and therefore should not be used in pregnancy. More controversially, the use of isotretinoin has been linked with psychological disturbances, such as depression, psychosis, and suicide. The mechanism responsible for these side effects is unknown. U.S. trade name (among others): Accutane.

**isotropy** n. the state of being the same, especially with respect to direction or orientation, symmetry of form, or uniformity of responses in the different parts of something. Compare anISOTROPY. —isotropic adj.

**ISP** abbreviation for INDIVIDUAL SERVICE PLAN.

**ISSP** abbreviation for INTERNATIONAL SOCIETY FOR PSYCHOLOGY.

**issue-relevant knowledge** see ATTITUDE-RELEVANT KNOWLEDGE.

**I statement** a communication tool in which the first person pronoun is used in talking about relationship issues. Therapists may coach clients to use “I” instead of “you” in statements, such as “I am bothered by your habit” rather than “You have a bad habit” (which is a you statement). I statements tend to reduce the negativity and blame directed toward the other person and put the ownership of the issue with the speaker, not the listener.

**IT** 1. abbreviation for INFORMATION TECHNOLOGY. 2. abbreviation for INSPECTION TIME.

**ITA** abbreviation for INITIAL TEACHING ALPHABET.

**ITBS** abbreviation for IOWA TESTS OF BASIC SKILLS.

**itch** n. a cutaneous sensory experience related to pain. The associated nerve endings are the same as those sensitive to the prick-pain sensation (see PRICK EXPERIENCE). A rapidly repeated prick-pain sensation produces the itch reaction.

**IT cortex** abbreviation for INFEROtemporal CORTEX.

**ITD** abbreviation for intertemporal time differences. See BINaural CUE.

**item analysis** a set of procedures used to evaluate the statistical merits of individual items comprising a psychological measure or test. These procedures may be used to select items for a test from a larger pool of initial items or to evaluate items on an established test. A variety of different statistics may be computed in item analyses, including difficulty values, INDEXES OF DISCRIMINATION, INTERITEM CORRELATIONS, and ITEM DISCRIMINABILITIES.

**item characteristic curve (ICC)** a plot of the probability that a test item is answered correctly against the examinee’s underlying ability on the trait being measured. The item characteristic curve is the basic building block of ITEM RESPONSE THEORY. The curve is bounded between 0 and 1, is monotonically increasing, and is commonly assumed to take the shape of a LOGISTIC FUNCTION. Each item in a test has its own item characteristic curve.

**item discriminability** a statistical measure of how well an item on a test differentiates among subgroups of test takers, typically those individuals who possess a high degree of some ability versus those who possess a low degree of the ability. Item discriminabilities typically are given as CORRELATION COEFFICIENTS ranging from −1 to +1 in value, with the latter indicating a perfect discriminator. INTERITEM CORRELATIONS also may be used in determining item discriminability. See ITEM ANALYSIS.

**item response theory (IRT)** a psychometric theory of measurement based on the concept that the probability that an item will be answered correctly is a function of an underlying trait or ability that is not directly observable; that is, a latent trait (see LATENT TRAIT THEORY). Item response theory models differ in terms of the number of parameters included in the model. For example, the RASCH MODEL is based on the single parameter of item difficulty, whereas other models additionally examine ITEM DISCRIMINABILITY and the chances of successful guessing. Compare CLASSICAL TEST THEORY. [developed in the 1950s by Frederick M. LORD]

**item scaling** the assignment of a test item to a scale position on some dimension, often that of item difficulty.

**item validity** the extent to which an individual item in a test or experiment measures what it purports to measure.

**iterated bootstrapping** a BOOTSTRAPPING procedure in which samples are randomly drawn (with replacement) from an observed data set. Values for different population characteristics are estimated, and the estimates averaged across the set of samples. Then, the samples created during this initial procedure are themselves sampled and their PARAMETERS estimated and averaged. The resampling and recalculating process continues until a stable parameter estimate is obtained. Iterated bootstrapping usually is less prone to error than is the use of a single set of bootstrapping samples.

**iteration** n. the repetition of a certain computational step until further repetition no longer changes the outcome or until the repetition meets some other predefined criterion.

**iterative design** in ergonomics, the practice of using results from prior testing or formative evaluation to make design changes during the DEVELOPMENT CYCLE of a new or improved product. The process of iteration continuously feeds previous results into the next design of the product, which is tested or evaluated in its turn, leading to further design changes, and so on.

**I–Thou** adj. denoting a relationship in which a subject (“I”) treats someone or something else as another unique subject (“Thou”). German Jewish philosopher Martin Buber (1878–1965), who introduced the term, held that the I–Thou relationship allows for full empathy between subjects that can be transformative, in contrast to the I–IT relationship, which objectifies the other. Buber also held that a person’s relationship with God is the ultimate I–Thou relationship, because God is quintessentially Thou. In forms of EXISTENTIAL–HUMANISTIC THERAPY especially, I–Thou moments are prized and denote a significant contact and understanding between client and therapist.

**itinerancy** n. see PEREGRINATION.

**itinerant teacher** a teacher who travels to several schools or classrooms, providing specialized instruction to children.
ITPA

ITPA abbreviation for ILLINOIS TEST OF PSYCHOLINGUISTIC ABILITIES.

IUD abbreviation for INTRAUTERINE DEVICE.

IUPsyS abbreviation for INTERNATIONAL UNION OF PSYCHOLOGICAL SCIENCE.

iv abbreviation for intravenous. See INTRAVENOUS INJECTION.

IV abbreviation for INDEPENDENT VARIABLE.

IVF abbreviation for IN VITRO FERTILIZATION.
jabberwocky n. meaningless but grammatically correct writing or speech. [from a nonsense poem in Through the Looking Glass (1871) by British writer Lewis Carroll (1832–1898)]

jackknife n. a statistical procedure used to estimate the variability of a parameter associated with a set of data, such as the standard error or confidence interval. It is particularly appropriate when the variance or underlying distribution is not known. A number of samples are obtained from the original data by eliminating one or more observations at a time, the parameter in question is calculated for each sample, and the individual parameters are combined to provide an estimate of the overall parameter for the entire data set. A jackknife is similar to bootstrapping, except that bootstrapping involves replacing observations after they have been sampled, such that after each observation is chosen it is reinserted into the data for possible selection again.

jacksonian march in a simple partial seizure involving motor symptoms, an older name for clonic motor movements in one region or side of the body that start in one muscle group and then move systematically (“march”) to adjacent motor groups. [John Hughlings Jackson]

Jackson's law the principle that when cognitive deterioration results from neurological disease, the higher and more recently developed functions are lost first. [John Hughlings Jackson]

Jacobson relaxation method see progressive relaxation.

Jacobson's organ see Vomeronasal System. [Ludvig Levin Jacobson (1835–1911), Danish anatomist]

jactatio capitis nocturnis see head rolling.

jactitation n. extreme restlessness marked by frequent movements and tossing about. Also called jactation.

Jakob–Creutzfeldt disease see Creutzfeldt–Jakob disease.

James–Lange theory the theory that different feeling states stem from the feedback from the viscera and voluntary musculature to the brain. This theory hypothesizes that there are as many physiological responses as there are different intrapsychic feelings and that each of these responses precedes rather than follows the feeling. [William James: Carl Georg Lange (1834–1900), Danish physiologist]

Janet’s test a test of tactile sensibility in which participants simply answer yes or no when asked if they feel the touch of the examiner’s fingers. [Pierre Janet]

Janis–Feyerabend hypothesis the notion that persuasive discourse will be more effective if one first refutes positive arguments on the other side of a question before answering negative attacks on one’s own side. [Irving L. Janis; Paul Karl Feyerabend (1924–1994), Austrian-born U.S. philosopher]

jargon n. 1. specialized words and forms of language used within a particular profession or field of activity. Although jargon is often unavoidable when dealing with technical or specialist subjects, inappropriate or unnecessary use can alienate outsiders, who find it unintelligible. 2. in prelinguistic children, babbling that sounds like plausible speech but is incomprehensible.

jargon aphasia 1. a form of fluent aphasia in which speech is completely meaningless to the listener, whether by violating the rules of syntax and grammar, using the wrong content words (e.g., nouns and verbs), using distorted or invented words (neologic jargon), or overusing imprecise words (e.g., it, thing) or grammatical words such as articles and prepositions. 2. see word salad.

JAS abbreviation for Jenkins Activity Survey.

jaundice n. a condition associated with a variety of disorders of the liver, gallbladder, and blood and marked by the deposition of bile pigments in the skin, eye surfaces, and excrement. The pigment, which is usually first observed in discoloration of the normally white areas of the eyes, is produced as bilirubin, a breakdown product of the hemoglobin of red blood cells. Jaundice is associated with liver infections but may also occur as an adverse reaction to certain drugs. It is also a causative factor in neurological birth defects (see kernicterus). Also called icterus.

jaw jerk a reflex test used in the diagnosis of lesions of the corticospinal tract: The examiner taps downward on a person’s lower jaw while it hangs open; if the lesion is present, the jaw closes reflexively. Also called chin reflex; jaw reflex; mandibular reflex; masseter reflex.

JCAHO abbreviation for Joint Commission on Accreditation of Healthcare Organizations. See joint commission.

J curve a pattern on a graph that resembles the letter J: There is an initial drop in value for a short period of time followed by a continuous increase. For example, a high achieving person training for a difficult job might show a J curve for performance—his or her performance initially might drop below that of other employees, while he or she learns difficult skills, but rapidly increase to excellence after the required job skills are fully attained. Also called J-shaped distribution.

J–curve hypothesis the predicted shape of the distribution of responses in conformity settings, which reflects the fact that most individuals conform to the prescribed norm or act in ways that only slightly deviate from the norm, and few individuals exhibit substantial deviation from the norm. A classic illustration is that of drivers at a stoplight: Most respond by stopping fully; some sharply or moderately reduce speed, and a few do not change speed at all. When graphed, the number of people displaying these different reactions approximates the shape of a letter J. [first proposed in 1934 by Floyd H. Allport]

JDI abbreviation for job descriptive index.

JDS abbreviation for job diagnostic survey.

jealousy n. a negative emotion in which an individual resents a third party for appearing to take away (or being
likely to take away) the affections of a loved one. Jealousy requires a triangle of social relationships between three individuals: the one who is jealous, the partner with whom the jealous individual has or desires a relationship, and the rival who represents a preemptive threat to that relationship. Romantic relationships are the prototypic source of jealousy, but any significant relationship (with parents, friends, etc.) is capable of producing it. It differs from envy in that three people are always involved. See also DELUSIONAL JEALOUSY. —jealous adj.

Jehovah complex a form of MEGALOMANIA in which the individual experiences delusions of grandeur and identifies with qualities associated with God.

Jellinek’s alcoholism species a categorization of types (or “species”) of alcoholism defined in 1960 by U.S. physiologist Elvin M. Jellinek (1890–1963). Alpha alcoholism is characterized by undisciplined drinking that disturbs the person’s interpersonal and family relationships and work life, with a reliance on the effects of alcohol to relieve physical or emotional pain, but without a loss of control or an inability to abstain. Beta alcoholism is characterized by serious medical complications (e.g., liver damage, gastritis, nutritional deficiency) associated with undisciplined drinking but does not involve physical or psychological dependence. Gamma alcoholism is characterized by physical and psychological dependence, tolerance, complete loss of control over drinking, and withdrawal symptoms if use is suspended. Jellinek considered this type to be the predominant form of alcoholism in the United States. Delta alcoholism is similar to gamma alcoholism but is distinguished by the person’s inability to abstain, as opposed to complete loss of control over drinking. Epsilon alcoholism is characterized by periodic drinking episodes or binges interspersed with dry periods lasting weeks or months.

Jenkins Activity Survey (JAS) a self-administered, multiple-choice survey that attempts to duplicate the clinical assessment of the Type A behavior pattern (see TYPE A PERSONALITY) by means of an objective psychometric procedure. It measures characteristics of this behavior pattern, such as extreme competitiveness, striving for achievement and personal recognition, aggressive, haste, impatience, and explosiveness. [Carlyle David Jenkins (1928– ), U.S. psychologist]

Jensenism n. the controversial theory that racial differences in IQ are at least partly heritable and that attempts to raise IQ through environmental interventions have been largely unsuccessful. [Arthur R. Jensen]

Jet lag a maladjustment of CIRCADIAN RHYTHMS that results from traveling through several time zones in a short span of time. Rest, work, eating, body temperature, and adrenocortical-secretion cycles may require several days to adjust to local time. See also CIRCADIAN RHYTHM SLEEP DISORDER.

Jiggle cage in experimental research, a box mounted on springs that records small oscillations caused by the enclosed animal.

Jigsaw method a team-learning technique initially designed to foster a cooperative learning environment that reduces prejudice and social isolation and improves academic achievement. Students work in groups on a content unit. The teacher assigns specific topics in the unit to each group member and allows students with the same topics to leave their group to study the topic with others who have that same assignment. The students then return to their original groups and teach their topics to the other members. Also called jig saw classroom. [developed in the 1970s by U.S. experimental social psychologist Elliot Aronson (1932– ) and his colleagues]

Jimsonweed n. a poisonous annual weed, Datura stramonium, of the nightshade family that grows wild in temperate and subtropical areas of the world and contains several potent anticholinergic agents, including the alkaloids SCopolamine and Atropine. It has been taken in small doses to treat asthma, whooping cough, muscle spasms, and other conditions and has also been applied externally for pain relief. Poisoning results in symptoms such as hyperthermia, flushing, dry mucous membranes, nausea and vomiting, rapid heartbeat, visual disturbances, hallucinations, delirium, coma, and potentially death; there is often amnesia for the period of intoxication. The name is a corruption of “Jamestown weed,” the name given to the plant by early settlers of Virginia. Also called devil’s trumpet.

Jinjina bemar see Koro.

Jiryan n. a CULTURE-BOUND SYNDROME found in India, with symptoms similar to those of SHEN-K’UEI.

Jittering n. deliberately adding a small amount of random noise to each observation in a SCATTERPLOT when the variables take on relatively few values, resulting in data points that stack on top of each other and thus are hard to interpret. Primarily a data visualization technique, jittering helps separate the points and make it easier to discern a pattern or relationship.

JLO abbreviation for JUDGMENT OF LINE ORIENTATION.

JND (just noticeable difference) abbreviation for just noticeable difference. See DIFFERENCE THRESHOLD.

Job analysis the collection and analysis of information about a specific job. Data are obtained through interviews with or written questionnaires from those doing or supervising the job, or through observation or audiovisual recordings of the job in action. Important classes of information include the behaviors, tools, working conditions and has also been applied externally for pain relief. Poisoning results in symptoms such as hyperthermia, flushing, dry mucous membranes, nausea and vomiting, rapid heartbeat, visual disturbances, hallucinations, delirium, coma, and potentially death; there is often amnesia for the period of intoxication. The name is a corruption of “Jamestown weed,” the name given to the plant by early settlers of Virginia. Also called devil’s trumpet.

Job-characteristics model a model that attempts to characterize the basic parameters of a job as they affect the psychological state of the employee, especially with regard to motivation. The five core job dimensions are identified as skill variety, TASK IDENTITY, TASK SIGNIFICANCE, autonomy, and feedback. The model holds that WORK MOTIVATION, job performance, and job satisfaction will all be improved if jobs are designed or redesigned to maximize these dimensions. See JOB DIAGNOSTIC SURVEY. See also JOB ENRICHMENT; JOB ENRICHMENT, [proposed by J. Richard Hackman and U.S. organizational behaviorist Greg R. Oldham (1947– )]

Job-component method a JOB-EVALUATION technique based on the assumption that similarities in job content impose similar demands on the employees and therefore warrant corresponding pay scales. The job-component method is often applied through a statistical analysis of data obtained from a POSITION ANALYSIS QUESTIONNAIRE.
job-component validity a SYNTHETIC VALIDITY method of estimating the ability of a test battery to predict suitability for a particular job that involves use of the POSITION ANALYSIS QUESTIONNAIRE.

job criterion the standard used to evaluate employees on a specific dimension of performance in a job. The criterion usually consists of a supervisor’s rating of employee performance, but objective measures, such as quantity of productivity or absence rate, may also be used. See CUTOFF SCORE; CRITERION DATA; CRITERION DIMENSIONS. See also EMPLOYEE EVALUATION; JOB PERFORMANCE.

job description a formal description of a specific job, as supplied by an organization’s HUMAN RESOURCES department to those holding or applying for the position. Although formats vary, a job description usually comprises three main elements: (a) identification information, including job title, location, and reporting structure (i.e., relations to superiors and subordinates); (b) a brief statement summarizing the purpose of the job; and (c) a more detailed description of JOB DIMENSIONS or of specific duties and responsibilities. The job description is usually compiled through a systematic process of JOB ANALYSIS and can be used in turn as the basis for a PERSONNEL SPECIFICATION describing the attributes required to perform the job effectively. Also called job profile.

Job Diagnostic Index (JDI) a 72-item JOB SATISFACTION scale used to measure the attitudes of employees in areas such as work, supervision, pay, promotions, and coworkers. Each item is an adjective or short phrase (e.g., “boring,” “good opportunities for promotion”), and the participant writes Y (yes), N (no), or R (cannot decide) to indicate whether the item applies to his or her job. Originally published in 1969, the JDI has undergone three major revisions, most recently in 2009. [developed by Patricia Cain Smith, Canadian psychologist Lorne M. Kendall (1933–1977), and U.S. organizational psychologist Charles L. Hulin (1936–)].

job design specification of the content (responsibilities and duties) of a given job with the goal of maximizing both job satisfaction and ORGANIZATIONAL EFFECTIVENESS. See also JOB REDESIGN.

Job Diagnostic Survey (JDS) a measure of the motivational components of a job, as identified by the JOB-CHARACTERISTICS MODEL of J. Richard Hackman and U.S. organizational behaviorist Greg R. Oldham (1947– ). The JDS is a self-report instrument in which employees’ answers are used to score a job in terms of five core dimensions that are held to determine employee motivation (skill variety, TASK IDENTITY, TASK SIGNIFICANCE, autonomy, and FEEDBACK). If scores are low, a program of JOB ENLARGEMENT or JOB ENRICHMENT may be recommended.

job dimensions 1. the general categories of tasks or duties that define the nature of a particular job, such as clerical duties, receptionist duties, or decision-making responsibilities. In compiling job descriptions, it is customary to define the key dimensions of a job instead of providing an exhaustive list of all the tasks that will be required. 2. general areas of competence, personality traits, or attitudes that are thought to be essential to the performance of a job, such as ambition, attention to detail, or interpersonal skills. These attributes may be included in PERSONNEL SPECIFICATIONS in addition to more specific skills and qualifications, such as directly related work experience or fluency in a particular language. 3. see JOB-CHARACTERISTICS MODEL.

job enlargement the expansion of the responsibilities associated with a particular job. In horizontal job enlargement (or horizontal loading), the employee is required to perform a greater number and variety of subtasks of the same level of complexity as his or her existing duties; in vertical job enlargement (or vertical loading), he or she is required to perform more complex tasks and to assume increased responsibility and autonomy.

job enrichment the enhancement of employees’ interest in and attitude toward work tasks by improving their quality of life on the job (see QUALITY OF WORKLIFE). Job enrichment methods include (a) reducing boredom by giving employees a variety of different tasks and (b) allowing employees to plan their own work activities.

job evaluation analysis and comparison of jobs for the purpose of determining the pay structure within an organization. Methods used in job evaluation include (a) ranking jobs on the basis of a subjective estimation of their relative overall value to the company (see RANKING METHOD); (b) assigning jobs to certain predefined classifications on the basis of job description (see CLASSIFICATION METHOD); (c) comparing jobs to certain identified BENCHMARK JOBS in terms of the COMPENSABLE JOB FACTORS entailed; (d) assigning point values to jobs according to a series of defined criteria such as education, experience, and the initiative or effort needed (see POINT METHOD); and (e) ranking jobs according to a statistical analysis of job content, as revealed by employees’ answers to a standard questionnaire (see JOB-COMPONENT METHOD).

job interview see EMPLOYMENT INTERVIEW.

job involvement the degree to which a person psychologically identifies with his or her job. A person who has a high level of job involvement usually obtains major LIFE SATISFACTION from the job. Job accomplishments lead to a strong sense of pride and self-esteem, whereas failures in the job lead to discontent and depression. See also JOB SATISFACTION.

job performance effectiveness of job-related behavior as measured against a specific criterion of success, such as quantity or quality of output, or against multiple CRITERION DIMENSIONS. See EMPLOYEE EVALUATION; JOB CRITERION; PERFORMANCE REVIEW.

job placement in organizations, the assignment of existing or newly hired employees to the particular jobs for which they are best qualified. Also called personnel placement; selective placement.

job-placement stage a level of rehabilitation and work-preparedness training at which a person with a disability is presumed to be ready to move into the competitive job market. Rehabilitation personnel may assist individuals with tasks such as filling out job applications and preparing for job interviews (see PLACEMENT COUNSELING).

job preview information provided to people applying for a position about what they can expect if they are hired to perform the job. A realistic job preview (RJP) will provide both positive and negative information in an attempt to avoid disillusionment and increase the JOB TENURE of those hired.

job redesign systematic efforts to improve work methods, equipment, and the working environment. Major ap-
Job requirements

approaches to job redesign include METHODS ANALYSIS, which focuses on the development of efficient work methods; HUMAN FACTORS ENGINEERING, which is primarily concerned with the design of equipment, facilities, and environments; and job enlargement or job enrichment, which aim to expand the variety, complexity, and responsibility of jobs.

**Job requirements** the personal qualities or skills that are necessary for performing work tasks safely and effectively. Job requirements may include, for example, good verbal communication skills, the ability to drive a truck, or the ability to perform complex mathematical calculations. They are normally identified in the PERSONNEL SPECIFICATION for a job.

**Job rotation** an employment practice in which workers are required to perform different duties on a regularly scheduled basis, usually as a means of increasing their motivation and developing their skills.

**Job-safety analysis** a specialized form of TASK ANALYSIS used to identify and control operating hazards in the workplace. It involves defining the job, identifying required tasks, identifying hazards, and making recommendations to eliminate or control the hazards. Also called job-hazard analysis. See also ACCIDENT ANALYSIS; ACCIDENT-DATA MODE; FAILURE MODES AND EFFECTS ANALYSIS; FAULT TREE ANALYSIS.

**Job satisfaction** the attitude of a worker toward his or her job, often expressed as a hedonic response of liking or disliking the work itself, the rewards (pay, promotions, recognition), or the context (working conditions, colleagues). See also JOB INVOLVEMENT.

**Job sharing** a flexible work option in which two people voluntarily share a single full-time position and are compensated according to the proportion of work each performs. Job sharing schedules can take the form of half-days, alternate days, or alternate weeks but generally have minimal overlap of individual work schedules.

**Job specification** see PERSONNEL SPECIFICATION.

**Job tenure** the length of time an employee spends in a position. See TURNOVER. 2. in certain professions, such as academia, a guarantee of lifelong employment. Also called tenure.

**Jocasta complex** in psychoanalytic theory, an abnormally close or incestuous attachment of a mother to her son. It is named for Jocasta, the mother and wife of Oedipus in Greek mythology. Compare OEDIPUS COMPLEX.

**Johari window** a model used to evaluate the extent of open and authentic communication between individuals. It is an imaginary window with four panes that each represent a dimension of knowledge about a person: (a) The open pane contains information about the person that is known both to the person and to others, (b) the blind pane contains information about the person that is known only to the person, (c) the hidden pane contains information about the person that is known only to others, and (d) the unknown pane contains information about the person that is known neither to the person nor to others. The goal is to increase the amount of information about the self that is known both to the self and to others. [devised in the 1950s by U.S. psychologist Joseph Luft and U.S. psychiatrist Harrington V. Ingham]

**John Henry effect** an effect in which rivalry between a control group and an experimental group leads to competitive efforts that disturb the whole basis of the experiment. It is a particular danger in industrial psychology experiments that attempt to compare the outputs of groups working under different task conditions. The term derives from the legend of John Henry, a railroad steel driver who worked himself to death with a steam drill.

**Johnson v. Louisiana** a case resulting in an influential 1972 U.S. Supreme Court decision establishing that there is no constitutional requirement that juries be unanimous in their verdict for crimes that are not punishable by death. The court concluded that peremptory strikes by a majority verdict does not violate DUE PROCESS rights.

**Joint attention** attention overtly focused by two or more people on the same object, person, or action at the same time, with each being aware of the other’s interest. Joint attention is an important developmental tool. Around 9 months of age infants can follow their parents’ gaze and begin to imitate what their parents do. By thus focusing attention on an object as well as on the adult’s reaction to it, children can learn about the world. This technique is also used in primate studies (see ENCUULTURATION). Also called shared attention.

**Joint Commission** a national, private, nonprofit organization, founded in 1951, whose purpose is to encourage the attainment of uniformly high standards of institutional medical care. Formerly known as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), it changed to its present name in 2007. The Joint Commission evaluates and accredits hospitals and health care organizations that provide MANAGED CARE (including HMOs, PPOs, and INTEGRATED DELIVERY SYSTEMS), HOME CARE, long-term care, behavioral health care, laboratory services, and ambulatory care services.

**Joint distribution** the pattern of values obtained when estimating the probability of occurrence of two or more RANDOM VARIABLES. For example, the probability values for drawing a heart and a jack in a deck of cards would form the following joint distribution: (13/52) × (4/52) to obtain a heart but not a jack; (39/52) × (4/52) to obtain a nonheart and a nonjack; (39/52) × (4/52) to obtain a nonheart and a jack; and (13/52) × (4/52) to obtain a heart that is also a jack. A joint distribution for two variables is referred to more specifically as a BIVARIATE DISTRIBUTION, whereas a joint distribution for more than two variables is called a MULTIVARIATE DISTRIBUTION.

**Joint probability** the chance that two events will occur simultaneously. For example, the joint probability of drawing a heart that is a jack from a deck of 52 cards is equal to (13/52) × (4/52), or 1/52. See also JOINT DISTRIBUTION.

**joke n.** a story or remark that is intended to provoke laughter. See HUMOR; INCONGRUITY THEORY OF HUMOR.

**joking mania** see WITZELSUCHT.

**JOL** abbreviation for JUDGMENT OF LEARNING.

**Jonah complex** in the humanistic psychology of Abraham MASLOW, inhibition of becoming fully self-actualized—that is, of fulfilling one’s potential—for fear of facing new challenges and situations. It is named for the biblical prophet Jonah, who attempted to evade the mission imposed on him by God. See also FEAR OF SUCCESS.

**Jost’s law** the principle that the newer of two ASSOCIATIONS of equal strength will show more loss over time than will the older association. [Adolph Jost (1874–1920), German psychologist]
judiciousness n. in the theory of French psychoanalyst Jacques Lacan (1901–1981), enjoyment or pleasure that goes beyond mere satisfaction of an INSTINCT. Such pleasure is seen as a subversive and destabilizing force. The term was later adopted by literary and philosophical critics in the traditions of DECONSTRUCTION and POSTSTRUCTURALISM. [French, literally: “enjoyment,” “pleasure”]

joy n. a feeling of extreme gladness, delight, or exultation of the spirit arising from a sense of well-being or satisfaction. The feeling of joy may take two forms: passive and active. Passive joy involves tranquility and a feeling of contentment with things as they are. Active joy involves a desire to share one’s feelings with others. It is associated with more engagement of the environment than is passive joy. The distinction between passive and active joy may be related to the intensity of the emotion, with active joy representing the more intense form. Both forms of joy are associated with an increase in energy and feelings of confidence and self-esteem.

J-shaped distribution see | CURVE.

judge-made law see COMMON LAW.

judgment n. 1. the capacity to recognize relationships, draw conclusions from evidence, and make critical evaluations of events and people. 2. in psychophysics, the ability to determine the presence or relative magnitude of stimuli.

judgment of learning (JOL) a METAMEMORY assessment of the extent to which to-be-learned information has been acquired. JOLs can be based on several different sources of information, including intrinsic cues (i.e., information from the to-be-learned material) and mnemonic cues (i.e., information based on performance during a learning task). See also EASE-OF-LEARNING JUDGMENT; RETROSPECTIVE CONFIDENCE JUDGMENT; UNDERCONFIDENCE-WITH-PRACTICE EFFECT.

Judgment of Line Orientation (JLO) a neuropsychological test that assesses visual perception of angular relationships and is sensitive to dysfunction of the right hemisphere of the brain. The task is to visually match two angled lines, which appear on top of each page of a spiral-bound book, to 11 numbered and angled lines forming a semicircle on the bottom of each page. The test has two versions, consisting of the same 30 items presented in different order. The score is the number of items with correct judgments for both lines and can range from 0 to 30. [developed in the 1970s by Arthur L. BENTON]

judgment sampling selecting a group from which to gather data on the basis of personal opinion as to what is representative of the population under study. For example, judgment sampling could involve choosing a number of well-informed people from different social groups and asking them who they believe will be the next U.S. president. The outcome from such a study may well not be consistent with the result of asking a random sample from the population. This means that although judgment sampling may be useful in a PILOT STUDY, it generally does not result in warranted inference to any population of interest. See DELIBERATE SAMPLING.

juke n. pseudonym of a family in New York, seven generations of which were studied by U.S. social scientist Richard Lewis Dugdale (1841–1883), with findings reported in 1877. He claimed that the study showed relationships between prostitution and illegitimacy, resulting in neglected offspring, and between exhaustion and alcohol consumption, resulting in criminality and inability to make sound judgments. This study, which drew from and contributed to SOCIAL DARWINISM, stimulated many further studies throughout the early 20th century. These later studies erroneously claimed to identify linkages between immorality and intellectual deficits and ignored conclusions by Dugdale that environmental factors were significant.

jumping Frenchmen of Maine syndrome a CULTURE-BOUND SYNDROME resembling LATAH, observed in lumberjacks of French Canadian descent living in Quebec and Maine. It is characterized by an extreme STARTLE RESPONSE involving yelling, imitative speech and behavior, involuntary jumping, flinging of the arms, and command obedience. Also called jumper disease of Maine: jumping disease. See also IMU: MYRACHT.

jumping stand a type of apparatus formerly used to study DISCRIMINATIONS. Rats were placed on a stand and had to obtain food by jumping through doors on a platform some distance away. Usually two doors were present, each displaying a distinctive stimulus. Jumping through one door (designated as correct) led to food. Jumping toward the other door, which was locked, led to a fall into a net. The apparatus has been abandoned because too many variables were left uncontrolled.

juncture n. a set of phonological features (usually a combination of PAUSE and STRESS) that signals the boundary between words or word elements, so that, for example, a nice cream van can be distinguished from an ice cream van.

Jungian psychology the psychoanalytical theory and approach to psychotherapy of Carl JUNG. See ANALYTIC PSYCHOLOGY.

Jungian typology a theory of personality that classifies individuals into types according to (a) attitudes of INTROVERSION and EXTRAVERSION (see ATTITUINAL TYPES) and (b) the dominant functions of the psyche (see FUNCTIONAL TYPES). [Carl JUNG]

junkie n. slang for a drug addict, especially a heroin addict.

junk science invalid or fraudulent research findings, especially when admitted into court. Junk science is a cause of concern because judges, attorneys, and juries often lack the scientific training to identify unsound research.

jurisprudential teaching model a teaching model that emphasizes the role of social interaction and uses case studies as a paradigm for information processing and evaluating social issues.

jury consultant see TRIAL CONSULTANT.

jury nullification a jury’s decision to exonerate a defendant who has clearly committed a criminal act. This can occur when the members of the jury believe that to find the defendant guilty would be unfair or unjust or would demand a sentence (e.g., death penalty) with which the jurors do not wish to be associated.

jury pool see VENIRE.

justice n. the impartial and fair settlement of conflict and differences, typically by legal process and the imposition of proportionate punishment. See also COMMONSENSE JUSTICE; PROCEDURAL JUSTICE; RESTORATIVE JUSTICE.

justification n. 1. in ethics, the process of determining right actions and appropriate beliefs. 2. in clinical psychology, defensive intellectualization, as in making an excuse
just noticeable difference

for an action, cognition, or affect that one knows to be or is considered to be wrong or indefensible. 3. in epistemology, a concept of intellectual responsibility regarding the norms of belief about ideas, actions, emotions, claims, theories, and so forth.

just noticeable difference (JND; jnd) see DIFFERENCE THRESHOLD.

just-noticeable-differences method see METHOD OF JUST NOTICEABLE DIFFERENCES.

just noticeable duration the duration for a comparison stimulus that is just perceptibly shorter or longer than the duration of a standard stimulus. Also called least perceptible duration.

just-world hypothesis the idea that the world is a fair and orderly place where what happens to people generally is what they deserve. In other words, bad things happen to bad people, and good things happen to good people. This view enables an individual to confront his or her physical and social environments as though they were stable and predictable but may, for example, result in the belief that the innocent victim of an accident or attack must somehow be responsible for or deserve it. Also called belief in a just world; just-world bias; just-world phenomenon. [postulated by Canadian psychologist Melvin J. Lerner (1929– )]

juvenile delinquency illegal behavior by a minor (usually identified as a person younger than 18 years) that would be considered criminal in an adult. Examples are vandalism, theft, rape, arson, and aggravated assault.

juvenile justice system the courts and other government entities involved in the ADJUDICATION of cases involving minors (usually identified as individuals younger than 18 years). Fundamentally, it differs from the criminal justice system for adults in its belief that young people are more amenable to treatment than adults. Consequently, there is greater emphasis on rehabilitation, and greater efforts are made than in the adult system to reduce the stigmatization associated with being labeled a criminal.

juvenile-onset diabetes (juvenile diabetes) see DIABETES MELLITUS.

juvenile period the period when an animal is no longer dependent on its parents for survival but is not yet sexually active. In nonhuman mammals, this constitutes the time between the cessation of weaning (the end of infancy) and the onset of sexual activity.

juvenile transfer hearing a formal presentation and assessment of facts during which the court decides whether a minor should be transferred to an adult court for ADJUDICATION.

juvenilism n. a sexual attraction to children or adolescents. See EPHEBOPHILIA; PEDOPHILIA.
k 1. symbol for COEFFICIENT OF ALIENATION. 2. symbol for the number of individuals, groups, or other units in a statistical analysis.

K2 n. see SPICE.

KABC abbreviation for KAUFMAN ASSESSMENT BATTERY FOR CHILDREN.

KAE abbreviation for KINESTHETIC AFTEREFFECT.

KAI abbreviation for KIRTON ADAPTION–INNOVATION INVENTORY.

Kainic acid a neuroexcitatory compound derived from the red seaweed *Digenea simplex*. It is commonly used in research to destroy brain tissue in experimental animals.

kairos n. in EXISTENTIAL PSYCHOLOGY, the moment of heightened awareness at which a person gains INSIGHT into the meaning of an important event. See also AHA EXPERIENCE; EPIPHANY. [from Greek, “fitness, opportunity, time”]

KAIT abbreviation for KAUFMAN ADOLESCENT AND ADULT INTELLIGENCE TEST.

Kalischer syndrome see STURGE–WEBER SYNDROME.

Kallikak n. pseudonym of a family, studied by Henry Herbert GODDARD in the early 1900s, that was purported to have one branch characterized as moral, upstanding, and productive and another as immoral, degenerate, and “leebleminded.” The study was claimed at the time to provide evidence of inheritance of moral traits and risk of moral degeneracy due to mental illness or disability. Goddard used these findings to support EUGENICS practices but later disavowed the argument that there was a linkage between morality and intellectual disability. Moreover, subsequent reviews of the study have called into question the findings it put forth; the most recent of these suggests that dietary deficiencies and fetal alcohol syndrome were likely sources identified in the study.

Kallmann’s syndrome a hereditary disorder characterized by HYPOGONADISM (sometimes in the form of underdeveloped male sexual organs), intellectual disability, color blindness, complete ANOSMIA (absence of the sense of smell), and MOTOR OVERFLOW. Kallmann’s syndrome is transmitted as an X-linked dominant trait. [Franz Josef Kallmann (1894–1965), German-born U.S. psychiatrist and geneticist]

Kamin effect a phenomenon of STIMULUS CONTROL in which previous learning restricts or prevents conditioning of a response to a new stimulus. For example, a light paired with an unconditioned stimulus for several trials results in some conditioning for the light. Adding a tone at this point, to form a COMPOUND STIMULUS, would result in the tone being less effective as an elicitor than it would if it had been present from the beginning. Also called Kamin blocking effect. [Leon J. Kamin (1927–), U.S. psychologist]

Kangaroo care an alternative to incubator care in which premature infants in stable medical condition are placed naked between their mother’s breasts for extended periods of time, allowing their body temperature to be regulated by their mother’s body heat.

Kanizsa figure any one of several figures that induce the perception of illusory contours defining a shape that appears to be brighter than the background. The most common example is the Kanizsa triangle, which is induced by three black circles placed as the apexes of a triangle. Each circle has a 60° wedge removed so that these wedges become the angles of the illusory triangle. Even though nothing connects the circles, a strong impression of a triangle that is brighter than the background is perceived. [Gaetano Kanizsa (1913–1993), Italian psychologist]

Kanner’s syndrome see AUTISM. [Leo Kanner (1894–1981), Austrian-born U.S. child psychiatrist]

Kansas v. Hendricks a case resulting in a controversial 1997 U.S. Supreme Court decision that upheld the INVOLUNTARY CIVIL COMMITMENT of an offender after he had already completed his sentence for a sex crime. The court ruled that laws permitting the confinement of sex offenders in mental hospitals after they have served their criminal sentences are not unconstitutional if the offender remains a threat.

Kansei engineering an engineering and design practice that elicits and analyzes users’ subjective feelings about aspects of a product or range of products and incorporates these findings into subsequent designs. Also called affective engineering; emotional engineering; sensory engineering. [Japanese: “psychological feeling”]

Kantianism n. the philosophical position of Immanuel KANT, most notably that consciously experienced phenomena (see PHENOMENON) represent all that humans can know about essentially unknowable realities (see noumenon) and that these phenomena result from the application of certain intrinsic categories of thought to the material of sense experience. —Kantian adj. n.

Kappa n. see COHEN’S KAPPA.

Kappa effect the interaction between the perceived duration of a stimulus and the spatial extent of the stimulus. When a small visual stimulus and a large visual stimulus are both flashed for the same length of time, the duration of the large stimulus is perceived as longer than that of the small stimulus. An analogous effect has been described for tactile sensations.

Kappa opioid receptor see OPIOID RECEPTOR.

Kappa wave a type of BRAIN WAVE with a frequency similar to that of an ALPHA WAVE (8–12 Hz) but with a much weaker amplitude. Kappa waves are associated with thinking, particularly such activities as problem solving or recall of a partly learned task.

Karezza n. see CAREZZA.

Karma n. 1. in HINDUISM, a concept signifying (a) a mental or physical action, (b) the consequence of a mental or physical action, (c) the sum of all consequences of the actions of a person in this or some previous life, and (d) the
karyotype

chain of cause and effect in the world of morality. 2. in BUDDHISM, the universal law of cause and effect. The effect of an action, which can be of the body, speech, or mind, is not primarily determined by the act itself but by the intention of the actor. When a deed cannot be done but the intention to do it exists, this still produces an effect. [Sanskrit, literally: " deed"]— karmic adj.

karyotype n. 1. the chromosomal constitution of a cell including the number of chromosomes, their structural features, and any abnormalities. 2. a photograph of an individual’s chromosomes that shows them in an ordered, numbered array. Karyotype testing is used clinically to look for chromosome alterations and mutations. It is also used for forensic comparison of genetic material from different sources. See also CHROMOSOMAL MAP.

katz n. see KAT.

kata- combining form see CATA-.

Katz Index of Activities of Daily Living an observer-based measure of the functional status of older adults and individuals with chronic disorders. An individual is rated on the degree of assistance required to perform six basic functions: bathing, dressing, feeding, toileting, transferring, and continence. Baseline measurements provide useful feedback when compared to periodic or subsequent measurements. Also called Katz Index of Independence in Activities of Daily Living. [originally developed in 1963 by Sidney Katz (d. 2012), U.S. physician and geriatrician]

Kaufman Adolescent and Adult Intelligence Test (KAIT) a test of intelligence based upon the theory of fluid and crystallized abilities, yielding scores that reflect these two kinds of abilities. Designed for use with individuals ages 11 and older, the KAIT may be administered in two forms: a standard battery of six core subtests or an expanded battery that includes four additional subtests. See CATTELL–HORN THEORY OF INTELLIGENCE. [Alan S. Kaufman (1944– ) and Nadeen L. Kaufman (1945– ), U.S. psychologists]

Kaufman Assessment Battery for Children (KABC) an intelligence test developed in 1983 and based on the theory of Alexander Luria, which posits that intelligence comprises separate abilities for simultaneous and for successive processing. An example of a simultaneous ability test would be a test requiring the solution of geometric problems, in which series of symbols are presented and individual’s chromosomes that shows them in an ordered, numbered array. Karyotype testing is used clinically to look for chromosome alterations and mutations. It is also used for forensic comparison of genetic material from different sources. See also CHROMOSOMAL MAP.

Kave n. an extract of the root of Piper methysticum, a shrub indigenous to certain southern Pacific islands, where it is used for ritual, social, and recreational purposes. It is a mild intoxicant, sedative, and analgesic agent. The primary active ingredients of the plant are kavain, dihydrokavain, methysticin, and dihydrodromyosist—alkaloids that have anticonvulsant and muscle relaxant properties and also produce sedation without clouding of consciousness. Kava is now widely available in Western countries as an herbal supplement promoted for relaxation (e.g., to relieve stress, anxiety, and tension) and as a remedy for sleeplessness and menopausal symptoms, among other uses. These benefits have largely not been definitively determined, and in fact kava-containing supplements have been shown to be ineffective for treating menopausal symptoms. In 2002, the U.S. Food and Drug Administration issued a consumer advisory warning of the potential risk of rare but serious reactions—including hepatitis, cirrhosis, and liver failure—associated with use of these supplements. Kava has also been associated with depression of the central nervous system or coma (particularly in combination with prescribed anxiolytics), and other less serious adverse reactions (e.g., skin rash) have been reported as well. There are several known and potential interactions of kava with other agents (see DRUG INTERACTIONS), including anticoagulants, MONOAMINE OXIDASE INHIBITORS, and drugs metabolized by the CYTOCHROME P450 3A4 enzyme (e.g., clonidine, nefazodone, St. John’s wort). Also called ava: kava kava.

KBS abbreviation for knowledge-based system. See EXPERT SYSTEM.

K complex a brief, high-amplitude spike-and-rebound waveform recorded in the scalp electroencephalograph during sleep onset. K complexes and SLEEP SPINDLES occur normally during Stage 2 NREM sleep (see SLEEP STAGES). It is postulated that they may suppress sleep disruptions and coordinate memory consolidation. K complexes can also be involved in nocturnal seizures.

keep-away pill see WAKE-PROMOTING AGENT.

Kegel exercises exercises designed to build strength and gain control of the pelvic-floor muscles. These exercises are used in the treatment of VAGINISMUS in women and play a role in increasing sexual pleasure in both women and men. The exercises are also used in the treatment of INCONTINENCE. [developed in 1948 by A. H. Kegel (1894–1981), U.S. gynecologist]

Keller plan a personalized system of education in which material to be learned is divided into units and students work at their own pace, using textbooks and other written materials as primary resources. Fundamental understanding of each unit’s content must be demonstrated before a student can advance to the next one. [Fred S. Keller]

Kemadrin n. a trade name for PROCYCLIDINE.

Kemp’s disease see HOMOSEXUAL PANIC. [Edward J. Kempf (1885–1971), U.S. psychiatrist]

Kendall’s coefficient of concordance see COEFFICIENT OF CONCORDANCE. [Maurice George Kendall (1907–1983), British statistician]

Kendall’s tau (symbol: \( \tau \)) a nonparametric measure of the degree of association between two ordinal variables (i.e., rank-ordered data). For example, a researcher could calculate Kendall’s \( \tau \) to assess how much of a relationship there is between the rankings of students’ performance provided by two observers (e.g., a teacher and a teaching assistant). Also called Kendall’s rank correlation coefficient. [Maurice Kendall]

Kendall’s W see COEFFICIENT OF CONCORDANCE. [Maurice Kendall]

Kennard principle the idea that brain damage sustained early in life is less debilitating than brain damage sustained later in life, presumably because of the enhanced
ability of the younger brain to reorganize. This principle is not always confirmed. [Margaret Kennard (1899–1976), U.S. psychologist]

**keratitis** n. inflammation of the cornea. Keratitis may be deep, as when the infection causing it is carried in the blood or spreads to the cornea from other parts of the eye; or superficial, as when caused by bacterial or viral infection or by an allergic reaction. See also COGAN’S SYNDROME.

**keratoconus** n. the most common of a group of noninflammatory disorders that affect the central cornea of both eyes. The earliest symptom is loss of vision due to irregular corneal astigmatism.

**keratometer** n. an instrument used to measure the curvature of the cornea of the eye, applied in the diagnosis of ASTIGMATISM. Also called **ophthalmometer**.

**kernel-of-truth hypothesis** the idea that STEREOTYPES, despite being exaggerated generalizations about a group of diverse individuals, sometimes contain elements that accurately describe the qualities of the stereotyped group.

**kernel sentence** in early versions of GENERATIVE GRAMMAR, a base version of a sentence upon which such operations as negation and interrogation are performed to produce variations of that base. For example, the kernel sentence *Jack kissed Jill* can be transformed into the sentences *Did Jack kiss Jill?* *Jack did not kiss Jill* *Jill was kissed by Jack*, and so forth. Psychological interest in this idea stems from its implications for the cognitive processes by which we form and interpret sentences. In later models of TRANSFORMATIONAL GENERATIVE GRAMMAR, the transformational rules are seen as operating upon the DEEP STRUCTURES underlying sentences, rather than on any actual sentence.

**kernicterus** n. a congenital disorder associated with excessive levels of BILIRUBIN in the newborn infant. It is characterized by severe JAUNDICE and has the potential to cause severe damage to the central nervous system. Kernicterus is often a complication of RH BLOOD-GROUP INCOMPATIBILITY. See also BILIRUBIN ENCEPHALOPATHY.

**Kernig’s sign** a reflex action that is a diagnostic sign for MENINGITIS. The test is positive if flexing the thigh at the hip while extending the leg at the knee results in resistance and pain. [Vladimir Michailovich Kernig (1840–1917), Russian physician]

**ketamine** n. a drug that is closely related to PCP (phencyclidine). It acts as an antagonist at NMDA RECEPTORS and was formerly used as a D ISSOCIATIVE ANESTHETIC. Disorientation and perceptual distortions may result from its use, which have limited its utility in surgical anesthesia and made it a sought-after drug of abuse. It is ingested in the form of tablets, capsules, or powder by drug users for its hallucinogenic effects. Low-dose intravenous infusions have been reported to improve symptoms in patients with treatment-resistant unipolar and bipolar depression. U.S. trade name: Ketalar.

**ketoconazole** n. an antifungal agent that has been suggested as a treatment for depression resistant to conventional drugs, due to its ability to inhibit the biosynthesis of steroids. No large-scale clinical data support this. Ketoconazole is a potent inhibitor of numerous CYTOCHROME P450 enzymes (particularly CYP3A4) and has significant interactions with psychotropic drugs that utilize this metabolic path. Its numerous interactions and propensity to cause liver damage limit its use. U.S. trade name: Nizoral.

**keyboard** n. a device that allows a user to input information to a computer by pressing specific alphanumeric, symbol, or function keys or key combinations. Many forms of specialized keyboards (e.g., enlarged, ergonomic, reduced in size) are available and can be particularly useful to individuals with disabilities.

**key-word method** a MNEMONIC technique sometimes used in learning foreign-language vocabulary. If the native language is English, the key word would consist of an English word associated with the sound of a foreign word and linked to the foreign word’s meaning in a mental image. For example, the French word livre (“book”) may remind an English speaker of the sound of leaf; the key word leaf can then be connected to book in a mental image, such as visualizing a leaf in a book as a bookmark.

**khat** (chat, kat, qat) n. an herbal CNS STIMULANT obtained from the leaves and other parts of an evergreen shrub, Catha edulis, indigenous to northeast Africa and the Arabian peninsula. The leaves are traditionally chewed to produce mild stimulant effects (e.g., mental alertness, suppression of appetite and the need for sleep, general sense of well-being); they can also be used to make a tea. The substance responsible for khat’s psychoactive properties is cathinone, a compound that is structurally similar to amphetamine. As with amphetamines, physiological tolerance and dependence and a variety of adverse reactions (e.g., behavioral disorganization and psychosis) may occur with continued or high-dose use. The use of khat has spread beyond its traditional boundaries to the United States and other Western countries. In many of those places, however, khat is illegal; it is classified by the U.S. Drug Enforcement Administration as a Schedule I controlled substance (see SCHEDULED DRUG).

**KiHOS** abbreviation for KRANTZ HEALTH OPINION SURVEY.

**kibbutz** n. in Israel, a communal living arrangement, typically centered on agriculture, manufacturing, or tourism, with collective economic, social, and child-rearing practices. See also COMMUNE.

**Kiddie Schedule for Affective Disorders and Schizophrenia (KSADS)** see SCHEDULE FOR AFFECTIVE DISORDERS AND SCHIZOPHRENIA.

**kids’ culture** the environments (e.g., playgrounds) and activities (e.g., games, rituals) that are unique to children and in which they create their own social structures separate from the adult world.

**Kilner screen** a special viewing apparatus that allegedly reveals the invisible AURAS emitted by human beings. It is essentially a light filter, originally consisting of two pieces of glass separated by a layer of dicyanine A (a blue dye used in photographic emulsions); more recently manufactured Kilner screens are usually made with less toxic chemicals. Adherents claim that the inspection of human auras through such a screen can play a vital role in the early diagnosis of disease. Also called Kilner goggles. See also KIRLIAN PHOTOGRAPHY. [Walter J. Kilner (1847–1920), British physician]

**kilocalorie** n. see CALORIE.

**kinase** n. any of a class of enzymes that catalyze the addition of a phosphate group to a molecule (e.g., a protein).

**kindling** n. an alteration in brain functioning that results from repeated minor electrical or chemical stimulation, culminating in the appearance of electrographic abnor-
kindness

malities and often generalized seizures. It is often used as an experimental model for epilepsy.

kindness n. benevolent and helpful action intentionally directed toward another person. Kindness is often considered to be motivated by the desire to help another, not to gain explicit reward or to avoid explicit punishment. See ALTRUISM. —kind adj.

kindred n. an extended family. The study in large kindreds of mutations that predispose to disease helps to identify the position and PENETRANCE of a particular gene mutation.

kinematics n. 1. the study of motion of the body or parts of the body in terms of limb and joint position, velocity, and acceleration. In ergonomics, these are studied in the course of work activity. 2. the patterns of movement of the limbs in motion. See also DYNAMICS. —kinematic adj.

kinesia n. see MOTION SICKNESS.

kinesics n. the study of the part played by body movements, such as hand gestures, eye movements, and so on, in communicating meaning. See BODY LANGUAGE.

kinesics technique the analysis of the BODY LANGUAGE of a person. The technique is used particularly during the interviewing of a criminal suspect.

kinesimeter n. 1. an instrument for measuring the extent of a movement. 2. a 19th-century instrument for measuring the cutaneous sensation of the body.

kinesiology n. 1. the study of the mechanics of body movement, especially their relationship to anatomical characteristics and physiological functions. 2. a discipline that encompasses all of the SPORT SCIENCES as well as the professional skills necessary for the application of sport and exercise knowledge. —kinesiological adj. —kinesiologist n.

kinesthesiologist n. 1.

kinesthesiology n. the application of progressive physical exercise and activities to treat individuals with FUNCTIONAL LIMITATION or to aid those interested in improving or maintaining general physical and emotional health. A kinesthesiologist is a certified professional who develops a specific treatment plan for each individual, determining appropriate therapeutic exercises and physical-education activities and directing their implementation. Formerly called corrective therapy.

kinetic depth effect the impression that a visual figure has three dimensions when in motion. For example, a stationary pattern of apparently random elements will organize into a coherent three-dimensional structure when set in motion. See DEPTH FROM MOTION.

kinetic information 1. the set of qualities perceived in objects that are in motion. 2. gestures, postures, and other body language that may be observed, for example, in a clinical evaluation of a patient.

kinetic tremor see ACTION TREMOR.

kingdom n. traditionally, the highest category used in BIOLOGICAL TAXONOMY, which contains related PHYLA. Modern classifications recognize five kingdoms—Bacteria, Protista (or Prototista), Animalia, Fungi, and Plantae—which in some systems are grouped into DOMAINS.

kinrecognition the ability to detect that another individual is closely related. A variety of cues—visual, auditory, and chemical—have been demonstrated to be effective. In many studies, kin recognition appears to be based on early social experience. That is, individuals recognize those they have interacted with during development but fail to recognize related individuals with whom they have never interacted. However, chimpanzees are able to recognize relationships, such as those between females and their male offspring, simply by observing similarities in photographs, even of chimpanzees they have never seen before. Kin recognition is important for directing support toward kin in KIN SELECTION.

kin selection a variation of NATURAL SELECTION that favors behavior by individuals that will increase the chances
of their relatives surviving and reproducing successfully (see altruism). Individuals share 50% of their genes with a parent or sibling, so if they risk their own ability to reproduce or survive but help their parents or more than two siblings to reproduce or survive, they will benefit indirectly by gaining inclusive fitness. Compare direct selection; individual selection.

**Kinsey Institute for Research in Sex, Gender, and Reproduction** a private nonprofit corporation affiliated with Indiana University, whose mission is to promote interdisciplinary research and scholarship in the fields of human sexuality, gender, and reproduction. It was founded in 1947 by Alfred Kinsey, who served as its first director and carried out much of his pioneering research into human sexual behavior there.

**Kinsey Scale** an index of an individual’s relative position on a 7-point continuum of sexual orientation, ranging from 0 (exclusively heterosexual, with no same-sex interest) to 6 (exclusively homosexual, with no heterosexual interest). Points 1 through 5 represent gradations of the homosexual–heterosexual spectrum. The tom of severe psychosis, Tourette's disorder, or autism. Kinsey Scale is also sometimes called the Kinsey (Six) Scale, a misnomer given that 0 is one of the scale's 7 points. See also sexual orientation grid. [developed in 1948 by Alfred Kinsey and colleagues]

**kinship** n. the state of being related by birth, common ancestry, marriage, or adoption. Notions of who is and who is not kin may vary considerably from one culture to another. For example, in strongly patriarchal societies (see patriarchy), some of one's mother's closest blood relatives may not be considered one's kin.

**kinship migration** 1. a type of residence change among older adults, especially widows, that involves moving closer to family members. 2. the movement of families, either all at once as a group or in phases as individual members or subgroups, from one geographic location to another.

**kinship network** the system of formal and informal relationships that make up an extended family in a given culture or society, typically based on blood ties, marriage, or adoption. The analysis of kinship networks and descent groups in preindustrial societies has been a major concern of cultural anthropology. See also relationship system. Also called kinship system.

**Kirlian photography** a technique that records on photographic film a corona discharge, sometimes characterized as the aura or “life force” emanating from a person, animal, plant, or object. It involves photographing subjects in a high-voltage electric field and produces images in which a colored halo or corona appears around the subject. Some claim that changes in the quality of the aura in the images of photographed persons can reflect changes in their health and emotional condition, making Kirlian photography of potential benefit in medical diagnosis. Skeptics maintain that there is scant evidence for this. See also kilner screen; reichenbach phenomenon; [Semyon Kirlian (1900–1980), Armenian-born Russian inventor and electrician, and his wife Valentina Kirlian, Russian biologist]

**Kirton Adaption–Innovation Inventory (KAI)** a questionnaire, used chiefly in organizational settings, that is designed to measure creativity, cognitive style, and the degree to which individuals are adaptive, innovative, or a range of both in their approach to problem solving. It comprises 33 items (32 scored, 1 unscored) requiring participants to rate how difficult it is for them to be the person described (e.g., a person who is thorough) using a 17-point likert scale format, ranging from very hard to very easy. [originally developed in 1976 by Michael J. Kirton, British psychologist]

**kissing** n. the activity of making contact with the lips, usually with another individual as a sign of friendship or affection. The kiss may involve lip contact with any part of the body and with varying degrees of pressure. Mouth-to-mouth kissing may include extension of the tongues (see French kiss). Kissing is possibly related to the licking behavior manifested by nonhuman animals. It is not observed in all cultures.

**klazomania** n. a mental state that produces compulsive or repetitive shouting (klazoclonia), which can be a symptom of severe psychosis. Tourette’s disorder, or autism.

**Kleblattschädel syndrome** a congenital disorder characterized by a three-lobed skull caused by upward and lateral bulging of the brain through skull sutures. Affected individuals also have hydrocephalus, severe intellectual disabilities, and abnormally short limbs. Also called cloverleaf skull. [from German Kleeblatt, “cloverleaf,” and Schädel, “skull”]

**Kleine–Levin syndrome** a rare disorder, primarily occurring in adolescent males, that is characterized by recurring episodes of excessive drowsiness and sleep (up to 20 hours per day). Symptoms, which may last for days to weeks, include excessive food intake, irritability, disorientation, lack of energy, and hypersensitivity to noise. It is possibly due to a malfunction of the hypothalamus, the part of the brain that governs appetite and sleep. [Willi Kleine, 20th-century German neuropsychiatrist; Max Levin (1901–1974), Russian-born U.S. neurologist]

**Kleinian** adj. denoting or in accordance with the theories and methods of the school of psychoanalysis founded by Melanie Klein, including concepts such as internalization, object relations, the depressive position, idealization, and the paranoid-schizoid position.

**kleptolagnia** n. a morbid urge to steal, considered by some theorists to be associated with sexual excitement. However, this association is controversial, and many consider the urge to be unrelated to sexual issues.

**kleptomaniac** n. an impulse-control disorder characterized by a repeated failure to resist impulses to steal objects that have no immediate use or intrinsic value to the individual, accompanied by feelings of increased tension before committing the theft and either pleasure or relief during the act. The stealing is not done out of anger or in response to a delusion or hallucination and is not better accounted for by another disorder, such as conduct disorder or a manic episode. Also called compulsive stealing. —kleptomaniac n.

**Klinefelter's syndrome** a disorder in which males are born with an extra X chromosome, resulting in small testes, absence of sperm, enlarged breasts, intellectual disability, and abnormal behavior. Also called XXY syndrome. [Harry E. Klinefelter Jr. (1912–1990), U.S. physician]

**klinotaxis** n. see taxes.

**Klippel–Feil syndrome** a congenital condition characterized by a short neck, low hairline, and a reduced number of vertebrae, some of which may be fused into a single mass. Also called Klippel–Feil anomaly. [Maurice Klippel
kismaphilia

(1858–1942), French neurologist; André Feil (b. 1884), French neurologist]

kismaphilia n. interest in, and arousal from, the use of enemas in sexual activity.

Klonopin n. a trade name for CLONAZEPAM.

Klüber–Bucy syndrome a condition resulting from damage to both medial temporal lobes and marked by hypersexuality and a tendency to examine all objects by touch or by placing them in the mouth. Other symptoms may include visual agnosia (inability to visually recognize objects), decreased emotional responsibility (including loss of normal fear and anger responses), distractability, and memory loss. The syndrome is observed in laboratory animals following temporal lobe ablation and, rarely, in humans following extensive bilateral temporal damage caused by HERPES-SIMPLEX ENCEPHALITIS or trauma. [Heinrich Klüver (1897–1975), German-born U.S. neurologist; Paul Bucy (1904–1992), U.S. neurosurgeon]

knee-jerk reflex see PATELLAR REFLEX.

knockdown n. the alteration of a particular gene in an individual organism or in a line of organisms by an experimenter so that the gene is present but its effects are not manifested. Also called gene knockout.

knockout n. the elimination or inactivation of a particular gene in an individual organism or in a line of organisms by an experimenter in order to better understand the function of that gene. Using GENETIC ENGINEERING, scientists replace a normal gene in an organism (such as a mouse) with a defective gene and assess the impact of the defect on the organism. Also called gene knockout.

knockout drops a popular name for a combination of chloral hydrate (formerly in common use as a sedative but now rarely employed clinically) and alcohol, used surreptitiously to produce a sudden loss of consciousness. This combination was called a Mickey Finn and might be considered an early example of a DATE-RAPE DRUG.

knowing n. see REMEMBER–KNOW PROCEDURE.

knowledge n. 1. the state of being familiar with something or aware of its existence, usually resulting from experience or study. 2. the range of one’s understanding or information. In some contexts, the words knowledge and memory are used synonymously.

knowledge base 1. an individual’s general background knowledge, which influences his or her performance on most cognitive tasks. 2. a repository of factual and heuristic information, usually in machine-processable form. 3. the body of accumulated information (research, best practices, and so on) that guides an organization’s approach to specific problems or challenges.

knowledge-based system (KBS) see EXPERT SYSTEM.

knowledge elicitation in ergonomics, a variety of methods used to elicit the content and structure of users’ knowledge or reasoning regarding a product or system. Techniques used include CASE-BASED REASONING, CONVERSATION ANALYSIS, and TASK ANALYSIS. Knowledge elicitation should take account of EXPERT–NOVICE DIFFERENCES.

knowledge function of an attitude the role an attitude can play in helping to interpret ambiguous information or to organize information. For example, a positive attitude toward a friend may assist in attributing that person’s negative behavior to situational factors rather than to personal characteristics. See also FUNCTIONAL APPROACH TO ATTITUDES.

knowledge of performance (KP) verbalized (or verbalizable) information about the nature of the movement pattern that has been used to achieve a goal.

knowledge of results (KR; KOR) verbalized (or verbalizable) information about the outcome of a response in relation to the goal. Learning theory suggests that a learner profits most from immediate availability of this information (e.g., about the accuracy of responses on a test or the speed and accuracy of a movement or an action sequence). Although knowledge of results is essential for guiding ACQUISITION, too much feedback can prevent the individual from forming an internal model of what is correct behavior.

knowledge representation the method used for encoding knowledge or semantic information in an ARTIFICIAL INTELLIGENCE program. This is usually not the computer language employed but rather systematically developed structures encoded in that language. Examples of knowledge representation include the predicate calculus, CONCEPTUAL DEPENDENCIES, and FRAME.

knowledge, skills, abilities, and other characteristics (KSAOs) attributes of an employee or applicant for a position that are measured for such purposes as PERSONNEL SELECTION, JOB PLACEMENT, PERFORMANCE REVIEW, and PERSONNEL TRAINING. The KSAOs required of an employee performing a job should be identified on the basis of a thorough analysis of the tasks involved in the job. See JOB REQUIREMENTS; PERSONNEL SPECIFICATION. See also BONA FIDE OCCUPATIONAL QUALIFICATION.

know thyself see GNOSIS.

Kocher–Debré–Sémélaïgne syndrome a disorder of infants and children marked by weakness and overgrowth of muscles. It is associated with CONGENITAL HYPOTHYROIDISM and intellectual disability in some cases. Also called Debré–Sémélaïgne syndrome. [reported in 1892 by Swiss surgeon Emil Theodor Kocher (1841–1917) and in the 1930s by French pediatricians Robert Debré (1882–1978) and Georges Sémeaïgne]

Kohlberg’s theory of moral development the concept that the cognitive processes associated with moral judgment develop through a number of universal variant stages. According to the theory, there are three main levels: the PRECONVENTIONAL LEVEL, the CONVENTIONAL LEVEL, and the POSTCONVENTIONAL LEVEL. Broadly speaking, the morally developed individual moves from a selfish concern with rewards and punishments, through a reliance on fixed rules and conventional attitudes, to a position of independent principled judgment. See also HEINZ DILEMMA. [Lawrence Kohlberg]

Köhler effect an increase in motivation that sometimes occurs among individuals working in groups on CONJUNCTIVE TASKS that require persistence but little coordination of effort. The effect is likely due to the increased effort expended by the less capable group members. Compare COMPENSATION EFFECT. [First observed in 1926 by German researcher Otto Köhler]

Kohnstamm test a demonstration frequently used to prepare an individual for hypnosis. The participant is asked to press an arm backward against a wall for a minute or two and then to step away, allowing the arm to relax. What follows is a natural reflexive tendency for the arm to rise,
Kohnstamm's phenomenon. Believing that the reflex had occurred because of the hypnotist's instructions for the task, the participant becomes more inclined to be susceptible to further suggestions during subsequent hypnosis. Also called Kohnstamm maneuver. [Öskar Kohnstamm (1871–1917), German physician]

Kohs Block Design Test a performance test of intelligence consisting of a set of 16 colored cubes that the participant must arrange into designs presented on 17 test cards. Although still available as a separate stand-alone instrument, the Kohs Block Design Test has been adapted for use as a component of various other assessment measures, most notably the intelligence scales devised by David Wechsler. [developed in 1919 by Samuel C. Kohs (1890–1984), U.S. psychologist]

kola nut (cola nut) the seed of a tree, Cola acuminata or Cola nitida, that is native to tropical Africa and is cultivated in South America and the West Indies. The active ingredient is caffeine, which comprises about 1.5% of the dry weight of the nut. Kola was discovered for the Western world in 1667 by a Congo missionary, Father Carl, who observed that local tribesmen chewed the nut before meals.

Kolmogorov–Smirnov goodness-of-fit test a nonparametric method for comparing the distribution from a sample data set to an expected distribution or the known distribution of a given population. If the test yields a discrepancy (D) larger than the critical value, then the sample data are considered to be significantly different from the reference distribution. Also called Kolmogorov–Smirnov D test. Kolmogorov–Smirnov one-sample test. Compare KOLMOGOROV–SMIRNOV TWO-SAMPLE TEST. [Andrei Nikolaevich Kolmogorov (1903–1987) and Nikolai Vasilevich Smirnov (1900–1966), Soviet mathematicians]

Kolmogorov–Smirnov two-sample test a nonparametric method for comparing the distributions from two samples to see if they are similar. A significant result from a Kolmogorov–Smirnov two-sample test indicates that the two samples are derived from different distributions. In contrast, the KOLMOGOROV–SMIRNOV GOODNESS-OF-FIT TEST is used when only one sample is available but the larger population distribution is known. [Andrei Kolmogorov and Nikolai Smirnov]

König bars a grating pattern of black and white bars used to assess visual acuity. [Karl Rudolf König (1832–1901), German-born French physicist]

Kopfermann cubes line drawings of cubes that are perceived as two-dimensional figures rather than as three-dimensional cubes. A hexagon equally divided into six triangles is one example. In this case, gestalt principles of perception have been invoked to explain the compelling perception of two-dimensional triangles, rather than sides of a three-dimensional figure. [Hans Kopfermann, 20th-century German physicist and experimental psychologist]

kopro-combining form see COPRO-.

koproagalia n. see COPROAGALIA.

koproagalia n. see COPROAGALIA.

KOR abbreviation for KNOWLEDGE OF RESULTS.

Koro n. a culture-bound syndrome observed primarily in males in China and southeast Asia. It is an acute anxiety reaction in which the male suddenly fears that his penis is shrinking and will disappear into his abdomen, bringing death. (In females, the fear is focused on the vulva and nipples.) Individuals may also experience shame if they associate the fear with immoral sexual behavior. Also called jinjina bemar; rok-joong; shuk yang; suke-young; suo yang.

Korsakoff's syndrome a syndrome occurring primarily in cases of severe, chronic alcoholism. It is caused by thiamine (vitamin B1) deficiency and damage to the mammary glands. Patients with Korsakoff's syndrome demonstrate dense anterograde and retrograde amnesia, which is thought to be due to lesions in the anterior or dorsal medial nuclei (or both) of the thalamus. Other symptoms include confabulation, lack of insight, apathy, and impoverished conversation. The selective and acute nature of the memory disorder in Korsakoff's syndrome sets it apart from alcoholic dementia (see alcohol-induced persisting dementia), a syndrome characterized by more global impairments in intellectual functioning that evolve gradually over time. Korsakoff's syndrome often follows an episode of Wernicke's encephalopathy (see wernicke–korsakoff syndrome). Also called Korsakoff's disease: Korsakoff's psychosis. [first described in 1887 by Sergei Korsakoff (1853–1900), Russian neurologist]

Korte's laws the laws describing the optimal conditions for the production of apparent motion that occurs when two or more stationary targets are presented in succession. The significant variables include the intensity of the stimuli, as well as their spatial separation, duration, and the interval between presentations. See also apparent movement. [Adolf Korte, German psychologist]

KP abbreviation for KNOWLEDGE OF PERFORMANCE.

KR abbreviation for KNOWLEDGE OF RESULTS.

K-R 20 abbreviation for Kuder–Richardson formula 20. See KUDER–RICHARDSON FORMULAS.

K-R 21 abbreviation for Kuder–Richardson formula 21. See KUDER–RICHARDSON FORMULAS.

Kraepelin's theory the concept of dementia praecox, the disorder now known as schizophrenia, that emphasized the progressive intellectual deterioration (dementia) and the early onset (praecox) of the disorder. [first presented in 1898 by Emil Kraepelin]

Krantz Health Opinion Survey (KHOS) a questionnaire to measure patient attitudes toward treatment and preferences for different approaches in health care. Participants indicate whether they agree or disagree with each of 16 statements (e.g., "I usually ask the doctor or nurse lots of questions about the procedures during a medical exam"), which are keyed so that high scores represent favorable attitudes toward self-directed care. [developed in 1980 by David S. Krantz (1949– )], U.S. medical psychologist, and colleagues at the Uniformed Services University of the Health Sciences, Bethesda, Maryland]

Krause end bulb a specialized sensory nerve ending enclosed in a capsule in the skin. It is associated with temperature sensations. [Wilhelm Krause (1833–1910), German anatomist]

Kretschmer typology a controversial classification of individuals based on a "clear biological affinity" between specific physiques and specific personality tendencies. According to this classification, the short, stocky pyknic type tends to be jovial and subject to mood swings; the frail asthenic type is likely to be introverted and sensitive; the muscular athletic type is usually energetic and aggressive; and the disproportional dysplastic type presents...
kriging

a combination of traits but tends toward the asthenic. These tendencies were attributed to endocrine secretions. [formulated in the 1920s by German psychiatrist Ernst Kretschmer (1888–1964)]

kriging n. a statistical method that uses INTERPOLATION to estimate an unknown value between two known values while minimizing prediction error. For example, a simple form of kriging could estimate that the unknown point halfway between two known points of 1 and 9 would be a value of 5. [Daniel Gerhardus Krige (1919–2003), South African geostatistician]

Kruskal–Shepard scaling a type of MULTIDIMENSIONAL SCALING applied to judgments of similarity or dissimilarity for pairs of items (e.g., cities). The dissimilarities are represented by distances between items in a highly dimensional space: Larger distances indicate greater dissimilarity. [William Henry Kruskal (1919–2005), U.S. statistician; Roger N. Shepard (1929– ), U.S. experimental and cognitive psychologist]

Kruskal–Wallis one-way analysis of variance a NONPARAMETRIC TEST for assessing whether the MEDIANs of multiple samples of ranked data are equal. It is an extension of the MANN–WHITNEY U TEST, which is conducted when there are only two independent samples. Also called Kruskal–Wallis test. [William Henry Kruskal (1919–2005) and Wilson Allen Wallis (1912–1998), U.S. statisticians]

KSADS abbreviation for Kiddie SCHEDULE FOR AFFECTIVE DISORDERS AND SCHIZOPHRENIA.

KSAOs abbreviation for KNOWLEDGE, SKILLS, ABILITIES, and OTHER CHARACTERISTICS.

K-strategy n. a reproductive strategy that involves a high degree of PARENTAL INVESTMENT in a relatively small number of offspring over an individual’s reproductive life, as in human beings and other primates. Populations of K-strategists expand to the maximum size that the habitat can support (its carrying capacity, or K). K-strategy implies that a constant, relatively small number of high-quality offspring is more likely to lead to REPRODUCTIVE SUCCESS than producing offspring at the maximum rate possible (see K-STRATEGY).

Kuder Preference Record a test used to assess participants’ suitability for various fields of employment. For each of 165 items, individuals select their preferred activity from a series of three choices. The test yields percentile scores in 10 vocational areas: clerical, computational, art, music, social service, outdoor, science, persuasive, literary, and mechanical. The Kuder Career Search and Kuder Occupational Interest Survey are updated versions. [Frederic Kuder (1903–2000), U.S. psychologist]

Kuder–Richardson formulas two methods. Kuder–Richardson formula 20 (K-R 20) and Kuder–Richardson formula 21 (K-R 21), for assessing the INTERNAL CONSISTENCY reliability of a test or subtest made up of dichotomous VARIABLES. The K-R 21 requires that all of the dichotomous variables be equally difficult, whereas the K-R 20 does not. For example, a teacher could use the K-R 21 formula to calculate internal consistency reliability for a test of 20 equally difficult items but would use the K-R 20 formula for test items differing in difficulty level. [Frederic Kuder (1903–2000) and Marion Webster Richardson (1896–1965), U.S. psychologists]

Kugelberg–Welander disease see SPINAL MUSCULAR ATROPHY. [Eric Kugelberg (1913–1983) and Lisa Welander (1909–2001), Swedish neurologists]

Kumho Tire Co. v. Patrick Carmichael a case resulting in a 1999 U.S. Supreme Court ruling that extended the GATEKEEPER ROLE of judges to cover both scientific expert testimony, as established in Daubert v. Merrell Dow Pharmaceuticals Inc. (see DAUBERT TEST), and nonscientific expert testimony.

Kundt’s rules the principles that (a) distances divided by graduated lines appear larger than undivided distances and (b) when bisecting a horizontal line using one eye, the observer tends to place the midpoint too near the nasal side of the eye. [August Kundt (1839–1894), German physicist]

kurtosis n. the fourth CENTRAL MOMENT of a PROBABILITY DISTRIBUTION. It is a statistical description of the degree of peakedness of that distribution. For example, the ages of a sample of college freshmen would probably show kurtosis, having a high peak at age 18. See LEPTOKURTIC; MESOKURTIC; PLATYKURTIC.

Kuru n. a progressive, ultimately fatal disease of the central nervous system that historically has affected the Fore people in the highlands of New Guinea. Symptoms include ataxia, tremors, difficulty in walking, and squint (strabismus). It is a PRION DISEASE, similar to CREUTZFELDT–JAKOB DISEASE, transmitted in cannibalistic rituals by eating the brains of individuals previously infected with the causative prion agent.

Kurzweil Personal Reader a computer system that reads print and outputs synthesized speech. It is intended for people who cannot read print (e.g., those with such disabilities as severe visual impairment and dyslexia). [Raymond Kurzweil (1948– ), U.S. computer scientist and inventor]

kwashiorkor n. a form of malnutrition caused by inadequate intake of protein (see PROTEIN DEFICIENCY). The symptoms include fluid accumulation in the tissues, liver disorders, impaired growth, distention of the abdomen, and pigment changes in the skin and hair. Cerebral development also may be impaired. Although it may occur at any age, it is most often seen in children up to 4 years old. The condition is most common in very poor countries. See also MARASMS.

kymograph n. an instrument for recording temporal data in psychological or physiological research by tracing the variations of a particular parameter on a sheet of paper attached to a revolving drum. The resulting trace on the paper is a kymogram. Computer-output systems have largely replaced such instruments.

kyphosis n. an abnormal outward curvature of the spine at the cervical level, producing a rounded back. This posture is sometimes called hunchback. See also LORDOSIS; SCOLIOSIS.
LaAM L-alpha-acetyl-methadol: a long-acting opioid agonist that is a chemical analog of methadone. A strong agonist at the mu opioid receptor, it can be used in oral form in the management of opioid dependence because of its ability to suppress physical withdrawal symptoms and block the reinforcing effects of opioids. It has a longer half-life (about 72 hours) than methadone and therefore needs to be taken less frequently, a major advantage over methadone (which is taken daily). However, due to its possible adverse effects on heart rate and its interactions with other drugs, LAAM is no longer manufactured in the United States, Europe, and Canada.

labeled lines nerve inputs to the brain, each one of which is conceptualized as reporting only one particular type of information.

labeled-line theory of taste coding a theory postulating that each gustatory neuron type comprises a private circuit through which the presence of its associated primary taste quality is signaled. The taste is perceived exclusively as a product of activity in that labeled line; activity in neurons outside the labeled line contributes only noise. Compare pattern theory of taste coding.

labeling n. 1. in psychological assessment, classifying a patient according to a certain diagnostic category. Patient labeling may be incomplete or misleading, because not all cases conform to the sharply defined characteristics of standard diagnostic categories. 2. medication information provided on a drug container or package insert (also called direction circular or package circular) that specifies indications, side effects, dosages, mechanisms of action, and other information necessary for a physician to prescribe the medication correctly. Drug labeling in the United States is regulated by the U.S. Food and Drug Administration. Also called prescribing information (PI); professional labeling.

labeling theory the sociological hypothesis that describing an individual in terms of particular behavioral characteristics may have a significant effect on his or her behavior, as a form of self-fulfilling prophecy. For example, describing an individual as deviant and then treating him or her as such may result in mental disorder or delinquency. Also called societal-reaction theory. See also primary deviance.

la belle indifference inappropriate lack of concern about the implications or seriousness of one's physical symptoms, often seen in conversion disorder.

labia pl. n. (sing. labium) four lip-shaped folds of tissue forming part of the female external genitalia (see vulva). The labia—comprising a larger, outer pair, the labia majora (sing. labium majus), and a thinner, inner pair, the labia minora (sing. labium minus)—enclose the clitoris and the openings of the urethra and vagina.

labial 1. adj. of or relating to the lips. 2. adj. denoting a speech sound made with the lips, for example, [b], [p], [m], [w], [f], or [v]. If the sound is made with both lips, it is described as bilabial; if the sound is made with the lower lip and the upper teeth, it is termed labiodental. 3. n. a labial speech sound.

labile adj. 1. liable to change, as in labile affect. 2. describing the early stage of memory formation that can be easily disrupted by factors influencing brain activity. —lability n.

labile affect highly variable, suddenly shifting emotional expression.

labio- combining form lips.

labiodental 1. adj. denoting a speech sound made with the lower lip touching or near the upper teeth, such as [f] or [v]. 2. n. a labiodental speech sound. Also called labial dental. See labial.

labor n. the first stage of childbirth, from the dilation of the cervix until the infant's head begins to enter the birth canal. See delivery.

laboratory-method model an approach to education in which the role of social interaction is emphasized. The development of personal awareness and interpersonal skills is a major area of concern.

laboratory research scientific study conducted in a laboratory or other such workplace, where the investigator has some degree of direct control over the environment and can manipulate the independent variables. Although laboratory research generally has greater internal validity than field research does, it tends to be less generalizable to the real world (i.e., has less external validity). See experimental research.

Labor Management Relations Act a series of amendments to the national labor relations act that were passed in 1947 to adjust the power balance between unions and employers in the United States, the previous system being regarded as too restrictive of management. The act identified and prohibited certain unfair labor practices of both unions and employers, created the Federal Mediation and Conciliation Service to aid in resolution of disputes, and provided a mechanism for dealing with strikes that create a national emergency. Sponsored by U.S. lawyer and politician Robert Alphonso Taft (1889–1953) and U.S. politician Fred Allan Hartley Jr. (1902–1969), it is also known as the Taft-Hartley Act.

labor relations 1. relations between employers and employees or between employers and unions, especially within the context of collective bargaining. 2. a multidisciplinary field of study devoted to understanding and managing employee–employer or union–employer relations. Also called industrial relations.

labor turnover see turnover.

labor union see union.

labyrinth n. in anatomy, the complex system of cavities, ducts, and canals within the temporal bone of the skull that makes up the inner ear. The bony (or osseous) labyrinth is a system of bony cavities that houses the
membranous labyrinth. a membrane-lined system of ducts containing the receptors for hearing and balance.

labyrinthine sense see SENSE OF EQUILIBRIUM.

labyrinthitis n. infection or inflammation of the inner ear, which may result in dizziness, loss of balance, or partial or temporary loss of hearing.

laceration n. a jagged tear or cut: a wound with rough, irregular edges.

lack of fit the degree to which the values predicted by a model—typically, one developed in REGRESSION ANALYSIS, STRUCTURAL EQUATION MODELING, or CONFIRMATORY FACTOR ANALYSIS—diverge from the corresponding empirical values. A large, significant value from a GOODNESS-OF-FIT test indicates a poorly fitting model.

lacrima gland (lachrymal gland) see EXOCRINE GLAND.

lacrimar reflex the secretion of tears in response to a variety of stimuli, including those that irritate receptors in the nose.

lacrimar n. crying, especially excessive crying.

lactate dehydrogenase (LDH) any of a group of enzymes that catalyze reversibly the conversion of lactate to pyruvate. They are found especially in the liver, kidneys, skeletal muscles, and myocardium. Increased blood levels may indicate injury to or disease of these organs. Also called lactic dehydrogenase.

lactation n. 1. the formation and release of milk by the MAMMARY GLANDS. It is a form of NURSING that occurs only in female mammals and is divided into lactogenesis—the initiation of milk production—and galactopoiesis—the subsequent maintenance of milk production and secretion. The former is itself divided into Lactogenesis Stage I, which in humans generally lasts from mid-pregnancy through 2 days following childbirth, and Lactogenesis Stage II, which occurs within 3 to 8 days after birth. In Lactogenesis Stage I, the various mammary cells enlarge, reorganize into large clumps resembling grapes, and start producing a nutrient- and antibody-rich fluid known as COLOSTRUM that is eventually released during the initial days of nursing. In Lactogenesis Stage II, the enlarged mammary cells fill with copious amounts of mature milk once the maternal placenta is expelled and no longer introducing PROGESTERONE, which inhibits milk formation, into the bloodstream.

In the subsequent galactopoiesis phase, beginning around 9 days after birth, the mammary cells continuously produce mature milk in response to its repeated removal by the suckling infant or by a breast pump. Lactation is regulated primarily by the hormones PROLACTIN, which facilitates and sustains milk production, and CORTICOTROPIN, which stimulates the MILK LETDOWN REFLEX to facilitate milk excretion. Lactation is an energy-intensive process that places significant metabolic demands on the female system, requiring not only increased caloric intake but also considerable amounts of calcium and other minerals. See also GALACTORRHEA.

2. the period during which this process occurs.

lacto- combining form milk.

lactogenesis n. see LACTATION.

lactogenic hormone see PROLACTIN.

lactotroph n. see PROLACTIN.

lactotropic hormone see PROLACTIN.

lacunae n. a gap or break, such as a gap in memory. —lacunar adj.

lacunar amnesia see LOCALIZED AMNESIA.

lacunar stroke a STROKE caused by small INFARCTIONS resulting from obstruction of small arterioles branching directly off large vessels in the brain. Lacunar strokes account for about 20% of all strokes.

LAD abbreviation for LANGUAGE ACQUISITION DEVICE.

laddering n. a knowledge elicitation technique used in interviews to impose a systematic framework upon questioning so as to reveal complex themes across answers. In ladderding, a respondent replies to a series of “why?” probes, thus requiring him or her to expose and explain choices or preferences and justify behavior in terms of goals, values, and personal constructs. Laddering is concerned with establishing links between concepts elicited from the participant (e.g., attitudes and beliefs associated with a particular consumer product) and provides greater scope for probing salient issues while optimizing the often limited time available with respondents.

Ladd-Franklin theory a formerly influential but now superseded theory of color vision. It is based on the notion that light of certain wavelengths causes substances to be released from a highly developed photosensitive molecule in the retina and that these substances stimulate the retina, causing the perception of red, green, or blue. [introduced in 1929 by Christine LADD-FRANKLIN]
laissez-faire leader n. the type of leader who provides little guidance for group activities, interacts only minimally with the group members, and provides input only when directly asked. Research suggests that groups with laissez-faire leaders are less effective than are groups with democratic leaders or with authoritarian leaders. [Defined by Kurt Lewin and his colleagues in experimental studies of leadership styles]

-lalia suffix abnormal or disordered speech (e.g., echola-

lalling n. an infantile form of speech characterized by the omission or substitution of sounds, particularly the substitution of the [l] sound for other sounds that are more difficult for the speaker to produce, for example, saying "lellow" for "yellow." Lalling is considered a speech disorder when it persists beyond the age at which accurate articulation should have been acquired. See also phonological disorder.

lalopathy n. any form of speech disorder.

L-alpha-acetyl-methadol n. see LAAM.

Lamarckism n. the theory that changes acquired by an organism during its lifetime—for example, through use, disuse, or injury of particular parts—can be inherited by its offspring. Extensive research over centuries failed to find proof of such inheritance of acquired characteristics; however, evidence now suggests that epigenetic modifications (i.e., natural or environmentally induced changes to DNA expression that occur during an organism’s lifetime) can result in acquired characteristics that may be inherited by offspring. Also called use-and-disuse theory. [Jean-Baptiste Lamarck (1744–1829), French natural historian] —Lamarckian adj.

Lamaze method a variation of the method of natural childbirth in which the mother learns about childbirth anatomy and physiology and practices pain management through relaxation, massage, and breathing exercises. The mother is aware and active during labor, guided by her partner, who shares in the birth experience (e.g., as a supportive coach). The method neither encourages nor discourages the use of medication during labor and delivery. See also LEROY TECHNIQUE. [Ferdinand Lamaze (1890–1957), French obstetrician]

lambda 1. (symbol: \( \lambda \)) see eigenvalue. 2. (symbol: \( \Lambda \)) see Wilky's LAMBDa.

lambda model (\( \lambda \) model) see equilibrium-point model.

Lambert's law the principle that the illuminance of a surface lit by light falling on it perpendicularly from a point source is inversely proportional to the square of the distance between the surface and the source. [Johann Heinrich Lambert (1728–1777), French-born Prussian mathematician]

lamellipodium n. (pl. lamellipodia) a sheetlike extension of a cell, for example, of the growth cone of a neuron.

laminar organization the horizontal layering of cells found in some brain regions. See cortical layers.

lamotrigine n. an anticonvulsant drug used as an adjunct in the treatment of adults with partial seizures and some generalized seizures and for maintenance treatment of bipolar disorder. Although ineffective in treating acute manic episodes, it has gained acceptance as a single-drug treatment for acute bipolar depression and rapid-cycling bi-
polar II disorder. Serious skin reactions, including STEVENS-JOHNSON SYNDROME, have been reported at the start of therapy, particularly in children. U.S. trade name: LAMi-
tal.

LAMP abbreviation for LEARNING ABILITIES MEASUREMENT PROGRAM.

Landau–Kleffner syndrome a rare childhood neurological disorder of unknown cause that is characterized by the sudden or gradual development of aphasia (inability to understand or express language) and an abnormal electroencephalogram (see ELECTROENCEPHALOGRAPHY). The syndrome usually occurs in children between the ages of 5 and 7 years who develop normally but then lose their language skills for no apparent reason. Many children with the disorder experience seizures, which generally disappear by adulthood. [First described in 1957 by William M. Landau and Frank R. Kleffner]

Landau reflex a normal reflex observed in infants between the ages of 3 and 12 months: When the child is supported horizontally in the prone position, the head rises and the back arches. Absence of the reflex is a sign of a neurological disorder, such as cerebral palsy or motor neuron disease.

Land effect a demonstration used to develop the RETINEX THEORY of color vision. To produce the effect, a multicolored scene is photographed with black and white film, once through a red filter and once through a blue–green filter. When the resulting images are projected simultaneously onto a screen through the opposite filter used to photograph the image, the original multicolored scene is perceived. [Edwin Herbert Land (1909–1991), U.S. inventor]

landmark n. an external reference point that is a major component of a cognitive map. The design and placement of landmarks can significantly affect way-finding behavior. See ENVIRONMENTAL COGNITION; LEGIBILITY.

Landmark Forum see ERHARD SEMINAR TRAINING.

Landolt circles a set of circles with gaps of varying size, used to test visual acuity. Also called Landolt Cs. [Edmund Landolt (1846–1926), French ophthalmologist]

landscaped office a modification of the open-office design in which emphasis is given to the interaction of people, such that the arrangement of work spaces is based on patterns of communication and facilitation of work flow. Landscaped offices typically place supervisors near workers and group people who communicate regularly with one another to perform their job duties in the same or adjacent spaces. Portable screens or partitions and other movable items, such as planters or cabinets, are used to separate areas and divide them into a variety of different yet easily accessible work spaces.

Land theory of color vision see RETINEX THEORY. [Edwin Herbert Land (1909–1991), U.S. inventor]

Langdon Down's disease see DOWN SYNDROME.

Langerhans cells dendritic cells found in the epidermis. [Paul Langerhans (1847–1888), German anatoomist]

language n. 1. a system for expressing or communicating thoughts and feelings through speech sounds or written symbols. See NATURAL LANGUAGE. 2. the specific communicative system used by a particular group of speakers, with its distinctive vocabulary, grammar, and phonological system. 3. any comparable nonverbal means
of communication, such as **SIGN LANGUAGE** or the languages used in computer programming (see **ARTIFICIAL LANGUAGE**).

**language acquisition** the process by which children learn language. Although often used interchangeably with **LANGUAGE DEVELOPMENT**, this term is preferred by those who emphasize the active role of the child as a learner with considerable innate linguistic knowledge.

**language acquisition device** (**LAD**) a hypothetical faculty used to explain a child’s ability to acquire language. In the early model proposed by U.S. linguist Benjamin Lee Whorf (1897–1941), the LAD is an inherited mechanism that enables children to develop a language structure from linguistic data supplied by parents and others. In Noam Chomsky’s reinterpretation, however, the LAD contains significant innate knowledge that actively interprets the input; only this can explain how a highly abstract competence in language results from a relatively deprived input. See **NATIVISTIC THEORY**.

**language acquisition support system** (**LASS**) the adults and older children who help a young child to acquire language. Children learn language in and from conversation: Family members talk to them, tailoring their language to the children’s level of comprehension and often using higher pitch and exaggerated intonation. The LASS is conceptualized as essential to language learning and may interact with the **LANGUAGE ACQUISITION DEVICE** of the younger child. [proposed by Jerome Seymour Bruner]

**language arts** the part of a school curriculum that teaches the language skills of listening, speaking, reading, writing, spelling, and handwriting.

**language center** any area of the cerebral cortex, such as Broca’s area or Wernicke’s area, that is involved in spoken or written language.

**language contact** the sociolinguistic situation in which two or more language communities come into contact for reasons of geographical proximity, commerce, or politics, leading to mutual influence in lexical or structural features. See also **CONTACT LANGUAGE**.

**language death** the extinction of a language. The usual cause is a gradual shift to the use of another language in the younger generations of a **SPEECH COMMUNITY**, so that the original language dies out with the older generation. In the early 21st century, it has been estimated that languages are dying out at a rate of two or three every month. By other estimates, which put the number of languages currently spoken at more than 6,000, roughly half will disappear by the end of the century. See **LANGUAGE SHIFT**.

**language deficit** an absence, loss, or delay in the normal speech and language development of a child due to some neurological dysfunction.

**language delay 1.** the acquisition of spoken language significantly later than is typical. The delay may or may not be symptomatic of abnormal language development. 2. a synonym for **SPECIFIC LANGUAGE IMPAIRMENT**.

**language development** the process by which children learn to use language. Although this term is often used interchangeably with **LANGUAGE ACQUISITION**, it is preferred by those who wish to emphasize the continuity of language development with cognitive and social development. See also **PRISPEECH DEVELOPMENT**.

**language disability** any significant difficulty with or impairment of language development or function. When the difficulty or impairment is restricted to a specific aspect of language development or a specific language function, it is termed **SPECIFIC LANGUAGE DISABILITY**. When the difficulty or impairment is more pervasive and not restricted to a particular aspect or function, the term **GENERAL LANGUAGE DISABILITY** is used.

**language disorder** see **SPEECH AND LANGUAGE DISORDER**.

**language-experience approach** a method of reading instruction that uses the child’s spoken language to supply the words and stories for teaching reading. In this approach, the child is encouraged to describe personal experiences, which are recorded by the teacher. They then read these written stories together until the child can associate written and spoken forms of words and read independently. [introduced in the 1960s by Roach Van Allen (d. 1998)]

**language learning disability** (**LLD**) see **SPECIFIC LANGUAGE IMPAIRMENT**.

**language localization** the processing of various functions of spoken and written words in particular areas of the brain. Since 1861, when Paul Broca postulated that speech processing was localized near the third frontal convolution of the left hemisphere, research has identified numerous other cortical centers associated with visual and auditory language processing, as well as neural pathways linking these areas. See Broca’s area; Wernicke’s area.

**language loyalty** a strong preference for using a minority language demonstrated by a **SPEECH COMMUNITY** or any of its members.

**language maintenance** the continued use of the ethnic language by an immigrant or minority community across successive generations.

**language-origin theory** speculation about the origin and early development of language in the human species. The numerous early theories on this subject tend to fall into three main categories: (a) those that see language developing from conscious imitation by early humans of nonhuman animal noises and other natural sounds; (b) those that see it emerging from the involuntary sounds produced to express rage, pleasure, hunger, and so on; and (c) **NATIVISTIC THEORIES** that see the language faculty as innate to human beings and postulate an inherent relation between sound and meaning (see **PHONETIC SYMBOLISM**). Modern research tends to ask whether language is, in fact, a uniquely human capacity and, if so, whether it evolved in response to various selective adaptations. See also **SPECIES SPECIFICITY OF LANGUAGE**.

**language pathology** see **SPEECH AND LANGUAGE PATHOLOGY**.

**language planning** a deliberate attempt by a government to change the way a language is used by a community. A policy of raising the status of a language (**STATUS PLANNING**) is often adopted in postcolonial situations, when the new government may take steps to promote the use of indigenous languages, rather than the colonial language, in government and education. This may be accompanied by **CORPUS PLANNING**, which refers to attempts to “improve” a language, usually by standardizing its structures, expanding or “purifying” its vocabulary, and reforming (or, in some cases, creating) its writing system.

**language retardation** delayed acquisition of language
skills, manifested, for example, by single-word utterances or unintelligible sounds, due to neurological causes.

**language shift** a movement in the language preference of an immigrant or minority community from its ethnic language to the majority language, eventually resulting in monolingualism in the majority language. See LANGUAGE DEATH.

**language socialization** the process by which children are socialized into the language practices, such as particular discourse routines, of the family and community.

**language therapy** see SPEECH THERAPY.

**language transfer** in second-language acquisition, the tendency to transfer the phonology, syntax, and semantics of the native language into the learning of the second language. Negative transfer (or interference) occurs when differences between the two languages’ structures lead to systematic errors in the learning of the second language or to fossilization. Positive transfer occurs when areas of similarity between the two languages facilitate learning. See CONTRASTIVE ANALYSIS; INTERLANGUAGE.

**language universal** 1. a linguistic feature that is common to all known human languages, such as words, sentences, or (more specifically) a set of pronouns or a set of color words. Such substantive universals can be formulated on the basis of observations across multiple languages, yielding an empirically testable hypothesis that “all languages have X.” 2. in the linguistics of Noam Chomsky, a fundamental formal property that is built into the rule structure of all or nearly all language systems. An example is the rule observed by U.S. linguist Joseph H. Greenberg (1915–2001) that “in declarative sentences with nominal subject and object, the predominant order is almost always one in which the subject precedes the object.” Unlike substantive universals, these formal universals cannot be explained by universal features of human life or the physical environment. In Chomsky’s view, they constitute a UNIVERSAL GRAMMAR that is innate to human beings and inseparable from the language faculty itself. Also called linguistic universal; universal.

**linguishing** n. the condition of absence of mental health, characterized by ennui, apathy, listlessness, and loss of interest in life. Compare FLOURISHING. —linguish v.b.

**Lanterman Developmental Disabilities Act** California legislation, introduced in 1969, that sets forth the rights of people with developmental disabilities and the structure of the system for planning, coordinating, and delivering services and supports to them. This act is noteworthy because, unlike similar statutes in most U.S. states, it has been interpreted judicially as establishing an entitlement to services. In 1990, a class action suit (William Coffelt v. California Department of Developmental Services) criticized and challenged California’s implementation of Lanterman; the settlement agreement in 1994 (the Coffelt decision) ordered a reduction in the use of institutional settings and movement of institutional residents to community settings, along with specific changes to processes for individual planning of services and supports. The reduction in institutionalization mandated by the Coffelt decision stalled, however, and in 2001 another suit was filed challenging its implementation. The case (Capital People First v. California Department of Developmental Services) was settled in 2009, with the Department of Developmental Services agreeing to develop, support, fund sufficiently, and publicize the existence of services to help people move from institutions to community settings.

**lapsus linguae** see SLIP OF THE TONGUE.

**large-sample method** see ASYMPTOTIC METHOD.

**Larian** n. a trade name for MEFLOQUINE.

**Larodopa** n. a trade name for LEVODOPA.

**laryngeal framework surgery** see THYROPLASTY.

**laryngeal neoplasm** a cancerous or noncancerous growth or tumor on the larynx or any of its parts, which may affect breathing, swallowing, or speech. See PHONOSURGERY.

**laryngeal paralysis** loss of use or feeling of one or both of the vocal cords caused by disease or injury to the nerves of the larynx.

**laryngeal reflex** the reaction to laryngeal irritation manifested by coughing.

**laryngectomy** n. the surgical removal of all or a part of the larynx, commonly because of laryngeal cancer.

**laryngopharynx** n. the portion of the PHARYNX that lies below the hyoid bone (a small, U-shaped bone below and supporting the tongue). —laryngopharyngeal adj.

**larynx** n. (pl. larynges) the muscular and cartilaginous structure at the top of the trachea (windpipe) and below the tongue that contains the VOCAL CORDS. Movements of the cartilages in the walls of the larynx, controlled by the laryngeal muscles, alter the tension of the vocal cords and change the frequency of the sound (thus, the pitch) emitted by the cords when they vibrate. —laryngeal adj.

**LASS** acronym for LANGUAGE ACQUISITION SUPPORT SYSTEM.

**Lasthénie de Ferjol syndrome** a type of PATHOMIMICRY consisting of life-threatening hemorrhages caused by secretly self-inflicted wounds. It is linked with the pathology of mourning and introjection: Patients with this disorder have all experienced traumatic losses. [named in 1967 by French hematologist Jean Bernard and colleagues after the heroine in Une histoire sans nom, a novel by French writer Jules Barbey D’Aurevilly (1808–1889)]

**LAT** abbreviation for LESCH’S ALCOHOLISM TYPOLOGY.

**latah** (lattah) n. a CULTURE-BOUND SYNDROME first observed in Malaysia and Indonesia, although similar syndromes have been found in many other parts of the world. The condition primarily affects middle-aged women and is characterized by an exaggerated startle reaction. Its major symptoms, besides fearfulness, are imitative behavior in speech (see ICHOLALIA) and body movements (see ICHOPRAXIA), a compulsion to utter profanities and obscenities (see COPROLALIA), command obedience, and disorganization. See also IMU; JUMPING FRENCHMEN OF MAINE SYNDROME; MYRIACHIT.

**latchkey children** children who return after school to a home that is without adult supervision because their parents or caregivers work. The name alludes to the idea that the children have their own key with which to let themselves into the empty home after school. Also called self-care children.

**late bilingualism** see EARLY BILINGUALISM.

**late luteal phase dysphoric disorder** see PREMENSTRUAL DYSPHORIC DISORDER.
**latency stage**

*latency stage* in classical psychoanalytic theory, the stage of **psychosexual development** in which overt sexual interest is sublimated and the child’s attention is focused on skills and peer activities with members of his or her own sex. This stage is posited to last from the resolution of the **OEDIPUS COMPLEX** at about age 6, to the onset of puberty. Also called *latency; latency period; latency phase; latent stage*.

*latent addition period* a brief time span when a second stimulus can add to the persisting effects of a preceding stimulus. The period varies with the size of the nerve and synaptic factors but lasts approximately 0.5 ms.

*latent class analysis (LCA)* a method for finding discrete subgroups of related cases (*latent classes*) from multivariate CATEGORICAL DATA. For example, a health researcher might use latent class analysis to determine into which one of 10 diagnostic categories to place each individual in a group on the basis of the presence or absence of several distinct symptoms. The procedure is analogous to CLUSTER ANALYSIS in that, from a given sample of cases measured on several variables, the researcher attempts to identify a smaller number of underlying dimensions upon which to classify them. The use of a categorical *latent variable*, however, is what distinguishes latent class analysis from more traditional clustering approaches such as *FACTOR ANALYSIS*, which involve continuous latent variables. Also called *latent class modeling*.

*latent construct* see *LATENT VARIABLE*.

*latent content* 1. the hidden or disguised meanings, wishes, and ideas beneath the manifest content of any utterance or other form of communication. 2. in psychoanalytic theory, the unconscious wishes seeking expression in dreams or fantasies. This unconscious material is posited to encounter censorship (see CENSOR) and to be distorted by the DREAM-WORK into symbolic representations to protect the EGO. Through DREAM ANALYSIS, the latent content may be uncovered. See also DREAM CENSORSHIP.

*latent factor* see *LATENT VARIABLE*.

*latent goal* an objective of a program or organization that is not publicly stated, although it may be known to the staff. The term is also applied to functions that result from the need for it arises. For example, a student writing an exam may be able to cite a quotation encountered earlier accurately without having made an effort previously to learn it. Among nonhuman animals, a rat allowed to explore a maze without reward will later learn to find the goal more rapidly than a rat without prior exposure to the maze does. See also INCIDENTAL LEARNING. [first described by Edward C. TOLMAN]

*latent need* a need that is assumed to be present in a person and determines behavior but is not in that person’s conscious awareness.

*latent stage* see *LATENCY STAGE*.

*latent structure analysis* any of various statistical procedures that attempt to explain relationships among observed variables in terms of underlying **LATENT VARIABLES**, whether continuous or categorical. Examples include *FACTOR ANALYSIS*, **LATENT CLASS ANALYSIS**, and **STRUCTURAL EQUATION MODELING**. Also called *latent structure modeling*.

*latent trait theory* a general psychometric theory containing that observed traits, such as intelligence, are reflections of more basic unobservable traits (i.e., latent traits). Several quantitative models (e.g., **ITEM RESPONSE THEORY**, **FACTOR ANALYSIS**) have been developed to allow for the identification and estimation of these latent traits from manifest observations.

*latent variable* a theoretical entity or construct that is used to explain one or more **MANIFEST VARIABLES**. Latent variables cannot be directly observed or measured but rather are approximated through various measures presumed to assess part of the given construct. For example, suppose a researcher is interested in student conscientiousness. Because conscientiousness is a concept that cannot be directly evaluated, the researcher might develop a survey containing items pertaining to behavior indicative of conscientiousness, such as consistently attending classes, turning in assignments on time, engaging in school-sponsored fundraising activities, and so forth. Participants’ responses could then be analyzed to identify patterns of interrelationships from which the values of the latent variable of conscientiousness are inferred. Also called *latent construct; latent factor*. See also *FACTOR ANALYSIS; STRUCTURAL EQUATION MODELING*.

*lateral** schizophrenia** a psychotic state that starts after middle age (typically after age 45). It is believed that those with late-onset schizophrenia experience more positive symptoms (particularly persecutory delusions and visual, tactile, and auditory hallucinations) and fewer negative symptoms than do those with early-onset schizophrenia.

*lateral paraphrenia* any delusional disorder with onset after age 60. Late paraphrenia is used as a diagnostic entity in Europe and Britain. Also called *late-onset paraphrenia*.

*lateral* adj., toward the side of the body or of an organ. Compare MEDIAL.—*lateral* adv.

*lateral bundle* a bundle of nerve fibers in the dorsolateral spinal cord that carry impulses from pain- and temperature-sensory end organs.

*lateral cervical nucleus* a part of the **LEMNISCAL SYSTEM** appearing as a small mass of gray matter beneath the MEDULLA OBLONGATA. Axons from the lateral cervical nucleus project to the MEDIAL LEMNISCI.

*lateral confusion* see **MIXED LATERALITY**.

*lateral corticospinal tract* the larger of the two subdivisions of the **CORTICOSPINAL TRACT**, the other being the anterior corticospinal tract. It originates on either side of the brain, in MOTOR AREAS of the cerebral cortex, and its fibers cross the midline at the PYRAMID of the medulla oblongata to descend laterally in the white matter on the con-
lateral difference the difference between the two cerebral hemispheres in controlling various behaviors or serving cognitive functions.

lateral dominance see DOMINANCE; HEMISPHERIC LATERALIZATION.

lateral fissure see LATERAL SULCUS.

lateral geniculate nucleus (LGN) either of a pair of nuclei that protrude slightly from each side of the thalamus to the rear. Each LGN receives the fibers of the retinal ganglion cells and relays information to the VISUAL CORTEX via OPTIC RADIATIONS. Also called lateral geniculate body. See MAGNOCELLULAR SYSTEM; PARVOCELLULAR SYSTEM. See also MEDIAL GENICULATE NUCLEUS.

lateral gyrus a convolution in the surface of the brain located in the area of the CINGULATE CORTEX above the CORPUS CALLSOM.

lateral hypothalamic syndrome a four-stage pattern of recovery from lesions of the LATERAL HYPOTHALAMUS induced in nonhuman animals. The first stage is marked by inability to eat and drink (aphagia and adipsia), and without assistance (including forced feeding), the animal is likely to die. The second stage includes a period of continued inability to drink and poor appetite for food (adipsia-anorexia), when only wet, palatable foods are accepted. In the third stage, the animal will eat hydrated dry food but continues to avoid water intake and may suffer dehydration. Recovery is the fourth stage, in which new, altered feeding and drinking habits are established and the animal maintains a stable, albeit lower, body weight. Compare VENTROMEDIAL HYPOTHALAMIC SYNDROME.

lateral hypothalamus (LH) the region of the hypothalamus that may be involved in the regulation of eating. Lesions of the lateral hypothalamus in animals result in fasting and weight loss. Stimulation of that part of the brain increases food intake.

lateral inhibition in perception, a mechanism for detecting contrast in which a sensory neuron is excited by one particular receptor but inhibited by neighboring (lateral) receptors. In vision, for example, lateral inhibition is seen in neurons that respond to light at one position but are inhibited by light at surrounding positions.

laterality n. the preferential use of one side of the body for certain functions, such as eating, writing, and kicking. See also HANDEDNESS; MIXED LATERALITY.

lateralization n. 1. one-sided preferences, such as HANDEDNESS, EYE DOMINANCE, and FOOTEDNESS. Observed more frequently in humans than in other primates, lateralization is manifested in the way tasks are performed and can also be inferred from the effects of localized brain damage. DIRECTIONAL CONFUSION and DYSLEXIA may be diagnosed through lateralization tests. See also HEMISPHERIC LATERALIZATION; SPEECH LATERALIZATION. 2. in audition, see AUDITORY LOCALIZATION.

lateralized readiness potential (LRP) an EVENT-RELATED POTENTIAL that is a measure of the difference in activation between the left and right motor areas of the brain. This potential is taken to indicate preparation to respond with one hand or the other, because each hand is controlled by the contralateral hemisphere.

lateral lemniscus a bundle of nerve fibers running from auditory nuclei in the brainstem upward through the PONS and terminating in the INFERIOR COLLICULUS and MEDIAL GENICULATE NUCLEUS. It is part of the LEMNISCAL SYSTEM.

lateral-line system a sensory system, found in many kinds of fish and some amphibians, that informs the animal of water motion in relation to the body surface.

lateral lisp see LISP.

lateral olfactory tract a bundle of axons of MITRAL CELLS that forms the primary communication between the olfactory system and portions of the brain. See also OLFACTORY TRACT; TUFTED CELL.

lateral posterior nucleus a group of visually responsive neurons in the THALAMUS that are used for brightness discrimination. They project to several areas in the occipital and parietal lobes.

lateral preoptic area (LPOA) a region of the anterior hypothalamus involved in reproductive PHOTOPERIODISM and sleep regulation.

lateral rectus an extrinsic EYE MUSCLE that rotates the eyeball laterally (i.e., outward, away from the midline). Also called external rectus.

lateral social comparison see SOCIAL COMPARISON THEORY.

lateral specialization the development of specialized capabilities in either the right or the left cerebral hemisphere. Examples include the tendency for speaking, writing, or calculation to involve the left hemisphere and for nonverbal ideation and spatial construction to involve the right hemisphere.

lateral spinothalamic tract see SPINOthalamic TRACT.

lateral sulcus a prominent groove that runs along the lateral surface of each CEREBRAL HEMISPHERE separating the TEMPORAL LOBE from the FRONTAL LOBE and PARITIAL LOBE. Also called fissure of Sylvius; lateral fissure; Sylvian fissure.

lateral thalamic nucleus either of a pair of large masses of cell bodies, one on each side of the THALAMUS, that relay incoming sensory impulses. The lateral nuclei are the most recently evolved parts of the thalamus.

lateral thinking creative thinking that deliberately attempts to reexamine basic assumptions and change perspective or direction to provide a fresh approach to solving a problem. This term is often used synonymously with DIVERGENT THINKING. [defined by British psychologist Edward de Bono (1933–)]

lateral ventricle a chamber of complex shape that lies within each cerebral hemisphere in the brain and serves as a reservoir of cerebrospinal fluid (see VENTRICLE). Each lateral ventricle communicates with the THIRD VENTRICLE at a point near the thalamus.

later life adjustment adaptation to stress caused by events associated with life as an older adult, including chronic disease, familial loss, and lifestyle changes.

lateropulsion n. a symptom of certain disorders of the central nervous system (e.g., parkinsonism) in which the individual makes involuntary sidewise movements.

lateroventral nucleus one of a group of relay nuclei...
late-sequence theory

in the thalamus that transmit impulses from the cerebellum to the motor cortex for coordination of muscular movements. Also called ventral lateral nucleus.

late-sequence theory any theory of attention proposing that selection occurs after stimulus identification. According to late-sequence theory, within sensory limits, all stimuli—both attended and unattended—are processed to the same deep level of analysis until stimulus identification occurs; subsequently, only the most important stimuli are selected for further processing. Compare early-sequence theory.

Latin square a type of within-subjects design in which treatments, denoted by Latin letters, are administered in sequences that are systematically varied such that each treatment occurs equally often in each position of the sequence (first, second, third, etc.). The number of treatments administered must be the same as the number of groups or individual participants receiving them. For example, for an experimental design involving four treatments (A, B, C, and D) and four people, one person might receive Treatment A, then B, then C, and then D; a second person might receive them in sequence B, C, D, and A; a third person in sequence C, D, A, and B; and a fourth person in sequence D, A, B, and C. It is important to note that although Latin squares control for order effects they do not control for carryover effects or practice effects. See also balanced Latin square; Graeco-Latin square.

latitude of acceptance in social judgment theory, a range of attitudinal positions that includes a person's preferred position and the range of positions that he or she considers acceptable. See also latitude of noncommitment; latitude of rejection.

latitude of noncommitment in social judgment theory, a range of attitudinal positions that a person considers to be neither acceptable nor objectionable. See also latitude of acceptance; latitude of rejection.

latitude of rejection in social judgment theory, a range of attitudinal positions that a person rejects. See also latitude of acceptance; latitude of noncommitment.

lattah n. see latah.

Latuda n. a trade name for lurasidone.

laudanum n. a mixture of alcohol and opium once commonly used as an analgesic and anesthetic. The mixture was introduced around 1530 by German alchemist and physician Paracelsus (1493–1541) and was widely consumed in 18th-century England.

laughing gas see nitrous oxide.

laugh n. vocal expression of amusement, enjoyment, or derision, characterized by inspiratory and expiratory movements occurring in rapid succession. Laughter is pleasurable because it serves to release tension built up when people listen to an amusing story or watch an amusing event (see release theory of humor). Laughter may also result when states of threat occur in a safe context (see arousal jag) or from an abrupt resolution of a cognitive incongruity. In psychoanalytic theory, laughter may be viewed as a defense against crying or embarrassment. Unrestrained or paroxysmal laughing spells have been found to precipitate cataplectic attacks, to be a common manifestation in manias, and to be an occasional symptom of psychomotor seizures among children. Spasmodic laughter, or gelasmatism, is also found in schizophrenia, hysteria, and organic (especially bulbar and pseudobulbar) diseases of the brain, as well as in choreomania. See also humor.

Launois–le Cleret syndrome see fröhlich's syndrome.

Laurence–Moon–Bardet–Biedl syndrome an autosomal recessive disorder first described in 1866 by British ophthalmologist John Zachariah Laurence (1830–1870) and his colleague, British-born U.S. ophthalmologist Robert C. Moon (1844–1914), in four siblings with progressive visual impairment, obesity, paralysis, and cognitive impairment. In 1920 and 1922, respectively, French physician George Bardet (1885–1970) and Romanian-born Austrian physician Artur Biedl (1869–1933) independently described patients sharing only some of the symptoms seen in the original siblings, plus additional symptoms that they did not exhibit (e.g., polydactyly, impaired speech, hypogonadism). The syndrome was thus divided into two related disorders, Laurence–Moon syndrome and Bardet–Biedl syndrome (BBS). However, because of overlapping phenotypes, it is thought to be one syndrome, with BBS being the term now commonly used to cover both syndromes. Also called Laurence–Moon–Biedl–Bardet syndrome.

law n. 1. a formal statement describing a regularity (e.g., of nature) to which no exceptions are known or anticipated. See causal law; natural law. 2. in science, mathematics, philosophy, and the social sciences, a theory that is widely accepted as correct and that has no significant rivals in accounting for the facts within its domain. 3. a formally established rule regulating the conduct of people within a particular jurisdiction that must be obeyed to avoid legal sanctions.

law-and-order orientation see conventional level.

law of advantage the principle that one of two or more incompatible or inconsistent responses has the advantage of being more beneficial or attractive and therefore occurs more frequently than the others.

law of assimilation 1. the principle that organisms respond to new situations in a manner similar to their reactions to familiar situations. See generalization. 2. see assimilation.

law of closure see closure.

law of combination the principle that (a) two or more stimuli occurring simultaneously or in proximity may produce a combined response and (b) that two responses may occur together when a stimulus eliciting either of them is presented.

law of common fate see common fate.

law of common region see common region.

law of constancy 1. the principle that visual stimuli retain a constant appearance despite alterations in stimulus conditions, such as the level of illumination (brightness constancy) or the angle subtended on the retina (size constancy). 2. in psychoanalytic theory, see principle of constancy.

law of contingency a principle of association stating that forming connections between ideas, events (e.g., stimuli and responses), or other items depends on their proximity in space or time. It has been supplemented by the principle of contingency: that is, the degree of association between events increases when the probability of one event occurring is increased by the occurrence of the other. The com-
bination of contiguity and contingency is now viewed as essential to forming associations and is a keystone of most contemporary theories of learning, memory, and knowledge.

**law of continuity** see GOOD CONTINUATION.

**law of contrast** a principle of association stating that opposites are reminders of one another; encountering or thinking about one (e.g., a snow-covered field) tends to bring to mind the other (e.g., a sunny beach). Initially proposed as a distinct, essential concept in ASSOCIATIONISM, the law of contrast later came to be viewed as a special case of the LAW OF CONTIGUITY.

**law of disuse** see LAW OF USE.

**law of effect** broadly the principle that consequences of behavior act to modify the future probability of occurrence of that behavior. As originally postulated by Edward L. THORNDIKE, the law of effect stated that if a response R produces a satisfying state of affairs (or a positive reinforcer), then an association is formed between R and the stimuli S present at the time R was made. As a result of this S–R association, R occurs whenever the organism encounters S. This part of the law of effect was the foundation of S–R theories of learning. Originally, THORNDIKE also proposed that the presentation of an aversive or annoying consequence serves to weaken S–R associations, with the consequence that responding becomes suppressed. He later revised the law to include only the response-strengthening effect of reinforcement; the original version of the law was called the strong law of effect, and the revised version was known as the weak law of effect.

**law of equality** a gestalt principle that parts of a figure perceived as equal tend to form a whole.

**law of equipotentiality** see EQUIPOTENTIALITY.

**law of exercise** the principle that repetition of some act makes that act more probable in the future. The law of exercise was first suggested and then discarded by Edward L. THORNDIKE.

**law of filial regression** the principle that inherited traits tend to revert toward the mean for the species; for example, very tall fathers tend to have sons shorter than themselves but taller than the population mean, and very short fathers tend to have sons taller than themselves but shorter than the population mean.

**law of forward conduction** the rule that, under natural conditions, nerve impulses always travel in the same direction, from the AXON HILLOCK, where the AXON originates at the cell body, to the terminal button of the axon. Also called forward-conduction law. Compare ANTIDROMIC CONDUCTION.

**law of frequency** a principle of association stating that the more often ideas, events (e.g., stimuli and responses), or other items co-occur, the stronger the connections between them. The law of frequency is a concept of ASSOCIATIONISM.

**law of good continuation** see GOOD CONTINUATION.

**law of good figure** the principle of Prägnanz as applied to vision. It states that any pattern is perceived so that the resulting figure is as simple as possible.

**law of good shape** see GOOD SHAPE.

**law of inclusiveness** see INCLUSIVENESS.

**law of initial values** the principle that the initial level of a physiological response is a major determinant of a later response in that system. Thus, if an individual’s pulse rate is high, his or her cardiovascular response to an emotion-provoking stimulus will be weaker than if the initial pulse rate had been low. Also called initial value dependency; initial values law; rate dependence effect. See RATE DEPENDENCY. [proposed in 1931 by U.S. neuropsychiatrist Joseph Wilder (1895–1976)].

**law of large numbers** a mathematical principle indicating that as the sample size increases, the theoretical expectations of its statistical properties will be more and more closely realized. For example, as the number of replications of an experiment increases, the average (MEAN) of the observed results will approach the true average (theoretical probability in the population) with increasing accuracy. According to the strong law of large numbers, the average of the results obtained from a large number of trials will converge upon the theoretically expected value, becoming closer as more trials are performed. In distinction, the weak law of large numbers states that the average is likely to converge upon the expected value as more trials are conducted. Thus, the essential difference between the two laws is that the former insists on convergence whereas the latter expects convergence.

**law of least action** see PRINCIPLE OF LEAST EFFORT.

**law of mass action** see MASS ACTION.

**law of neurobiotaxis** the principle that DENDRITES of developing neurons grow in the direction of the AXONS of nearby active neurons. See NEUROBIOTAXIS.

**law of parsimony** the principle that the simplest explanation of an event or observation is the preferred explanation. Simplicity is understood in various ways, including the requirement that an explanation should (a) make the smallest number of unsupported assumptions, (b) postulate the existence of the fewest entities, and (c) invoke the fewest unobservable constructs. Also called economy principle; principle of economy; principle of parsimony. See ELEGANT SOLUTION; OCCAM’S RAZOR.

**law of Prägnanz** see PRÄGNANZ.

**law of precision** in GESTALT PSYCHOLOGY, the principle that all percepts tend to become organized into regular, symmetrical forms with precise contours. The term is used occasionally as a synonym for the principle of PRÄGNANZ.

**law of primacy** see PRIMACY EFFECT.

**law of prior entry** the principle that when two stimuli are presented simultaneously, one attended to and the other not, the attended stimulus will be perceived as having occurred before the other. See COMPLICATION EXPERIMENT.

**law of proximity** see PROXIMITY.

**law of recency** see RECENCY EFFECT.

**law of similarity** 1. a principle of association stating that like produces like: Encountering or thinking about something (e.g., one’s birthday month) tends to bring to mind other similar things (e.g., other people one knows with the same birthday month). The law of similarity is fundamental to ASSOCIATIONISM. 2. see SIMILARITY.

**law of specific nerve energies** see SPECIFIC-ENERGY DOCTRINE.

**law of sufficient reason** the proposition, introduced
by Gottfried Wilhelm Leibniz, that if something exists, it is necessarily the case that there is sufficient reason for its existence. The principle implies an inherent rationale for the universe. It is complemented by Leibniz’s law of insufficient reason, which states that if there is not sufficient reason for the existence of something, it will not exist.

**law of symmetry** see **SYMMETRY**.

**law of use** the principle that the more an association is used, the stronger it becomes. The complementary law of disuse states that the less an association is used, the weaker it becomes. Both laws were first suggested and then discarded by Edward L. Thorndike.

**laws of grouping** see **GESTALT PRINCIPLES OF ORGANIZATION**.

**laws of learning** statements describing the circumstances under which learning generally occurs. Over the centuries, such laws have been hypothesized and studied by philosophers such as Aristotle, John Locke, and John Stuart Mill and physiologist Ivan Pavlov, among others. The modern laws of learning were formalized in 1911 by Edward L. Thorndike and have been modified numerous times since. Among the currently accepted laws of learning are the law of effect, the law of contiguity, the law of frequency, the primacy effect, and the recency effect.

**laws of thought** certain principles of logic, such as the identity principle, that are deemed to be so essential to rational thought as to assume the character of law. Indeed, such principles define the very idea of logical thought. Which logical principles should be included in a set of such laws is, however, a matter of debate.

**laxative addiction** a dependence on the use of laxatives to induce bowel movements. The addiction is a vicious cycle, in which the use of laxatives gradually reduces bowel activity so that further use becomes the only way to avoid constipation. Laxative addiction is often associated with eating disorders in which laxatives are routinely used for purging. See also enema addiction; kismaphilia.

**lay analysis** historically, psychoanalytic therapy performed by a person who had been trained in psychoanalytic theory and practice but was not a physician (i.e., a layperson). Beginning in the 1950s, psychoanalytic training institutions began training licensed mental health professionals who are linked to the leader by a strongly positive LMX relationship (a) leaders develop exchange relationships with each one of their subordinates and (b) the quality of these leader-member exchange (LMX) relationships affects subordinates' responsibility, influence over decisions, access to resources, and performance. Those group members who are linked to the leader by a strongly positive LMX relationship are part of the unit’s ingroup, whereas those who have a low-quality LMX relationship are relegated to the outgroup.

**leader categorization theory** an information-processing model that assumes that perceivers automatically and spontaneously appraise the extent to which people, including themselves, can be classified as leaders. Such judgments are determined by implicit leadership theories that organize perceivers’ general beliefs about the characteristics that most leaders possess. See also Attribution Theory of Leadership; Leader Prototype.

**leaderless group discussion** an exchange of opinions, ideas, and information on some topic by the members of a group with no identified leader. Such discussions are used in studies of group productivity and leadership emergence to evaluate specific interpersonal and leadership skills; in training and educational settings to provide participants with insights into their own and others’ behaviors in open, unstructured group situations; and in screening candidates for positions in business, social work, teaching, and the military.

**leaderless group therapy** a form of group therapy in which leaderless meetings are held either (a) on an occasional or regularly scheduled basis as an adjunct to the traditional therapist-led process or (b) on an entirely self-directed basis in which a group always meets without a designated leader.

**leader match** an approach to leadership training based on the contingency theory of leadership of Fred Fiedler. It proposes (a) that effective leadership is dependent on a match between the individual's leadership style and the particular group situation and (b) that individuals usually find it difficult to alter their established style of leadership but (c) that leaders can be trained to diagnose a situation and alter it to fit their own style.

**leader–member exchange theory (LMX theory)** a dyadic, relational approach to leadership that assumes that (a) leaders develop exchange relationships with each one of their subordinates and (b) the quality of these leader–member exchange (LMX) relationships affects subordinates' responsibility, influence over decisions, access to resources, and performance. Those group members who are linked to the leader by a strongly positive LMX relationship are part of the unit’s ingroup, whereas those who have a low-quality LMX relationship are relegated to the outgroup.

**leader prototype** a cognitive representation of an actual or abstract leader who is thought to possess features shared by most or all individuals considered to be leaders and so to exemplify that construct. See also Attribution Theory of Leadership; Leader Categorization Theory.

**leadership** n. 1. the processes involved in leading others, including organizing, directing, coordinating, and motivating their efforts toward achieving certain group or organizational goals. Leadership tends to be reciprocal (leaders influence followers, and followers influence leaders), trans-
actional (leaders and followers exchange their time, energies, and skills to increase their joint rewards), transformational (leaders inspire and motivate followers), and cooperative rather than coercive (followers voluntarily accept the leader's suggestions). See TRANSACTIONAL LEADERSHIP; TRANSFORMATIONAL LEADERSHIP. 2. the traits or behaviors characteristic of an effective leader. See LEADERSHIP THEORIES.

leadership emergence the process by which an individual is recognized (formally or informally, perceptually or behaviorally, implicitly or explicitly) as the leader of a formerly leaderless group. See EMERgent LEADER.

leadership labyrinth a metaphor for the series of detours, dead ends, and unusual paths that women and members of minority groups encounter in many organizations and that serve as obstacles to reaching the highest positions of authority. For women, these obstacles include not only sex discrimination but also domestic responsibilities (see Moomy TRACK) and sometimes women's own doubts and failure to believe in themselves. Compare Glass Ceiling. [proposed in 2007 by U.S. social psychologists Alice H. Eagly (1938— ) and Linda L. Carli]

leadership role 1. structurally, the position occupied by the person who is responsible for guiding others in their pursuits. 2. behaviorally, a relatively coherent set of task and relationship behaviors expected of the individual who is formally or informally identified as a group's leader.

leadership style 1. the stable behavioral tendencies and methods displayed by a particular leader when guiding a group. Common styles include those of autocratic leaders (see AUTHRITARIAN LEADER), BUREAUCRATIC LEADERS, CHARISMATIC LEADERS, DEMOCRATIC LEADERS, and LAISSEZ-FAIRE LEADERS. 2. in style and contingency LEADERSHIP THEORIES, the extent to which the leader's approach can be characterized as TASK MOTIVATED and RELATIONSHIP MOTIVATED. Most such theories argue that effective leaders balance these two basic orientations in the groups they lead. See also LEAST PREFERRED COWORKER SCALE.

leadership substitute any aspect of the social setting, including the nature of the work task, the characteristics of the group members, or the qualities of the group or organization itself, that reduces or eliminates the need for a specific individual who performs such typical leadership behaviors as organizing, directing, coordinating, supporting, and motivating the group members.

leadership theories theories advanced to explain the effectiveness or ineffectiveness of leaders. The main types include TRAIT THEORIES OF LEADERSHIP, which focus on such characteristics as supervisory ability, intelligence, self-assurance, and decisiveness; BEHAVIORAL THEORIES OF LEADERSHIP, which focus on the task-based and relationship-based activities of the leader; CONTINGENCY THEORIES OF LEADERSHIP, which attempt to describe what type of leadership style is most effective in different situations; and COGNITIVE THEORIES OF LEADERSHIP, such as LEADER CATEGORIZATION THEORY or the Attribution Theory of Leadership, which describe the way subordinates' perceptions of their leaders influence leadership effectiveness. See also IMPLICIT LEADERSHIP THEORIES.

lead-pipe rigidity MUSCULAR RIGIDITY that produces a smooth, steady resistance to passive movement of the limbs of people with parkinsonism or cerebral palsy. Compare Cogwheel Rigidity.

leaf node see GRAPH: TREE.

leaf switch a nonrigid, flexible LEVER SWITCH that is activated by a slight bending, enabling it to be operated by a user with a disability.

leakage n. the unintended revelation that a person has a feeling or motive different from the one intended to be communicated to others. It may be manifested, for example, by frequent speech pauses when a person describes an event untruthfully. See VERBAL LEAKAGE. See also DECEPTION CLUE.

lean medium see MEDIA RICHNESS.

learned helplessness a phenomenon in which repeated exposure to uncontrollable stressors results in individuals failing to use any control options that may later become available. Essentially, individuals are said to learn that they lack behavioral control over environmental events, which, in turn, undermines the motivation to make changes or attempt to alter situations. The phenomenon was first described in 1967 by U.S. psychologists J. Bruce Overmier (1938— ) and Martin E. P. Seligman (1942— ) after experiments in which nonhuman animals exposed to a series of unavoidable electric shocks later failed to learn to escape these shocks when tested in a different apparatus, whereas animals exposed to shocks that could be terminated by a response did not show interference with escape learning in another apparatus. A syndrome with three features developed: (a) a motivational deficit characterized by a failure to respond when challenged with further aversive events, (b) an associative deficit characterized by impairment of learning from successful coping, and (c) an emotional deficit characterized by apparent underreactivity to painful events—although later research revealed by assay- ing corticoid levels that the animals were very stressed.

In the 1970s, Seligman extended the concept from nonhuman animal research to clinical depression in humans and proposed a learned helplessness theory to explain the development of or vulnerability to depression. According to this theory, people repeatedly exposed to stressful situations beyond their control develop an inability to make decisions or engage effectively in purposeful behavior. Subsequent researchers have noted a robust fit between the concept and POSTTRAUMATIC STRESS DISORDER.

learned optimism an explanatory style that attributes causes for negative events to factors that are external, unstable, and specific. That is, problems are believed to be caused by other people or situational factors, the cause are seen as fleeting in nature, and they are localized to one or a few situations in one's life. According to LEARNED HELPLESSNESS theory, the manner in which individuals routinely explain the events in their lives can drain or enhance motivation, reduce or increase persistence, and enhance vulnerability to depression or protect against it, making learned optimism a putative mechanism by which therapy ameliorates depression.

learned response see ACQUIRED RESPONSE.

learned taste aversion see CONDITIONED TASTE AVERSION.

learned treatise exception an exception to the hearsay rule (which states that evidence from statements by individuals other than the testifying individual is inadmissible in court) that allows expert witnesses to speak for others if they are reporting an opinion shared by the experts in their field. Therefore, an expert may report findings contained in journal articles or similar published treatises for the purpose of informing the court of the general expert
learning
goal in the analysis of personality and goal-directed motivation of U.S. personality psychologist Carol S. Dweck (1946– ), a goal to acquire mastery of a task or subject matter. Also called mastery goal.

learning model a general perspective on human development in which children are viewed as passively absorbing the relevant features of the environment in a continuous line of development. This emphasis on environmental conditions is less influential within developmental psychology than previously, rapidly being eclipsed by the life span perspective and other approaches.

learning paradigm an experimental design used to research incidental learning. Groups of participants are shown the same stimuli (e.g., a list of 20 words) but asked to perform different tasks with them (e.g., picture associated words, determine the average number of letters in each word). Afterward, the participants unexpectedly are asked to recall as many of the presented items as possible.

Learning Potential Assessment Device (LPAD) a test that dynamically assesses individuals’ learning potential. First used primarily for individuals with intellectual disability, it has since been used for participants displaying a wide variety of skill levels. The test exists in individual and group versions; it is dynamic in that the examinee receives feedback about his or her performance while actually taking the test. The LPAD is intended primarily for professionals, who is trained to identify and assist students with problems associated with learning disabilities.

learning disability (LD) any of various conditions with a neurological basis that are marked by substantial deficits in acquiring certain scholastic or academic skills, particularly those associated with written or expressive language. Learning disabilities include learning problems that result from perceptual disabilities, brain injury, and minimal brain dysfunction but exclude those that result from visual impairment or hearing loss; intellectual disability; emotional disturbance; or environmental, cultural, or economic factors. For diagnostic purposes, learning disability is the condition that exists when a person’s actual performance on achievement testing is substantially (typically 2 standard deviations) below that expected for his or her established intelligence, age, and grade.

learning disorder (LD) in DSM–IV–TR, any neurologically based information-processing disorder characterized by achievement that is substantially below that expected for the age, education, and intelligence of the individual, as measured by standardized tests in reading and mathematics and written material. In standard practice, a discrepancy of 2 standard deviations must exist between general intelligence testing scores (as measured by a standard normed IQ test) and achievement scores (as measured by a standard normed achievement test). A discrepancy of 1 to 2 deviations can be considered a learning disorder if some other special feature is present, such as a cognitive-processing disorder, a relevant mental disorder, a prominent medical disability, or exceptional absence from formal education. Major types of learning disorders are disorder of written expression, mathematics disorder, nonverbal learning disorder, and reading disorder. This term essentially is synonymous with learning disability and in DSM–5 is called specific learning disorder, a category that subsumes impairments of reading, mathematics, and written expression as specifiers rather than as distinct diagnostic entities themselves.

Learning Abilities Measurement Program (LAMP) a cognitive-assessment program most often associated with the measurement of occupational work skills. It is exemplified by an information-processing model of assessment, such as that used by the British Army Recruitment Battery (BARB). LAMP assists in interpretive analysis of job- and task-ability clusters.

learning by doing see progressive education.

learning center 1. an educational technique in which skill-specific sets of activities are developed for students to work on independently at their own pace for a particular length of classroom time during each school day. For example, a kindergarten teacher may create a center for counting, where students color shapes numbered 1 through 10 and then glue them in sequence onto a piece of construction paper; a center for vocabulary, where students illustrate their own personal dictionaries with pictures that correspond to the words; and a center for fine motor skills, where students trace an animal from a pattern and then cut out and decorate it. During learning center time, students are divided into small groups that each have a different task to complete, with the tasks periodically rotating among the groups. Commonly seen in the elementary-school grades, such self-directed learning is intended to demonstrate or strengthen skills with which students already are familiar rather than to facilitate the acquisition of new skills. 2. more generally, any educational establishment or program that facilitates students’ acquisition of knowledge or understanding of topics by providing additional support and personalized instruction outside of regular school hours. Learning centers may be government funded or privately funded, and they may be offered within existing community or educational facilities, in stand-alone facilities, or online. They serve a range of skill levels. The test exists in individual and group versions; it is dynamic in that the examinee receives feedback about his or her performance while actually taking the test. The LPAD is intended primarily for
clinical use, yielding interpretive data to help the examiner understand the examinee’s pattern of strengths and weaknesses. [devised in 1985 by Romanian-born Israeli psychologist Reuven Feuerstein (1921–2014) and colleagues]

**learning set** a phenomenon observed when a participant is given a succession of discrimination problems to learn, such as learning that one object contains a food reward and a different object does not. After a large number of such problems, the participant acquires a rule or MENTAL SET for solving them, and successive discriminations are learned faster. See LEARNING TO LEARN. [introduced in 1949 by Harry Harlow]

**learning skills** the abilities involved in gathering knowledge and increasing understanding, especially those abilities demonstrated in educational settings and developed through study, classroom instruction, and the like.

**learning strategy** a mental or behavioral approach or method used to facilitate learning, such as forming a mental image, organizing items, searching for existing associations, or practicing RETRIEVAL.

**learning style** see COGNITIVE STYLE.

**learning support center** see LEARNING CENTER.

**learning technologies** electronic tools or advanced machines used to facilitate learning, such as film, television, computers, and the Internet. Web-based instruction plays a growing role in modern DISTANCE LEARNING.

**learning theory** a body of concepts and principles that seek to explain the learning process. Learning theory actually encompasses a number of specific theories whose common interest is the description of the basic LAWS OF LEARNING, usually derived from studies of classical and instrumental conditioning and verbal learning. These include Hull’s mathematico-deductive THEORY OF LEARNING, the purposive behaviorism of Edward C. Tolman, the Rescorla–Wagner Theory, and the COMPARATOR HYPOTHESIS, among others.

**learning to learn** 1. repeated practice with one kind of task but learning different material each time, which facilitates the ability to learn new material. Harry Harlow demonstrated learning to learn by teaching monkeys to discriminate between pairs of objects. The animals eventually became skilled at rapidly learning new discriminations, sometimes in a single trial. See LEARNING SET; TRANSFER OF TRAINING. 2. acquiring effective learning strategies such as planning; goal-setting; scheduling; using mnemonics, outlines, and flashcards; and monitoring progress.

**learning trial** a single presentation of the information to be learned in a learning experiment. Examples of learning trials are a single pairing of the conditioned stimulus and the unconditioned stimulus in classical conditioning and a single presentation of a word to be remembered in a memory experiment. The amount of learning is typically expressed as a function of the number of learning trials given, as in a LEARNING CURVE. Also called ACQUISITION trial.

**learning types** individual differences in people’s preferred ways of organizing and processing information (see COGNITIVE STYLE). For example, some people may prefer to remember auditory information and develop strategies to recall verbal information; others may prefer visual and imaginal coding of material.

**least squares regression** a type of REGRESSION ANALYSIS in which the researcher strives to develop a LEAST-SQUARED-ERRORS SOLUTION or LEAST SQUARES SOLUTION to describe the relationship between an outcome or DEPENDENT VARIABLE and one or more predictors or INDEPENDENT VARIABLES. That is, one develops a model that is the best fit for the data because it yields the smallest squared difference.
leaving the field

ences between the actual observations and their values as predicted by the model. Also called least squares estimation: ordinary least squares (OLS) regression. See LEAST SQUARES CRITERION.

leaving the field the act of removing oneself from a situation when confronted with seemingly insurmountable obstacles, insoluble conflicts, or intensely frustrating problems. It may involve physical withdrawal, escape into psychogenic illness, or some other behavior, such as distraction or changing the subject during a conversation.

Leber's disease a hereditary visual disorder characterized by slowly progressive optic atrophy with normal peripheral vision but blind areas of the retina toward the center. The genetic defect is transmitted by females, but males are most often affected, with symptoms beginning around the third decade of life. Also called Leber's optic atrophy. See also AMAUROSIS. [Theodor Leber (1840–1917), German ophthalmologist]

Leboyer technique an approach to childbirth that focuses on the feelings and sensations of the baby. It advocates dim lights, quiet, delay in severing the umbilical cord, body contact between newborn and parents, and an immediate warm bath that approximates the conditions within the womb. See also LAMAZE METHOD. [Frédéric Leboyer (1918–), French obstetrician]

lecanomancy n. a system of divination in which a sensitive or clairvoyant looks into a basin, bowl, or vase of water, often after rocks have been dropped in or oil has been added, and sees alleged visions of the future or interprets the observed patterns or ripples. —lecanomancer n.

Lectopam n. a trade name for BROMAZEPAM.

lecture method the formal, verbal presentation of information or other material by an instructor to a group of students or other learners. The lecture method is used mainly when groups are large or time is limited (e.g., in personnel training). It can also be used to introduce other instructional methods, such as audiovisual presentations or role play, or to summarize material developed by other means.

Lee–Boot effect a prolonged diestrus phase, induced by pheromones, that occurs when a female animal is housed with other females. [first reported in 1955 by S. van der Lee and L. M. Boot. Dutch biologists]

left brain the left cerebral hemisphere of the brain. The term is sometimes used to describe functions or COGNITIVE STYLE supposedly mediated by the left (rather than by the right) hemisphere, such as analytical thinking. Compare RIGHT BRAIN. See also HEMISPHERIC LATERALIZATION.

left censoring the situation in which a researcher cannot determine the precise time at which a target event occurred for some individuals within a sample because those participants experienced the event prior to the observation period. For example, left censoring might arise in a study of alcohol initiation among high school students because a subset of the sample is likely to have initiated use prior to high school entry. See also RIGHT CENSORING.

left-handedness n. the preferential use of the left hand for major activities, such as eating, writing, and throwing. See also LATERALITY; SINISTRALITY. Compare RIGHT-HANDEDNESS.

left hemisphere the left half of the cerebrum, the part of the brain concerned with sensation and perception, motor control, and higher level cognitive processes. The two CEREBRAL HEMISPHERES differ somewhat in function; for example, in most people, the left hemisphere has greater responsibility for speech. See HEMISPHERIC ENCODING–RETRIEVAL ASYMMETRY; HEMISPHERIC LATERALIZATION. Compare RIGHT HEMISPHERE.

left-hemisphere consciousness the claim by U.S. cognitive neuropsychologist Michael S. Gazzaniga (1939– ) that the “speaking hemisphere” of the brain (the left hemisphere in most people) is the seat of consciousness. Others, including Roger SPERRY, have proposed that the right hemisphere may also have its own form of consciousness. See RIGHT-HEMISPHERE CONSCIOUSNESS.

legal blindness see BLINDNESS.

legal capacity the ability to acquire the knowledge and understanding necessary to make a rational choice regarding any issue that has legal implications (e.g., entering into contracts, making a will, standing trial). See also COMPETENCY TO STAND TRIAL.

legal psychiatry see FORENSIC PSYCHIATRY.

legal psychology see FORENSIC PSYCHOLOGY.

legal testimony evidence given by an individual in court under oath or affirmation, either orally or in a written affidavit. Written evidence that was obtained during a deposition (an official pretrial questioning of an individual) may also be presented as testimony.

legasthenia n. a controversial syndrome in which the primary symptom is difficulty in synthesizing letters into words and analyzing words by breaking them down into their component letters, despite adequate intellectual and perceptual ability.

legend n. 1. a traditional story that has been passed down from an earlier period and may or may not contain elements of historical truth. Legends usually grow by a process of CHAIN REPRODUCTION. See also MYTHOLOGY. 2. a caption or key that explains illustrations or symbols on a graph, map, or chart. —legendary adj.

legibility n. 1. capability of being read or deciphered. 2. the ease with which an environment can be cognitively represented, which determines one's ability to navigate or find one's way within an environment or setting. LANDMARKS, the overall shape or configuration of street grids, and building layout can significantly influence legibility. See also COGNITIVE MAP; ENVIRONMENTAL COGNITION. —legible adj.

legitimate authority see AUTHORITY.

legitimate power a capacity to influence others that is based on the influencer’s position or role in the group and members’ recognition that an individual in such a position has the right to require and demand compliance with his or her directives.

leisure lifestyle a way of life in which leisure and free time play a prominent role. Leisure activities (e.g., hobbies, recreation, self-selected activities) largely or entirely replace obligatory activities (e.g., work for pay), as is the case for people who have retired from full-time paid employment.

Lejeune syndrome see CRI DU CHAT SYNDROME.

lek mating a mating system in which several males congregate at one location during the mating season, forming small individual territories and competing with each other.
for mates by giving complex, elaborate visual and vocal displays. Females are attracted by these displays and move among the males to choose their mate. Typically, the males provide no parental care to resulting offspring.

**lemma n.** 1. in logic, a subsidiary proposition used as a part of the proof of a subsequent proposition. The proof of the lemma may or may not be included in the argument. 2. in linguistics, a word considered to be the word in its basic dictionary form together with all of its inflected forms. For example, the lemma be consists of be plus am, are, is, was, were, being, and been.

**lemniscal system** a major somatosensory system consisting of long, ascending neural pathways projecting to the thalamus. It includes the medial lemniscus, lateral lemniscus, and secondary trigeminal projections.

**length of stay (LOS)** the length of an inpatient’s continuous stay in a hospital. A utilization review will normally compare the LOS under review with regional norms, as expressed by the average LOS for the relevant diagnosis.

**leniency error** a type of rating mistake in which the ratings are consistently overly positive, particularly regarding the performance or ability of the participants. It is caused by the rater’s tendency to be too positive or tolerant of shortcomings and to give undeservedly high evaluations. Also called leniency bias. Compare severity error.

**lens n.** 1. in vision, a transparent, biconvex structure in the anterior portion of the eyeball (just behind the iris) that provides the fine, adjustable focus of the optical system. It is composed of tiny hexagonal prism-shaped cells, called lens fibers, fitted together in concentric layers. 2. an artificial enhancer to the eyes’ natural structure, made of glass or plastic, that serves to focus vision (e.g., eyeglasses or contact lenses). See accommodation.

**lens model** a metaphorical model intended to characterize the fact that organisms do not perceive the environment directly and objectively but instead use available cues to make inferences, judgments, or interpretations of the environment. A variety of cues are available, and the organism selects those it will use and then assigns each a relative weight or importance in the interpretive process. [proposed by Egon Brunswik]

**lenticular nucleus** see basal ganglia.

**Leonardo’s paradox** the apparent curvature of straight elements at the margins of a wide-angle scene containing linear perspective. [Leonardo da Vinci (1452–1519), Italian artist and scientist]

**leptin n.** a protein, manufactured and secreted by fat cells, that may communicate to the brain the amount of body fat stored and may help to regulate food intake. Leptin receptors have been found in the hypothalamus, and, when they are stimulated, food intake is reduced.

**leptokurtic adj.** describing a frequency distribution that is more peaked than the normal distribution, having more scores in the center and fewer at the two extremes. See also mesokurtic; platykurtic.

**leptomorph n.** see body-build index.

**leptosome type** see asthenic type.

**LEQ** abbreviation for lifetime of experiences questionnaire.

**LES** abbreviation for local excitatory state.

**lesbian feminism** a type of feminism that emphasizes the sociopolitical meaning of lesbianism. Beyond the implications that lesbianism may have for women’s right to control their own sexuality, it is suggested that lesbianism is the ultimate rejection of patriarchy. See also lesbian separatism.

**lesbianism n.** female–female sexual orientation or behavior. The name is derived from Lesbos, an Aegean island where the poet Sappho (c. 600 BCE) wrote glowing accounts of erotic activities between women. Formerly called Sapphism. See also homosexuality. —lesbian adj., n.

**lesbian separatism** a radical form of lesbian feminism arguing that feminist women should reject heterosexuality to effect a complete separation from patriarchal society and its institutions.

**Lesch–Nyhan syndrome** an X-linked recessive disorder associated with deficiency of the enzyme hypoxanthine–guanine phosphoribosyltransferase, which leads to overproduction of uric acid. Affected individuals have severe kidney problems; moderate cognitive disabilities; and a compulsive, self-mutilating tendency to bite their lips and fingers. Motor development deteriorates after the first 6 to 8 months of life, marked by spasticity, chorea (involuntary jerky movements), and ataxia (sinuous involuntary movements). Also called hereditary choreoathetosis: hereditary hyperuricemia. [described in 1964 by Michael Lesch (1939–2008) and William L. Nyhan (1926– ), U.S. pediatricians]

**Lesch’s alcoholism typology** (LAT) a four-part categorization of individuals with alcohol dependence. Type I individuals do not experience cravings when not drinking but develop strong cravings once they start; they experience withdrawal symptoms much sooner in their drinking experiences than do other alcoholics. This type of dependence may be related to anomalies in alcohol metabolism. Type II individuals drink in response to conflict and to self-medicate psychiatric symptoms; they are identified as possibly suffering from low self-esteem. Type III individuals generally have underlying addictive disorders and often sleep disorders; they usually have a family history of alcoholism and affective disorders. Type IV individuals have usually experienced either brain trauma or a difficult childhood and have a tendency toward impulsivity. A specific LAT questionnaire is available to determine a person’s typology within this classification. [developed by Austrian psychiatrist Otto-Michael Lesch]

**lesion n.** any disruption of or damage to the normal structure or function of an organ or part of an organ due to injury, disease, or a surgical procedure. A lesion may be a wound, ulcer, tumor, cataract, or any other pathological change in tissue. See also temporary lesion.

**less-is-more hypothesis** the proposition that the cognitive limitations of infants and young children may serve to simplify the body of language they process, thus making it easier for them to learn the complicated syntactical system of any human language. The name is derived from the famous design dictum of German-born U.S. architect Ludwig Mies van der Rohe (1886–1969). [proposed by 21st-century U.S. psychologist Elissa L. Newport]

**lethal catatonia** a form of acute manicidal excitement that in some cases leads to unexplained death. Also called Bell’s mania: deadly catatonia: exhaustion death. See also hypomania. [first described in 1849 by U.S. physician Luther Vose Bell (1806–1862)].
lethal dose (LD) the minimum amount of a drug that is required to cause death. It is generally expressed in terms of the median lethal dose (LD$_{50}$; LD-50), the amount required to cause death (within a specified time frame) in 50% of nonhuman animals to which the drug is administered. See also THERAPEUTIC RATIO.

lethality n. the degree of dangerousness or likelihood of death associated with a particular course of action. The word is often used when comparing methods of committing suicide. —lethal adj.

lethality scale a set of criteria used to predict the probability of a suicide or attempted suicide occurring. A variety of such scales exist, most including gender, prior suicide attempts, and psychiatric diagnosis and history.

lethargy n. low energy level and lack of motivated behavior, often occurring in depression and a number of other conditions. —lethargic adj.

letter-by-letter reading the process in which individuals identify a word by building up its constituent letters in sequence rather than by recognizing the whole word. It is characteristic of pure ALEXIA.

letter cancellation test any of a variety of tests that measure attentional skills, visuomotor abilities, and other functions by requiring the participant to cross out a specific letter repeatedly interspersed among long lines of random letters. Letter–Number Sequencing an attentional subtest on more recent versions of the WECHSLER ADULT INTELLIGENCE SCALE and the WECHSLER INTELLIGENCE SCALE FOR CHILDREN in which the participant must sequence a random order of numbers and letters. Specifically, the participant must first say the numbers in ascending order and then the letters in alphabetical order. It is generally considered to be a test of verbal working memory.

letting go discontinuing the struggle for life after a strenuous period of effort and suffering during the DYING PROCESS. See also ACCEPTANCE STAGE.

leuco- (leuc-; leuk-; leuk-) combining form white or colorless.

leukocyte (leucocyte) n. a type of blood cell that plays a key role in the body’s defense against infection (see IMMUNE RESPONSE). Leukocytes include neutrophils, basophils, and eosinophils (known collectively as granulocytes because their cytoplasm contains granules), which ingest foreign particles by PHAGOCYTOSIS; and lymphocytes, which are involved in the production of antibodies and other specific immune responses. Also called white blood cell.

leukotomy (leucotomy) n. see Lobotomy.

leuprolide n. an analog of GONADOTROPIN-RELEASING HORMONE that opposes the action of androgens and estrogens through inhibition of GONADOTROPIN secretion. It is used for the treatment of uterine tumors, some forms of precocious puberty, and advanced prostate cancer. Because of its potent antiandrogen effects, it has been used controversially to perform CHEMICAL CASTRATION in repeat sex offenders. U.S. trade name (among others): Lupron.

level n. in an experimental design, the quantity, magnitude, or category of the INDEPENDENT VARIABLE (or variables) being studied. For example, if a researcher is assessing the effect of alcohol on cognition, each specific amount of alcohol included in the study is a level (e.g., 0.0 oz, 0.5 oz, 1.0 oz, 1.5 oz).

Level I–Level II theory the theory that cognitive abilities can be viewed as being arranged hierarchically at two different levels. The first level is of associative processing (exemplified by rote learning and short-term memory), the second of more conceptual processing (exemplified by categorization, abstraction, and reasoning). [developed by Arthur R. Jensen]

level of analysis the level chosen when examining a multilevel phenomenon, such as the individual (micro-) level, the group or organizational (meso-) level, or the societal (macro-) level.

level-of-aspiration theory a conceptual approach to group and individual performance that assumes that one’s initial goals and ambitions influence both particular performances and their emotional, motivational, and behavioral consequences.

level of measurement see MEASUREMENT LEVEL.

level of significance see SIGNIFICANCE LEVEL.

levels of consciousness 1. varying degrees of alertness, arousal, or vigilance, ranging from the degree experienced in normal wakefulness, to that experienced in unfocused wakefulness, drowsiness, light sleep, or slow-wave (deep) sleep, to that experienced minimally or not at all, as in a MINIMALLY CONSCIOUS STATE, VEGETATIVE STATE, and COMA. Levels of consciousness are defined both behaviorally and by electroencephalography and other kinds of brain imaging. 2. in certain mystical philosophies, states of pure consciousness that may involve changes in perception, feeling, and thought and that may occur either spontaneously or as a result of practices such as yoga, meditation, breathing techniques, and fasting.

levels of intelligence in theories proposing that intelligence can be envisaged as a series of levels, GENERAL ABILITY comes at the top of the hierarchy and successively narrower abilities come at lower levels. In one variant, the top level comprises general ability; the second level major group factors, the third level minor group factors, and the fourth level specific factors. Major group factors are those that are measured by many (but not all) intelligence tests, whereas minor group factors are ones that are measured by a smaller number of tests. Specific factors are measured only by single tests.

levels-of-processing model of memory the theory that ENCODING into memory and therefore subsequent RETENTION depend on the depth of cognitive ELABORATION that the information receives and that deeper encoding improves memory. In early critical experiments, depth was achieved by processing the meaning of to-be-remembered words rather than focusing on shallower dimensions, such as the sound of the words. [formulated in 1972 by Canadian psychologist Fergus I. M. Craik (1935– ) and Robert S. Lockhart]

Levene test for equality of variance a method for evaluating whether the VARIANCE in a set of scores is equivalent across two or more groups being studied. Equality of variance is required in ANALYSIS OF VARIANCE and other statistical techniques to obtain valid results. See HOMOGENEITY OF VARIANCE. [Howard Levene (1914–2003), U.S. statistician and geneticist]

lever switch a switch mounted on a device at one end with the opposite end free to move within fixed or variable limits. The lever may be any length or shape, requires the use of pressure on the end, and enables individuals with
limited fine motor control to operate electrical devices. See also LEAF SWITCH.

**Levinson’s adult development theory** a model of human development in which adulthood is divided into early, middle, and late segments, each period consisting of (a) transitional, or entry, stages (e.g., age-30 transition, age-40 transition), which are often times of uncertainty, self-examination, exploration, and modification of the quality and significance of life commitments, and (b) intervening periods of relative stability, when individuals consolidate new interpretations, structures, and goals and move forward. The adaptations associated with transitional periods may be relatively smooth and uneventful or may be experienced as psychologically difficult and painful (e.g., as a MIDLIFE CRISIS). [proposed by Daniel Levinson (1920–1994), U.S. psychologist]

**levitation** n. an allegedly paranormal phenomenon in which a person or thing appears to ascend into the air and hover there without physical cause. Levitation is mainly associated with PSYCHOKINESIS and POLTERGEIST activity. A sensation of levitating is also common in dreams. —levitate vi.

**levodopa** (L-dopa) n. the naturally occurring form of dihydroxyphenylalanine (see DOPA), a precursor of the neurotransmitter dopamine. Synthetic levodopa is used in the treatment of Parkinson’s disease (see DOPAMINE-RECEPTOR AGONIST), usually in combination with carbidopa (see SINEMET) or in combination with carbidopa and a catechol-O-methyltransferase (COMT) inhibitor (see STALEVO). U.S. trade names: Dopar; Laronopa.

**Levo-Dromoran n.** a trade name for LEVORPHANOL.

**levomepromazine** n. see METHOTRIMEPRAZINE.

**Levoprome n.** a trade name for METHOTRIMEPRAZINE.

**levorphanol** n. an OPIOID ANALGESIC produced by manipulation of the morphine molecule. Levorphanol is approximately four to six times more potent as an analgesic than morphine and possesses similar risks of dependence and respiratory depression. U.S. trade name: Levo-Dromoran.

**Lewy body dementia** a specific type of DEMENTIA associated with the presence of abnormal proteins called Lewy bodies in the brain. It is characterized by hallucinations and delusions occurring early in the disease process, marked day-to-day fluctuations in cognition, and spontaneous PARKINSONISM. [Friedrich Heinrich Lewy (1885–1950), German neurologist]

**lexical access** in psycholinguistics, the process by which an individual produces a specific word from his or her MENTAL LEXICON or recognizes it when used by others. See PRODUCTIVE VOCABULARY; RECEPTIVE VOCABULARY.

**lexical agraphia** a disorder characterized by an impaired ability to spell irregular words (e.g., yachts) or ambiguous words. The ability to spell other words or nonwords is not affected. Also called SURFACE AGRAPIA.

**lexical ambiguity** the property of a word that has more than one possible meaning. See AMBIGUITY.

**lexical decision** a task in which the participant is presented with strings of letters, such as HOUSE or HOPE, and is required to determine whether each string spells a word. The REACTION TIME required to make the decision is usually measured.

**lexical—gustatory synesthesia** see SYNESTHESIA.

**lexical hypothesis** the supposition that any significant individual difference, such as a central personality trait, will be encoded into the natural-language lexicon; that is, there will be a term to describe it in any or all of the languages of the world. Also called FUNDAMENTAL LEXICAL HYPOTHESIS. [first proposed in 1884 by Francis GALTON]

**lexical memory** see MENTAL LEXICON.

**lexical-selection rules** in linguistics, rules governing which lexical items may appear in which sentence structures. For example, intransitive verbs, such as smile or lie, do not allow direct objects and are therefore incompatible with certain syntactic structures. The relationship between lexical selection and sentence structure is of major interest in GENERATIVE GRAMMAR.

**lexical word** see CONTENT WORD.

**lexicology** n. the study of the meanings of words and the relationships between them. Applied lexicology is called lexicography, the science and art of compiling dictionaries.

**lexicon** n. the vocabulary of a language and, in psychology, the lexical knowledge of an individual. See MENTAL LEXICON. See also PRODUCTIVE VOCABULARY; RECEPTIVE VOCABULARY.

**LFA** see LOW-FUNCTIONING AUTISM.

**LGBTQ** abbreviation for lesbian, gay, bisexual, transgender, and questioning or queer: an inclusive term used to refer to the homosexual population in all of its diverse forms, to those with both homosexual and heterosexual preferences, and to those whose GENDER IDENTITY differs from the culturally determined gender roles for their birth sex.

**LGN** abbreviation for LATERAL GENICULATE NUCLEUS.

**LII** 1. abbreviation for LATERAL HYPOTHALAMUS. 2. abbreviation for LUTEINIZING HORMONE.

**liability** n. 1. in a civil lawsuit, the defendant’s legal responsibility to pay monetary damages for injury or other harm that a court has deemed he or she has caused the plaintiff through, for example, professional MALPRACTICE. 2. see MULTIFACTORIAL MODEL.

**liberalism** n. 1. an attitude characterized by acceptance of alternative, even noncompliant, forms of thinking or acting and sometimes (but not necessarily or wholly) by advocacy of change to the status quo and tradition. 2. historically, a broad political philosophy emphasizing individual freedom, constitutional government, and social progress through open debate and the pragmatic reform of existing institutions and laws. —liberal adj.

**liberation psychology** a movement that emerged in South America with the intention of making psychology a force in the emancipation of peoples from poverty and injustice rather than a force for maintaining the status quo. The movement was so named by analogy with the liberation theology that arose in Latin American churches in the late 1960s and early 1970s.

**libidinal development** see PSYCHOSEXUAL DEVELOPMENT.

**libidinal stage** in classical psychoanalytic theory, any of the various defined stages of PSYCHOSEXUAL DEVELOPMENT.

**libidinal transference** in classical psychoanalysis, the TRANSFERENCE of the patient’s LIBIDO, or feelings of love,
libidinal types

from his or her parents or other loved object onto his or her therapist.

**libidinal types** in classical psychoanalytic theory, a personality classification based on the distribution of LIBIDO, or sexual energy, in the psyche. In the *erotic type*, the libido remains largely in the ID and the main interest is in loving and being loved. In the *obsessional type*, the libido is largely invested in the SUPEREGO and the individual is dominated by conscience. In the *narcissistic type*, the libido is primarily invested in the EGO and the main interest is in self-preservation, with little concern for others or for the dictates of the superego. [devised by Sigmund Freud]

**libidinizm** n. see EROTIZATION.

**libido** n. 1. in psychoanalytic theory, either the PSYCHIC ENERGY of the LIFE INSTINCT in general or the energy of the SEXUAL INSTINCT in particular. In his first formulation, Sigmund Freud conceived of this energy as narrowly sexual, but subsequently he broadened the concept to include all expressions of love, pleasure, and self-preservation. See also EROS. 2. in the ANALYTIC PSYCHOLOGY of Carl Jung, the general life force that provides energy for all types of activities: biological, sexual, social, cultural, and creative. 3. more generally, sexual energy or desire. —libidinal adj. —libidinize vb. —libidinous adj.

**libido-binding activity** an activity in which members of a therapy group concentrate libidinal energies on a specific interest or occupation rather than on activities that stimulate the libido. [introduced by Russian-born U.S. psychotherapist Samuel Richard Slavson (1890–1981)]

**Librium** n. a trade name for CHLORIDAZEPOXIDE.

**license** n. permission granted by a government agency for an individual or organization to engage in a given occupation or business on the basis of examination, proof of education, or both rather than on measures of performance. See PROFESSIONAL LICENSING. —licensed adj. —licensure n.

**licensed practical nurse** (LPN) a graduate of an accredited school of practical nursing who has been legally authorized to practice as a nurse. Also called licensed vocational nurse (LVN).

**licking behavior** the licking by an animal of itself or another animal, particularly an offspring. Licking behavior appears to be part of the maternal behavior of many mammals; the pregnant female licks itself before giving birth, then licks the offspring, thereby establishing a means of identifying its own young. Licking of the offspring’s urine may serve to maintain the female in fluid HOMEOSTASIS during lactation.

**lickometer** n. see DRINKOMETER.

**lid apraxia** see OCULOMOTOR APRAXIA.

**lie** n. a false statement or a false presentation, known to be untrue, that is made with the intention to deceive. Despite the moral and legal proscription against lies, they are a cognitive signal that the liar understands enough of what others are thinking to be motivated to lie to them. In children, acquiring an understanding of this sort represents a cognitive milestone usually reached around age 3 (see THEORY OF MIND). At that age, a child’s initial lies tend to be indiscriminate; he or she is not yet aware of the moral qualms associated with them. By age 4, children can reliably tell the difference between harmful lies and white lies, and they stop lying indiscriminately. As they grow older, their lying becomes more sophisticated (i.e., plausible), a social skill that is influenced by their particular culture, which plays a pivotal role in determining how they lie and when they feel it is appropriate to lie. See also FABRICATION; PATHOLOGICAL LYING; Compare CONFABULATION; FABULATION. —lair n. —lie, lying vb.

**Liebmann effect** the perceived merger of different visual stimuli that occurs when the border between them is defined only by hue. [Susanne E. Liebmann (1897–1990), German psychologist]

**lie detector** see POLYGRAPH.
on average, expect to live. Life expectancy is based on statistical probabilities and increases with improvements in medical care and hygiene.

**life force** see **ÉLAN VITAL**.

**life goal** in the individual psychology of Alfred Adler, the individual’s concept of what he or she could attain in life, seen as a means of compensating for real or imagined inferiority. See also **LIFE PLAN**.

**life history** in therapy and counseling, a systematic account of the client’s development from birth to the present, including the meaningful aspects of the client’s emotional, social, and intellectual development. The account is taken by the therapist or counselor directly from the client and may additionally be derived from autobiographical material.

**life-history method** a **STRUCTURED INTERVIEW** that attempts to summarize historical data about events that are relevant to evaluating a person’s current functioning.

**life instinct** in psychoanalytic theory, the drive comprising the **SELF-PRESERVATION INSTINCT**, which is aimed at individual survival, and the **SEXUAL INSTINCT**, which is aimed at the survival of the species. In the **DUAL INSTINCT THEORY** of Sigmund Freud, the life instinct, or **ÉROS**, stands opposed to the **DEATH INSTINCT**, or ** THANATOS**. Also called **erotic instinct**.

**life lie** 1. the false conviction held by some individuals that their life plan is bound to fail due to other people or to circumstances beyond their control. This was postulated as a method of freeing oneself from personal responsibility. [defined by Alfred Adler] 2. any false belief around which an individual’s life is built.

**lifeline** n. a therapeutic technique used in group or individual therapy in which each individual draws lines representing his or her life, marking past and future expected events with angles indicating even, upward, or downward progression of functioning, as well as specific dates and the affect surrounding these events. Discussion of this diagram with the therapist can enhance awareness and understanding of the individual’s life patterns.

**life plan** in the individual psychology of Alfred Adler, an individual’s style of life and **GUIDING FICTION** as he or she strives to reach his or her **LIFE GOAL**.

**life review** the process whereby individuals, especially older adults, reflect upon and analyze past life experiences. Life review, or analytical reminiscence, is often made use of in counseling older adults with symptoms of mild depression or people of any age with terminal illness, sometimes as an adjunct to psychotherapy. [defined in 1961 by U.S. gerontologist and psychiatrist Robert N. Butler (1927–2010)]

**life rhythm** see **BIOLOGICAL RHYTHM**.

**life satisfaction** the extent to which a person finds life rich, meaningful, full, or of high quality. Numerous standardized measures have been developed to provide an index of a person’s life satisfaction in comparison to various normative groups (e.g., **SATISFACTION WITH LIFE SCALE**). Improving life satisfaction is often a goal of treatment, especially with older people. See also **QUALITY OF LIFE**.

**life space** in the **FIELD THEORY** of Kurt Lewin, the “totality of possible events” for one person at a particular time: a person’s possible options together with the environment that contains them. The life space is a representation of the environmental, biological, social, and psychological influences that define one person’s unique reality at a given moment in time. Contained within the life space are positive and negative valences, that is, forces or pressures on the individual to approach a goal or move away from a perceived danger.

**life-space interview** a form of **CRISIS INTERVENTION** in which children in day and residential treatment are interviewed by staff members during moments of crisis or stress, for example, immediately after receiving an upsetting letter or after being attacked by another child. Efforts are made to convert these events into therapeutic experiences by such means as restoring the children’s belief in themselves and strengthening their ego. [originated by Austrian-born U.S. psychologist Fritz Redl (1902–1988)]

**lifespan** n. 1. the maximum age that can be obtained by any given individual within a particular species. 2. the precise length of an individual’s life.

**lifespan contextualism** a perspective on human development that views people as both products and producers of their own development, interacting throughout life with family, peers, and other social groups and institutions.

**lifespan developmental psychology** the study of psychological and behavioral change across and within individuals from conception through death using a **LIFESPAN PERSPECTIVE**. Such an approach assumes that human developmental processes are complex, interactive, and fully understood only in the context of influencing events. It also assumes that there is no end state of maturity and that not all developmental change is related to chronological age.

**lifespan perspective** a general perspective emphasizing (a) that human development is a lifelong process of change from conception to death; (b) that developmental change is multidimensional and multidirectional, involving both growth and decline in one’s performance (e.g., of cognitive tasks); and (c) that there is plasticity in human behavior throughout the entire lifespan.

**life stress** severe strain produced by **CRITICAL LIFE EVENTS** or similar experiences, such as failure at work, marital separation, or loss of a loved one.

**lifestyle** n. 1. the typical way of life or manner of living that is characteristic of an individual or group, as expressed by behaviors, attitudes, interests, and other factors. 2. in the individual psychology of Alfred Adler, an individual’s characteristic way of overcoming or compensating for feelings of inadequacy. According to Adler, a lifestyle is first adopted in childhood, when the key factors informing it will be genetic endowment, upbringing, and interpersonal relations within the family.

**Lifetime of Experiences Questionnaire (LEQ)** a questionnaire given to older people (those over 65 years old or who have already retired) to assess both their current level of mental activity and the full range of their mental pursuits during earlier life, including their educational, occupational, social, and leisure activities throughout young and middle adulthood. The questionnaire is designed to estimate **COGNITIVE RESERVE** in older adults; higher scores (i.e., more engagement in complex mental activities) are supposed to predict a slower rate of age-related cognitive decline and a reduced risk of dementia. [developed in 2007 by Australian neuropsychiatrists Michael J. Valenzuela and Perminder Sachdev]
lifetime personality

**lifetime personality** the pattern of behavior that dominates a person’s life between birth and death. [from the personality theory of Henry Alexander Murray]

**lifetime risk** the odds that one will be diagnosed with a disease or condition during one’s lifetime (usually stated in terms of 70 to 85 years). It is often important for individuals undergoing GENETIC COUNSELING to differentiate lifetime risk from the risk of being diagnosed with the disease in the next 5 or 10 years.

**ligand** n. a molecule that binds to a specific site on another molecule, for example, a hormone binding to its receptor molecule at the surface of a cell.

**ligand-gated ion channel** an ION CHANNEL that opens or closes in response to the binding of a molecule (the ligand) to a receptor. An example is the VOLTAGE-GATED ION CHANNEL.

**light adaptation** the process by which the eye adjusts to conditions of high illumination, as occurs when a person exits a dark theater into a sunny parking lot. It takes less than 10 minutes and involves constriction of the pupil and a shift in the sensitivity of the retina so that the RETINAL CONES become active in place of the RETINAL RODS. Compare DARK ADAPTATION.

**light cell** see TYPE B CELL.

**light–dark cycle** the schedule according to which the lights are turned on and off in rooms housing research animals. A 12-hour light–dark cycle, in which the lights are on for 12 consecutive hours and then off for 12 consecutive hours, is commonly used.

**light induction** the production or alteration of sensation in one part of the visual field by stimulation in an adjacent part of the field (e.g., INDUCED COLOR).

**lightness constancy** see BRIGHTNESS CONSTANCY.

**lightness contrast** see BRIGHTNESS CONTRAST.

**lightning calculator** an individual capable of extremely rapid mental calculations. Although some of these individuals have a high IQ, most of them are people with a very well-developed SPECIFIC ABILITY but not a particularly high IQ.

**light pointer** a form of HEADSTICK fitted with a light that can activate an ASSISTIVE TECHNOLOGY device.

**light reflex** see PUPILLARY REFLEX.

**light sensitivity** see PHOTOPHOBIA.

**light therapy** see PHOTOTHERAPY.

**light trance** see TRANCE.

**likelihood** n. in statistics, the probability of obtaining a particular set of results given a set of assumptions about the DISTRIBUTION of the phenomena in the population and the PARAMETERS of that distribution.

**likelihood function** a formula that yields the probability of obtaining a particular distribution of values in a sample for each known value of an associated population PARAMETER. In other words, it indicates how likely a particular population is to produce the observed sample data under certain conditions.

**likelihood principle** 1. the generality originally proposed in 1867 by Hermann von Helmholtz that an observer will tend to perceive the most likely interpretation of a visual stimulus (i.e., the one with the highest probability of being correct). This is in contrast to the simplicity principle, elaborated in 1953 by U.S. psychologist Julian E. Hochberg (1923– ) with Edward McAlister, which states that an observer will tend to perceive the simplest interpretation (i.e., the one with the shortest description). 2. a foundational tenet of statistical inference stating that where there is an unknown population PARAMETER, $\theta$, and an observed sample distribution, $x$, all relevant information about the population distribution is contained in the LIKELIHOOD FUNCTION for $x$.

**likelihood ratio (LR)** the ratio of two probabilities, $a/b$, where $a$ is the probability of obtaining the data observed if a particular research hypothesis ($A$: the NULL HYPOTHESIS) is true and $b$ is the probability of obtaining the data observed when a different hypothesis ($B$: the ALTERNATIVE HYPOTHESIS) is true.

**Likert scale** a type of direct attitude measure that consists of statements reflecting strong positive or negative evaluations of an object. Five-point scales are common and a neutral middle point may or may not be included. For example, an assessment item using a Likert scale response format (i.e., a Likert-type question or Likert-type item) might include the following statement choices: strongly disagree, disagree, neither disagree nor agree, agree, and strongly agree. The respondent chooses the option most representative of his or her view (e.g., on whether same-sex marriages should be permitted) and these ratings are summed to provide a total attitude score for a topic of interest. Also called Likert summed rating procedure. [Rensis Likert (1903–1981), U.S. psychologist]

**liking scale** a measure of a person’s degree of attraction to another individual, usually involving a willingness to be in the other’s company as well as a positive evaluation of the other’s personality characteristics. One such scale was published by U.S. social psychologist Zick Rubin (1944– ) in 1970. Although Rubin distinguished between this measure and his LOVE SCALE, studies have shown that the two indices are usually positively correlated.

**Lilliputian hallucination** a VISUAL HALLUCINATION of objects, animals, or people greatly reduced in size, which may result from a number of conditions, such as DELIRIUM TREMENS, typhoid, or brain tumors in the temporal lobe. The name is derived from Jonathan Swift’s Gulliver’s Travels (1726), in which Gulliver journeys to the imaginary land of Lilliput, populated by tiny people. Also called diminutive visual hallucination; microptic hallucination. See also MICROSIA.

**limbic cortex** the portions of the cerebral cortex, especially the CINGULATE CORTEX, that are associated with the LIMBIC SYSTEM.

**limbic epilepsy** a type of neurological disorder in which recurrent seizures spontaneously arise in areas of the LIMBIC SYSTEM. Recent research suggests that altered connectivities between hippocampal GRANULE CELLS and PYRAMIDAL CELLS—as mediated by NEUROTROPHINS and their receptors—play a crucial role in the development of limbic epilepsy by potentially changing the balance of excitation and inhibition in the hippocampus and amygdala, which are essential to memory and emotion. ACETYLCHOLINE and other amino acid neurotransmitters have also been implicated in the etiology of limbic epilepsy as have early life stressors, such as maternal separation. Additionally, FEVERISH SEIZURES may contribute to the generation of subsequent limbic epilepsy by increasing hippocampal ex-
citability. Also called medial temporal lobe epilepsy: mesial temporal lobe epilepsy.

**limbic lobe** a fifth subdivision of each cerebral hemisphere that is often distinguished in addition to the four main lobes (see cerebrum). It comprises the cingulate cortex, parahippocampal gyrus, and hippocampal formation.

**limbic system** a loosely defined, widespread group of brain nuclei that innervate each other to form a network that is involved in autonomic and visceral processes and mechanisms of emotion, memory, and learning. It includes portions of the cerebral cortex (see limbic lobe), thalamus, and certain cortical and subcortical structures, such as the hippocampus, amygdala, and septal area.

**Limbitrol** *n.* a trade name for a combination of the tricyclic antidepressant amitriptyline and the benzodiazepine chlordiazepoxide, appropriate for the treatment of concurrent anxiety and depression but not now commonly used.

**limbic kinetic apraxia** see apraxia.

**lumen** *n.* see threshold.

**limerence** *n.* an intense sexual desire and a strong concern for the other person in a romantic relationship, accompanied by great sensitivity to how that other person is reacting to oneself. Limerence typically diminishes in intensity a month or two after the relationship is formed. See also PASSIONATE LOVE; ROMANTIC LOVE. [first described in 1979 by U.S. psychologist Dorothy Tennov (1928–2007)]

**liminal** adj. relating to the threshold of a sensation.

**limited-capacity system** a conceptualization of working memory in which resource constraints restrict the processing of information. When new information is encountered, older information is either relegated to long-term memory or eliminated, providing the resources to retain the newer data. Attention and consciousness are often similarly conceived of as limited-capacity systems. See also chunking.

**limited competency** a determination by a court that a person has the capacity to manage some but not all of his or her activities. A limited guardian is appointed to assist the individual in exercising certain legal rights, such as the right to enter into contracts, get married, provide consent (e.g., for medical treatment), or vote.

**limited guardianship** a form of legal guardianship of a child or adult with a disability (e.g., intellectual disability) in which a guardian has authority with respect to some areas of activity (e.g., legal, financial, health-related) in which the ward is not capable. In some jurisdictions, the term is used interchangeably with conservatorship.

**limited hold** a feature that can be added to a schedule of reinforcement in which the opportunity for reinforcement is limited to a fixed period. For example, if a fixed-interval schedule in which reinforcement is given after 1 minute had a 2-second limited hold, then only responses occurring within 2 seconds of the end of the 1-minute interval would be reinforced.

**limited responsibility** see diminished responsibility.

**limophthisis** *n.* the physical and mental signs of emaciation caused by severe undernourishment.

**Limulidae** *n.* see horseshoe crab.
linear transformation

If an input is increased by a certain factor, the output must increase by the same factor.

**linear transformation** the transformation of a set of raw data using an equation that involves addition, subtraction, multiplication, or division with a constant. An example is the transformation of \( x \) to \( y \) by means of the equation \( y = a + bx \), where \( a \) and \( b \) are numerical constants. A plot of such transformed data would form a straight line. Data are often subjected to linearizing to determine whether a linear model provides a better fitting or more parsimonious explanation of the variables. Compare nonlinear transformation.

**linear type** a body type characterized by a slender, narrow-chested, long-necked, long-nosed physique, sometimes equated with the asthenic type in kretschmer typology.

**line graph** a graph in which data points representing a series of individual measurements are shown connected by straight line segments. Line graphs are often used to show trends over time, such as population growth. Also called line chart.

**line management** a system of management in which individuals have authority over those immediately below them in the chain of command and are accountable to those immediately above. See unity of command.

**line of beauty** an S-shaped curve said by the British painter William Hogarth (1697–1764) to possess maximal beauty.

**line of fixation** a straight line between the object of visual focus and the fovea centralis.

**line of regard** a straight line between an object being viewed and the center of rotation of the eye.

**line spectrum** see sound spectrum.

**lineup n.** an identification procedure in which several individuals are presented to an eyewitness of a crime at the same time or in a sequence. The witness is asked to indicate if he or she recognizes one of the lineup members as the perpetrator of the crime.

**lingering trajectory** see trajectories of dying.

**lingua franca** a common language used by people of different mother tongues for purposes of communication. Such a language may, but need not, be a hybrid of the mother tongues. Compare creole; pidgin.

**lingual adj.** of or relating to the tongue or to speech and languages.

**lingual frenulum** see frenulum.

**lingual gland** any of the glands on the surface of the tongue whose seromucous secretions are thought to circulate tastants among the taste cells.

**lingual gyrus** a relatively short convolution of the inferior (lower) brain structure that extends from the occipital to temporal lobes and is medial to the fusiform gyrus. It is important in recognizing faces and landmarks and has been implicated in the generation and recall of dreams.

**lingual nerve** a branch of the trigeminal nerve that supplies fibers to the mucous membranes of the mouth and the anterior (front) two thirds of the tongue, including the taste-bud papillae. Also called gustatory nerve.

**lingual papilla** see papilla.

**linguist n.** a scholar who specializes in the study of linguistics or any of its branches. A linguist may focus on the characteristics of a specific language or group of languages or on certain features of human language in general. He or she will not necessarily have a command of multiple languages, the more precise term for such a person being a polyglot.

**linguistic approach** a method of reading instruction that applies what the child already knows about language from having learned to speak it. Letters and sound equivalents are taught by being embedded in meaningful words with regular spelling patterns to maximize the similarities between the familiar spoken language and the unfamiliar written language.

**linguistic awareness** see metalinguistic awareness.

**linguistic determinism** the hypothesis, most commonly associated with the U.S. linguists Edward Sapir (1884–1939) and Benjamin Lee Whorf (1897–1941), that the semantic structure of a particular language determines the structure of mental categories among its speakers. Because languages differ in how they refer to basic categories and dimensions, such as time, space, and duration, native speakers of these languages are assumed to show corresponding differences in their ways of thinking. Also called Sapir–Whorf hypothesis. Whorfian hypothesis. Compare linguistic relativity. See also anthropological linguistics; contrastive rhetoric.

**linguistic intergroup bias** the tendency to describe and evaluate positive behaviors by in-group members and negative behaviors by out-group members more abstractly than negative ingroup and positive outgroup behaviors. See also ingroup bias.

**linguistic–kinesic method** the objective study of disordered behavior in terms of language and movement involved in interactions between individuals.

**linguistic minority** the group of individuals in a polity who are native speakers of a minority language.

**linguistic relativity** the observation that languages differ in the ways in which semantic space is identified and categorized. For example, the Native American language Hopi uses one word for water in a natural setting and another word for water in a vessel but has only one word for flying objects, which is applied to birds, insects, airplanes, and the like. Linguistic relativity is not to be equated with linguistic determinism, which is a theoretical commitment to the idea that these differences have cognitive consequences. See anthropological linguistics.

**linguistics n.** the scientific study of the physical, structural, functional, psychological, and social characteristics of human language. See also psycholinguistics; sociolinguistics.

**linguistic typology** the classification of languages with respect to their structural characteristics rather than their historical relationships (genetic linguistics) or geographical distribution (areal linguistics).

**linguistic universal** see language universal.

**link analysis** in ergonomics, the analysis of operational sequences and the movements of workers or objects that these entail to determine the design of tools, equipment, jobs, and facilities that will best serve worker efficiency and safety.

**linking verb** see copula.
lip biting habitual biting of the lips, which may be a nervous habit, a stereotyped behavior (see STEREOTYPY), or a symptom of a disorder, such as LESCH–NYHAN SYNDROME. Also called morsicatio labiorum.

lip eroticism the use of the lips to obtain sexual arousal or satisfaction.

lipid-metabolism disorders a group of metabolic anomalies characterized by abnormal levels of fatty substances in the blood or other tissues resulting from genetic, endocrine, or external factors or organ failure. Lipid-metabolism disorders include NIEMANN–PICK DISEASE and Tay–Sachs DISEASE.

lipodystrophy n. any disorder of lipid metabolism. Kinds of lipodystrophy include intestinal lipodystrophy, in which a malabsorption of fats from the digestive tract may be associated with lesions in the central nervous system (as in Whipple’s disease), and progressive lipodystrophy, marked by a symmetrical loss of subcutaneous fat deposits and abnormal deposits of fat around the kidney, heart, and abdominal cavity. No consistent neurological abnormalities are associated with the latter form of lipodystrophy, but nearly 20% of the patients in one study showed signs of intellectual disability. The cause of progressive lipodystrophy is unknown. Lipodystrophy is also associated with diabetes mellitus in a form marked by loss of subcutaneous fat in areas injected with insulin; this is known as lipotrophic diabetes mellitus or insulin lipodystrophy. Manifestations of lipodystrophy are also often found in people with HIV. See also PARTIAL LIPODYSTROPHY; TOTAL LIPODYSTROPHY.

lipostatic hypothesis a hypothesis stating that the long-term regulation of food intake is governed by the concentration in the blood of free fatty acids, which result from the metabolism of fat. High concentrations indicate the breakdown of fat, and food consumption increases accordingly: low concentrations are associated with reduction in consumption. Also called lipostatic theory. See also GLUCOSTATIC THEORY. [originally proposed in 1953 by Gordon C. Kennedy]

lipotropic diabetes mellitus see LIPODYSTROPHY.

Lips illusion theory a theory that explains the perception of a variety of visual illusions as visual distortions induced by the emotional state of the observer. [Theodor Lipps (1851–1914), German philosopher and psychologist]

lip pursing a facial contortion in which the lips protrude in a manner that resembles pouting or a snout. First described (as Schnauzkrampf) by German psychiatrist Karl Ludwig Kahla (1828–1899), it is most commonly associated with CATATONIC SCHIZOPHRENIA.

lip reading n. a method used by some people with hearing loss to understand spoken words in which the listener interprets the speaker’s lip movements. Some authorities claim that only about one third of speech sounds can be accurately read in this way and that attention to facial expression and general body language, with the additional use of SIGN LANGUAGE, assist significantly in comprehension. Also called speechreading.

liquid 1. adj. in phonetics, denoting a frictionless speech sound produced when the SOFT PALATE is raised and the airstream is only partially obstructed, such as [l] or [r]. 2. n. a liquid speech sound.

liquidation of attachment the process of freeing a patient from a painful situation by unraveling the ATTACHMENTS by which he or she is bound. [defined by Pierre JANET]

lisdexamfetamine n. a prodrug of DETROXAMFETAMINE used in the treatment of attention-deficit/hyperactivity disorder. Potentially serious side effects include slowed growth in children, cardiovascular risks (e.g., myocardial infarction, hypertension), and psychotic or manic symptoms. U.S. trade name: Vyvanse.

lip 1. n. incorrect production of SIBILANT sounds caused by faulty tongue placement or abnormalities of the articulatory mechanism. Speech and language pathologists have described various types of lisps, including four primary forms: the interdental (or frontal) lisp, in which the tongue protrudes between the front teeth and airflow is directed forward and only partially obstructed; the dental lisp, in which the airflow is partially impeded by contact with the tongue as it rests on or pushes against the front teeth or ALVEOLAR RIDGE; the lateral lisp, in which airflow and saliva are pushed forward over the sides of the broadly extended tongue, creating a wet sound; and the palatal lisp, in which the airflow is partially disrupted by the middle area of the tongue touching the rear portion of the SOFT PALATE. See also LISP. 2. vb. to speak using a lisp. —lisp ing n.

LISP n. LIS(t) P(rocessing): the second oldest high-level computer programming language still in use. It was the primary language for writing ARTIFICIAL INTELLIGENCE programs from the 1960s through the 1980s. The list is the primary data structure, and the basic unit of the language, the s-expression (symbolic expression), is defined recursively (i.e., if X is an s-expression, then so is the list of X). [created by U.S. computer scientist John McCarthy (1927–2011)]

lissencephaly n. severe malformation of the convolutions (gyri) in the cerebral cortex due to abnormal neuronal migration during development. It is an umbrella term encompassing several conditions: agyria, the complete absence of convolutions; pachygyria (or macrogyria), unusually thick convolutions; and polymicrogyria (or microgyria), unusually small but numerous convolutions. Lissencephaly results in severe developmental delay, severe to profound intellectual disability, motor impairment, and epilepsy.

listening n. an essential activity in therapy and counseling that involves attending to the words and actions of the client as well as to the intentions conveyed by the words. See also ACTIVE LISTENING.

listening attitude 1. in a therapeutic setting, a therapist’s openness to a client’s personal experience, or a client’s openness to his or her own personal experience. 2. a behavior set in which a person expects and prepares to receive a message. Italian-born U.S. psychiatrist Silvano Arieti (1914–1982) claimed that a person with schizophrenia who is habitually prepared to experience a hallucination may learn to avoid it when made aware of this attitude.

listening strategy the tendency for listeners to pay
listwise deletion

more attention at the beginning and end of a talk than in the middle.

listwise deletion a strategy for dealing with the problem of missing data in which an entire case record is excluded from statistical analysis if values are found to be missing for any variable of interest. For example, consider a researcher examining the relationships among grade point averages in high school, scores on college admissions tests, and grade point averages in college. If, for whatever reason, a value has not been recorded for one of those variables for certain participants, all of the information for those individuals is removed from the data set and analyses are performed only on the remaining (complete) records. Also called casewise deletion: complete-case analysis. Compare pairwise deletion.

literacy n. 1. the ability to read and write in a language. See also biliteracy. 2. the quality of being educated as well as knowledgeable. 3. the quality of having a clear understanding of traditional and contemporary literature. —literate adj.

literacy test any test that examines the ability to read and write or an individual’s understanding of literature.

literal alexia a form of alexia in which a person cannot recognize individual letters or numerals and confuses such letters as d and b. Also called literal dyslexia.

literalism n. 1. adherence to observable facts, as exhibited in Jean Piaget’s construct of objective responsibility. 2. verbal or nonverbal answers of “yes” or “no,” without cognitive elaboration, to questions during hypnosis, asserted by some but strongly refuted by others to be a marker of hypnotic trance. 3. adherence to the explicit meaning of a text or doctrine, as in biblical literalism.

literal paraphasia a type of speech disturbance in which phonemes are substituted, exchanged, deleted, or added in speech, making it difficult to comprehend what the individual is trying to say. For example, tar may be used for car. Also called phonological paraphasia. See paraphasia.

literal replication see replication.

lithium n. an element of the alkali metal group whose salts are used in psychopharmacotherapy as mood stabilizers. Lithium salts were first used for the treatment of mania in the 1940s, but widespread use was limited by their toxicity. However, after further investigations into their role in treating bipolar depression and better appreciation of the appropriate dosage, lithium salts entered broader clinical practice in the 1970s. Although its primary indication is in managing bipolar disorder, lithium has some efficacy in managing acute manic phases and in reducing relapse. Its mechanism of action remains unclear; it may work via inhibition of the recycling of inositol from the inositol phosphates, which are second messengers in cellular signaling. Toxic doses are no more than two to three times the therapeutic dose, and serum monitoring is required. Symptoms of acute toxicity include tremors, diaphoresis, vomiting, and incoordination; at higher doses, disturbances of heart rhythm and neurological function leading to coma and death may occur. Long-term lithium use can cause thyroid and renal dysfunction in a small percentage of patients. Lithium has been associated with fetal malformation (elective abortion) and its use during pregnancy is not recommended. U.S. trade names (among others): Eskalith, Lithobid.

litigious paranoia a type of paranoid disorder characterized by constant quarreling, claims of persecution, and insistence that one’s rights have been breached. The individual usually threatens to go to court—and frequently does so—to seek redress for exaggerated or imagined wrongs. Also called paranoia querulans: paranoid litigious state.

Little Albert the name of a boy used by John B. Watson and his graduate student Rosalie Rayner (1899–1935) to demonstrate classical (or Pavlovian) fear conditioning in humans.

Little Hans a landmark case of Sigmund Freud’s illustrating the oedipus complex. Freud traced a child’s phobia for horses to castration anxiety stemming from masturbation, to repressed death wishes toward the father, and to fear of retaliation owing to rivalry with the mother, with displacement of these emotions onto horses. Freud never actually met the boy but analyzed him through written communication with the father. The case was reported in “Analysis of a Phobia in a Five-Year-Old Boy” (1909).

living will see advance directive.

LLD abbreviation for language learning disability. See specific language impairment.

Lloyd Morgan’s canon the principle that the behavior of a nonhuman animal should not be interpreted in complex psychological terms if it can instead be interpreted with simpler concepts. Lloyd Morgan’s canon, proposed in 1894, helped eliminate the older concept of anthropomorphism, or the endowment of animals with human traits, although some recent authors have argued that its application oversimplifies the abilities of animals. Also called Morgan’s canon: Morgan’s principle. [Conway Lloyd Morgan]

LLR abbreviation for log-likelihood ratio.

L-methylfolate n. the active form of the B vitamin folate. It is available as a prescription medical food to treat people with folate deficiencies, depression (as an adjunct to antidepressants), or schizophrenia (as an adjunct to antipsychotics). U.S. trade name: Deplin.

LMX theory abbreviation for leader–member exchange theory.

LNNB abbreviation for Luria–Nebraska neuropsychological battery.

lobe n. a subdivision of an organ, such as the brain or the lungs, particularly when rounded and surrounded by distinct structural boundaries, such as fissures. The four main lobes of each cerebral hemisphere of the brain are the frontal lobe, parietal lobe, temporal lobe, and occipital lobe. There are also subdivisions of each of these lobes; for example, the temporal lobe comprises the inferior, middle, and superior temporal lobes. —lobar adj. —lobate adj.

lobectomy n. complete or partial surgical removal of a lobe, particularly in the brain. The most frequently performed lobectomy is done for seizure control and involves the anterior temporal lobe (see temporal lobectomy).

lobotomy n. incision into various nerve tracts in the frontal lobe of the brain. The original surgical procedure, called prefrontal (or frontal) lobotomy, was introduced in 1936 by Portuguese neurologist Antonio Egas Moniz (1874–1955): Connections between the frontal lobe and other brain structures—notably the thalamus—were severed by manipulating a narrow blade known as a leu-
kotome inserted into brain tissue through several small holes drilled in the skull. A second procedure, called trans-orbital lobotomy, was devised in 1945 and involved the manipulation of a pointed instrument resembling an ice pick driven with a mallet through the thin bony wall of the eye socket and into the prefrontal brain. Both procedures were widely used to relieve the symptoms of severe mental disorder (including depression and schizophrenia) until the advent of antipsychotic drugs in the 1950s. These operations did, on occasion, result in improved function for some patients, but others either died as a consequence of the surgery or suffered major personality changes, becoming apathetic and prone to inappropriate social behavior: some also developed a seizure disorder. Such procedures have since been replaced by more sophisticated, stereotactic forms of neurosurgery that are less invasive and whose effects are more certain and less damaging. Also called leukotomy.

LOC abbreviation for LOSS OF CONSCIOUSNESS.

local circuit see NEURAL CIRCUIT.

local circuit neuron a neuron with short processes that do not extend far from the cell body. Also called Golgi Type II neuron. Compare PROJECTION NEURON.

local enhancement a form of SOCIAL LEARNING in which one or more individuals engaging in some behavior with an object in a particular location draw the attention of another to that location, which facilitates the acquisition of similar behavior by that observer. The attraction of attention to a particular place in the environment, not any specific social interactions among the demonstrators and observer, is what leads to learning. For example, ducks in a pen may ignore an escape hole unless they are near another duck who escapes through the hole, thus drawing their attention to it.

local excitatory state (LES) the localized increase in negative potential on the surface of a neuron in response to stimulation below threshold level, which results in temporarily increased NEURAL IRITABILITY. Also called local excitatory potential.

local-global distinction the difference between perceiving a whole form and perceiving the subunits that make up that form. For example, if a large letter is formed receiving a whole form and perceiving the subunits that make up that form. For example, if a large letter is formed from an arrangement of small letter Ss, perception is at the local level if it focuses on the S and at the global level if it focuses on the S.

local independence in FACTOR ANALYSIS and other models involving LATENT VARIABLES, the basic assumption that individual observations have no direct influence on one another and that any relationship between them is to be explained by the latent variable underlying them.

localization n. the ability to determine the physical position or spatial location of a stimulus in any sensory modality.

localization of function the concept that specific parts of the cerebral cortex are relatively specialized for particular types of cognitive and behavioral processes. Also called cortical localization.

localized amnesia a memory loss restricted to specific or isolated experiences. Also called circumscribed amnesia; lacunar amnesia.

local potential the phase of a GRADED POTENTIAL that precedes the ACTION POTENTIAL if the localized stimulation is above threshold level. Also called local response.

local regression (loess; lowess) a form of REGRESSION ANALYSIS in which a model of the relationship between outcomes and predictors is obtained by fitting different linear or quadratic functions to different segments or intervals of data. Variables are assigned different weights in the REGRESSION EQUATIONS to reflect their relative importance at each point and no assumptions are made about the associations among the variables. The overall curve obtained by combining the individual fitted curves for the different data segments shows the general shape of the relationship between the variables. Also called locally weighted regression.

location constancy the tendency for a resting object and its setting to appear to have the same position even if the relationship between setting and observer is altered as the observer shifts position. See also OBJECT CONSTANCY.

location-invariant neuron any of various neurons located in EXTRASTRIATE VISUAL AREAS, particularly those in the INFEROTEMPORAL CORTEX, that respond regardless of the location of a stimulus in the receptive field. Because the receptive fields in these areas are so large, a stimulus may be located almost anywhere in the visual field. Many of these cells are also size-invariant neurons, which respond when presented with a particular object, regardless of its size.

loci pl. n. see LOCUS.

loci method see METHOD OF LOCI.

lock-and-key theory 1. generally, any theory that posits a specific fit between two or more of its components, in a manner analogous to the fit of a key in a lock. 2. in olfaction, see STEROEOMICAL SMELL THEORY.

locked-in syndrome a condition in which a person cannot speak or move but is fully cognizant and aware of his or her surroundings. The individual has normal metabolic functions and sleep–wake cycles but is able to communicate only with eye movements (e.g., blinking, looking up or down). Electrical activity of the brain (including EVENT-RELATED POTENTIALS) generally is normal as well, as demonstrated through ELECTROENCEPHALOGRAPHY, SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY, and other imaging techniques. Locked-in syndrome is poorly understood and frequently misdiagnosed as COMA or a VEGETATIVE STATE; research suggests that physicians fail to recognize signs of consciousness in more than half of cases. It is associated with disruption of motor neurons in the brainstem—typically the PONS—from hemorrhage, occlusion or infarction, traumatic brain injury, tumor, encephalitis, neuromuscular disorders (e.g., AMYOTROPHIC LATERAL SCLEROSIS, GUILLAIN-BARRE SYNDROME), and other causes. Life expectancy of an individual with locked-in syndrome may be several decades with appropriate medical care, but the probability of significant motor recovery is small. See also BRAIN–COMPUTER INTERFACE; [term coined in 1966 by U.S. neurologists Fred Plum (1924–2010) and Jerome B. Posner]

locked ward a secured hospital unit in which patients with severe mental disorders reside. The present trend is toward elimination of locked wards. Factors leading to their less frequent use are improvements in psychological interventions, the use of psychoactive drugs, and the concepts of the OPEN HOSPITAL and THERAPEUTIC COMMUNITY.
Locke's theory of goal setting

Locke's theory of goal setting a theory suggesting that (a) specific goals direct activity more effectively than do vague or general goals, (b) difficult or challenging goals produce better performance than do moderate or easy goals, and (c) short-term goals can be used to attain long-range goals. At least four mechanisms explain why goal setting improves performance: (a) it focuses and directs activities, (b) it regulates expenditure of energy, (c) it enhances persistence because the effort is continued until the goal or subgoal is reached, and (d) it can promote the development of new strategies for improving performance. Goal setting only works if there is timely feedback showing performance or progress in relation to the goal. Goals must be accepted to be effective, and their attainment is facilitated by a plan of action or strategy. Competition can be viewed as a form of goal setting. [Edwin A. Locke (1938– ), U.S. industrial psychologist]

lockout n. a tactic used by an employer when negotiating a contract with a union in which employees are barred from entering the workplace and performing their jobs until they agree to the employer’s terms.

locomotion n. movement of an organism from one place to another. Different species may have different typical modes of locomotion, such as crawling, swimming, flying, bipedal walking, and quadrupedal walking. —locomotor adj.

locomotor arrest the inhibition of movement, which can be produced by volition, drugs, or electrical stimulation of the hippocampus.

locomotor ataxia severe incoordination in walking, producing an unsteady gait. It involves degeneration of the dorsal columns of the spinal cord and is seen in individuals with neurosyphilis. See general paresis. Also called tabes dorsalis.

locomotor play play that involves exaggerated, repetitious movement and is physically vigorous, such as chasing, climbing, and wrestling. There are three distinctive forms: rhythmic stereotypy, exercise play, and rough-and-tumble play. Locomotor play is one of three traditionally identified basic types of play, the others being object play and social play.

loco plant any of certain plants belonging to the genera Astragalus or Oxytropis that grow wild in western North America, particularly in the Rocky Mountains, and that if ingested damage nerve tissue. The substances responsible include misericotin, swainsonine, and selenium. Symptoms of poisoning include muscular trembling or incoordination, staggering gait, and impairment of depth and other sensory perception (loco is the Spanish word for “crazy”). In sufficient doses, these toxins produce irreversible changes in the central nervous system, including brain lesions and eventual paralysis, and may cause coma or death. Also called loco weed.

locura n. a culture-bound syndrome found among Latino groups in the United States and Latin America and attributed to hereditary vulnerability, the consequences of stressful and difficult life events, or a combination of the two. Symptoms include incoherence, agitation, auditory and visual hallucinations, social dysfunction, erratic behavior, and possibly violence.

locus n. (pl. loci) 1. the place or position of an anatomical or pathological entity (e.g., a hemorrhage in the brain, a butterfly rash on the skin). 2. the position of a gene on a chromosome.

locus ceruleus (locus coeruleus) locus caeruleus a small bluish-tinted nucleus in the brainstem whose neurons produce norepinephrine and modulate large areas of the forebrain. It is involved in arousal and likely has a role in anxiety.

locus of causality attribution of the causes of an event to sources internal or external to the self, which may influence subsequent behavior in relation to that event. For example, a student who fails an exam may attribute his or her poor performance to an inherent lack of ability—an internal cause—and decide not to study at all for the next exam because “it won’t do any good,” whereas another student may attribute the same poor performance to distractions from a neighbor’s loud party during a review session the night before—an external cause—and hence study twice as long in a quiet setting for the next exam. Research suggests that consistent performance tends to be attributed to internal factors whereas highly variable performance tends to be attributed to external factors. [described in 1979 by U.S. social psychologist Bernard Weiner (1935– )]

locus of control a construct that is used to categorize people's basic motivational orientations and perceptions of how much control they have over the conditions of their lives. People with an external locus of control tend to behave in response to external circumstances and to perceive their life outcomes as arising from factors out of their control. People with an internal locus of control tend to behave in response to internal states and intentions and to perceive their life outcomes as arising from the exercise of their own agency and abilities. [introduced into psychology by Julian Rotter]

locus of stability attribution of the causes of an event sources that are constant and unlikely to change over time or to sources that are dynamic and subject to variability over time, which may influence a person's subsequent behavior in relation to that event. For example, a supervisor who believes that an employee unexpectedly absent from a recent meeting will also miss future meetings may reprimand the person, whereas a supervisor who believes the absence is not likely to be habitual may overlook the indiscretion. [proposed in 1979 by U.S. social psychologist Bernard Weiner (1935– )]

locutionary act see illocutionary act.

LOD score log of the odds score: an estimate of whether data indicate that two gene loci are linked, that is, are likely to lie near each other on a chromosome and therefore are likely to be inherited together. A LOD score of 3 or more generally indicates that the two loci are close.

loess n. see local regression.

log- combining form see logo-.

logarithm (log) n. the number of times that a given value (the base) has to be multiplied by itself to produce a specific quantity. For example, the logarithm for the quantity 81 and the base 3 is the number 4 (3 × 3 × 3 × 3 = 81). Logarithms are given by the generic formula $y = \log_{x}^{a}$, thus $4 = \log_{3}^{81}$.
logarithmic transformation the conversion of raw data values into another form via the use of LOGARITHMS. In turning multiplicative relationships into additive ones and eliminating exponential trends, logarithmic transformations allow researchers to analyze data using LINEAR MODELS. Additionally, such transformations may be used to convert raw data into a form that more closely matches the assumptions required in particular statistical analyses, particularly that of NORMALITY.

logic n. 1. the branch of EPistemology that is concerned with the forms of argument by which a valid conclusion may be drawn from accepted premises. As such, it is also concerned with distinguishing correct from fallacious reasoning (see fallacy). See also DEDUCTIVE REASONING; INFERENCE. 2. a particular rule-governed form of symbolic expression used to analyze the relations between propositions. See SYMBOLIC LOGIC. —logical adj.

logical inference see INFERENCE.

logical-mathematical intelligence in the MULTIPLE INTELLIGENCES THEORY, the set of skills used in reasoning, abstraction, and numerical analysis and computation. These abilities are alleged to be relatively independent of the abilities involved in other types of intelligences.

logical necessity a necessarily valid conclusion that follows from the operations of a system of FORMAL LOGIC on a set of premises or initial conditions.

logical paradox see PARADOX.

logical positivism a philosophical perspective that is committed to the principle of verification, which holds that the meaning and truth of all nontautological statements are dependent on empirical observation. In the early 20th century, the positivists of the VIENNA CIRCLE sought to establish the essential unity of logic, philosophy, and science and to distinguish these disciplines from others such as metaphysics, ethics, and religion, which were dismissed for their speculative character. The positivist view of science was influential during the period in which psychology emerged as a science and has had a recognizable influence on the discipline. This is most pronounced in BEHAVIORISM and in psychology’s commitment to empirical scientific methods. See POSITIVISM. See also PHYSICALISM; POSTPOSITIVISM; REDUCTIONISM.

logical thinking thinking that is consistent with formal principles of logic. See also DEDUCTIVE REASONING.

logico-grammatical, disorder a manifestation of SEMANTIC APHASIA that affects individuals with lesions of the dominant PARietal LOBE. An individual uses the correct words but in a sequence that gives a different meaning; for example, the words plate and table may be transposed in the sentence The plate is on the table to produce The table is on the plate.

logistic function a basic function of the form \( y = c/(1 + a \exp(-bx)) \), where \( y \) and \( x \) are variables, \( a \), \( b \), and \( c \) are constants, and \( \exp \) is the EXPONENTIAL FUNCTION. When graphed, values derived from a logistic function form an S shape called the logistic curve. The logistic function is used to describe LONGITUDINAL DATA and growth rates in particular, in which an initial stage of growth is approximately exponential and then, as saturation begins, slows and ultimately ceases altogether.

logistic regression (LR) a form of REGRESSION ANALYSIS used when the outcome or DEPENDENT VARIABLE may assume only one of two categorical values (e.g., pass or fail) and the predictors or INDEPENDENT VARIABLES are either categorical or CONTINUOUS. For example, a researcher could use logistic regression to determine the likelihood of graduating from college (yes or no) given such student information as high school grade point average, college admissions test score, number of advanced placement courses taken in high school, socioeconomic status, and gender. Also called logistic modeling.

logistic transformation a TRANSFORMATION in which measurements on a LINEAR scale are converted into probabilities between 0 and 1. It is given by the formula \( p = e^y/(1 + e^y) \), where \( y \) is the scale value and \( e \) is the Eulerian number. The inverse of logits, logistic transformations are used in such statistical procedures as LOGISTIC REGRESSION.

log likelihood the LOGARITHM of a probability value or estimate.

log-likelihood ratio (LLR) a ratio whose numerator and denominator comprise LOG LIKELIHOODS. It is used (in the log-likelihood test) to evaluate the GOODNESS OF FIT of the NULL HYPOTHESIS and the ALTERNATIVE HYPOTHESIS in explaining sample data. The simpler LIKELIHOOD RATIO indicates how many times more likely the observed values are to occur under one model than under the other, and the LOGARITHMS of those values yield a log-likelihood ratio.

log-linear analysis a method of examining relationships between two or more CATEGORICAL VARIABLES that involves an analysis of the natural LOGARITHMS of frequency counts within a CONTINGENCY TABLE. Log-linear analyses do not distinguish between INDEPENDENT VARIABLES and DEPENDENT VARIABLES but rather attempt to model all significant associations among all variables, including interactions between any combination of the variables, using sets of ODDS and ODDS RATIOS for different category outcomes. Also called log-linear modeling.

log-normal distribution a THEORETICAL DISTRIBUTION in which the LOGARITHMS of values on a variable follow the bell-shaped NORMAL DISTRIBUTION.

Logo n. a computer programming language designed at the Massachusetts Institute of Technology’s Artificial Intelligence Research Laboratory in conjunction with the research firm Bolt, Beranek and Newman to encourage the development of problem-solving skills. A dialect of LISP, Logo was directed primarily at children and is based on Jean Piaget’s research in the development of thinking. [designed by U.S. computer scientist Wally Feurzeig and South African-born U.S. mathematician Seymour Papert (1928– )]

logo- (log-) combining form speech or words.

log odds see LOGIT.

logogen n. a theoretical memory unit corresponding to a word, letter, or digit, which, when excited, results in the output (recognition) of the unit and recall of characteristics and information associated with that unit. For example, the logogen for table is activated by hearing the component sounds or seeing the typographical features of the word, bringing to mind such knowledge as the typical structure and shape of a table and its general function. [proposed by British psychologist John Morton (1933– )]
logographic

logographic adj. denoting or referring to writing systems that use a separate symbol (logogram or logograph) to represent each word or morpheme.

logopathy n. a speech disorder of any kind.

logopedics n. primarily in Britain, the study and treatment of speech disorders. See SPEECH AND LANGUAGE PATHOLOGY.

logorrhea n. rapid, uncontrolled, and incoherent speech, sometimes occurring as part of a MANIC EPISODE.

logotherapy n. an approach to psychotherapy that focuses on the “human predicament,” helping the client to overcome crises in meaning. The therapeutic process typically consists of examining three types of values: (a) creative (e.g., work, achievement), (b) experiential (e.g., art, science, philosophy, understanding, loving), and (c) attitudinal (e.g., facing pain and suffering). Each client is encouraged to arrive at his or her own solution, which should incorporate social responsibility and constructive relationships. Also called meaning-centered therapy. See also EXISTENTIAL PSYCHOTHERAPY, EXISTENTIALISM. [developed in the 1950s and 1960s by Victor E. Frankl.]

-logy (-ology) suffix field of study (e.g., PHONOLOGY).

Lokian personality a personality pattern characterized by the desire to cause distress to others, manipulative behavior, and deceit. The name is derived from Loki, the Norse god of mischief.

Lolita complex see NYPHOLEPSY.

London syndrome explicit and constant resistance and refusal by hostages to do what captors expect during a hostage-taking incident in London. It may result in serious injury and death to the resisters.

loneliness n. affective and cognitive discomfort or uneasiness from being or perceiving oneself to be alone or otherwise solitary. Psychological theory and research offer multiple perspectives: Social psychology emphasizes the emotional distress that results when inherent needs for intimacy and companionship are not met; cognitive psychology emphasizes the unpleasant and unsettling experience that results from a perceived discrepancy (i.e., deficiency in quantity or quality) between an individual’s desired and actual social relationships. Psychologists from the existential or humanistic perspectives may see loneliness as an inevitable, painful aspect of the human condition that nevertheless may contribute to increased self-awareness and renewal. See UCLA LONELINESS SCALE.

long axis see AXIS.

long-delay conditioning in DELAY CONDITIONING, the period during which the conditioned stimulus is presented long enough to produce INHIBITION OF DELAY.

longevity n. 1. long life. 2. the actual length of an individual’s life. See also LIFE EXPECTANCY.

longilneal adj. denoting a constitutional type of body that is long rather than broad and roughly equivalent to the ASTHENIC TYPE in KRETSCHEMER TYPOLOGY.

longitudinal adj. 1. in anatomy, referring to the long AXIS of the body. 2. in research, referring to the time dimension—that is, running over an extended period.

longitudinal data information obtained through multiple measurements of the same individuals over a period of time. For example, a researcher investigating the use of coping strategies in college students may evaluate stress levels at the beginning, middle, and end of the fall and spring semesters.

longitudinal design the study of a variable or group of variables in the same cases or participants over a period of time, sometimes several years. An example of a longitudinal design is a multiyear comparative study of the same children in an urban and a suburban school to record their cognitive development in depth. A longitudinal study that evaluates a group of randomly chosen individuals is referred to as a panel study, whereas a longitudinal study that evaluates a group of individuals possessing some common characteristic (usually age) is referred to as a cohort study. Also called longitudinal research: longitudinal study. Compare CROSS-SECTIONAL DESIGN.

longitudinal fissure a deep groove that marks the division between the left and right cerebral hemispheres of the brain. At the bottom of the groove, the hemispheres are connected by the CORPUS CALLOSUM. Also called interhemispheric fissure: sagittal fissure.

longitudinal stability the degree to which an individual’s possession or expression of a psychological characteristic is consistent over a period, as compared with other people.

long-term care provision of health, mental health, or other services over a prolonged or extended period to someone with a chronic illness, mental illness, or disability. Care can be provided in an institutional setting or the community (e.g., at home) by health care professionals, family, or friends.

long-term care facility an EXTENDED CARE institution, such as a NURSING HOME, that provides medical and personal services for patients who are unable to live independently but do not require the inpatient services of a hospital.

long-term depression (LTD) a long-lasting decrease in the amplitude of neuronal response due to persistent weak synaptic stimulation (in the case of the hippocampus) or strong synaptic stimulation (in the case of the cerebellum). Compare LONG-TERM POTENTIATION.

long-term memory (LTM) a relatively permanent information storage system that enables one to retain, retrieve, and make use of skills and knowledge hours, weeks, or even years after they were originally learned. Various theories have been proposed to explain the biological processes by which this occurs (e.g., the PERSEVERATION–CONSOLIDATION HYPOTHESIS), and a major distinction is made between LTM and SHORT-TERM MEMORY. Additionally, LTM is divided into several categories, including DECLARATIVE MEMORY and PROCEDURAL MEMORY. See also SECONDARY MEMORY.

long-term potentiation (LTP) enhancement of synaptic transmission (see SYNAPSE), which can last for weeks, caused by repeated brief stimulations of one nerve cell that trigger stimulation of a succeeding cell. The capacity for potentiation has been best shown in hippocampal tissue. LTP is studied as a model of the neural changes that underlie memory formation, and it may be a mechanism involved in some kinds of learning. Compare LONG-TERM DEPRESSION.

long-term therapy psychotherapy over a period of
many months or years. Classic psychoanalysis, which may last 2 to 5 years or longer, is a primary example.

**long-wavelength pigment** the photopigment, present in one of the three populations of retinal cones, that has maximum sensitivity to a light wavelength of 558 nm. The absence of the gene for the long-wavelength pigment causes protanopia (red color blindness). See also medium-wavelength pigment; short-wavelength pigment.

**look angle** in ergonomics, the direction in which the operator looks during task performance. The goal is to design equipment and workstations in such a way that the viewing angle is central or forward rather than requiring head movements or eye glances to the left or right. See also head-up display.

**looking-glass self** a self-concept formed by incorporating other people’s views of oneself into one’s own selfviews. The term suggests a self-concept that is, in part, a reflection of other people’s impressions, reactions, and opinions. See reflected appraisals; symbolic interactionism. [introduced by U.S. social thinker Charles Horton Cooley (1844–1929)]

**look-say** n. see whole-word method.

**looming** n. a type of space perception in which the retinal image of an object is magnified as the object approaches the observer. Reactions to looming vary: Chicks run away, kittens avert their heads, monkeys leap backward while making alarm cries, and human infants attempt to withdraw their heads at 2 weeks and blink at 3 weeks.

**loose culture** a heterogeneous social group whose diverse members tend to value originality, risk taking, and a flexible adherence to the collective norms of their culture or group. Compare tight culture. [coined by Greek-born U.S. psychologist Harry C. Triandis (1926–)]

**loosening of associations** a thought disturbance demonstrated by speech that is disconnected and fragmented, with the individual jumping from one idea to another unrelated or indirectly related idea. It is essentially equivalent to derailment.

**loperamide** n. an opioid that slows gastrointestinal motility and is used for the treatment of diarrhea. Because it is not effectively transported across the blood–brain barrier, it has few (if any) psychotropic effects and its abuse potential is low. U.S. trade name: Imodium.

**lorazepam** n. a highly potent benzodiazepine approved for the treatment of anxiety and as premedication in surgical anesthesia. Unlike many other benzodiazepines, it has no active metabolic products and therefore minimal processing in the liver. This, together with its predictable duration of action, make it a favored drug in the management of alcohol withdrawal in patients with liver impairment. U.S. trade name (among others): Ativan.

**lordosis** n. 1. an abnormal inward curvature of the spine in the lumbar and cervical regions. In extreme cases, the condition is known as hyperlordosis. See also kyphosis; scoliosis. 2. in many rodents, a similar but normal posture that is assumed by females during periods of sexual receptivity and serves to facilitate copulation with a male. In the absence of lordosis, males are physically unable to mate with the female. See presenting.

**Lord’s paradox** an effect in which the relationship between a continuous outcome variable and a categorical independent variable (e.g., treatment or control) is reversed when an additional covariate is introduced to the analysis. For example, suppose that a researcher is studying change in knowledge about a topic following an intervention and obtains results indicating that those who received the treatment had a better outcome (i.e., had learned more) than those in the control group. If, however, the researcher decides to use an analysis of covariance to adjust the treatment effect according to general educational level, the pattern of findings could be reversed: If participants receiving the treatment had a substantially higher level of education than those in the control group, it might now appear that they did not gain from the intervention. [Frederick M. Lord]

**Lorenzini ampullae** see electric sense.

**LOS** abbreviation for length of stay.

**loser effect** in many species, the reduced likelihood that an individual will win future contests over resources after repeated experiences of losing in such contests. Physiological changes, such as increased glucocorticoids (e.g., cortisol, cortisone) or decreased testosterone, often occur with the loser effect. Compare winner effect.

**loss aversion** see behavioral economics.

**loss of affect** loss of the ability to respond emotionally, which results in flat affect.

**loss of consciousness (LOC)** a state in which an organism capable of consciousness can no longer experience events or exert voluntary control. Examples of conditions associated with loss of consciousness include deep sleep (slow-wave sleep), fainting (syncope), hypoglycemia, traumatic brain injury, coma, general anesthesia, narcolepsy, and some epileptic seizures.

**lost letter procedure** an indirect attitude measure used at an aggregate group level. Two sets of stamped envelopes are created, one addressed to a group likely to adopt a particular attitudinal position on the target issue and the other addressed to a group likely to adopt the opposite position. Equal numbers of each version of the envelope are randomly distributed in a particular community. The procedure is based on the logic that a person finding a letter that has apparently been inadvertently dropped is more likely to place the letter in a mailbox if it is addressed to a group that shares his or her position. The percentage of people in that community supporting the two positions is then inferred from the number of envelopes that are ultimately mailed to each address. Also called lost letter technique. [originally developed by Stanley Milgram]

**lot acceptance sampling** see acceptance sampling.

**loudness** n. the subjective magnitude of sound. It is determined primarily by intensity but is also affected by other physical properties, such as frequency, spectral configuration, and duration. The unit proposed for loudness is the sone: One sone is defined as the subjective magnitude of a 1 kHz tone presented at 40 dB SPL (decibels sound-pressure level), based on loudness judgments by listeners. Loudness approximately doubles for each 10 dB increase in intensity. The loudness level is the level in decibels SPL of a 1 kHz tone that is judged to be equally as loud as the test sound. The unit is the phon: A sound whose loudness level is 40 phons has a loudness equal to that of a 1 kHz tone presented at 40 dB SPL.

**loudness summation** a situation in which the loudness of different sounds presented together is the sum of
Lou Gehrig's disease

their individual loudnesses. For example, if Sound A at 40 dB SPL (decibels sound-pressure level) has a loudness of 1 sone and Sound B at 50 dB SPL, has a loudness of 2 sones, then loudness summation is said to occur if the loudness of A and B presented together is 3 sones. Loudness summation depends on the frequency composition of the sounds. See also CRITICAL BAND.

Lou Gehrig's disease see AMYTROPHIC LATERAL SCLEROSIS. [Henry (Lou) Gehrig (1903–1941), U.S. baseball player who died of the disease]

Louis-Bar syndrome see ATAXIA TELANGECTASIA. [Denise Louis-Bar (1914– ), Belgian neuropathologist]

love n. a complex emotion involving strong feelings of affection and tenderness for the love object, pleasurable sensations in his or her presence, devotion to his or her well-being, and sensitivity to his or her reactions to oneself. Although love takes many forms, including concern for one's fellow humans (brotherly love), parental love, EROTE LOVE, SELF-LOVE, and identification with the totality of being (love of God), the TRIANGULAR THEORY OF LOVE proposes three essential components: passion, intimacy, and commitment. Social psychological research in this area has focused largely on PASSIONATE LOVE, in which sexual desire and excitement predominate, and COMPANIONATE LOVE, in which passion is relatively weak and commitment is strong.

lovemap n. a person’s mental image of the ideal lover, the ideal love relationship, and ideal sexual activity with the partner, expressed in fantasy and in actual sexual behavior. It incorporates issues of SEXUAL ORIENTATION and also of desire for deviant behaviors (see PARAPHILIA). [proposed by John Money] loveness n. see LOCAL REGRESSION.

love need in MASLOW’S MOTIVATIONAL HIERARCHY, the third level of the hierarchy of needs, characterized by the striving for affiliation and acceptance. Also called social need.

love object 1. the person toward whom an individual directs affection, devotion, and (usually) sexual interest. 2. in psychoanalytic theory, the person who is loved by the individual’s EGO, as opposed to the OBJECT that satisfies an INSTINCT.

love scale a measure of the strength of one person’s feeling of love for another. Because love is a complex state occurring in many different forms, the various scales that have been devised do not always recognize the same components of this multifaceted emotion. As examples, the measure assessing PASSIONATE LOVE developed by U.S. social psychologist Elaine Hatfield (1937– ) concentrates on items dealing with sexual desires as well as other, more cognitively oriented items, reflecting a preoccupation with the love object and idealization of this person, whereas the ROMANTIC LOVE scale devised by U.S. social psychologist Zick Rubin (1944– ) involves elements of both passionate and COMPANIONATE LOVE and includes items dealing with willingness to confide in the loved person and the desire to be with him or her. See also LIKING SCALE.

love withdrawal a form of discipline in which parents threaten to withdraw their love and affection from children if they misbehave.

low-ball technique a procedure for enhancing COMPLIANCE by first obtaining agreement to a request and then revealing the hidden costs of this request. Compliance to the target request is greater than would have been the case if these costs had been made clear at the time of the initial request. See also DOOR-IN-THE-FACE TECHNIQUE; FOOT-IN-THE-DOOR TECHNIQUE; THAT’S NOT-ALL TECHNIQUE.

low birth weight (LBW) infant weight at birth of less than 5.5 pounds (2,500 g) regardless of gestational age. Very low birth weight (VLBW) refers to weight of less than 3.5 pounds (1,500 g) and extremely low birth weight (ELBW) is used to describe an infant weight of less than 2.2 pounds (1,000 g) at birth. Children born with VLBW are at an increased risk for serious health problems and reduced scores on measures of intelligence. Children born with moderately low birth weight (i.e., 1,500–2,499 g, 3.5–5.8 lbs) are at risk for similar, albeit less severe, outcomes. However, the research base is far less available within the moderate low birth weight category. The vast majority of studies have focused on the VLBW and ELBW categories. These categories encompass only 15% of all low birth weights and approximately 1.2% of all births in a given year. Compare SMALL FOR GESTATIONAL AGE.

lower hinge the point in a distribution of values below which lie one fourth of the data. It is equivalent to the first QUARTILE and lies midway between the MEDIAN and the minimum point of the distribution. Compare UPPER HINGE.

lower motor neuron see MOTOR NEURON.

lower quartile see QUARTILE.

lower real limit see REAL LIMIT.

lowess n. see LOCAL REGRESSION.

Loxapine n. an ANTIPSychotic introduced into the U.S. market in the early 1970s. Loxapine differs from the conventional antipsychotics in that it binds strongly to serotoninergic as well as dopaminergic receptors. Although its chemical structure (see DIbENzoXAZEPINE) is similar to that of the atypical antipsychotic CLOzapine,loxapine has the same antipsychotic, antiemetic, sedative, and extrapyrami-
Period of delirium, disorganization, or confusion brought on effect: Understanding how good people turn evil

Serotonin and presumably exerts its psychoactive effects by

Effect: Understanding How Good People Turn Evil

For iniquitous social conditions, texts to negatively influence and transform human behavior.

Progress of the dream narrative.

Situation

LNV adj. referring to the lower part of the back or spinal cord.

Lumbosacral plexus a network of nerve fibers derived from the spinal roots of the fourth and fifth lumbar nerves and first through fourth sacral nerves (see Spinal Nerve). It supplies the muscles of the leg and foot. The largest derivative of the lumbosacral plexus is the SCIATIC NERVE. Also called lumbosacral plexus.

Lumen (symbol: lmn) n. the unit of LUMINOUS FLUX equal to the flux emitted by a uniform point source of 1 candela in a solid angle of 1 steradian.

Luminal n. a trade name for PHENOBARBITAL.

Luminance n. the amount of light reflected or emitted from an object as measured in candelas per square meter.

Luminosity n. the visual sensation of the brightness of a light source. It depends on the power emitted by the source and on the sensitivity of the eye to different wavelengths of light. Other factors can also influence the luminosity: for example, a light of a given LUMINOUS INTENSITY will appear brighter in a room with white walls than in a room with dark walls.

Luminosity coefficient see COEFFICIENT OF VISIBILITY.

Luminosity curve a graph of visual sensitivity (perceived luminosity) as a function of the wavelength of light.

Luminous flux (symbol: Φ) the rate at which light is emitted from a source or reflected from a surface. It is measured in LUMENS by reference to a standard source.

Luminous intensity (symbol: I) the LUMINOUS FLUX emitted per unit solid angle by a point source in a given direction, measured in candelas.

Lunacy n. 1. an obsolete name for any mental illness. 2. in legal use, an obsolete name for mental incompetence or legal INSANITY. 3. the theory that some forms of mental illness correspond with the phases of the moon. See also MOON-PHASE STUDIES. —lunatic adj., n.

Lunatic asylum see INSANE ASYLUM.

Lunesta n. a trade name for ESZOPICLONE.

Lupron n. a trade name for LEUPROIDE.

Lupus erythematosus (LE) an autoimmune disorder causing chronic inflammation of connective tissue and characterized by joint pain, a butterfly-shaped rash on the nose and cheeks, and scaly red patches on the skin. The condition may be limited to the skin, or it may also affect internal organs, such as the heart, lungs, and central nervous system (systemic lupus erythematosus; SLE), and involve neurological abnormalities, such as seizures and psychosis.

Lurasidone n. an atypical antipsychotic of the benzisothiazol derivative class that is thought possibly to exert its effect by acting as a serotonin 5-HT₂A and dopamine D₂
lure n. an incorrect item presented among correct items in testing memory, to serve as a DISTRACTER.

Luria–Nebraska Neuropsychological Battery (LNNB) a set of tests to assess the cognitive functioning of individuals 15 years and older that is intended to represent a standardized, quantitative version of Alexander Luria's neuropsychological testing procedures that were initially collected and organized by Danish neuropsychologist Anne-Lise Christensen. The battery is available in two versions (Form I comprising 269 items and Form II comprising 279 items) and includes 11 clinical scales, each representing different aspects of relevant skills: motor functions, tactile functions, visual functions, rhythm, receptive speech, expressive speech, writing, reading, arithmetic, memory, and intellectual processes. Form II also includes an intermediate-term memory scale. Originally developed in 1978 by U.S. clinical psychologists Charles J. Golden (1949–), Thomas A. Hammekne (1950–), and Arnold D. Purisch (1951–), the LNNB became widely used as a stand-alone battery to diagnose general and specific cerebral dysfunction and to localize impaired brain areas. Currently, however, it is used as part of a larger group of other neuropsychological measures. A similar version for children 8 to 12 years old, the Luria–Nebraska Neuropsychological Battery–Children’s Revision (LNNB–C), was developed by Charles Golden in the 1980s.

lurking variable see HIDDEN VARIABLE.

lust murder an extreme form of SEXUAL SADISM in which an individual experiences sexual arousal from the murder of a partner during the sexual act, often including elaborate staging of the act and mutilation of the victim’s body. Also called erotophonophilia. See also HOMICIDOPHILIA.

luteal phase see MENSTRUAL CYCLE.

luteinizing hormone (LH) a GONADOTROPIN secreted by the anterior pituitary gland that, in females, stimulates the rapid growth of a GRAAFIAN FOLLICLE in the ovary until it ruptures and releases an ovum (see MENSTRUAL CYCLE). In males, it stimulates the interstitial cells of the TESTIS to secrete androgens. Also called interstitial cell-stimulating hormone (ICSH).

luteotropic hormone see PROLACTIN.

luteotropin n. see PROLACTIN.

Luvox n. a trade name for FLUOXAMINE.

lux n. the standard unit of ILLUMINANCE, equal to the illumination produced by a luminous flux of 1 lumen per square meter.

LVP abbreviation for licensed vocational nurse. See LICENSED PRACTICAL NURSE.

LVP abbreviation for lysine VASOPRESSIN.

lycanthropy n. 1. the supposed transformation of a human being into a wolf or other animal (from Greek λυκός, “wolf”). Belief in lycanthropy reached epidemic proportions in Europe during the 16th century, when 600 supposed lycanthropes were sentenced to death for having committed violent crimes in animal form. Also called zoanthropy. 2. a condition in which a person has delusions that he or she is or can become a wolf or other animal.

lygophilia n. an abnormal desire to be in dark or gloomy places.

Lyme disease a multisystemic illness caused by spirochete bacteria transmitted through the bite of an infected deer tick. Initial effects are a red rash around the site of the bite as well as flulike symptoms of fever, fatigue, headache, and body aches. If left untreated, the disease can result in arthritis; neurological symptoms (e.g., severe headache, temporary paralysis; mood changes; and problems with memory loss, concentration, and sleep. Its manifestation of physical, cognitive, and psychiatric symptoms makes it difficult to diagnose. The disease was first recognized in 1975 after a large number of children in Lyme, Connecticut, were initially diagnosed with rheumatoid arthritis.

lymphocyte n. a type of blood cell (see LEUKOCYTE) that plays a key role in specific IMMUNE RESPONSES. There are two main classes. B lymphocytes (or B cells), which develop and mature in the bone marrow, are responsible for humoral immunity: They produce circulating antibodies when they bind to an appropriate antigen and are costimulated by certain T cells. T lymphocytes (or T cells), which mature in the thymus, are responsible for cell-mediated immunity: They are characterized by the presence of particular cell-surface molecules and are capable of antigen recognition. There are two main subclasses: cytotoxic T cells, which release proteins that destroy invading cells, and helper T cells, which assist in this or other aspects of the immune response. See also NATURAL KILLER CELL. —lymphocytic adj.

lyphokine n. any of a group of proteins, secreted by lymphocytes, that have a role in cell-mediated immunity by inducing other cells of the immune system to divide. See CYTOKINE.

lynching n. an instance of a group or mob of vigilantes killing a person, especially by hanging. The Lynch mob often justifies its actions by claiming that the victim is guilty of some crime and the group is administering an appropriate punishment. Most lynchings in the United States were racially motivated acts of violence perpetrated by White Americans against African Americans. The first documented U.S. lynching occurred in 1882; by 1950, lynch mobs had killed more than 3,000 people. —lynch vb.

lysergic acid diethylamide see LSD.

lysine n. an essential AMINO ACID that cannot be synthesized by the body and must be supplied in the diet. It is often added to human or nonhuman animal foods to improve their nutritive value.

lysine vasopressin (LVP) see VASOPRESSIN.

lysinuric protein intolerance an autosomal recessive metabolic disorder caused by mutations in the SLC7A7 gene and characterized by the body’s inability to digest and use the amino acids lysine, arginine, and ornithine. Symptoms usually develop after infants begin to eat solid foods. Early signs include nausea and vomiting after ingestion of protein-rich foods. Enlarged liver and spleen, short stature, muscle weakness, osteoporosis, and a life-threatening lung disorder are also associated with this condition.

lysis suffix dissolution or breaking down (e.g., PARALYSIS).

lysosome n. see PHAGOCYTOSIS.
Mm

Mm

M abbreviation for memory. See PRIMARY ABILITY.

M abbreviation for SAMPLE MEAN.

MA abbreviation for MENTAL AGE.

MacArthur Scale of Subjective Social Status a measure of an individual’s perceived social standing, reflecting his or her impressions of current circumstances, background variables, and future opportunities. The scale consists of two 10-rung ladders on which respondents place an X to indicate their rank relative to others in their community and to others in the general population in terms of typical indicators of SOCIOECONOMIC STATUS, including income, education, and occupational status. The score for each ladder is the number of the rung chosen to represent one’s status, with a possible low score of 1 and a high score of 10. Research increasingly suggests that relative social position is an important predictor of overall functioning; High subjective social status has been linked to psychological factors that predispose individuals to better health trajectories and well-being. [developed in 2000 by U.S. psychologist Nancy E. Adler and colleagues]

Maccheroni Mm n. A typical pasta shape (see PASTA). Mmm (plural mm) mm a prefix indicating a measure of length.

Maccheroni Mm n. A typical pasta shape (see PASTA). Mmm (plural mm) mm a prefix indicating a measure of length.

Machian positivism the subjectivist form of positivism, that sensory experience is the touchstone of knowledge; however, unlike most other positivists, he held that sensations do not faithfully represent the reality of an EXTERNAL WORLD. Thus, from this antirealist perspective, empirical knowledge is subjective.

Machiavellian hypothesis the hypothesis that the evolution of intelligence, especially in its social aspects, was largely dependent on behavior characterized by a desire and striving for power. According to the hypothesis, individuals who are more Machiavellian in their behavior are more likely to be successful in adaptation and thus more likely to spread their genes to future generations. [Niccolò Machiavelli (1469–1527), Italian political theorist]

Machiavellianism n. A personality trait marked by a calculating attitude toward human relationships and a belief that ends justify means, however ruthless. A Machiavellian is one who views other people more or less as objects to be manipulated in pursuit of his or her goals, if necessary through deliberate deception. [Niccolo Machiavelli, who argued that an effective ruler must be prepared to act in this way]

Machine consciousness 1. functions simulated by computers or robots as a way of modeling and investigating the behavioral, cognitive, and neural components of human consciousness. 2. an artificial system (e.g., robot) constructed to have phenomenal consciousness (called artificial consciousness). 3. broadly, the entire interdisciplinary research effort behind both aforementioned senses, involving such areas as artificial intelligence, robotics, computer science, cybernetics, cognitive science, cognitive psychology, philosophy of mind, and neuroscience. See also CHINESE ROOM ARGUMENT; TURING TEST.

Machover Draw-a-House Test (DAH Test) a projective technique based on the interpretation of drawings of human figures. The participant is given a sheet of blank paper and asked first to draw an entire person, without specification of details of age, sex, clothing, and so forth, and then to draw another person, without any specification other than that it must be of opposite sex from the first. The examiner, relying on clinical experience, then interprets the drawings and any verbalizations the participant made while creating them in order to formulate a description of the participant’s personality and identify signs of pathology. Various features of the drawings that are assessed include sequence of sex (whether a male or female is drawn first), the order in which body parts are drawn, distortions, omissions, size, and clothing, as well as more structural elements, such as direction of pencil strokes, shadings, and erasures. Analogous to this test is the Machover Draw-a-House Test (DAH Test), [developed in 1949 by Karen Machover (1902–1996), U.S. psychologist]

mACHR abbreviation for MUSCARINIC RECEPTOR.

Mach scale a measurement of the degree to which individuals condone, tolerate, or condemn the use of manipulation and deceit in pursuit of material or other aims. Persons low in Mach (or MACHIAVELLIANISM) affirm abso-
MacLean's theory of emotion

MacLean's theory of emotion

**MacLean's theory of emotion** an extension of Papez's theory of emotion emphasizing the importance of all parts of the limbic system, especially the hippocampus and amygdala, in the control of emotional experience. Also called Papez-MacLean theory of emotion. See also Cannon-Bard theory. [Paul D. MacLean (1913–2007), U.S. physician and neuroscientist]

**macro-** (macr-) combining form large or enlarged.

**macrobiosic** n. a theory of nutrition that is based on achieving balance and harmony between foods that are classified, according to the Chinese concept, as either yin or yang (see **YIN AND YANG**). Macrobiosic diets consist mainly of whole grains and vegetables, with fruit and occasional fish; animal products are avoided. Food is prepared and cooked in particular ways to preserve the yin and yang characteristics, [introduced to the West by Japanese educator George Ohsawa (1893–1966)]

**macrocephaly** n. a head circumference that is more than two standard deviations above the mean for age, gender, race, and gestation. Although it can be caused by hydrocephalus or macroencephaly, it does not necessarily indicate abnormality. Benign familial macrocephaly describes a genetic tendency toward large head size that does not result in cognitive or neurological impairment. Compare microcephaly. **—macrocephalic adj.**

**macroelectrode** n. a conductor of electrical current usually with a diameter of a millimeter or more, used, for example, to stimulate or record from tissue. Compare microelectrode.

**macroergonomics** n. an approach to ergonomics that examines any given work system from a broad perspective in which all of its various elements—physical, organizational, environmental, and cognitive—are given due consideration. Compare microergonomics. See also socio-technical systems approach; systems engineering.

**macrogliosis** n. a relatively large type of nonneuronal central nervous system cell (Glia), including astrocytes, ependymal cells, and oligodendrocytes. **—macrogial adj.**

**macroglossia** n. an abnormally large tongue, affecting the production of lingual sounds in speech.

**macrogryia** see **LISENCEPHALY**.

**macromastia** n. abnormally large breasts in a female.

**macropsia** n. a **VISUAL ILLUSION** in which an object appears to be larger than it is in reality. Also called **MEGALOPSIASIS**. See also metamorphopsia, compare microopsia.

**macroskelic** adj. denoting a constitutional type of body build in which the most prominent characteristic is abnormally long legs. The macroskelic individual would be classified as the **ASTHETIC TYPE** in KLEINSMITH TYPOLOgy.

**macropsidias** n. a type of body build in which the trunk is disproportionately large compared with the limbs. Also called **MACROPLANCHNIC BUILD**. [described by Italian physician Giacinto Viola (1870–1943)]

**macrosystem** n. 1. in **ECOLOGICAL SYSTEMS THEORY**, the level of environmental influence that is most distal to the developing individual and that affects all other systems. It includes the values, traditions, and sociocultural characteristics of the larger society. Compare chronosystem; exosystem; mesosystem. [introduced by Urie Bronfenbrenner] 2. in sociology, any social system or structure.

**macula** n. (pl. maculae) 1. in hearing, a patch of sensory tissue in the **UTRICLE** and **SACCULE** of the inner ear that provides information about the position of the body in relation to gravity. The macula contains sensory **HAIR CELLS** whose processes (stereocilia) are embedded in a gelatinous matrix (cupula) containing calcareous particles (otoliths). When the orientation of the head changes, the relatively dense otoliths respond to gravity, causing the gelatinous mass to shift and the stereocilia to flex. This triggers nerve impulses in the hair-cell fibers, which act as signals to the brain. 2. in vision, see **MACULA LUTEA**.

**macula lutea** a small spot in the retina that is in direct alignment with the optics of the eye. It contains a yellow pigment and a central depression, the **FOVEA CENTRALIS**. Also called macula.

**macular degeneration** dystrophy of the **MACULA LUTEA**, which affects both eyes and causes progressive loss of central vision. Macular degeneration occurs at various ages from birth to old age. **AGE-RELATED MACULAR DEGENERATION** is among the most common causes of **VISUAL IMPAIRMENT** in older people, with an incidence of about 5% in those ages 55 to 64 and up to about 45% in those ages 75 to 84. There are two types: **EXUDATIVE** (or **WET**) **MACULAR DEGENERATION**, in which blood vessels grow under the retina and hemorrhage in the area of the macula; and **ATROPHIC** (or **DRY**) **MACULAR DEGENERATION**, in which one of the retinal layers degenerates or atrophies. Apart from age, other risk factors for the disease include exposure to ultraviolet light, smoking, hypertension, and possibly zinc deficiency in the diet.

**macular sparing** see **VISUAL FIELD SPARING**.

**macular splitting** see **VISUAL FIELD SPARING**.

**maculopathy** n. damage to the **MACULA LUTEA**, resulting in deterioration of visual acuity. It is caused by leakage from abnormal retinal capillaries, leading to the formation of hard exudate and edema.

MADD abbreviation for **MOTHERS AGAINST DRUNK DRIVING**.

**Maddox rod test** a test of eye-muscle balance. The individual views a light source through glass rods, which convert it into a line of light: the differential images perceived by the two eyes indicate the degree of **HETEROPHORIA**. [Ernest Edmund Maddox (1860–1933), British ophthalmologist]

**Mad Hatter’s disease** a condition caused by chronic mercury poisoning and characterized by changes in mental status, emotional disturbance, gastrointestinal disturbances, and weakness or partial paralysis of the legs. The condition may also cause psychosis, behavioral changes, ERETHISMA, and several other symptoms. The name derives from the prevalence of this condition among hatters whose occupation, until the mid-20th century, exposed them to vapors from the mercury used to treat felt for hats. Also called Mad Hatter’s syndrome.

**madness** n. an obsolete name for mental illness or for legal insanity.

**MAE** 1. abbreviation for MOTION AFTEREFFECT. 2. abbreviation for MULTILINGUAL APHASIA EXAMINATION.

**MAF** abbreviation for MINIMAL AUDIBLE FIELD.
magazine training in operant conditioning, the training needed to familiarize an experimental animal with the mechanism (usually a feeder) that delivers the reinforcer.

magic n. 1. a system of practices in which humans attempt to manipulate natural or supernatural forces through such means as rituals, incantations, and spells. Magic had an important social role in many prescientific societies, where its practitioners often held great power and authority. In the modern world, magical belief has survived most obviously as an underground esoteric tradition (see occult) but also in many popular superstitions and New Age practices. Magical rituals can be said to differ from religious rituals in that they involve a direct attempt to control certain physical facts (e.g., the weather), as opposed to a supplication to a higher power or powers. 2. in some individuals with obsessive-compulsive disorder, attempts to allay anxiety by invoking certain numbers or performing certain rituals. See also magical thinking.
—magical adj.

magical number see seven plus or minus two.

magical thinking the belief that events or the behavior of others can be influenced by one’s thoughts, wishes, or rituals. Magical thinking is typical of children up to 4 or 5 years of age, after which reality thinking begins to predominate. See also thought—action fusion.

magic circle a group technique mostly used with children, who gather in a circle and discuss personal issues and concerns. A variation for use in school was developed by U.S. psychiatrist William Glasser (1925–2013) to increase motivation for learning.

magic mushroom see psilocin.

MAGL abbreviation for monoacylglycerol lipase. See endocannabinoid.

magnetic resonance imaging (MRI) a noninvasive diagnostic technique that uses the responses of hydrogen in tissue molecules to strong magnetic impulses to form a three-dimensional picture of body organs and tissues (e.g., the brain) with more accuracy than computed tomography. See also functional magnetic resonance imaging.

magnetic sense the ability of an organism to orient itself according to the lines of force of a magnet or the magnetic fields of the earth. Some migrating birds tend to follow magnetic fields of the earth with the aid of a sensory apparatus that detects the force of magnetism. Homing pigeons use their magnetic sense as a backup system when solar cues for navigation are lacking, for example, on overcast days.

magnetic source imaging (MSI) see magnetoencephalography.

magnetoencephalography (MEG) n. the measurement of the magnetic fields arising from the electrical activity of the brain, using a device called a magnetoencephalograph (MEG). Also called magnetic source imaging (MSI). See also superconducting quantum interference device.

magnification factor see cortical magnification factor.

magnification power see focusing power.

magnitude effect see behavioral economics.

magnitude estimation a psychophysical procedure in which participants make subjective judgments of the magnitude of stimuli by assigning them numerical values along a 7- or 10-point scale. The resulting scales often follow a power law (see Stevens law).

magnitude of effect see effect size.

magnitude production a direct scaling procedure in which the observer is provided with a number representing the magnitude of a stimulus and is required to adjust the stimulus to produce a sensation that corresponds to this number with reference to a standard stimulus to which a magnitude number has also been assigned. Also called production method.

magnitude scaling of attitudes a procedure for measuring attitudes and other constructs by representing them as physical stimuli. Participants indicate their attitudes by regulating some perceptual property of a stimulus, such as the brightness of a light, the length of a line, or the pitch of a tone. For example, they might indicate their evaluation of an object by turning a brightness dial on a light, with no light representing an extremely negative attitude and maximum brightness representing an extremely positive attitude. This procedure usually involves reporting the attitude on two different perceptual properties and then validating the measurement procedure by confirming that the mathematical relationship between these two modalities is close to established numerical values for the specific modalities. [primarily developed by U.S. political scientist Milton G. Lodge (1936–)]

magnocellular system the part of the visual system that projects to or originates from large neurons in the two most ventral layers (the magnocellular layers) of the lateral geniculate nucleus. It allows the rapid perception of movement, form, and changes in brightness but is relatively insensitive to stimulus location and color. See also M-cell. Compare parvocellular system.

main clause see clause.

main diagonal the line of values running from the upper left to the lower right of a square matrix. The first value in the main diagonal is the number in the first row and the first column of the matrix, the second value is the number in the second row and second column, and so on.

main effect the consistent total effect of a single independent variable on a dependent variable over all other independent variables in an experimental design. It is distinct from, but may be obscured by, an interaction effect between variables.

mainlining n. slang for taking illicit drugs by intravenous injection. See intravenous drug use. —mainliner n.

mainstreaming n. 1. the placement of children with disabilities into regular classroom environments on a part-time basis, such that they attend only some regular education classes during the school day and spend the remaining time in special education classes. The aim is to offer each child the opportunity to learn in an environment that has the highest probability of facilitating rehabilitation efforts and supporting academic growth, although some critics have denounced the practice as requiring that children with disabilities “earn” their opportunity to participate in a regular classroom. See also full inclusion; least restrictive environment. 2. the return of recovered or deinstitutionalized patients to the community, where they receive rehabilitative assistance to help them achieve as full and normal a life as possible.
compliance
See also INFORMED CONSENT. Also called INFORMED
DISCUSSION.

majority
See also MAJORITY GROUP.

majority vote technique in parapsychology experi-
ments, a technique in which the participant makes several
“calls,” or guesses, about a single TARGET, the most fre-
cent being considered the participant’s response.

major neurocognitive disorder in DSM–5, a new
diagnosis combining and replacing DEMENTIA and
AMNESTIC DISORDER.

major tranquilizer see ANTIPSYCHOTIC.

mal- prefix 1. bad or wrong (e.g., MALPRACTICE), 2. dis-
eased or abnormal (e.g., MALNUTRITION).

maladaptation n. a condition in which biological traits
or behavior patterns are detrimental, counterproductive,
or otherwise interfere with optimal functioning in various
domains, such as successful interaction with the environ-
ment and effectual coping with the challenges and stresses
of daily life. COMPARE ADAPTATION. —maladaptive adj.

maladjustment n. 1. inability to maintain effective rela-
tionships, function successfully in various domains, or
cope with difficulties and stresses. 2. any emotional dis-
turbance of a relatively minor nature. —maladjusted adj.

malaise n. a vague feeling of general illness, discomfort,
or uneasiness.

malapropism n. a linguistic error in which one word is
mistakenly used for another having a similar sound, often
to ludicrous effect, as in She was wearing a cream casserole
(for camise) or I can’t eat pasta without marzipan (for parme-
san). The term is named for Mrs. Malaprop, a character in
Richard Brinsley Sheridan’s play The Rivals (1775), whose
speech is full of preposterous errors of this kind.

Malcolm horizon an improvement in flight instru-
ments, based on ergonomic principles, in which the ground
representation of the display is extended across the cockpit.
This makes it easier to detect small angular motions. [Rich-
ard Malcolm, Canadian aviator]

mal de ojo a CULTURE-BOUND SYNDROME, reported in
many Mediterranean regions, that is characterized by
fever, sleep disturbances, and gastrointestinal problems. It
most commonly affects children; the Spanish name trans-
lates to EVIL EYE.

mal de pelea a CULTURE-BOUND SYNDROME found in Pu-
terio Rico that is similar to AMOK. Individuals experience a
period of brooding and then suddenly become violent and
attack others around them (the Spanish name literally means
“fighting sickness”). Also called PUERTO RICAN syn-
drome.

maldevelopment n. the abnormal development of an
individual because of genetic, dietary, or external factors.

male chauvinism see CHAUVINISM.

male climacteric a hypothetical period in some men’s
lives that has been compared to female menopause (see CL-
MACTERIC). Also known as MALE MENOPAUSE, it occurs some
10 years later than in women and appears to be associated

maintaining cause

maintaining cause an influence in a person’s environ-
ment that tends to maintain and reinforce maladaptive be-
havior. An example is the required participation at cocktail
parties of a business professional with alcoholism.

maintenance function any of the processes that keep
an organism’s physiological activities in HOMEOSTASIS.

maintenance rehearsal repeating items over and over
to maintain them in SHORT-TERM MEMORY, as in repeating
a telephone number until it has been dialed (see REHEARSAL).
According to the LEVELS-OF-PROCESSING MODEL OF MEMORY,
maintenance rehearsal does not effectively promote long-
term retention because it involves little ELABORATION of
the information to be remembered. Also called ROTE RE-
HEARSAL. See also PHONOLOGICAL LOOP.

maintenance therapy treatment or therapy designed
to maintain patients in a stable condition and to promote
gradual healing or prevent relapse. It usually (but not al-
ways) refers to MAINTENANCE DRUG THERAPY (MAINTENANCE
PHARMACOTHERAPY or PROPHYLACTIC MAINTENANCE). Drug ther-
apy is generally divided into three phases—acute, continu-
ation, and maintenance—roughly corresponding to
intervals of 1 month, 6 months, and a year or longer. Pa-
tients who respond in the acute and continuation phases
may be placed on maintenance pharmacotherapy in the
hopes of preventing relapse. Drugs that may be used for
maintenance include methadone (see MAINTENANCE
THERAPY), buprenorphine, antipsychotics, lithium,
and antidepressants. Prophylactic maintenance alone,
however, does not eliminate relapse; for several conditions,
evidence suggests that psychotherapy must also be in-
cluded to minimize relapse. Although maintenance ther-
apy is often continued indefinitely, patients should be
periodically reassessed to determine if such treatment is
still necessary.

major depressive disorder in DSM-IV–TR and DSM–
5, a mood disorder characterized by persistent sadness and
other symptoms of a MAJOR DEPRESSIVE EPISODE but with-
out accompanying episodes of mania or hypomania or
mixed episodes of depressive and manic or hypomaniac
symptoms. Also called MAJOR DEPRESSION.

major depressive episode in DSM–IV–TR, a period in
which an individual experiences ANEHELIONA or is persis-
tently sad, pessimistic, or otherwise overly negative. Ad-
ditional symptoms include poor or increased appetite with
significant weight loss or gain; insomnia or excessive sleep;
PSYCHOLOGICAL AGITATION or PSYCHOMOTOR RETARDATION;
loss of energy with fatigue; feelings of worthlessness or in-
appropriate guilt; reduced ability to concentrate or make
decisions; and recurrent thoughts of death, SUICIDAL IDE-
ATION, or ATTEMPTED SUICIDE. DSM–5 retains these same
symptomatic criteria but has removed its predecessor’s
qualified exclusion of bereavement with respect to major
depressive episode and replaced it with a broader advisory
(see BEREAVEMENT EXCLUSION). One or more major de-
pressive episodes are a characteristic feature of MAJOR DEPRES-
SIVE DISORDER and BIPOLAR DISORDER.

major histocompatibility complex (MHC) a gene
complex that regulates responses of the immune system
protecting an organism from disease. The MHC varies
greatly among individuals within a species and has been
suggested as a basis for MATE SELECTION and KIN RECOGNI-
TION. Mice prefer mates whose MHC differs from their own
and can base this choice on differences in individual odors.

majority influence social pressure exerted by the
greater part of a group on individual members and smaller
factions within the group. The majority tends to push for
CONFORMITY and stability, and members usually respond to
this either by accepting the majority’s position as their own
(CONVERSION) or by conforming publicly but retaining their
own position privately (COMPLIANCE). COMPARE MINORITY
INFLUENCE.
with declines in the levels of various hormones, such as testosterone. Symptoms, when they occur, include fatigue, problems with memory and concentration, decreased sexual desire, erectile dysfunction, and (in some cases) depression. Also called andropause; male climacterium. See also GONADOpaUSE.

**male continence** see COITUS RESERVATUS.

**male erectile disorder** in *DSM–IV–TR*, persistent or recurrent inability in a man to achieve or maintain an erection adequate to complete the sex act. It causes marked distress and impairment of interpersonal relations and is not due to the physiological effects of a physical disorder, medication, or a substance of abuse. The disorder may be lifelong or acquired and either situational (occurring only in certain situations or with certain partners) or generalized (occurring in all situations). It is called erectile disorder in *DSM–5*. See also ERECTILE DYSFUNCTION; IMPOTENCE.

**male genitalia** see GENITALIA.

**male homosexual prostitution** sexual contact between males for the financial or other gain of one of the participants. Studies indicate that a social hierarchy exists among male prostitutes, as among female prostitutes. Lowest in status are the street hustlers, who are usually teenage boys and not necessarily gay themselves; next are the bar hustlers; and highest in prestige are the call boys, who do not solicit in public.

**male hypactive sexual desire disorder** see HYPOACTIVE SEXUAL DESIRE DISORDER.

**male–male competition** in species in which the operational sex ratio leads to more reproducitively active males than females, the rivalry that ensues as males compete over which will be able to mate with receptive females. In some species, such as cooperative-breeding mammals, male parental care is a limiting resource to female reproduction, and there is extensive female–male competition.

**male menopause** see MALE CLIMACTERIC.

**maleness** n. the quality of being male in the anatomical and physiological sense by virtue of possessing the XY combination of sex chromosomes. Compare masculinity.

**male orgasmic disorder** in *DSM–IV–TR*, persistent or recurrent delay in, or absence of, male orgasm during sexual stimulation that produces arousal. The man’s age and the quality and duration of stimulation are considered in making this diagnosis, which does not apply if the condition is due only to the effects of drugs or medical conditions. It is identified as delayed ejaculation in *DSM–5*. Sometimes also called retarded ejaculation.

**male pseudohermaphroditism** see ANDROGEN-INSENSITIVITY SYNDROME.

**malevolent transformation** the feeling that one lives among enemies and can trust no one. This attitude, purported to be the result of harsh or unfair treatment during childhood, has been posited to be the basis for social withdrawal, hostility, and, in some cases, mental disorder of a persecutory nature. [First described by Harry Stack SULLIVAN]

**malformation** n. any abnormality of structure: a deformity.

**malfuction** n. failure to work properly.

**malice aforesight** the mental elements of PREMEDITATION and deliberation or extreme disregard for human life that are required for a person to be convicted of first-degree murder.

**malignant** adj. 1. describing a disorder that gets progressively worse or is resistant to treatment, eventually causing death. 2. describing a tumor that invades and destroys tissues and may also spread to other sites (i.e., undergo metastasis). Compare benign.

**malignant hypertension** see HYPERTENSION.

**mali-mali** n. a CULTURE-BOUND SYNDROME found in the Philippines, with symptoms similar to those of CATAH.

**malingering** n. the deliberate feigning of an illness or disability to achieve a particular desired outcome. For example, it may take the form of faking mental illness as a defense in a trial, faking physical illness to win compensation, or faking an injury or misinformatio:ng people of one’s state of rehabilitation to avoid practicing or playing sport. Malingerer is distinguished from FACTITIOUS DISORDER in that it involves a specific external factor as the motivating force.

—*maligner* n.

**malleation** n. a spasmodic tic in which the hands twitch in a hammering motion against the thighs.

**malleus** n. see OSSICLES.

**malnutrition** n. a state characterized by an unhealthy balance of carbohydrates, fats, proteins, vitamins, and minerals in the diet. Malnutrition may be due to excessive intake of certain food categories, as in OBESITY and hypervitaminosis (see VITAMIN A TOXICITY; VITAMIN D TOXICITY), or inadequate food intake. Dietary deficiencies play a role in many physical and psychological disorders. For example, nicotinic acid deficiency is marked by depression and other mental disturbances (see PELLAGRA). Research suggests that mild nutritional deficiencies have little, if any, effect on intelligence but that moderate and (especially) severe deficiencies can result in intellectual deficits. See also KWAISHO ORKOR; MARASMUS; THIAMINE; VITAMIN DEFICIENCY.

**malpractice** n. professional misconduct or negligent behavior on the part of a practitioner (e.g., psychotherapist, psychiatrist, doctor, lawyer, financial adviser) that may lead to legal action.

**mal puesto** see ROOTWORK.

**Malthusian theory** the doctrine proposed by British economist Thomas Malthus (1766–1834) that exponential increases in population growth would surpass arithmetic increases in food supply with dire consequences, unless population growth was arrested by such means as famine, war, or the control of reproduction through moral restraint. In the Western world, Malthus was proved wrong owing to increased prosperity from industrialization. However, his analysis has remained influential (see NEO-MALTHUSIAN). Also called Malthusianism Malthus theory.

**maltreatment** n. the abuse or neglect of another person, which may involve emotional, sexual, or physical action or inaction, the severity or chronicity of which can result in significant harm or injury. Maltreatment also includes such actions as exploitation and denial of basic needs (e.g., food, shelter, medical attention).

**malum** n. a painful degenerative state of a joint as a result of aging.

**malum in se** in law, an action that is considered wrong because it is “evil in itself,” such as murder. Compare MALUM PROHIBITUM.
malum prohibitum

malum prohibitum in law, an action that is considered wrong because it is against the law, such as driving without a valid license. Compare MALUM IN SE.

mammalingus n. the act of sucking the breast during sexual intercourse, particularly in terms of the concept proposed by British psychoanalyst Ernest Jones (1879–1958), that the act represents a type of fellatio. Mammalingus is distinguished from the normal interest and pleasure derived from caressing or orally stimulating the breasts as a part of sexual activity.

mammary gland any of the glands in female mammals that secrete milk. In humans, the mammary glands are called breasts.

mammillary body either of a pair of small, spherical nuclei at the base of the brain, slightly posterior to the infundibulum (pituitary stalk), that are components of the limbic system. Also called corpus mammillare.

mammillothalamic tract the tract that connects the mammillary bodies to the thalamus at the base of the brain.

mammography n. a diagnostic procedure that uses low-dose X-ray photography to detect breast tumors or other abnormalities, either noncancerous (benign) or cancerous (malignant). The X-ray negative produced is called a mammogram.

managed behavioral health organization (MBHO) a health maintenance organization (see HMO) that specializes in the management, administration, and provision of health care benefits with an emphasis on behavioral health.

managed care any system of health care delivery that regulates the use of member benefits to contain expenses. The term originally referred to prepaid health plans (e.g., HMOs) but is now applied to many different kinds of reimbursement and utilization review mechanisms. It is also used to denote the organization of health care services and facilities into groups to increase cost-effectiveness.

Managed care organizations (MCOs) include HMOs, PPOs (preferred provider organizations), point-of-service plans (POSs), exclusive provider organizations (EPOs), physician-hospital organizations (PHOs), integrated delivery systems (IDSs), and independent practice associations (IPAs).

management by objectives (MBO) a type of organizational development program that focuses on the setting of goals and objectives and the evaluation of performance on the basis of their achievement. Such programs may also involve the introduction of new incentive systems, participative decision making, and a process of job design.

management development programs used to improve the effectiveness with which people in managerial or executive positions perform their roles. Management development can involve a variety of interventions, including classroom training, counseling, mentoring, and executive coaching as well as business games and other role-play techniques. See also organizational development; personnel training.

management fashion management practices that are currently popular but not necessarily well-grounded in either theory or practice. [defined in 1996 by U.S. management theorist Eric Abrahamson (1958–)]

management information systems (MIS) systems that combine information technology, data, procedures for processing the data, and people who collect and use the data with the objective of helping managers to make informed decisions.

management psychology see managerial psychology. See also industrial and organizational psychology.

management-simulation game see business game.

managerial grid see Blake–Mouton managerial grid.

managerial psychology the application of knowledge of human behavior to issues that arise in the management of organizations, especially with regard to decision making, problem solving, leadership, and human relations in the workplace. Although often used synonymously with industrial and organizational psychology, the term suggests an approach that adopts the perspective of the employer. Also called management psychology.

MANCOVA acronym for MULTIVARIATE ANALYSIS OF COVARIANCE.

mand n. in linguistics, a category of utterances in which the speaker makes demands on the hearer, as in Listen to me or Pass the salt, please. According to the behaviorist analysis of language, this form of verbal behavior is reinforced by the compliance of the listener. See behaviorism. [coined by B. F. Skinner from command and demand]

mandated reporting the legal requirement in the United States that psychologists and other human services personnel (e.g., social workers, nurses) report any suspected or known cases of abuse or neglect of a child, a dependent adult, or an older person. Those who fail to report such cases may be subject to legal and professional sanctions.

mandate phenomenon a tendency for leaders to overstep the bounds of their authority when they feel they have the overwhelming support of the group. As the number of people favoring a particular person for leadership increases, that leader is less likely to anticipate criticism for his or her actions, is less concerned about dissenting others, and may even attach invulnerability to his or her decisions.

mandibular reflex see jaw jerk.

mandibulofacial dysostosis see Treacher Collins syndrome.

mandrake n. the root or other parts of the plant Mandragora officinarum, traditionally used as an anesthetic, aphrodisiac, hallucinogen, and folk remedy for asthma, whooping cough, stomach ulcers, and other conditions. The name derives from the supposed resemblance of the root to the human form; -drake (from the Old English word for dragon) alludes to the alleged magical powers of the plant. A member of the nightshade family, it contains the anticholinergic alkaloids scopolamine, mandragorine, and hyoscyamine, which are poisonous and potentially fatal. Symptoms of poisoning include flushed, puffy eyelids, dry mucous membranes, and dry mouth, progressing to visual disturbances, hallucinations, restlessness, agitation, delirium, and possibly death from respiratory failure.

mania n. 1. generally a state of excitement, overactivity, and psychomotor agitation, often accompanied by over-optimism, grandiosity, or impaired judgment. 2. more specifically, a manic episode or, sometimes, a hypomanic...
mania a potu see IDIOSYNCRATIC INTOXICATION.

**mania n.** 1. a lay term for a mentally or emotionally disturbed person, particularly one who is considered dangerous to others. 2. an obsolete name for a person who experiences MANIA.

**manic adj.** relating to MANIA. 2. n. an obsolete name for a person experiencing a MANIC EPISODE.

**manic-depressive illness** see BIPOLAR DISORDER.

**manic episode** a period characterized by elevated, expansive, or irritable mood, often with several of the following symptoms: an increase in activity or PSYCHOMOTOR AGITATION; talkativeness or PRESSURED SPEECH; FLIGHT OF IDEAS or racing thoughts; inflated self-esteem or grandiosity; a decreased need for sleep; extreme distractibility; and intense pursuit of activities that are likely to have unfortunate consequences (e.g., buying sprees, sexual indiscretions). In DSM–IV–TR and DSM–5, a distinguishing criterion between a manic and a HYPOMANIC EPISODE is their duration, with manic episodes lasting at least a week and hypomanic episodes lasting at least 4 consecutive days. One or more manic episodes are characteristic of BIPOLAR DISORDER. See also MIXED EPISODE.

**manifest anxiety** in psychoanalysis, anxiety with overt symptoms that indicate underlying emotional conflict or repression.

**Manifest Anxiety Scale** see CHILDREN’S MANIFEST ANXIETY SCALE; TAYLOR MANIFEST ANXIETY SCALE.

**manifestation n.** an observable expression, indication, or sign of a physical or psychological condition.

**manifest content** 1. the matter that is overtly expressed and consciously intended in any utterance or other form of communication. 2. in psychoanalytic theory, the images and events of a dream or fantasy as experienced and recalled by the dreamer or fantasist, as opposed to the LATENT CONTENT, which is posited to contain the hidden meaning. See also DREAM ANALYSIS; DREAM CENSORSHIP; DREAM-WORK.

**manifest goal** in evaluation research, an openly stated, objectively defined goal of an organization or program. Manifest goals are specified by indicators of success and assessed in an evaluation program. Compare LATENT GOAL.

**manifest variable** a variable whose values can be directly observed or measured, as opposed to one whose values must be inferred. In STRUCTURAL EQUATION MODELING and FACTOR ANALYSIS, manifest variables are used to study LATENT VARIABLES. Also called INDICATOR VARIABLE.

**manipulandum n.** (pl. manipulanda) an object designed to be manipulated in a psychological test or experiment.

**manipulation n.** 1. behavior designed to exploit, control, or otherwise influence others to one’s advantage. 2. in an EXPERIMENTAL DESIGN, the researcher’s adjustment of an independent variable such that one or more groups of participants are exposed to specific treatments while one or more other groups experience a CONTROL CONDITION. For example, a health researcher could introduce a manipulation so that a portion of the participants in a study randomly receive a new drug, whereas the remaining participants receive only a PLACEBO. See EXPERIMENTAL VARIABLE.

**manipulation check** any means by which an experimenter evaluates the efficacy of an EXPERIMENTAL VARIABLE, that is, verifies that a manipulation affected the participants as intended.

**man–machine system** see HUMAN–MACHINE SYSTEM.

**mannerism n.** a gesture, facial expression, or verbal habit peculiar to the individual.

**manners pl. n.** respectful, polite, and socially acceptable ways of behaving. Codes of manners vary greatly from one culture to another and may also vary between classes or subcultures in a society.

**manning theory** see STAFFING THEORY.

**Mann–Whitney U test** a NONPARAMETRIC TEST of central tendency on ordinal data that contrasts scores from two INDEPENDENT SAMPLES to assess whether there are significant differences between the two sets of rankings. The statistic obtained from this test, \( U \), is calculated by summing the number of ranks in one group that are smaller than each of the ranks in the other group. A Mann–Whitney \( U \) test is analogous to a ONE-WAY ANALYSIS OF VARIANCE, except that the former is conducted with ranked data and the latter is conducted with continuous data. See also WILCOXON–MANN–WHITNEY TEST. [Henry Berthold Mann (1905–2000), Austrian-born U.S. mathematician; Donald Ransom Whitney (1915–2001), U.S. statistician]

**manoptoscope n.** a hollow cone used for measuring EYE DOMINANCE. The observer views a small target by placing the base of the cone near the eyes and then viewing the target through the small end of the cone while closing first one eye and then the other. The eye through which the target is actually seen is the dominant eye.

**MANOVA** acronym for MULTIVARIATE ANALYSIS OF VARIANCE.

**mantle layer** in neuroanatomy, the middle layer of the embryonic NEURAL PLATE, which develops into cerebral GRAY MATTER.

**mantra n.** 1. in Hinduism and Buddhism, a sacred utterance, such as a syllable, phrase, or hymn (often in Sanskrit). 2. any verbal formula used for spiritual, religious, or meditative purposes to help block out extraneous thoughts and induce a state of relaxation that enables the individual to reach a deeper level of consciousness. See also CONCENTRATIVE MEDITATION; TRANSCENDENTAL MEDITATION. Compare YANTRA.

**manual arts therapy** training in industrial arts, such as woodworking and metalworking, for therapeutic purposes as part of the rehabilitation process. See also OCCUPATIONAL THERAPY.

**manual-assisted therapy** see MANUALIZED THERAPY.

**manual-based therapy** see MANUALIZED THERAPY.

**manual communication** communication with the hands rather than by speech. Manual communication encompasses SIGN LANGUAGE and FINGERSPELLING and is used primarily with or between people who are deaf or have severe hearing loss.

**manual-control effects** in the manual control of aircraft or spacecraft, the effects on human performance of the nature and complexity of the task, G forces (accelera-
**manual dominance**

**manipulation** n. the number of people who make that association. [Karl Marbe (1869–1953), German psychologist]

**manipulate** v. a reciprocal process through which an individual or group with distinctive qualities, such as idiosyncratic values or customs, becomes identified as one that is not accepted fully into the larger group. See also AC-CULTURATION STRATEGIES. —marginalize v.

**marginal** 1. adj. borderline or on the periphery. 2. n. in statistics, see MARGINAL FREQUENCY.

**marginal consciousness** contents of CONSCIOUSNESS that are not at the center of attention. Marginal stimuli are not equivalent to subliminal stimuli. See PRINCE CONSCIOUSNESS: SUBLIMINAL PERCEPTION.

**marginal frequency** the sum of any one of the rows or columns in a data matrix. For example, in a table of students classified by sex and area of study, the number of female students, regardless of area of study, would be one marginal frequency, and the number of students enrolled in a specific area of study, regardless of sex, would be another.

**marginal group** in a relatively homogeneous country or community, a distinct group that is not assimilated into the social mainstream because it differs (or is viewed as differing) in one or more significant ways, as in its religious or cultural beliefs. Also called MARGINALIZED GROUP.

**marginal intelligence** an intelligence level between average and mental disability.

**marginalization** n. a reciprocal process through which an individual or group with distinctive qualities, such as idiosyncratic values or customs, becomes identified as one that is not accepted fully into the larger group. See also AC-CULTURATION STRATEGIES. —marginalize v.

**marginal sulcus** a branch of the CINGULATE SULCUS that turns upward between the paracentral lobule and superior frontal gyrus on the surface of each cerebral hemisphere.

**marginal value theorem** a part of OPTIMAL FORAGING THEORY that predicts when an organism should leave one food source and travel to the next. Decisions are based on the benefits and costs of staying in a location where food sources are known but declining compared with the costs and benefits of traveling to a new, unknown food source. In experimental work, the time and effort needed to travel to a new area appears to regulate how long animals remain foraging in the current area.

**margin of error** (MOE) a statistic expressing the CONFIDENCE INTERVAL associated with a given measurement; it is an allowance for a slight miscalculation or an acceptable deviation. The larger the margin of error for the sample data, the less confidence one has that the results obtained are accurate for the entire population of interest.

**marianismo** n. in many Latin American or Hispanic cultures, an idealized traditional feminine gender role characterized by submissiveness, sellessness, chastity, hyperfemininity, and acceptance of machismo in males. Although
clearly derived from the traditional ideal of the Virgin Mary, marvelism is not to be confused with a specific religious practice of the Roman Catholic Church.

maritana (maritana) n., see CANNABIS.

Marinesco–Sjögren syndrome an autosomal recessive hereditary disorder marked by cataxacts, short stature, CEREBELLAR ATAXIA (incoordination of voluntary movements), and mild to moderate intellectual disability. Affected individuals may live well past middle age but often lose their ability to walk because of progressive muscle weakness. [reported in the 1930s by Georges Marinesco (1864–1938), Romanian neurologist, and Torsten Sjögren (1896–1974), Swedish physician]

Marinol n., a trade name for dronabinol. See TETRAHYDROCANNABINOL.

marital adjustment the process by which married couples attain mutual gratification and achieve common goals while maintaining an appropriate degree of individuality. Especially important to marital adjustment are (a) the sharing of experiences, interests, and values; (b) respect for the partner’s individual needs, aims, and temperament; (c) maintenance of open lines of communication and expression of feeling; (d) clarification of roles and responsibilities; (e) cooperation in decision making, problem solving, and rearing of children; and (f) attainment of mutual sexual gratification.

marital conflict open or latent antagonism between marriage partners. The nature and intensity of conflicts vary greatly, but studies indicate that the prime sources are often sexual disagreement, child-rearing differences, temperamental differences (particularly the tendency of one partner to dominate), and, to a lesser extent, religious differences, differences in values and interests, and disagreements over money management.

marital counseling see MARRIAGE COUNSELING.

marital schism a condition of open discord between marital partners that puts a strain on the marriage and may lead to separation or divorce.

marital separation the situation in which a previously cohabiting married couple stops living together and instead maintains individual residences, finances, and so forth. When the couple has children, the term parental separation is often used. Separation may be informal via mutual agreement or legally arranged via an official, enforceable document. In both cases, the partners remain married, which distinguishes separation from DIVORCE. In increasingly common in Western societies, separation has the potential for significant consequences, including diminished psychosocial functioning, deterioration of the parent–child relationship, and long-term emotional disturbances and mental health problems (e.g., anxiety, depression).

marital skew an unhealthy pattern in which the pathological behavior of the dominant partner in a couple is accepted by the other partner. See also COLLUSIONAL MARRIAGE.

marital subsystem the relationship between two spouses or partners in a family and their particular interactional rules for cooperation, conflict, and conflict resolution over marital issues (e.g., child rearing).

marital therapy see COUPLES THERAPY.

mark-and-recapture sampling see CAPTURE–TAG–RECAPTURE SAMPLING.

marker n. 1. a detectable sign, as in a GENETIC MARKER or CLINICAL MARKER. 2. any variation in a process or characteristic that is associated with a condition, event, or other object of interest. For example, enlarged perivascular spaces are a promising neuroimaging marker of small vessel disease. See BIOCHEMICAL MARKER; BIOLOGICAL MARKER.

marketing orientation in the existential psychoanalysis of Erich Fromm, a character pattern in which the individual regards people as commodities and evaluates personal worth in terms of salability. Attributes perceived as leading to business or social success are valued more than knowledge, creativity, integrity, or dedication. According to Fromm, the marketing orientation contributes to shallow relationships and alienation from self and society. Also called marketing character. Compare EXPLOITATIVE ORIENTATION; HOARDING ORIENTATION.

market research research undertaken to understand the size and nature of a particular market, together with any significant trends or challenges. This may involve interviews to assess the relative positions of various suppliers in the minds of consumers. For example, a comparison may be made between restaurants that are perceived to offer good service and high-quality food at a low price with those perceived to provide good service and high-quality food at a high price. The term MARKETING RESEARCH is used more specifically to mean research into the effectiveness of marketing techniques.

Markov chain a sequence of steps or events in which the probability of each transition depends only on the immediately preceding step and not on any earlier step. For example, when a person considers a behavior change such as losing weight he or she experiences certain stages: The individual could move from not thinking about losing weight (precontemplation) to considering a weight loss plan (contemplation), through to sustaining a reasonable weight (maintenance), and conceivably back to not wanting to think about weight loss. This process could be described as a Markov chain. Also called Markov process. Compare RANDOM WALK. [Andrei Markov (1856–1922), Russian mathematician]

Marlowe–Crowne Social Desirability Scale (M–C SDS) a widely used research scale that attempts to assess the degree to which participants answer questions in such a manner as to present themselves in a favorable light. Test scores are often used in research wherein people might be inclined to bias their behavior in a socially desirable direction, rather than being perfectly frank. Although currently available in a variety of forms, the Marlowe–Crowne scale as it was originally developed in 1960 consisted of 33 self-descriptive statements (e.g., “I am sometimes irritated by people who ask favors of me”) to which participants responded true or false. [David Marlowe (1931–1990) and Douglas P. Crowne (1928– ), U.S. psychologists]

Maroteaux–Lamy syndrome an inherited disorder of connective tissue and skeletal development: one of the MUCOPOLYSACCHARIDOSES. It is marked by dwarfishm of the trunk and extremities and in some cases delayed closure of the cranial sutures, maldevelopment of the facial bones, and hearing loss. Also called mucopolysaccharidosis VI; systemic mucopolysaccharidosis. [Pierre Maroteaux (1926– ), French geneticist; Maurice Lamy (1895–1975), French physician]
Marplan n. a trade name for ISOCARBONAZID.

marriage n. the social institution in which two (or, less frequently, more) people commit themselves to a socially-sanctioned relationship in which sexual intercourse is legitimated and there is legally recognized responsibility for any offspring as well as for each other. Although there are exceptions, the marital partners typically live together in the same residence. See also COMMON-LAW MARRIAGE; DOMESTIC PARTNERSHIP; GROUP MARRIAGE; SAME-SEX MARRIAGE. —marital adj.

marriage counseling COUPLES COUNSELING with partners who are married. Also called marital counseling.

marriage-enrichment group a support or therapy group in which married couples meet under the guidance of a professional or nonprofessional leader to discuss marriage-related problems and issues. See also COUPLES THERAPY.

marsupial n. a nonplacental animal of the subclass Metatheria, such as the opossum or Tasmanian devil. Marsupials are born at a very early developmental stage and spend a prolonged period of development in the maternal pouch. Most marsupials are found in the southern hemisphere, particularly in Australia, New Guinea, and nearby islands.

Marxism n. a philosophical position and economic theory drawn directly or indirectly from the works of Karl MARX. Although there is much debate about the true nature of Marxism, there is general agreement that it emphasizes the role of economics (control of the means of production) in subtly determining other social institutions, the importance of labor as the foundation of an economic system, and a utopian vision of social equality. Marxism has spawned, or beget, and is presumed to be characteristic of a boy or man, as contrasted with MALENESS, which is genetically determined. —masculine adj.

masculinity n. possession of social role behaviors that are presumed to be characteristic of a boy or man, as contrasted with MALENESS, which is genetically determined. —masculine adj.

masculinity–femininity test any test designed to measure the degree of masculinity or femininity in participants. The earliest was the Terman–Miles Attitude–Interest Analysis Test (1918); others, usually in inventory form, are the MINNESOTA MULTIPHASIC PERSONALITY INVENTORY, the GUILFORD–ZIMMERN TEMPERAMENT SURVEY, and the Gough Femininity Scale. The BEM SEX ROLE INVENTORY is one of the few masculinity–femininity tests to include androgyny.

masculinization n. see VIRILISM.

masked audiogram see MASKING PATTERN.

masked depression a condition in which an individual experiencing a MAJOR DEPRESSIVE EPISODE complains of physical symptoms (e.g., headache, backache) rather than mood disturbance, and no biological cause of the physical symptoms can be found.

masking n. 1. in perception, the partial or complete obscuring of one stimulus (the target) by another (the masker). The stimuli may be sounds (see AUDITORY MASKING), visual images (see VISUAL MASKING), tastes, odorants, or tactile stimuli. Forward masking occurs when the masker is presented a short time before the target stimulus, backward masking occurs when it is presented shortly afterward, and simultaneous masking occurs when the two stimuli are presented at the same instant. Also called perceptual masking. 2. in statistics, the obscuring of the effect of one variable by the effect of another variable. For example, a researcher interested in whether risky sexual behavior is related to alcohol use might find that an experience of sexual abuse exerts a stronger influence on sexual behavior, thus masking the effect of alcohol use. —mask vi.

masking level difference (MLD) a change in detection threshold for auditory stimuli produced by changes in the interaural characteristics of the masker or the signal (see AUDITORY MASKING). The typical reference is the signal threshold in the DIOTIC condition (N0S0), in which a puretone signal and noise masker are both presented in phase at the ears. For a dichotic condition, such as N0S0 (noise in phase, signal 180° out of phase), the detection threshold may be 15 dB lower. The MLD and related phenomena have provided valuable insights into the mechanisms involved in BINAURAL hearing and sound localization (see AUDITORY LOCALIZATION). Also called binaural masking level difference (BMLD).

masking pattern the detection thresholds as a function of frequency for a pure-tone signal masked by a sound whose spectral characteristics and level are fixed. The g-axis may be either the level of the signal at threshold (in DECIBELS sound-pressure level) or the amount of masking. Also called masked audiogram. See AUDITORY MASKING.

Maslach Burnout Inventory (MBI) a method for the evaluation of BURNOUT on three dimensions: emotional exhaustion, DEPERSONALIZATION, and reduced personal accomplishment. It consists of 22 statements about feelings and attitudes to which participants respond in terms of frequency on a 7-point scale ranging from never to every day. [Christina Maslach (194— ), U.S. psychologist]

Maslow’s motivational hierarchy the hierarchy of human motives, or needs, as described by Abraham MASLOW, which he developed in part as a reaction against the determinism of the theories of Sigmund FREUD and B. F. SKINNER. PHYSIOLOGICAL NEEDS (air, water, food, sleep, sex, etc.) are at the base; followed by safety and security (the SAFETY NEEDS); then love, affection, and gregariousness (the LOVE NEEDS); then prestige, competence, and power (the ESTIM NEEDS); and, at the highest level, aesthetic needs, the need for knowing, and self-actualization (the METANEEDS).

Maslow’s theory of human motivation the humanistic view of motivation proposed by Abraham MASLOW, in which the higher human needs for understanding, aesthetic values, self-realization, and PEAK EXPERIENCES are emphasized. Maslow contrasted the METAMOTIVATION arising from such METANEEDS with the DEFICIENCY MOTIVATION arising from physical needs, insecurity, and alienation.

masochism n. the derivation of pleasure from experiencing pain and humiliation. The term generally denotes SEX-
mastery tests

mastery tests are assessments used to determine acquisi-

ual. Masochism but is also applied to experiences not
involving sex, such as martyrdom, religious illogilation, or
asceticism. In classical psychoanalytic theory, masochism
is interpreted as resulting from the DEATH INSTINCT or from
aggression turned inward because of excessive guilt feel-
ings. [Leopold Sacher Masoch (1835–1895), Austrian
writer]—masochist n. —masochistic adj.

masochistic fantasies fantasies of being whipped,
choked, or otherwise hurt or abused as an expression
of masochistic tendencies, particularly as a means of achiev-
ing sexual excitement. See SEXUAL MASOCHISM.

masochistic personality disorder a personality dis-
order in which individuals persistently and characteristi-
cally obtain gratification or freedom from guilt feelings as a
consequence of humiliation, self-degradation, self-sacrifice,
wallowing in misery, and, in some instances, submitting to
physically sadistic acts. This disorder was listed in DSM-
III–R as SELF-DEFEATING PERSONALITY DISORDER but was de-
leted from DSM–IV–TR. The term is controversial because
many believe that in some cases it blames the victim of abuse.

mass action Karl S. LASHLEY’s generalization that the
size of a cortical lesion, rather than its specific location,
determines the extent of any resulting performance decre-
ment. Proposed in 1929 following experimental observa-
tions of the effects of different brain lesions on rats’ ability
to learn a complex maze, the concept reflects Lashley’s be-

mass action: principle of mass action. See also LAW
OF POTENTIALITY.

massage n. the structured stroking or kneading of a body
area or of the entire body by hand or by a mechanical or
electrical device. Manual massage is usually administered
for therapeutic and rehabilitative purposes because the
hands can detect abnormalities, such as swellings or mus-
cle spasms. Among the benefits of massage are improved
circulation, reduced pain, the promotion of relaxation and
healing from injury, and release from tension and psycho-
logical stress.

massa intermedia see INTERTHALAMIC ADHESION.

mass contagion a form of SOCIAL CONTAGION in which
behaviors, attitudes, or affect rapidly spread throughout
large groups or populations, including those who are
widely dispersed across a large area. See also BEHAVIORAL
CONTAGION; EMOTIONAL CONTAGION.

massed practice a learning procedure in which prac-
tice trials occur close together in time, either in a single
lengthy session or in sessions separated by short intervals.
Massed practice is often found to be less effective than dis-
tributed practice.

massed repetition see REPEITION EFFECT.

masseter reflex see JAW JERK.

mass hysteria see COLLECTIVE HYSTERIA.

mass media sources of public communication to a wide
audience, traditionally including news and entertainment
publications (primarily newspapers and magazines) and
radio and television broadcasts intended for the general
public, but now also including the Internet.

mass murder the act of killing several to many people.

The mass murder of an entire population (e.g., a racial or
ethnic group) is called GENOCIDE. See also SPREE MURDER.

Masson disk a device for measuring the threshold of
brightness vision. The disk is white with a black segmented
line along one radius. When it is rotated, varying shades of
gray are seen, the darkest at the center. The point at which
the disk becomes indistinguishable from the background
provides the required measurement. [Antoine-Philibert
Masson (1806–1860), French physicist]

mass psychology 1. the mental and emotional states
and processes that occur in a large body of individuals
who, although they may not have any common character-
istics, are considered as a whole. 2. the scientific study of
these phenomena, including the study of mass move-
ments, collective hysteria, and the effects of the media.

mass reflex 1. an indiscriminate response of many body
effectors to a single stimulus, as in “freezing” with fear. 2. a
life-threatening condition associated with spinal cord in-
jury in which uncontrolled activation of both autonomic
and somatic motor systems occurs.

mass-spring model see EQUILIBRIUM-POINT MODEL.

mass suicide the deliberate ending of the lives of all or
most of the members of an intact social group or aggregate
by the members themselves, either directly through self-in-
jurious behavior or indirectly by choosing a course of ac-
tion that will likely be fatal. Examples include extremely
hazardous missions undertaken by combat units (see AL-
TRISTIC SUICIDE) and the suicides of the more than 900
members of the People’s Temple in Jonestown, Guyana, in
1978; the 70 members of the Order of the Solar Temple in
Europe and Canada between 1994 and 1997; and the 39
Heaven’s Gate followers of Marshall Applewhite in San
Diego in 1997. Mass suicide often occurs at the command
of a charismatic leader and may be provoked not by despair
but by the desire to seek a “higher state of existence” prom-
ised by the leader. Also called collective suicide. Compare
CLUSTER SUICIDE.

mass-to-specific development in fetal and infantile
development, progression from gross, random movements
involving the whole body to more refined movements of
body parts.

MAST acronym for MICHIGAN ALCOHOLISM SCREENING
TEST.

mastery goal see LEARNING GOAL.

mastery learning 1. the process of gaining knowledge in
a certain subject or domain, with the intent of under-
standing the full scope of that subject area. 2. a theory of
education in which students learn material in several dif-
ferent ways over a series of study sessions until they under-
stand the material well enough to teach it to others. 3. the
acquisition of material beyond basic recognition, recall,
and understanding to a point of thorough cognitive inte-
gration at a conceptual level.

mastery orientation an adaptive pattern of achieve-
ment behavior in which individuals enjoy and seek chal-
lenge, persist in the face of obstacles, and tend to view their
failings as due to lack of effort or poor use of strategy
rather than to lack of ability.

mastery play play that leads to mastering new skills,
such as language and intellectual abilities.

mastery tests assessments used to determine acquisi-
Mastery training

tion of the full scope of knowledge in a particular subject area or to evaluate ongoing progress and comprehension.

Mastery training experimental or real-world training that prepares individuals for aversive situations or conflict by teaching them methods of assertion and constructive control over environmental conditions.

Mastoid n. a projection from the anterior part of the temporal bone containing air spaces that communicate with the cavity of the middle ear.

Masturbation n. manipulation of one’s own genital organs, typically the penis or clitoris, for purposes of sexual gratification. The act is usually accompanied by sexual fantasies or erotic literature, pictures, or videos. Masturbation may also include the use of mechanical devices (e.g., a vibrator) or self-stimulation of other organs, such as the anus or nipples. —masturbate vb.

Masturbatory reconditioning see orgasmic reconditioning.

Masturbatory satiation a behavioral treatment aimed at altering the deviant sexual preferences of individuals who commit sex offenses, including rape, pedophilia, and child molestation. The technique has been inappropriately applied to alter homosexual behavior as well. In one version of masturbatory satiation, participants masturbate for prolonged periods of time—continuing even after orgasm—so that the act eventually becomes unsatisfying. In another version, known as verbal satiation, participants voice their deviant sexual fantasies while masturbat- ing past orgasm, continuing until the deviant sexual imagery is no longer arousing. In a third version, participants mastur- bate to orgasm using appropriate sexual fantasies and afterward continue masturbating to their deviant sexual fantasies in order to pair the pleasurable experience of orgasm with appropriate stimuli and the deviant behavior with excessive, unsatisfying masturbation. All three forms of masturbatory satiation lack a sound empirical basis for effectiveness.

MAT abbreviation for Miller Analogies Test.

Mata elap see amok.

Matched-pairs design a study involving two groups of participants in which each member of one group is paired with a similar person in the other group, that is, someone who matches them on one or more variables that are not the main focus of the study but nonetheless could influence its outcome. For example, a researcher evaluating the effectiveness of a new drug in treating Alzheimer’s disease might identify pairs of individuals of the same age and intelligence and then randomly assign one person from each pair to the treatment condition that will receive the drug and the other to the control condition that will not. A matched-groups design (matched-samples design: matched-subjects design) is a similar approach but broader in that it allows for the inclusion of more than two groups of participants.

Matched-pairs t test a statistical procedure used to test for significant differences between the two sets of data obtained from a matched-pairs design. For example, a researcher could use a matched-pairs t test to assess whether relationship satisfaction significantly differs between two sets of individuals who have been matched for age and gender, where one set has been married for 5 years and the other for 10 years. Also called paired-samples t test.

Matched samples two or more sets of study partici- pants that are equivalent to one another with respect to certain relevant variables.

Matching n. a procedure for ensuring that participants in different study conditions are comparable at the begin- ning of the research on one or more key variables that have the potential to influence results. After multiple sets of matched individuals are created, one member of each set is assigned at random to the experimental group and the other to the control group. For example, a researcher could create two groups whose members are of the same sex and have the same family history of a disease; one group would be given a treatment whereas the other would not. Such an approach would enable the researcher to rule out sex and family history as potential explanations of the study outcome, thereby allowing greater validity to attributing any changes between the groups to the treatment. See also matched-pairs design.

Matching Familiar Figures Test (MFF) a visual test in which the participant is asked to identify from among a group of six similar figures the one that matches a given sample. Items are scored for response time to first selection, number of correct first-choice selections, and number of errors. The test is used to measure conceptual tempo, that is, the relative speed with which an individual makes decisions on complex tasks (see reflection–impulsivity). [Originally published in 1965 by Jerome Kagan]

Matching hypothesis the proposition that people tend to form relationships with individuals who have a similar level of social value, often with an emphasis on equality in physical attractiveness. Research indicates that this similarity tends to be greater for couples having a romantic relationship than for friends.

Matching law in Operant Conditioning, a law that de- scribes the distribution of responses when numerous task options are available. It states that the proportion of responses allocated to an alternative will match the propor- tion of reinforcement obtained from that alternative. For example, if a pigeon receives two thirds of its food alloca- tion from Alternative A and one third from Alternative B, it will make two thirds of its responses (and give two thirds of its time) to Alternative A. If the pigeon makes fewer than two thirds of its responses to Alternative A—that is, has less sensitivity to reinforcement than the law predicts—then undermatching has occurred. If, however, the pigeon makes more than two thirds—that is, has greater sensi- tivity to reinforcement than the law predicts—then over- matching has occurred. See also generalized matching law.

Matching patients the process of prescribing specific interventions or choosing specific therapists for particular patients or diagnostic groups of patients to improve adherence with or effectiveness of treatment. The process is based on the diagnoses, needs, problems, and characteristics of particular patients: on therapist variables, such as race, ethnicity, and experience levels; and on setting variables, such as inpatient or outpatient clinics. Also called psychotherapy matching.

Matching to sample a conditional-discrimination procedure that involves both successive discrimination and simultaneous discrimination. Each trial begins with presentation of a sample stimulus. Once the organism responds to that sample, two or more additional stimuli appear, only one of which matches the sample. Reinforce- ment is contingent on responding to the stimulus that
mate selection

mate guarding a method of preventing a mate from reproducing with others. In nonhuman animals, a male stays close to its mate immediately after copulation and prevents other males from approaching or mating with the female until such time as additional mating will not result in fertilization. In some cases, a copulatory lock literally keeps mates connected for several minutes or hours. See also MATE POACHING; SPERM COMPETITION.

mate poaching behavior that is intended to sexually attract someone who is involved in a committed romantic relationship with another partner. In evolutionary theory, mate poaching is one of several evolved adaptations, or strategies, for increasing or improving one’s reproductive opportunities. Partners in committed romantic relationships often engage in MATE GUARDING to thwart the possibility of mate poaching. Research shows that mate-poaching attempts are commonplace in most cultures in the world. Among nonhuman animals, SNEAK MATING is a somewhat similar behavior in some males.

material cause see CAUSE.

material feminism a movement in 19th-century and early 20th-century FEMINISM that concentrated on improving the material conditions of women’s lives. Campaigners in this tradition sought to end women’s legal, educational, and employment disabilities and to ease the burden of their domestic duties.

materialism n. 1. the philosophical position that everything, including mental events, is composed of physical matter and is thus subject to the laws of physics. From this perspective, the mind is considered to exist solely as a set of brain processes (see MIND–BODY PROBLEM). Such philosophies can be traced back to ancient times but gained a new impetus from advances in the physical sciences beginning in the 17th century. A particular form of materialism is the DIALECTICAL MATERIALISM of classical MARXISM. 2. the position that the causes of behavior are to be found in the material of the body, particularly the nervous system. It is nearly always associated with HARD DETERMINISM. See also IDENTITY THEORY; PHYSICALISM. Compare IDEALISM; MATERIALISM. 3. a value system that emphasizes the pursuit and acquisition of material goods and luxuries, typically perceived by the individual as a measure of personal worth and achievement, often at the expense of moral, psychological, and social considerations. —materialistic adj.

materialization n. in SPIRITUALISM, the alleged production of a spirit in bodily form during a seance or of some other physical object by apparently supernatural means (see APPORT). See also ECTOPLASM. —materialize vb.

material self see EMPIRICAL SELF.

maternal aggression a form of aggression in nonhuman animals in which females defend their offspring against potential threats from intruders by means of THREAT DISPLAYS or ATTACK BEHAVIOR.

maternal attitudes attitudes of the mother toward her children, particularly those attitudes that play an important role in her children’s health, character formation, emotional adjustment, and self-image, as well as in her own self-perception as a mother.

maternal behavior the actions of females associated with caring for their young. These can range from feeding or NURSING to protection, thermoregulation, and teaching skills to the young. Its exact expression, however, depends on a number of factors, including the developmental status of the young at birth, levels of various hormones (e.g., ESTROGEN, OXYTOCIN, PROGESTERONE, PROLACTIN), and environmental influences. The analogous male behavior is known as PARENTAL BEHAVIOR. See also PARENTAL BEHAVIOR.

maternal brain in the mammalian female nervous system, the expression of inherent neuroplasticity that is associated with and necessary for reproduction and in which multilevel changes to neurons and neuronal activity occur that enhance a mother’s cognition and behavior toward her young during the pre- and postnatal period.

maternal deprivation lack of adequate nurturing for a young animal or child due to the absence or premature loss of, or neglect by, its mother or primary caregiver, postulated to affect an individual’s early behavioral, physical, social, and emotional development negatively. See also FAILURE TO THRIVE; MARASMUS.

maternal drive the motivation of female animals to care for offspring.

maternal environment conditions in the uterus of a pregnant woman that affect fetal development and are hypothesized to have long-term postnatal effects on the health of the child. See FETAL PROGRAMMING.

maternal memory the long-term retention of memory for maternal behavior. Once a female animal has experienced a pregnancy and interaction with her offspring, she retains the memory of the requisite behaviors for their care. For example, a female rat that has already had pups will be quicker to display maternal behavior when placed with foster pups than with a real female rat that has not experienced pregnancy and pup-rearing. See also MATERNAL BRAIN.

maternal PKU a condition in women who have PHENYLKETONURIA (PKU) and become pregnant. Expectant mothers with high levels of blood phenylalanine—HYPERPHENYLALANINEMIA—are at risk of giving birth to offspring with high rates of congenital heart defects, intrauterine growth retardation, intellectual disability, and microcephaly (a small head). Treatment entails dietary management for the expectant mother before and during pregnancy to reduce blood levels of phenylalanine.

maternal reverter a mother’s capacity to understand what her infant is feeling and to ameliorate the infant’s anxiety and distress. See also ATTUNEMENT; PRIMARY MATERNAL PREOCCUPATION. [first described in 1962 by British psychoanalyst Wilfred Bion (1897–1979)]

maternity blues see BABY BLUES.

mate selection the choice of an appropriate partner for reproduction. In species where female PARENTAL INVESTMENT is high, females are thought to be more careful in their choice of mates than males. However, in species where parental contribution to survival of offspring is more nearly equal, mate selection is shown by both sexes. Mate selection may be based on (a) behavioral traits, such as the ability to defend a territory or to be dominant over others; (b) exaggerated signals of quality, such as bright tail plumage in the peacock; or (c) evaluations made during COURTSHIP. In species where females are smaller than males, females may mate with several males, either selectively keeping the sperm of only one or two or mating with...
mate swapping

the most dominant male at the time closest to possible conception (see CRYPTIC FEMALE CHOICE: SEXUAL AGGRESSION). See also SEXUAL SELECTION. Compare RANDOM MATING.

mate swapping see PARTNER SWAPPING.

mate value an overall assessment of a person’s desirability as a romantic or reproductive partner. Many factors contribute to a person’s mate value, such as youthfulness, physical attractiveness, status, and wealth. The higher a person’s mate value, the more selective he or she can be when choosing a partner. The concept of mate value was proposed by evolutionary theorists on the basis of ethological research with nonhuman animals, although it is now used by researchers with diverse approaches. Research has demonstrated that people generally form committed relationships with others who have roughly similar levels of mate value.

mathematical ability the ability used to solve various kinds of quantitative problems, such as mathematical word problems, computational problems, and number-concept problems. It comprises a number of distinct skills.

mathematical biology a branch of biology that deals with the development of mathematical models of biological phenomena, such as conditioning and nerve conduction.

mathematical learning theory any of a variety of theories that use quantitative terms to characterize the learning of individuals or groups or the results of learning trials. An important example is the STIMULUS SAMPLING THEORY.

mathematical model the representation of a psychological or physiological function, or other process, in mathematical terms, such as formulas or equations (e.g., FECHNER’S LAW).

mathematical psychology an approach to psychological phenomena that uses mathematical techniques to model the underlying processes and to predict the outcomes of these processes. Closely related to PSYCHOMETRICS and STATISTICS, it is used across several major subdisciplines, especially cognitive psychology, psychophysics, and perception.

mathematical statistics see THEORETICAL STATISTICS.

mathematico-deductive method 1. the use of postulates and corollaries in mathematical form to develop a system or theory. 2. see HYPOTHETICO-DEDUCTIVE METHOD.

mathematics anxiety apprehensiveness and tension associated with the performance of arithmetic and other mathematical tasks. Often thought to be related to TEST ANXIETY, mathematics anxiety has been proposed as an important factor underpinning the development of mathematical skills: It frequently causes distress, disrupts the use of working memory for maintaining task focus, negatively affects achievement scores, and potentially results in dislike and avoidance of all math-related tasks. It is seen in students of all ages, regardless of their actual math abilities, and is considered more prevalent in females than males. A number of factors are related to the phenomenon, including low SELF-ESTEEM and SELF-EFFICACY, lack of confidence, TRAIT ANXIETY, perfectionism, and previous negative experiences with the subject material. Teacher-based instruction that encourages students as they work through a math problem, teaches them effective skills in solving such problems, and demonstrates positive attitudes toward mathematics can reduce this type of anxiety. COOPERATIVE LEARNING, COMPUTER-ASSISTED INSTRUCTION, and the use of mathematical games to make the learning process more relaxed are also effective.

mathematics disorder in DSM–IV–TR, a LEARNING DISORDER in which mathematical ability is substantially below what is expected given the person’s chronological age, education, and measured intelligence. It may involve (among other problems) difficulties in counting, learning multiplication tables, understanding mathematical problems and performing mathematical operations, reading numerical symbols, and copying numbers. In DSM–5, the disorder has been subsumed within a category labeled SPECIFIC LEARNING DISORDER and is no longer considered a distinct entity.

mating behavior the activities that are involved in reproduction, including COURTSHIP, MATE SELECTION, and COPULATION. Mating behavior varies with the species and may have several functions in addition to successful conception: preparing both mates physiologically, providing cues for mate selection, and coordinating behavior of mates for NEST BUILDING and subsequent care of young.

mating system the organization of typical mating patterns within a species. Mating systems include MONOGAMY, in which two individuals mate exclusively with each other; POLYGAMY, in which a male mates with multiple females; POLYANDRY, in which a female mates with multiple males; and POLYGYNANDRY, in which both sexes mate with multiple partners.

matriarchy n. 1. a society in which descent and inheritance is MATRILINEAL, that is, traced through the female only. See UNILATERAL DESCENT. See also DESCENT GROUP. 2. more loosely, a family, group, or society in which women are dominant. Compare PATRIARCHY. —matriarchal adj.

matricide n. 1. the killing of one’s own mother. 2. a person who kills his or her own mother. Compare PATRICIDE. —matricidal adj.

matrifocal adj. describing a family centered on the mother or a culture in which the role of the mother is central.

matrilineal adj. see Matriarchy.

matrilocal adj. denoting a living arrangement in which a married couple resides with or in proximity to the wife’s mother or relatives, or a culture in which this is the norm. Also called UXORILOCAL. Compare NEOLOCAL; PATRILOCAL.

matrix n. 1. a context or environment within which something else is enclosed, embedded, originates, or develops. 2. a rectangular ordered arrangement (ARRAY) of numbers in rows and columns. Individual items in a matrix are called ELEMENTS or entries. Many different types of matrices are used in statistics, such as the CORRELATION MATRIX and the COVARIANCE MATRIX.

matrix algebra a set of mathematical rules for analyzing large numbers of variables arranged in matrices. Matrix algebra procedures may involve basic calculations, such as adding and subtracting matrices, and also more complex processes, such as multiplying and dividing matrices.

matrix organization a complex type of organizational structure in which employees are grouped not only by the function they perform (e.g., marketing, production, research and development, engineering) but also by the product or project on which they are working. Employees
working within a matrix organization report to both a functional boss and a product or project boss. Compare UNITY OF COMMAND.

Matthew effect 1. a phenomenon in the sociology of science whereby established researchers receive more credit for a discovery than less well known researchers who may have made an equal or greater contribution. [first described by U.S. sociologist Robert K. Merton (1910–2003) and named for a verse in the Gospel according to St. Matthew: “For to everyone who has will be given, and he will have abundance, but from him who doesn’t have, even that which he has will be taken away” (25:29)] 2. in child development, the tendency for the difference between high and low performers (e.g., good and poor readers) to increase over time. Also called accumulated advantage. [described by Canadian psychologist Keith E. Stanovich]

maturation n. 1. the biological processes involved in an organism’s becoming functional or fully developed. 2. naturally occurring time-related changes in a participant (e.g., growth, aging, fatigue, boredom, attention shifts) that pose a threat to the INTERNAL VALIDITY of a study, particularly a longitudinal one. These processes—as opposed to the specific treatment or intervention—may explain any changes in participants during the experiment. For example, a researcher may study substance use in a set of individuals from early adolescence to late adulthood. In the study, substance use may naturally decline as a function of the development of the participants rather than because of the influence of an experimental intervention. Thus, the investigator would want to assess and possibly control for this maturation effect in order to maintain the internal validity of the study.

maturational crisis a life-changing event, such as marriage or retirement, that often is encountered during the typical course of development and that requires significant psychological, behavioral, or other adjustments. Also called developmental crisis: normative crisis.

maturational lag slowness or delay in some aspects of neurological development that may affect cognition, perception, and behavior.

maturation hypothesis a generalization that some behaviors and processes, such as language acquisition, are innate but do not appear until appropriate organs and neural systems have matured.

maturity n. a state of completed growth or development, as in adulthood. See DEVELOPMENTAL LEVELS.

Maximally Discriminative Facial Movement Coding System (MAX) a system for coding facial configurations theorized to correspond to universally recognized facial expressions of emotion. For example, lowered, knitted eyebrows would be coded to correspond to anger. MAX is primarily used in research on emotional expressions in infants and young children. Compare FACIAL ACTION CODING SYSTEM. [developed in 1979 by Carroll E. Izard]

maximin strategy in GAME THEORY or decision making, a tactic in which an individual chooses the best of a set of worst possible outcomes or payoffs. For example, participants in a study may need to choose whichever outcome would best maximize a minimum advantage: withdrawing from a scenario in which they are currently performing poorly, or continuing and possibly doing even worse. Compare MINIMAX STRATEGY.

maximum likelihood a statistical technique in which the set of possible values for the PARAMETERS of a distribution is estimated based on the most probable sample of observations that one might have obtained from that population. The values derived from this procedure are referred to as maximum likelihood parameter estimates or maximum likelihood estimates and can be used to obtain an overall estimate of how well a given model fits the data. Maximum likelihood techniques are used in several statistical methods, such as LOGISTIC REGRESSION, HIERARCHICAL LINEAR MODELING, and STRUCTURAL EQUATION MODELING. Also called maximum likelihood estimation (MLE).

maximum-security unit a section of a mental institution reserved for patients who are likely to harm themselves or others.

Maxwell disks a series of slotted color disks on a rotating spindle, used as a COLOR MIXER. [James Clerk Maxwell (1831–1879), British physicist]

Maxwellian view an optical arrangement that causes a visual stimulus to be confined to the center of the pupil. The alternative, a Newtonian view, allows light to pass through all parts of the pupil. [James Clerk Maxwell]

maze n. a system of intersecting paths and blind alleys that must be navigated from an entrance to an exit. Various types of mazes are used in experiments with both human and nonhuman animals. They are often used, for example, in studies of animal cognition that investigate spatial learning and memory (see MORRIS WATER MAZE; RADIAL MAZE), organization of cognitive maps, and the foraging strategies of predators searching for prey. A common human maze is a printed paper pattern on which the participant traces the correct pathway with a pencil; an example is the FORTEUS MAZE TEST, which tests planning and problem-solving ability. See also ALLEY MAZE; ELEVATED MAZE; T MAZE; Y MAZE.

maze-bright and maze-dull rats two groups of rats that were separated based on their performance in a standardized maze problem. Those that performed best were bred with each other, as were those that performed most poorly. Over relatively few generations, there was a complete separation in performance, with none of the maze-bright rats overlapping in scores with maze-dull rats. However, the selective breeding appeared to be specific to the maze tests that were used and did not affect learning ability more generally; moreover, maze-dull rats reared in an enriched environment (see ENRICHMENT) could perform as well as maze-bright rats.

maze learning learning to reach the goal object or objects in a maze by starting from a designated point and following various paths, some of which do not lead to the goal. The maze-learning process usually involves multiple trials and is regarded as successful when the participant can reach the goal in the most direct way with minimal errors.

maze task a measure of visual planning in which partic-
**MBD**

abbreviation for MINIMAL BRAIN DYSFUNCTION.

**MBE**

abbreviation for mind–brain–education. See NEUROEDUCATION.

**MBIO**

abbreviation for MANAGED BEHAVIORAL HEALTH ORGANIZATION.

**MBO**

abbreviation for MANAGEMENT BY OBJECTIVES.

**MBT**

abbreviation for mentalization-based treatment. See MENTALIZATION.

**MBTI**

abbreviation for MYERS–BRIGGS TYPE INDICATOR.

**MCA**

abbreviation for multiple classification analysis. See MULTIPLE DISCRIMINANT ANALYSIS.

**M-Cat**

n. see MEPHEDRONE.

**McCarthy Scales of Children’s Abilities**

a comprehensive instrument used to measure the cognitive and motor abilities of children between 2½ and 8½ years of age, comprising 18 subtests on 6 overlapping scales: Verbal, Perceptual-Performance, Quantitative, General Cognitive, Memory, and Motor. [developed in 1972 by Dorothea McCarthy (1906–1974), U.S. developmental psychologist]

**McCarthy Screening Test (MST)**

an assessment that predicts the ability of a child to cope with schoolwork at an early age. It comprises six subtests (verbal memory, right–left orientation, leg coordination, draw-a-design, numeric memory, and conceptual grouping) designed to measure the cognitive and sensorimotor functions needed to successfully perform school tasks. Poor performance on this assessment may indicate the need for further evaluation and the possible presence of a learning disability. [originally developed in 1978 by Dorothea McCarthy]

**McCullough effect**

see CONTINGENT AFFECT EFFECT. [Celeste McCollough (1926–98), U.S. psychologist]

**MCE**

abbreviation for MEDICAL CARE EVALUATION.

**M-cell**

n. any of various large neurons in the two most ventral layers of the LATERAL GENICULATE NUCLEUS. M-cells are the origin of the MAGNOCELLULAR SYSTEM. The large RETINAL GANGLION CELLS that provide input to the M-cells of the lateral geniculate nucleus are called M-GANGLION CELLS. See also P-CELL.

**MC4-R**

abbreviation for MELANOCORTIN-4 RECEPTOR.

**MCI**

abbreviation for MILD COGNITIVE IMPAIRMENT.

**MCL**

abbreviation for MOST COMFORTABLE LOUDNESS.

**MCM**

abbreviation for METACOGNITIVE MODEL OF ATTITUDES.

**MCMI**

abbreviation for MILLON CLINICAL MULTIAXIAL INVENTORY.

**McNaughton rule**

(McNaughten rule) see M’NAUGHTEN RULE.

**MCO**

abbreviation for managed care organization. See MANAGED CARE.

**MCS**

abbreviation for MINIMALLY CONSCIOUS STATE.

**M–C SDS**

abbreviation for MARLOWE–CROWNE SOCIAL DESIRABILITY SCALE.

**MD**

abbreviation for MUSCULAR DYSTROPHY.

**MDA**

n. 1. 3,4-methylenedioxyamphetamine: a synthetic HALUCINOGEN of the phenylisopropylamine family (see PHENYLETHYLAMINE). Because at low doses it acts as a CNS STIMULANT and euphoriant, MDA was once proposed as an aid to psychotherapy, but this use has not been supported. It is thought that MDA’s psychostimulant properties occur through enhanced neurotransmission of norepinephrine and its hallucinogenic action through augmentation of serotonin transmission. MDA is a metabolite of MDMA and may be responsible for much of MDMA’s action; there is some concern that these drugs and other synthetic amphetamine derivatives cause neuronal degeneration. 2. abbreviation for MULTIPLE DISCRIMINANT ANALYSIS.

**MDMA**

n. 3,4-methylenedioxyamphetamine: a substituted PHENYLETHYLAMINE that, like its analog MDA, is a catecholamine-like HALUCINOGEN with amphetamine-like stimulant properties that may produce visual disturbances and hallucinations at high doses. It is among the most commonly used illicit drugs, generally sold under the name Ecstasy. Taken orally, onset of effects is rapid; the high lasts several hours, and residual effects can be experienced for several days. Intoxication is characterized by euphoria, feelings of closeness and spirituality, and diverse symptoms of autonomic arousal. Widespread illicit use of MDMA as a CLUB DRUG has caused increasing concern as nerve damage and serotonin dysfunction have been established as resulting from prolonged use. Persistent memory dysfunction and impaired decision making and self-control as well as depressed mood have been well documented. When used during periods of intense activity (as often occurs during rave parties), it may be toxic or fatal. It may, however, have some beneficial clinical use and is being studied as a possible treatment for posttraumatic stress disorder.

**MDS**

abbreviation for MULTIDIMENSIONAL SCALING.

**me**

pron. the objective pronoun referring to the self. In William James’s psychology, the “me” is the EMPIRICAL SELF.

**mean**

n. the numerical average of a set of scores, computed as the sum of all scores divided by the number of scores. For example, suppose a health researcher sampled five individuals and found their numbers of hours of exercise per week to be 3, 1, 5, 4, and 7, respectively. The mean number of exercise hours per week thus would be (3 + 1 + 5 + 4 + 7)/5 = 20/5 = 4. The mean is the most widely used statistic for describing CENTRAL TENDENCY. Also called arithmetic mean: arithmetic average. See also GEOMETRIC MEAN; HARMONIC MEAN.

**mean deviation**

for a set of numbers, a measure of dispersion or spread equal to the average of the differences between each number and the mean value. It is given by (∑|xᵢ - μ|)/n, where μ is the mean value and n the number of values.

**mean difference**

a measure of variability in a data set calculated as the average of the distances between each score and each of the other scores, disregarding whether the deviation is positive or negative. For example, consider the following three scores: 1, 3, and 9. The mean difference would be calculated as (|1 - 3| + |1 - 9| + |3 - 1| + |3 - 9| + |9 - 1| + |9 - 3|)/6 = (2 + 8 + 2 + 6 + 8 + 6)/6 = 32/6 = 5.33.

**mean effect size**

in a META-ANALYSIS, a measure of the average EFFECT SIZE across multiple studies. For example, an investigator analyzing several studies assessing a new
treatment may determine a mean effect size by calculating the average standardized difference between treatment and control groups over all of the studies. Calculations of mean effect size often take variance and reliability into account by assigning different weights to the values derived from different studies. A study with a large sample, for instance, or one that uses more precise measurement techniques may be weighted to have a greater impact in determining the mean effect size.

**mean-gradation method** see METHOD OF EQUAL-APPEARING INTERVALS.

**meaning** n. the cognitive or emotional significance of a word or sequence of words, or of a concept, sign, or symbolic act. This may include a range of implied or associated ideas (connotative meaning) as well as a literal significance (denotative meaning). The study of meaning in language is SEMANTICS, and that of meaning in symbolic systems generally is SEMIOTICS. —meaning vb. —meaningful adj.

**meaning-centered therapy** see LOGOTHERAPY.

**meaningful learning** learning new material or information by relating it to the learner’s experience or existing knowledge base, as contrasted with the ROTE LEARNING of material that has less relevance. See also READINESS.

**meaninglessness** n. a pervasive sense of the absence of significance, direction, or purpose. A sense of meaninglessness regarding one’s life or life in general is sometimes a focal issue in psychotherapy. The perception of meaninglessness poses the central problem that the existential approach attempts to solve or accommodate. See also EXISTENTIAL PSYCHOThERAPY; LOGOTHERAPY; WILL TO MEANING.

**mean length of utterance (MLU)** a measure of language development in young children based on the average length of utterances in their spontaneous speech. It is usually calculated by counting MORPHEMES rather than words and is based on at least 100 successive utterances. [introduced in 1973 by Roger BROWN to characterize the different stages of early language development]

**means-ends analysis** 1. in ARTIFICIAL INTELLIGENCE, a technique to solve problems that sets up subgoals as means to achieve the goals (ends) and compares subgoals and goals using a recursive goal-reduction search procedure. See GENERAL PROBLEM SOLVER. 2. more generally, any problem-solving strategy that assesses the difference between the current state and a desired end state and attempts to discover means to reduce that difference. Such a strategy would not discard means to the end that appear to be “blocked,” but it would consider possible ways to overcome any such intermediate problem.

**means object** in PURPOSEFUL BEHAVIORISM, any object, response, event, or condition that contributes to an organism’s progress toward a GOAL. Also called Means situation.

**mean square** (symbol: MS) an estimator of variance calculated as a SUM OF SQUARES divided by its DEGREES OF FREEDOM. It is used primarily in the ANALYSIS OF VARIANCE, in which an F RATIO is obtained by dividing the mean square between groups by the mean square within groups. The mean square also is used to determine the accuracy of REGRESSION ANALYSIS models, indicating the amount of variance explained by a model (MS_explained) compared to the amount of error or unexplained variance (MS_residual).

**mean square error** (symbol: MSE) the average amount of ERROR VARIANCE within a data set, given as the typical squared distance of a score from the mean score for the set. Mean square error may be calculated in both ANALYSIS OF VARIANCE and REGRESSION ANALYSIS. In the former it is referred to more specifically as the withingroups mean square and used as the denominator when calculating an F RATIO. In the latter it is known as a residuals mean square (or mean square residual) and gives the mean difference between actual scores and those predicted by a regression model. A large mean square error indicates that scores are not homogeneous within groups or are not consistent with prediction, such that there is more “noise” than “signal.” For example, a large mean square error in gender research would show no significant differences between groups of males and groups of females.

**mean square residual** (symbol: MSR) see MEAN SQUARE ERROR.

**measure** n. an item or set of items that provides an indication of the quantity or nature of the phenomenon under study. It is sometimes necessary in research to have more than one measure for each of the main variables of interest.

**measurement** n. the act of appraising the extent of some amount, dimension, or criterion—or the resultant descriptive or quantified appraisal itself. A measurement is often, but not always, expressed as a numerical value.

**measurement error** in CLASSICAL TEST THEORY, any difference between an observed score and the true score. Measurement error may arise from flaws in the assessment instrument, mistakes in using the instrument, or random or chance factors. For example, an investigator may obtain biased results from a survey because of problems with question wording or response options, question order, variability in administration, and so forth.

**measurement invariance** the situation in which a scale or construct provides the same results across several different samples or populations. For example, an intelligence test could be said to have measurement invariance if it yields similar results for individuals of varying gender, ethnicity, or age. Measurement invariance may apply to a single relevant characteristic (e.g., gender only), several characteristics (e.g., gender and ethnicity), or all possible characteristics and situations. Compare SELECTION INVARiance.

**measurement level** the degree of specificity, accuracy, and precision in a particular set of observations or scores, as reflected in the MEASUREMENT SCALE used.

**measurement model** in STRUCTURAL EQUATION MODELING, a model that quantifies the association between observations obtained during research (indicators) and theoretical underlying constructs or factors. When carrying out a CONFIRMATORY FACTOR ANALYSIS, for example, one assesses a hypothesized measurement model that specifies the relationships between observed indicators and the LATENT VARIABLES that support or affect them.

**measurement scale** any of four common methods for quantifying attributes of variables during the course of research, listed in order of increasing power and complexity: NOMINAL SCALE, ORDINAL SCALE, INTERVAL SCALE, and RATIO SCALE. More specifically, nominal scales consist of named categories with no numerical meaning (e.g., gender, birthplace); ordinal scales comprise rankings from highest to lowest or vice versa (e.g., birth order, contest winners); interval scales provide equal distance between numerical val-
measurement theory

ues but have an arbitrary zero point (e.g., degrees Fahrenheit, cookbook balance), and ratio scales provide equal distance between numerical values with an exact zero point (e.g., height, weight).

measurement theory a field of study that examines the attribution of values to traits, characteristics, or constructs. Measurement theory focuses on assessing the true score of an attribute, such that an obtained value has a close correspondence with the actual quantity, with high reliability and little measurement error. See also CLASSICAL TEST THEORY.

measure of association any of various indices of the degree to which two or more variables are related. One of the most commonly measures of association is the CORRELATION COEFFICIENT.

measures of intelligence a series of norm-referenced tests used to determine an individual’s ability to learn, reason, understand concepts, and acquire knowledge. See EIQ, MEASURES OF INTELLIGENCE, ERP MEASURES OF INTELLIGENCE, FMRI MEASURES OF INTELLIGENCE. See also ASSESSMENT OF INTELLIGENCE.

mecamylamine n. a GANGLIONIC BLOCKING AGENT formerly widely used in the treatment of hypertension. Because of the severity of its side effects, which include tremor, sedation, and movement disorders, this use is now rare. However, because mecamylamine has preferential antagonistic action at NICOTINIC RECEPTORS, it has been investigated as a possible antismoking agent. It has also been used in the treatment of Tourette’s disorder and is being studied as an augmenting agent to SSRIs for the treatment of depression. U.S. trade name: Inversine.

mechanical aptitude an ability to comprehend and deal with machines or mechanisms and the principles underlying their construction and function.

mechanical-aptitude test any of various tests designed to measure abilities related to mechanical work, such as mechanical knowledge, spatial relations, perceptual skills, understanding of mechanical principles, mechanical assembly, and manual dexterity.

mechanical causality a construct that explains the causes of things and events, including behaviors, in terms of underlying physical processes and not subject to nonphysical phenomena, such as consciousness. This is often called mechanism. See MECHANICAL CAUSALITY; MECHANISTIC THEORIES. See also MECHANICAL-APTITUDE TEST.

mechanism n. 1. in general, a device or physical property by which something is accomplished, or an explanation that relies on such a device or property. 2. a philosophical position, similar to that of MATERIALISM, that provides explanations in terms of underlying physical properties. See MECHANICAL CAUSALITY; MECHANISTIC THEORY. 3. the concept of the human being as a machine. See MECHANICAL-MAN CONCEPT. [credited to Julien Offray de LA METTRIE] 4. in psychodynamics, see MENTAL MECHANISM.

mechanistic interactionism a theory that considers both individual (dispositional) and situational variables in the determination of behavior. The relative weight assigned to dispositional and situational factors may be affected by certain moderating variables, including the nature of a situation: A highly structured situation may influence behavior more than will dispositional factors, and a highly ambiguous situation may allow dispositional factors to play a larger role in determining behavior.

mechanistic theory the assumption that psychological processes and behaviors ultimately can be understood in the same way that mechanical or physiological processes are understood. Its explanations of human behavior are based on the model or metaphor of a machine and invoking MECHANICAL CAUSALITY, reducing complex psychological phenomena to simpler physical phenomena. Also called mechanistic approach. See REDUCTIONISM.

mechanoreceptor n. a receptor that is sensitive to mechanical forms of stimuli. Examples of mechanoreceptors are the receptors in the ear that translate sound waves into nerve impulses, the touch receptors in the skin, and the receptors in the joints and muscles (see PROPRIORECEPTOR).

Meckel’s syndrome a congenital disorder marked by MICROCEPHALY; eye, ear, and olfactory abnormalities; and varying degrees of brain-tissue anomalies. Some affected children show premature closure of skull sutures. The patients either are stillborn or die in early infancy. [Johann Friedrich Meckel (1781–1833), German anatomist]

Medea complex a mother’s wish to kill her children as a means of revenge against the father. The term is derived from Greek mythology, in which Medea killed her children fathered by Jason after he deserted her for a younger woman. See also FILICIDE.

medial adj. toward or at the middle of the body or of an organ. Compare LATERAL. —medially adv.

medial amygdala a portion of the AMYGDALA that receives olfactory and pheromonal information and participates in fear responses.

medial bundle a group of sensory fibers located in the middle portion of a body structure. For example, there is a medial bundle in the knee.

medial forebrain bundle a collection of nerve fibers passing through the midline of the forebrain to the hypothalamus. It includes tracts originating in the LOCUS CERULEUS, SUBSTANTIA NIGRA, and VENTRAL TRIGEMINAL AREA and provides the chief pathway for reciprocal connections between the hypothalamus and the BICOREATIC AMINE systems of the brainstem.

medial geniculate nucleus either of a pair of nuclei in the THALAMUS, toward the middle of the LATERAL GENICULATE NUCLEUS, that receive, process, and relay auditory information. Each nucleus receives input from the INFERIOR COLICULUS and sends output to the AUDITORY CORTEX. Also called medial geniculate body.

medial lemniscus either of a pair of somatosensory
tracts in the midbrain carrying fibers from the spinal cord that communicate with the thalamus. They form part of the lemniscal system.

**medial prefrontal cortex** the midline region of the prefrontal cortex, roughly the frontal third of the two inner walls of the cortical hemispheres. This region plays a prominent role in executive functions, conflict resolution, and mood regulation.

**medial preoptic area (mPOA)** a region of the anterior hypothalamus implicated in the regulation of many behaviors, including thermoregulation, sexual behavior, parenting behavior, and gonadotropin secretion (see sexually dimorphic nucleus).

**medial rectus** an extrinsic eye muscle that rotates the eye medially (i.e., toward the midline).

**medial temporal amnesia** anterograde and retrograde amnesia caused by damage to the medial temporal lobe. Causes of the damage include infarction of the posterior cerebral artery, anoxia, encephalitis, temporal lobectomy, and trauma. See amnestic disorder.

**medial temporal gyrus** see middle temporal gyrus.

**medial temporal lobe** the region toward the middle of the temporal lobe of each cerebral hemisphere. It contains the pyriform area, the amygdala, and the hippocampus. It is involved particularly in learning and memory.

**medial temporal lobe epilepsy** see limbic epilepsy.

**median** n. the midpoint in a distribution, that is, the score or value that divides it into two equal-sized halves. The median is a measure of central tendency that is particularly useful when analyzing data that have skewness (i.e., lopsidedness), because it is more resistant to the influence of extreme values.

**median-cleft-face syndrome** see frontonasal dysplasia.

**median effective dose** see effective dose.

**median lethal dose** see lethal dose.

**median nerve** a nerve that supplies sensory and motor fibers to the arm and hand. Its fibers run through the brachial plexus.

**median test** a nonparametric method that assesses the equality of the midpoints (medians) in two or more samples of data to determine whether they come from the same population. Although previously used to indicate any of several alternative procedures, the term generally is used now to refer to the Wilcoxon–Mann–Whitney test.

**media psychology** a subspecialty in psychology that studies the influence of television, film, radio, the Internet, social media, advertising, mobile communications, and various other media on people’s thoughts, perceptions, emotions, beliefs, behaviors, and relationships.

**media richness** the relative intensity and complexity of a communication channel. Face-to-face communication is a good example of a rich medium, as it involves a complex interaction of verbal and nonverbal cues; by contrast, communication exclusively via written messages is a lean medium. [proposed in 1984 by U.S. organizational and management theorists Richard L. Daft and Robert H. Lengel]

**mediated generalization** a type of stimulus generalization in which a conditioned response is elicited by a new stimulus that is notably different from, but in some way associated with, the original conditioned stimulus. For example, a person conditioned to feel anxious on hearing a bell may also become anxious on hearing the word bell. See stimulus equivalence.

**mediated response** a response that is elicited by a stimulus and is subsequently responsible for the initiation of a behavior.

**mediate experience** conscious awareness and interpretation of external events and stimuli. Mediate experience provides meaning and additional information not contained in the event or stimulus itself. It is contrasted with immediate experience, the elements or characteristics of the event or stimuli as perceived directly and without interpretation. Introspection makes use of immediate experience in analyzing the contents of mediate experience. [defined by Wilhelm Wundt]

**mediating behavior** behavior that improves either the rate or the probability of reinforcement of a target behavior for which reinforcement is arranged. Compare adjunctive behavior; collateral behavior; interim behavior.

**mediation** n. in dispute resolution, use of a neutral outside person—the mediator—to help the contending parties communicate and reach a compromise. The process of mediation has gained popularity, particularly for couples involved in separation or divorce proceedings (see divorce mediation).

**mediational deficiency** in problem solving, a person’s inability to make use of a particular strategy to benefit task performance even if it has been taught to him or her. Compare production deficiency; utilization deficiency.

**mediational learning** a form of learning that involves the use of mediators to bridge the association between two or more events that are not directly contiguous in space or time. The mediators are events or processes that serve as cues.

**mediation process** any of the cognitive processes that are presumed to occur in the mind between reception of a stimulus and initiation of a response. These may include interpretation of sense data, retrieval of stored information, judgments and evaluations, computations, reasoning, and other mental operations.

**mediation theory** the hypothesis that stimuli affect behavior indirectly through an intervening process, as opposed to a simpler stimulus–response model. For example, cognitive therapists maintain that the effect an external event has on an individual is influenced by the individual’s thoughts and perceptions of that event.

**mediator** n. 1. an unseen process, event, or system that exists between a stimulus and a response, between the source and destination of a neural impulse, or between the transmitter and receiver of communications. 2. a person—for example, a lawyer or psychologist—who helps contending parties communicate and reach a compromise. See also divorce mediation. 3. in statistical analyses, an intermediary or intervening variable that accounts for an observed relation between two other variables. For example, a researcher may posit a model involving an independent variable of ability, a mediator of self-efficacy, and a dependent variable of achievement. Thus, ability is hypothesized to influence self-efficacy, which in turn is thought to influence achievement.
Medicaid

Medicaid n. a joint federal and state program, instituted by law in 1965 (Title XIX of the Social Security Act), that provides medical benefits for people with low income and limited resources. Medicaid programs follow broad federal guidelines, but each state determines specific benefits and amounts of payments.

Medicaid Waiver see HOME AND COMMUNITY-BASED SERVICES.

medical anthropology a subspeciality in cultural ANTHROPOLOGY that applies anthropological theory and research methodology to the study of topics relating to health, health care, disease, and other medical areas.

medical audit a systematic evaluation of the effectiveness of diagnostic and treatment procedures. A retrospective medical audit is based on a review of a patient's chart after he or she has been discharged; a concurrent medical audit is conducted while the patient is still under treatment.

medical care evaluation (MCE) a health care review in which an assessment of the quality of care and its utilization is made. It will include an investigation of any suspected problems, analysis of the problems identified, and a plan for corrective action.

medical family therapy a form of psychotherapy that combines a BIPSYCHOSOCIAL systems approach with FAMILY SYSTEMS THEORY to help families deal with the health problems of a family member. This therapy emphasizes collaboration with others—physicians, nurses, occupational therapists, nutritionists, and the like—in the individual family member’s health care team.

medical food a product specifically developed to meet the nutritional needs of a person who cannot eat or digest ordinary foods or who has a condition that precludes receiving sufficient nutrition from ordinary foods. Medical foods are taken under medical supervision.

medical history the portion of the developmental history, or ANAMNESIS, that focuses on the patient’s health throughout life, including congenital or acquired illnesses and disorders. The object is to uncover, where possible, clues to the cause of the patient’s current condition.

medical home see HEALTH HOME.

medical model 1. the concept that mental and emotional problems are analogous to biological problems—that is, they have detectable, specific, physiological causes (e.g., an abnormal gene or damaged cell) and are amenable to cure or improvement by specific treatment. 2. in evaluation research, a systems-analysis approach to evaluation that considers the interrelatedness of all the factors that may affect performance and monitors possible side effects of treatment. Compare ENGINEERING MODEL.

medical psychology 1. an area of applied psychology devoted to psychological questions arising in the practice of medicine, including emotional reactions to illness, treatment adherence, attitudes toward terminal illness and impending death, psychological means of relieving pain (e.g., hypnotic suggestion), and reactions to disability. See also HEALTH PSYCHOLOGY. 2. see PRESCRIBING PSYCHOLOGY.

medical psychotherapy psychotherapy that makes use of medication and other medical techniques in the treatment of mental illness.

medical rehabilitation the process of restoring to the fullest possible degree the physical functioning of an individual who has a physiological or anatomical impairment.

medical social worker a licensed social worker, usually with a master’s degree in social work, who assists patients and their families with health-related problems in such areas as employment, finances, living arrangements, marriage, child care, social life, and emotional adjustment.

medical tourism travel to another country or location to obtain surgery (e.g., hip replacement) or other medical treatment (e.g., alternative cancer therapy) that is more expensive or unavailable in the country or location where the patient lives.

Medicare n. a federal program of HEALTH INSURANCE operated by the Centers for Medicare and Medicaid Services of the U.S. Department of Health and Human Services for those over 65, certain younger people with disabilities, and people with end-stage renal disease. Monies from payroll taxes and premiums from subscribers are deposited in trust funds to meet the expenses of the insured. Medicare consists of two basic programs: Part A includes inpatient costs and Part B provides supplementary medical insurance. Other options include a Medicare Advantage plan (Part C), in which medical services are covered by private health insurance companies in contract with Medicare, and an outpatient prescription drug plan (Part D).

medication n. any drug available by prescription or over the counter to aid in the treatment of an illness, disease, disorder, or condition. Medications specifically used to treat mental health disorders tend to be prescribed therapeutic agents with psychoactive effects (see PSYCHOACTIVE DRUG). Overmedication—the taking of more than the prescribed dose of a drug or drugs—may occur when medication is not properly monitored. Self-medication is usually associated with individuals who use drugs or alcohol inappropriately to alleviate emotional problems. See also PRESCRIBING PSYCHOLOGY.

medication-induced movement disorder any movement disorder that occurs as an adverse effect of medication. It may involve rigidity, tremor, hypertonia (increased muscle tone), and other motor symptoms and is commonly seen after treatment with antipsychotic drugs. See TARDIVE DYSKINESIA.

mediodorsal nucleus see DORSOMEDIAL NUCLEUS.

meditation n. profound and extended contemplation or reflection in order to achieve focused attention or an otherwise ALTERED STATE OF CONSCIOUSNESS and to gain insight into oneself and the world. Traditionally associated with spiritual and religious exercises, meditation is now also used to provide relaxation and relief from stress; treat such symptoms as high blood pressure, pain, and insomnia; and promote overall health and well-being. See also CONCENTRATIVE MEDITATION; MINDFULNESS MEDITATION; TRANSCENDENTAL MEDITATION.

medium n. 1. the state of being in the middle of or between two factors or conditions or midway on some scale. 2. (pl. media) any means or agency through which messages are transmitted or information is diffused (e.g., the medium of television). 3. (pl. media) a substance, such as air or water, that serves to transmit a physical effect, such as sound or light. 4. (pl. media) a nutritive substance in which molds or other organisms are grown in a laboratory. 5. in SPIRITUALISM, a person who functions as the instrument of alleged communication between the living and the...
dead. Some mediums often claim paranormal abilities, such as clairvoyance, astral projection, or powers of psychic healing.

**medium trance** see trance.

**medium-wavelength pigment** the photopigment present in one of the three populations of retinal cones, that has maximum sensitivity to a wavelength of 531 nm. The absence of the gene for the medium-wavelength pigment causes deuteranopia (red–green color blindness). See also long-wavelength pigment; short-wavelength pigment.

**medulla** n. 1. the central or innermost region of an organ, such as the adrenal medulla, the central portion of the adrenal gland. Compare cortex. 2. see medulla oblongata.—**medullary** adj.

**medulla oblongata** the most inferior (lowest), or caudal (tailward), part of the hindbrain. It contains many nerve tracts that conduct impulses between the spinal cord and higher brain centers, as well as autonomic nuclei involved in the control of breathing, heartbeat, and blood pressure. Also called myelencephalon.

**medullary reticular formation** the hindmost portion of the brainstem reticular formation, implicated in motor control and copulatory behavior.

**medullary sheath** see myelin sheath.

**medullation** n. see myelination.

**mefloquine** n. a chemical analog of quinine used in the treatment of malarial infections and prevention of malaria. It has been associated with seizures or psychological disturbances, including sleep disturbance, depression, panic attacks, and psychotic symptoms. Although such reactions are rare, mefloquine should not be taken by individuals who possess only one of each chromosome, instead of the normal diploid complement of homologous pairs of chromosomes. During the process of fertilization, the ova and spermatozoa undergo fusion, which restores the double set of chromosomes within the nucleus of the zygote thus formed. Compare mitosis.

**Meissner's corpuscle** a type of small, oval sensory nerve ending that is sensitive to touch. Meissner's corpuscles are abundant in the fingertips, nipples, lips, and the tip of the tongue. [Georg Meissner (1829–1905), German anatomist and physiologist]

**megadose pharmacotherapy** a dosing strategy popular in the 1970s and 1980s in the United States and other countries, generally involving the rapid administration of very high doses of an antipsychotic drug in the hope that this would hasten an antipsychotic response. It was based on the presumption that rapid blockade of postsynaptic dopaminergic D2 receptors would lead to faster resolution of psychotic symptoms. This strategy was largely ineffective in producing a more rapid response and had numerous adverse effects, such as severe movement disorders and death due to neuroleptic malignant syndrome. Research published in the late 1980s showed that lower doses were as effective as higher doses and had fewer adverse consequences. Because of the lack of clinical benefit and the high incidence of adverse side effects associated with megadose pharmacotherapy, it has fallen into disuse. Also called rapid neuroleptization.

**megencephaly** n. an abnormally large, heavy, and usually malfunctioning brain. Large head size (macrocephaly) may be present at birth, or the head may become enlarged in early childhood. Symptoms of megencephaly can include delayed development, seizures, and corticospinal (brain cortex and spinal cord) dysfunction. Hemimegalencephaly is a rare condition that is characterized by the enlargement of one side of the brain. Children with hemimegalencephaly may have a large and asymmetrical head, seizures, partial paralysis, and intellectual disability. Also called megalencephaly.—**megencephalic** adj.

**megalomania** n. a highly inflated conception of one's importance, power, or capabilities, as can be observed in many individuals with mania and paranoid schizophrenia. In the latter, megalomania is often accompanied or preceded by delusions of persecution. See delusion of grandeur.

**megalopsia** n. see macropsia.

**Megan's law** an amendment to the Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Act requiring that state registries of convicted but released sex offenders be disseminated to the public so that communities will be notified of offenders' presence in a particular neighborhood. More formally known as the Community Notification Act, it was initially passed in New Jersey in 1994 after a repeat sex offender murdered a 7-year-old girl named Megan Nicole Kanka; it became a federal law in 1996.

**megavitamin therapy** the use of very high doses of vitamins and mineral supplements, particularly vitamin C (ascorbic acid), nicotinic acid (niacin), vitamin B6 (pyridoxine), and magnesium, to treat certain mental disorders. Such an approach has not been widely adopted, and effectiveness is uncertain.

**meiosis** n. a special type of division of the cell nucleus that occurs during the formation of the sex cells (ova and spermatozoa). During meiosis, a parental cell in the gonad produces four daughter cells that are all haploid; that is, they possess only one of each chromosome, instead of the normal diploid complement of homologous pairs of chromosomes. During the process of fertilization, the ova and spermatozoa undergo fusion, which restores the double set of chromosomes within the nucleus of the zygote thus formed. Compare mitosis.

**melancholia** n. an archaic name for depression.—**melancholic** adj.

**melancholia agitata** a 19th-century term for catatonic excitement. It is occasionally still used for agitated depression.

**melancholic features** in DSM–IV–TR, characteristics that may be associated with a major depressive episode, including loss of pleasure in activities, sadness that worsens in the morning, early morning awakening, psychomotor agitation or retardation, loss of appetite or weight, and excessive guilt.
**melancholic type** the morose personality type that Galen attributed to an excess of black bile. See *Humoral theory*.

**melan(o-)** combining form black or dark.

**melanocortin-4 receptor** (MC4-R), a receptor that is activated by alpha-MELANOCYTE-STIMULATING HORMONE. It may play a role in the regulation of eating and body weight.

**melanocyte-stimulating hormone** (MSH) a hormone secreted by the anterior pituitary gland that stimulates dispersal of melanin granules within pigment cells (melanophores) of the skin of certain vertebrates (e.g., amphibians), thereby darkening the skin. In mammals, it may play a role in regulating eating behavior (see ALPHA-MELANOCYTE-STIMULATING HORMONE).

**melatonin** an AMINE HORMONE, produced mainly by the pineal gland as a metabolic product of the neurotransmitter serotonin, that helps to regulate seasonal changes in physiology and may also influence puberty. It is implicated in the initiation of sleep and in the regulation of the sleep–wake cycle. Melatonin has been investigated in clinical studies as a hypnotic and for the management of circadian rhythm sleep disorders. Although these studies are as yet inconclusive, melatonin is widely available as an over-the-counter medication.

**mellioration** n., in behavioral studies, allocating time to two or more activities such that local rates of REINFORCEMENT (i.e., reinforcements obtained per unit of time for each activity) are equal.

**Mellaril** a trade name for THIORIDAZINE.

**Melnick–Needles syndrome** see OTOPALATO DIGITAL SPECTRUM DISORDERS.

**melodic intonation therapy** (MIT) speech therapy that uses melody to regain or improve speech in individuals with certain kinds of APHASIA, MOTOR SPEECH DISORDER, or EXPRESSION LANGUAGE DISORDER, Based on the theory of right-hemisphere dominance for music, MIT trains the speaker to intone, or “sing,” text in pitches and rhythms that parallel natural spoken prosody. MIT is primarily an auxiliary to other forms of speech therapy.

**member check** a procedure used in QUALITATIVE RESEARCH whereby a researcher returns to a participant and requests feedback on his or her original responses as recorded and sometimes on their interpretation by others. Conducting a member check is intended to ensure the accuracy and INTERNAL VALIDITY of a qualitative study. However, some researchers question the merit of the process, viewing it as inconsistent with qualitative research in that it assumes participants’ experiences are objective and finite. Also called **member validation: respondent validation**.

**membership group** a social body or organization to which people belong as members, especially when they feel that the group has formally or informally accepted them into its ranks. Such groups, which include clubs, societies, cliques, teams, and political parties, often explicitly distinguish between individuals who belong to the group and those who do not. Compare ASPIRATIONAL GROUP; REFERENCE GROUP.

**membrane** n., a thin layer of tissue that covers a surface, lines a cavity, or connects or divides anatomical spaces or organs. One of the fundamental functions of a membrane is to contain the components within it. In cells, the membrane surrounds the cytoplasm and is composed of proteins and lipids. It is semipermeable and acts to control the passage of substances in and out of the cell (see ION CHANNEL).

**membrane potential** a difference in electric potential across a membrane, especially the plasma membrane of a cell. At rest, the membrane potential intracellulurally is usually negative; that is, the inside of a cell membrane is comparatively negative versus the outside. See also RESTING POTENTIAL.

**membranous labyrinth** see LABYRINTH.

**meme** n., a unit of practice or belief through which a society or culture evolves and that passes from one generation (or even one person) to the next. In this sense, the term—coined in 1976 by British biologist Richard Dawkins (1941– ) and derived from the Greek word for “imitation”—is a kind of metaphorical parallel to the term GENE.

Relatedly, an Internet meme is an idea (e.g., a word or phrase, hashtag, hyperlink, picture, or video), usually rooted in popular culture, that is widely popularized and distributed on the World Wide Web, for example, via social networks, blogs, e-mail, and news sources.

**memorandum as a whole** see OBJECTIVE PSYCHOTHERAPY.

**memorize** vb. to commit to memory. Memorizing usually impliesrote learning or drill as the method of learning, although use of an active MNEONIC strategy is likely to be more effective. —memORIZATION n.

**memory** n., 1. the ability to retain information or a representation of past experience, based on the mental processes of learning or encoding; retention across some interval of time, and retrieval or reactivation of the memory. 2. specific information or a specific past experience that is recalled. 3. the hypothesized part of the brain where traces of information and past experiences are stored. See MEMORY STORAGE; MEMORY SYSTEM. See also EXPLICIT MEMORY; IMMEDIATE MEMORY; IMPLICIT MEMORY; LONG-TERM MEMORY; SHORT-TERM MEMORY.

**memory abilities** abilities involved in remembering information, as assessed by tests of FREE RECALL (recall of words in any order), SERIAL RECALL (recall of words in a fixed order), PAIRED-ASSOCIATES LEARNING (recall of a word paired with the word presented), and RECOGNITION memory (skill in stating correctly whether a presented word was previously presented on some list). Psychometric data suggest that, typically, various memory abilities are only weakly related to each other. Moreover, IMPLICIT MEMORY is largely independent of EXPLICIT MEMORY.

**memory aid** see MNEONIC.

**memory attribution** the ascribing of a memory to a source (e.g., a previously experienced event, another person, one’s imagination), depending on the source details retained in memory. Misattributions of memory can occur due to a number of factors (e.g., nonconscious influence of attitudes), resulting in a SOURCE MONITORING error. Common examples of misattributions include CRYPTO MNEONIA and FALSE MEMORY.

**memory color** any object’s color as modified in memory. The quality of remembered color often differs substantially from the actual hue. Color perception is considered to be a compromise between the memory color and present sensory input.
memory consolidation see CONSOLIDATION; PERSERVATION—CONSOLIDATION HYPOTHESIS.

memory curve see RETENTION CURVE.

memory decay see DECAY THEORY.

memory disorder any impairment in the ability to encode, retain, or retrieve information or representations of experiences. A notable example is AMNESIA. Memory disorders may be partial or global, mild or severe, permanent or transitory, and anterograde (pertaining to difficulty with new information) or retrograde (pertaining to difficulty with previously known information). The causes include medical conditions leading to structural lesions of the brain or metabolic disruption of brain function, aging, psychological trauma, fugue states, or intrapsychic conflicts.

memory distortion any inaccurate or illusory recall or recognition, such as DEJA VU, a FALSE MEMORY, or a MEMORY ILLUSION.

memory drum a device formerly used to present items in memory experiments. The drum turned at a given speed, allowing one item at a time to be seen through an opening. The memory drum has been replaced by presentation of items on a computer screen.

memory-enhancing drug see COGNITIVE ENHANCER.

memory illusion a distortion in remembering, analogous to a perceptual illusion, in which one remembers inaccurately or remembers something that in fact did not occur. The DEISE—ROEDERER—MCERMOTT PARADIGM is a memory illusion. See FALSE MEMORY.

memory impairment the loss of memory associated with a MEMORY DISORDER.

memory-operating characteristic curve (MOCC) a graphic representation of the proportion of items accurately remembered against the proportion mistakenly remembered (called false positives).

memory retraining strategies to help individuals with neurological deficits improve their ability to process information in WORKING MEMORY. These strategies are typically applied with patients with brain injury or dementia and those with HIV/AIDS who are experiencing memory problems.

memory span the number of items that can be recalled immediately after one presentation. Usually, the items consist of letters, words, numbers, or syllables that the participant must reproduce in order. A distinction may be drawn between VISUAL MEMORY SPAN and AUDITORY MEMORY SPAN, depending on the nature of the presentation. See also DIGIT SPAN; OPERATION SPAN.

memory storage the retention of memories in an organism. Historically, explanations of this process have included the continuous operation or “reverberation” of loops of neurons in cell assemblies (see CELL. ASSEMBLY; REVERBERATING CIRCUIT), the growth of new nerve endings grouped in synaptic knobs, and the encoding of information in complex molecules, such as RNA. Contemporary biological research suggests changes in synaptic efficiency as the basis of memory storage, as postulated in the research of Austrian-born U.S. neuroscientist Eric Kandel (1929— ).

memory system any of several different kinds of memory that are hypothesized to be located in separate brain areas and employed primarily in different sorts of memory tasks. Examples of hypothesized systems include WORKING MEMORY (a temporary store used in manipulating information), SEMANTIC MEMORY (general knowledge), EPISODIC MEMORY (memories of one's personal past), and PROCEEDURAL MEMORY (habits and skills). See also PERCEPTUAL REPRESENTATION SYSTEM.

memory trace a hypothetical modification of the nervous system that encodes a representation of information or a learning experience. See ENGRAM.

menarche n. the period of a woman’s life cycle in which she experiences menstrual activity (i.e., from puberty to menopause).

ménage à trois 1. a sexual relationship involving three people who are members of the same household. 2. three people having sex together (see TROILISM).

Mendelian inheritance a type of inheritance that conforms to the basic principles developed around 1865 by Austrian monk Gregor Mendel (1822–1884), regarded as the founder of genetics. Mendelian inheritance is essentially determined by genes located on chromosomes, which are transmitted from both parents to their offspring. It includes autosomal dominant, autosomal recessive, and SEX-LINKED inheritance. Mendel proposed two principles. The principle of segregation, or Mendel's first law, states that recessive traits are neither modified nor lost in future generations as both DOMINANT ALLELES and RECESSIVE ALLELES are independently transmitted and so are able to segregate independently during the formation of sex cells. The principle of independent assortment, or Mendel's second law, states that there is no tendency for genes of one parent to stay together in future offspring.

Ménière's disease a disorder of balance and hearing due to excessive fluid in the inner ear, resulting in dizziness, nausea, TINNITUS, and progressive DEAFNESS. [Prosper Ménière (1799–1862), French physician]

meninges pl. n. (sing. meninx) the three membranous layers that provide a protective cover for the brain and spinal cord. They consist of a tough outer DURA MATER, a middle ARACHNOID MATER, and a thin, transparent PIA MATER, which fits over the various contours and fissures of the cerebral cortex.

meningocele n. a benign BRAIN TUMOR that develops in the arachnoid layer of the MENINGS, accounting for 15% to 25% of all tumors of the brain and spinal cord. Meningoceles are typically slow growing and cause damage mainly by pressure against the brain. Patients may complain of headaches or seizures as first symptoms.

meningitis n. inflammation of the meninges, the three membranous layers that cover the brain and spinal cord, usually due to infection by bacteria, viruses, or fungi. Symptoms include high fever, nausea, vomiting, stiff neck, and headache. BACTERIAL MENINGITIS includes meningococcal meningitis and TUBERCULOUS MENINGITIS. Viral (or aseptic) meningitis is a milder nonbacterial disease; causes include the mumps, poliomyelitis, herpes viruses, and the ECHOVIRUSES (which mainly affect young children during the summer). If untreated or not treated promptly, many
types of meningitis can result in confusion, lethargy, coma, and eventually death.

**meningocele** n. a congenital herniation (protrusion) of the meninges (the three membranous layers that cover the brain and spinal cord) through an abnormal opening in the skull or spinal cord, with seepage of cerebrospinal fluid into the protrusion. The disorder is sometimes associated with hydrocephalus or other neurological defects, which reduces the chances of a favorable prognosis. If the herniation contains neural tissue, the condition is identified as an encephalocele.

**meningococcal meningitis** see bacterial meningitis.

**meningoencephalitis** n. inflammation of the brain and the meninges covering it.

**meningomyelocele** n. protrusion of the spinal cord and its covering meninges through a defect in the spinal column. This results in an external sac containing cerebrospinal fluid, poorly formed meninges, and a malformed spinal cord. Also called myelomeningocele. See SPINA BIFIDA.

**menkeiti** n. see MYRACHT.

**menopausal depression** severe dysphoria occurring during the female climacteric (menopause) or immediately before menopause (i.e., perimenopause), particularly among women who have had a prior tendency to depression.

**menopause** n. see CLIMACTERIC. —menopausal adj.

**menorrhagia** n. excessive bleeding during menstruation. Also called epimennorrhagia. Mensa n. an organization of individuals whose sole admission requirement is an IQ in the upper 2% of the population.

**menses** pl. n. see MENSTRUATION.

**men's liberation movement** a variety of social movements and positions united only by taking men and masculinity as their topic of interest. Some positions acknowledge the justice of feminist critiques of male dominance and recommend measures whereby men can overcome exploitation of women by men. Others aim to liberate men from their expressing emotions and forming attachments to other men. A quite different type of movement seeks to help men rediscover traditional forms of masculinity and to become more responsible husbands and fathers. Yet another is essentially antifeminist, arguing that men are now essentially antifeminist, arguing that men are now subject to various injustices in education, employment, and the law (e.g., in divorce settlements and child-custody agreements). No one area of emphasis has become dominant under the rubric of men's liberation.

**mens rea** the malicious or blameworthy state of mind (Latin, "guilty mind") that must be proved in addition to the ACTUS REUS to establish CRIMINAL RESPONSIBILITY and secure a conviction. It involves a conscious disregard for the law, which is presumed to be known by the defendant. For some crimes, the mens rea may be recklessness or negligence rather than a deliberate intention to bring about certain consequences. Also called criminal intent.

**menstrual age** the age of a fetus calculated from the beginning of the mother's last MENSTRUATION. At full term, it is normally 280 days or 40 weeks—that is, usually 2 weeks longer than the gestational age.

**menstrual cycle** a modified estrous cycle that occurs in most primates, including humans (in which it averages 28 days). The events of the cycle are dependent on cyclical changes in the concentrations of gonadotropins secreted by the anterior pituitary gland, under the control of gonadotropin-releasing hormone, and can be divided into two phases. In the follicular phase, follicle-stimulating hormone (FSH) and luteinizing hormone (LH) stimulate development of an ovum and secretion of estrogen within the ovary, in a granaian follicle, culminating in ovulation, which occurs halfway through the cycle. The estrogen stimulates thickening of the endometrium of the uterus in preparation to receive a fertilized ovum. The luteal phase begins immediately after ovulation, when the ruptured follicle becomes the corpus luteum and secretes progesterone, which inhibits further secretion of releasing hormone and testosterone (and hence of FSH and LH). If fertilization does not occur, this phase ends with menstruation and a repeat of the follicular phase.

**menstrual synchrony** the similar timing thought to occur in the menstrual cycles of women who live together or spend a lot of time together. Whether this phenomenon actually occurs is controversial.

**menstrual taboo** any culture-bound prohibition associated with menstruating women, typically involving physical separation from men, abstention from sexual intercourse, or the exclusion of women from certain daily activities (e.g., the preparation of food).

**menstruation** n. a periodic discharge of blood and endometrial tissue from the uterus through the vagina that occurs in women as part of the MENSTRUAL CYCLE. Also called menses: menstrual (or monthly) period.

**mental** adj. 1. of or referring to the mind or to processes of the mind, such as thinking, feeling, sensing, and the like. 2. phenomenal or consciously experienced. In contrast to physiological or physical, which refer to objective events or processes, mental denotes events known only privately and subjectively; it may refer to the COGNITIVE PROCESSES involved in these events, to differentiate them from physiological processes.

**mental aberration** a pathological deviation from normal thinking, particularly as a symptom of a mental or emotional disorder.

**mental abilities** abilities as measured by tests of an individual's spatial visualization, perceptual speed, number facility; verbal comprehension, word fluency, memory, inductive reasoning, and so forth, depending on the theory or test. See also PRIMARY ABILITY.

**mental accounting** a cognitive process in which individuals track and evaluate their income and expenditures by grouping them into consumption categories or mental accounts; this in turn affects future transactions by influencing how economic activities are perceived. The topical organization of mental accounts leads people to evaluate gains and losses in relative rather than in absolute terms. For example, a person who finds that a $10 bill is missing while waiting in line to buy a $10 theater ticket is likely to buy the ticket anyway, whereas the same person might be unwilling to spend another $10 to repurchase a new theater ticket to replace one he or she lost. In such a case, going to the theater is viewed as a transaction in which the
mental age (MA) a numerical scale unit derived by dividing an individual’s results in an intelligence test by the average score for other people of the same age. Thus, a 4-year-old child who scored 150 on an 10 test would have a mental age of 6 (the age-appropriate average score is 100; therefore, MA = (150/100) × 4 = 6). The MA measure of performance is not effective beyond the age of 14.

mental apparatus see PSYCHIC APPARATUS.

mental asymmetry an imbalance in mental abilities, as in individuals with WILLIAMS SYNDROME, who may exhibit severe impairment in visuospatial abilities but possess good to exceptional language abilities.

mental ataxia see INTRAPSYCHIC ATAXIA.

mental balance INTEGRATION of mental processes.

mental block see BLOCK.

mental chemistry a concept proposed by John Stuart MILL as an alternative to the MENTAL MECHANICS described by his father, James MILL. The concept is modeled on a common phenomenon in physical chemistry, in which two chemical substances combine to form a compound with properties not present in either of the components. Similarly, MILL held that compound ideas were not merely combinations of simpler ideas but that they possessed other qualities not present in any of the constituent ideas. Thus, such an idea could be an essentially new one. See ASSOCIATIONISM; ASSOCIATION OF IDEAS.

mental chronometry see CHRONOMETRIC ANALYSIS.

mental claudication a temporary interruption of blood flow to a portion of the brain that results in brief episodes of mental status changes.

mental coaching in education, a field of teaching expertise, used mainly for counseling, business, and sports, that is focused on the direct cognitive features of behavior. It can improve overall performance, restore confidence, enhance motivation, reduce mental errors, and upgrade underperformance. It can also teach how to enhance concentration, overcome a slump or block in performance, focus better under pressure, and perform more consistently.

mental combination in PIAGETIAN THEORY, a type of cognitive processing typical of the final subphase of the SENSORIMOTOR STAGE, in which children of 18 to 24 months of age begin to use mental images to represent objects and to engage in mental problem solving. It facilitates the transition between the action-oriented world of the infant and the symbol-oriented world of the child. Also called invention of new means through mental combination.

mental confusion see CONFUSION.

mental defective an obsolete name for a person with an intellectual disability or learning disability.

mental deficiency another (and now seldom used) name for intellectual disability, sometimes referring to severe or profound intellectual disability with known biological causes.

mental development the progressive changes in mental processes due to maturation, learning, and experience. See COGNITIVE DEVELOPMENT.

mental diplopia the experience of illusions, hallucinations, or false memories with concurrent awareness that these experiences are not real and are an abnormal occurrence.

mental disease an obsolete name for a MENTAL DISORDER.

mental disorder any condition characterized by cognitive and emotional disturbances, abnormal behaviors, impaired functioning, or any combination of these. Such disorders cannot be accounted for solely by environmental circumstances and may involve physiological, genetic, chemical, social, and other factors. Specific classifications of mental disorders are elaborated in the American Psychiatric Association’s Diagnostic and Statistical Manual of Mental Disorders (see DSM–IV–TR; DSM–5) and the World Health Organization’s INTERNATIONAL CLASSIFICATION OF DISEASES. Also called mental illness; psychiatric disorder; psychiatric illness; psychological disorder. See also PSYCHIATRIC DISORDER.

mental effort the amount of cognitive work required by a given task. See also COGNITIVE LOAD; EFFORTFUL PROCESSING.

mental energy see PSYCHIC ENERGY.

mentalesse n. a hypothetical language of thought that combines cognitive and semantic systems and operates on concepts and propositions.

mental examination a comprehensive evaluation of an individual’s behavior, attitudes, and intellectual abilities for the purpose of establishing or ruling out pathology.

mental faculty see COGNITIVE FACULTY; FACULTY PSYCHOLOGY.

mental fog see CLOUDING OF CONSCIOUSNESS.

mental function any cognitive process or activity, such as thinking, sensing, or reasoning.

mental growth the incremental improvement in a mental function, usually intelligence, with increasing age.

mental handicap impaired cognitive ability that interferes with independent functioning in the community. Use of the term is now generally discouraged in preference to INTELLECTUAL DISABILITY.

mental healing the process of alleviating or attempting to alleviate mental or physical illness through the power of the mind, typically using such methods as visualization, suggestion, and the conscious manipulation of energy flow. See also FAITH HEALING; PSYCHIC HEALING.

mental health a state of mind characterized by emotional well-being, good behavioral adjustment, relative freedom from anxiety and disabling symptoms, and a capacity to establish constructive relationships and cope with the ordinary demands and stresses of life. See also FLOURISHING; NORMALITY.

Mental Health America (MHA) a U.S. nonprofit organization that addresses all aspects of mental health and illness. Established in 1909, its mission is to promote mental health and to overcome mental disorders and substance
mental health care

abuse through advocacy, education, research, and service. Formerly known as the National Mental Health Association, MHA adopted its present name in 2007.

mental health care a category of health care service and delivery provided by several fields involved in psychological assessment and intervention (psychology, psychiatry, neurology, social work, etc.). This type of care includes but is not limited to psychological screening and testing, psychotherapy and family therapy, and neuropsychological rehabilitation. Also called behavioral health care. See also MENTAL HEALTH SERVICES.

mental health clinic an outpatient facility for the diagnosis and treatment of psychological and behavioral problems.

mental health consultation a model of mental health service provision to communities or specific settings (e.g., schools, organizations) in which a clinically trained mental health specialist acts as a consultant to assist and guide an individual or group of individuals (known as consultees; including professionals, such as teachers, nurses, primary care doctors, peer counselors, and employers, and nonprofessionals, such as parents or caregivers) in addressing a problem presented by clients under the consultees’ supervision or care (such as students, patients, employees, or family members). There is often a dual purpose to mental health consultation: (a) problem solving with a consultee on a specific mental health issue with a client and (b) giving the consultee added skills and insights that will enhance his or her future functioning in dealing with a client’s problems. Mental health consultation has several subtypes, including client-centered consultation, which focuses the consultant’s attention on effective intervention for the client; and consultee-centered consultation, in which the consultant focuses on remedying shortcomings in the consultee instead of solely addressing the problems of the client. See also BEHAVIORAL CONSULTATION; CONSULTING PSYCHOLOGY. [developed by British physician Gerald Caplan (1917–2008)]

mental health counselor a certified mental health professional who provides counseling services either independently or as part of a treatment team.

mental health nursing see PSYCHIATRIC NURSING.

mental health parity in U.S. health care law, the mandate that the treatment limits and financial requirements that insurers apply to benefits for treatment of mental health and substance use disorders must not be more restrictive than those applied to medical and surgical benefits in group health plans that provide all such benefits to more than 50 employees.

mental health program a treatment, prevention, rehabilitation, or educational service offered by a community mental health center or other entity for the purpose of maintaining or improving the mental health of an individual or community.

mental health services any interventions—assessment, diagnosis, treatment, or counseling—offered in private, public, inpatient, or outpatient settings for the maintenance or enhancement of mental health or the treatment of mental or behavioral disorders in individual and group contexts.

mental health support organization any organization established to give support to individuals living with mental illness. Such organizations provide access to mutual support groups and may also advocate for improved delivery of mental health services and improved access to such services, raise money for mental health research, and work to increase public awareness of mental health issues. The NATIONAL ALLIANCE ON MENTAL ILLNESS is an example. See also EX-PATIENT CLUB.

mental health worker a member of a mental health treatment team who assists professional staff in a wide range of services.

mental history a record of information relating to a person’s mental health (see CASE HISTORY). A mental history, which may be compiled by means of structured or unstructured interviews, usually covers the history of both the individual and family members.

mental hospital see PSYCHIATRIC HOSPITAL. See also MENTAL INSTITUTION; PRIVATE MENTAL HOSPITAL; PUBLIC MENTAL HOSPITAL.

mental housecleaning hypothesis the hypothesis that dreams support the reorganization of material learned during the prior waking period, particularly by simplifying and reducing overlapping information. [developed by U.S. psychiatrist J. Allan Hobson (1933—)]

mental hygiene a general approach aimed at maintaining mental health and preventing mental disorder through such means as educational programs, promotion of a stable emotional and family life, prophylactic and early treatment services (see PRIMARY PREVENTION), and public health measures. The term itself is now less widely used than formerly.

mental illness see MENTAL DISORDER.

mental imagery see IMAGERY.

mental institution a treatment-oriented facility in which patients with severe psychological disorder are provided with supervised general care and therapy by trained psychologists and psychiatrists as well as auxiliary staff. The patients of a mental institution will generally be those who are unable to function independently as outpatients when supported by psychoactive drugs. See also PSYCHIATRIC HOSPITAL.

mentalism n. 1. a position that insists on the reality of explicitly mental phenomena, such as thinking and feeling. It holds that mental phenomena cannot be reduced to physical or physiological phenomena (see REDUCTIONISM). The term is often used as a synonym for IDEALISM, but some forms of mentalism may hold that mental events, although not reducible to physical substances, are nonetheless grounded in physical processes. Most modern cognitive theories are examples of this latter type of mentalism. Compare ELIMINATIVISM; IDENTITY THEORY. See also CONSCIOUS MENTALISM. —mentalist adj.

mentality n. 1. the capacity for thought. 2. an attitude or way of thinking, especially one that is seen as limited in some way.

mentalization n. the ability to understand one’s own and others’ mental states, thereby comprehending one’s own and others’ intentions and affects. It has been theorized that this ability is a component of healthy PERSONALITY DEVELOPMENT and is achieved through a child’s secure attachment to the parent. The concept has had particular application in the understanding and treatment of BORDERLINE PERSONALITY DISORDER (BPD), characterized in this context as a disorder marked in part by an inability to men-
talize due to poor attachment in early life. Mentalization-based treatment (MBT) is a psychodynamically oriented psychotherapy that was developed specifically to address mentalization deficits in patients with BPD; by mitigating these deficits, MBT aims to decrease the problems with impulse control and affect regulation that are common to such patients and to improve their interpersonal functioning. Also called reflective functioning. [proposed in 1996 by Hungarian-born British psychoanalyst Peter Fonagy (1952–) ]—mentalize vb.

mental lexicon the set of words that a person uses regularly (see PRODUCTIVE VOCABULARY) or recognizes when used by others (see RECEPTIVE VOCABULARY). Psycholinguistics has proposed various models for such a lexicon, in which words are mentally organized with respect to such features as meaning, lexical category (e.g., noun, verb), frequency, length, and sound. Also called lexical memory.

mental load see COGNITIVE LOAD.

mentally defective 1. in some legal jurisdictions in the United States, a descriptor for persons who have a mental disorder or neurological deficit that renders them incapable of appraising the nature of their conduct. 2. an obsolete and pejorative descriptor for a person with intellectual disability.

mental map 1. a mental representation of the world or some part of it based on subjective perceptions rather than objective geographical knowledge. Such a map will vary widely with nationality, region, ethnicity, gender, education, and socioeconomic class. Among them are (a) language, which enables expression of thoughts; (b) memory, which stores information needed in solving problems; and (c) perception, which involves recognition and interpretation of phenomena. In addition, in psychoanalytic and psychodynamic theory, various defense mechanisms, such as rationalization and compensation, help to prevent anxiety and protect self-esteem.

mental model any internal representation of the relations between a set of elements, as, for example, between workers in an office or department, the elements of a mathematics or physics problem, the terms of a syllogism, or the configuration of objects in a space. Such models may contain perceptual qualities and may be abstract in nature. They can be manipulated to provide dynamic simulations of possible scenarios and are thought to be key components in decision making. In the context of ergonomics, for example, a mental model of a system or product would include its various attributes, rules for operation and handling, and expectations regarding use and consequences and would be used to guide the individual's interactions with the system or product in question. See also shared mental model.

mental paper-folding test a test that requires the participant to indicate what sheets of paper, with directions for folding, will look like once folded to form a three-dimensional shape. The test measures three-dimensional spatial visualization ability.

mental practice the use of imagery to practice a specific skill whereby the performance of a task (e.g., a double lutz in figure skating) is visualized but not carried out.

mental process any process that takes place in the mind. This term is often used synonymously with COGNITIVE PROCESS. See also higher mental process.

mental rehearsal the use of imagery to practice behavioral patterns or skills, for example, reacting without impatience to a request that seems unnecessary or performing a defensive play in basketball.

mental representation a hypothetical entity that is presumed to stand for a perception, thought, memory, or the like during cognitive operations. For example, when doing mental arithmetic, one presumably operates on mental representations that correspond to digits and numerical operators: when one imagines looking at the reverse side of an object, one presumably operates on a mental representation of that object; when one repeats a phone number aloud while dialing it, one presumably operates on mental representations of the names of the digits. However, there is no consensus yet as to what mental representations might be. See thinking.

mental retardation (MR) in DSM-IV-TR, a disorder characterized by intellectual function that is significantly, below average: specifically, that of an individual with a measured IQ of 70 or below on tests with a standard deviation of 15, whose adaptive behavior is impaired and in whom the condition is manifested during the developmental period, defined variously as below the ages of 18 or 22. In infants, diagnosis is based on clinical judgment. The disorder may be the result of brain injury, disease, or genetic causes and is typically characterized by an impairment of educational, social, and vocational abilities. It is now more commonly known, and is identified in DSM-5, as INTELLECTUAL DISABILITY. See also mild mental retardation; moderate mental retardation; profound mental retardation; severe mental retardation; unspecified mental retardation.

mental rotation the ability to mentally manipulate stimuli some degree clockwise or counterclockwise from their normal orientations. This ability was originally measured using a laboratory task, developed by U.S. psychologist Roger Newland Shepard (1929–), that required participants to make judgments about stimuli that had been rotated out of their normal orientation.
Mental scale

Mental scale see BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT.

mental set 1. a temporary readiness to perform certain psychological functions that influences the response to a situation or stimulus, such as the tendency to apply a previously successful technique in solving a new problem. It is often determined by instructions but need not be. Essentially synonymous with the older term EINSTELLUNG, mental set is the embodiment of the earlier concepts of AUFGABE and DETERMINING TENDENCY. 2. the situation in which a preparedness to perform one type of task causes a decrement in the ability to perform on some other category of task. See TASK SWITCHING.

mental shift a switch from one MENTAL SET to another, as in moving from an arithmetic-based problem to one involving a simple numerical code. Research has shown that efficiency suffers noticeably when tasks require abrupt or frequent mental shifts.

mental status the global assessment of an individual’s cognitive, affective, and behavioral state as revealed by a MENTAL EXAMINATION that covers such factors as general health, appearance, mood, speech, sociability, cooperativeness, facial expression, motor activity, mental activity, emotional state, trend of thought, sensory awareness, orientation, memory, information level, general intelligence level, abstraction and interpretation ability, and judgment.

mental status examination (MSE) a comprehensive WORKUP of a patient, based on interviews, tests, and other sources of information and including details of mental status, personality characteristics, diagnosis, prognosis, and treatment options.

mental synthesis the process by which ideas and images are combined and formed into objects of thought, or by which objects of consciousness are brought together into meaningful wholes.

mental test 1. any test that measures one or more cognitive abilities. 2. an intelligence test.

mental testing see MENTAL MEASUREMENT.

mental topography see TOPOGRAPHICAL PSYCHOLOGY.

mental workload see COGNITIVE LOAD.

mentation n. thinking or mental activity in general.

mentor n. an experienced person who provides instruction, encouragement, guidance, advice, and other support to, and helps develop the skills of, a less experienced person.

mentoring n. the provision of instruction, encouragement, and other support to an individual (e.g., student, youth, colleague) to aid his or her overall growth and development or pursuit of greater learning skills, a career, or other educational or work-related goals. Numerous mentoring programs exist within occupational, educational, and other settings; they use frequent communication and contact between mentors and their respective protégés as well as a variety of techniques and procedures to develop productive relationships.

meperidine n. a synthetic opioid used in the acute management of moderate to severe pain (see OPIOID ANALGESIC). It is an agonist at the mu OPIOID RECEPTOR and has the side effects of other opioid analgesics. Fatal reactions have resulted when meperidine is administered to patients taking monoamine oxidase inhibitors (MAOIs), and it should therefore not be used in patients who have taken MAOIs within 14 days. Patients taking phenothiazine antipsychotics or tricyclic antidepressants concurrently with meperidine may experience severe respiratory depression. Also called pethidine. U.S. trade name (among others): Demerol.

mephedrone (4-methyl-N-methylcathinone) n. an illegal recreational drug related to METHAMPHETAMINE that can be taken orally, injected, or inhaled. Effects may include euphoria, hallucinations, agitation, panic attacks, reduced motor control, and increased heart rate. Also called drone and M-Cat, among other colloquialisms.

mephenytoin n. see HYDANTOIN.

meprobamate n. one of the drugs introduced into the U.S. market in the early 1950s as an alternative to the barbiturates. It was commonly and widely prescribed in the 1950s and 1960s for daytime sedation and the treatment of anxiety. Meprobamate is a less potent respiratory depressant than the barbiturates unless taken in combination with other CNS depressants, such as alcohol and OPIOIDS. Like the barbiturates, use of meprobamate has been almost completely supplanted by the benzodiazepines. U.S. trade name: Miltown. See also SEDATIVE, HYPNOTIC, AND ANXIOLYTIC DRUG.

mercury switch an on–off interface between a device and the user that comprises a glass tube containing mercury with electrodes at one end. It can be attached to the hand, wrist, arm, or other body part of users with severe upper extremity disabilities and is activated by slight body movements that tilt it from a neutral position.

mercy n. kindness, compassion, or leniency toward a transgressor, toward someone over whom one has power or authority, or toward someone in distress.

mercy killing a direct action intended to end what would otherwise be the prolonged agony of a dying person or animal. The concept has been known since ancient times: Warriors often were expected to kill a desperately wounded comrade or enemy. Severely injured animals are also put out of their misery by mercy killing. See also ASSISTED DEATH; EUTHANASIA.

mere-exposure effect the finding that individuals show an increased preference (or liking) for a stimulus as a consequence of repeated exposure to that stimulus. This effect is most likely to occur when there is no preexisting negative attitude toward the stimulus object, and it tends to be strongest when the person is not consciously aware of the stimulus presentations. [identified in 1968 by Robert B. Zajonc]

mere-thought polarization the finding that merely thinking about an attitude can result in polarization in the direction of that attitude. For example, thinking about a moderately positive attitude can result in that attitude becoming extremely positive. [originally demonstrated by U.S. psychologist Abraham Tesser (1941– )]

Meridia n. a former trade name for SIBUTRAMINE.

meridional amblyopia an abnormal condition, caused by ASTIGMATISM, in which contours of oblique orientation appear sharply focused whereas other orientations (vertical and horizontal) appear blurred, even when the astigmatism is optically corrected. This indicates that the astigmatism, prior to optical correction, altered orientation-selective mechanisms in the visual cortex in a direction favoring oblique over horizontal and vertical
orientations. Presumably, individuals with meridional amblyopia have a paucity of cortical cells tuned to vertical and horizontal orientations.

Merital n. a former trade name for nomifensin.

Meritocracy n. a political or social system in which rewards are given to individuals on the basis of their accomplishments. —meritocratic adj.

Meritor Savings Bank v. Vinson a case resulting in an influential 1986 U.S. Supreme Court ruling that a hostile work environment constitutes sexual harassment and that victims do not bear the burden of demonstrating they were harmed by the harassment.

Merkel's corpuscle see Merkel's tactile disk.

Merkel's law the principle that equal suprathreshold (above-threshold) differences in sensation correlate with equal differences in stimuli intensity. [Julius Merkel (1834–1900), German psychologist]

Merkel's tactile disk a type of sensory-nerve ending in the glabrous skin of the hands and feet and in the hairy skin. Also called Merkel's corpuscle: Grandry–Merkel corpuscle. [Friedrich Sigmund Merkel (1845–1919), German anatomist; M. Grandry, 19th-century Belgian physician]

mercyism n. see rumination.

mescal buttons see peyote.

mescaline n. a hallucinogen derived from the peyote cactus and long used by indigenous peoples of the southwestern United States and Central America as part of certain religious ceremonies. Its effects often include nausea and vomiting as well as visual hallucinations involving lights and colors; they have a slower onset than those of LSD and usually last 1 to 2 hours. Mescaline is the oldest classic hallucinogen known to Western science; its pharmacology was defined in 1896, and its structure was verified by synthesis in 1919. It is a substituted phenylethylamine, and its likely mechanism of action is via serotonin and dopamine receptors. Mescaline is classified by the U.S. Drug Enforcement Administration as a Schedule I controlled substance (see SCHEDULED DRUG).

mesencephalic nucleus one of the three nuclei of the mesencephalon, forming an indirect corticospinal tract. It extends through the pons into the lower part of the midbrain (mesencephalon), and its fibers innervate the muscles and joints of the head.

mesencephalic tegmentum a region of the dorsal midbrain (mesencephalon) with neural connections between the cerebral, spinal cord, thalamus, and subthalamus, forming an indirect corticospinal tract.

mesencephalon n. see midbrain. —mesencephalic adj.

mesial temporal lobe epilepsy see limbic epilepsy.

meserism n. a therapeutic technique popularized in the late 18th century by Franz Anton Mesmer, who claimed to effect cures through the use of a vitalistic principle that he termed animal magnetism. The procedure involved the application of magnets to ailing parts of a patient’s body and the induction of a trance-like state by gazing into the patient’s eyes, making certain “magnetic passes” over him or her with the hands, and so forth. Variants of meserism remained popular for much of the 19th century, when they were gradually superseded by hypnosis. —meserist n. —meseric adj. —meserize vb.
mesostriatal system

scores for height and chest measurements have been multiplied (see BODY-BUILD INDEX).

mesostriatal system a set of DOPAMINERGIC neurons whose axons arise from the midbrain and innervate the BASAL GANGLIA. It includes neurons connecting the substantia nigra to the striatum (see NIGROSTRIATAL TRACT).

mesosystem n. in ECOLOGICAL SYSTEMS THEORY, the groups and institutions outside the home (e.g., day care, school, a child’s peer group) that influence the child’s development and interact with aspects of the microsystem (e.g., relations in the home). Compare CHRONOSYSTEM; EXOSYSTEM; MACROSYSTEM. [introduced by Urie BRONFENBRENNER]

message factors characteristics of a persuasive message that can influence the effectiveness of the message itself. Such characteristics include whether the message is one-sided or two-sided (see ONE-SIDED MESSAGE) and whether or not it is a RHETORICAL-QUESTION MESSAGE.

message-learning approach a theory that conceptualizes ATTITUDE change as a type of learning process in which the extent of attitude change is determined by how well the ARGUMENTS in a persuasive message are learned. This process is seen as having five steps: exposure, attention, comprehension, yielding, and retention. The theory postulates that performance of these steps can be affected by four different types of variables: SOURCE FACTORS; MESSAGE FACTORS; CHANNEL FACTORS, and RECIPIENT FACTORS. Also called Hovland model; Yale model. [originally developed by Carl I. Hovland and his colleagues at Yale University]

messenger RNA (mRNA) a type of RNA that carries instructions from a cell’s genetic material (usually DNA) to the protein-manufacturing apparatus elsewhere in the cell and directs the assembly of protein components in precise accord with those instructions. The instructions are embodied in the sequence of bases in the mRNA, according to the GENETIC CODE.

Messiah complex the desire and compulsion to redeem or save others or the world. The individual may harbor the delusion of being divine. See also JEHOVAH COMPLEX.

Mestinon n. a trade name for PYRIDOSTIGMINE.

MET symbol for METABOLIC EQUIVALENT.

meta- (met-) prefix 1. beyond or behind (e.g., METAPHYSICS). 2. change or alteration (e.g., METABOLISM).

meta-analysis n. a quantitative technique for synthesizing the results of multiple studies of a phenomenon into a single result by combining the EFFECT SIZE estimates from each study into a single estimate of the combined effect size or into a DISTRIBUTION of effect sizes. For example, a researcher could conduct a meta-analysis of several studies on the association between self-efficacy and achievement, integrating the findings into an overall correlation. Although meta-analysis is ideally suited for summarizing a body of literature in terms of its impact, limitations, and implications, there are conditions that limit its applicability. For example, there is no minimum number of studies nor participants required, and information of potential interest may be missing from the original research reports upon which the procedure must rely.

meta-attention n. awareness of the factors that influence one’s attention.

metabolic anomaly see INBORN ERROR OF METABOLISM.

metabolic defect any deficiency in the structure or enzymatic function of protein molecules or in the transport of substances across cell membranes due to INBORN ERRORS OF METABOLISM or disturbances caused by toxic agents or dietary excesses (e.g., alcoholism, cholesterol-rich foods).

metabolic disorder a disruption in the body’s physical and chemical processing of food into energy (see METABOLISM), caused when one or more organs (e.g., liver, pancreas) do not function properly. Metabolic disorders may be congenital (e.g., cystic fibrosis, sickle-cell anemia, Tay–Sachs disease) or acquired (e.g., some cases of nonalcoholic fatty liver disease).

metabolic encephalopathy a form of ENCEPHALOPATHY arising from a metabolic disorder. Also called toxic-metabolic encephalopathy.

metabolic equivalent (symbol: MET) a unit of measurement of heat, or energy, produced by the body: 1 MET = 50 kcal/h/m² body surface. MET units are used to assess the expenditure of oxygen in a given activity; for example, 1 MET indicates that the body is at rest. 3 to 5 units would indicate light work, and more than 9 units indicates heavy work.

metabolic–nutritional model a system of studying mental disorders in which the emphasis is on long-term assessments of the influence of such factors as toxins and deprivations in populations.

metabolic rate the rate of use of energy of an organism during a given period. It is measured in kilojoules or kilocalories per day. See also BASAL METABOLISM.

metabolic screening examination procedures used in predicting or diagnosing a possible INBORN ERROR OF METABOLISM (e.g., phenylketonuria). The procedures include routine blood tests for newborns, GENETIC COUNSELING of parents with known familial metabolic deficiencies, and AMNIOCENTESIS.

metabolic syndrome a collection of conditions that increases an individual’s risk for cardiovascular disease, stroke, and Type 2 diabetes. These include hypertension, elevated insulin levels, nonalcoholic fatty liver disease, and obesity. Metabolic syndrome may be congenital, acquired, or both.

metabolic tolerance see PHARMACODYNAMIC TOLERANCE.

metabolism n. the physical and chemical processes within a living cell or organism that are necessary to maintain life. It includes CATABOLISM, the breaking down of complex molecules into simpler ones, often with the release of energy; and ANABOLISM, the synthesis of complex molecules from simple ones. See also BASAL METABOLISM; CARBOHYDRATE METABOLISM; FAT METABOLISM; PROTEIN METABOLISM. [term coined by German physiologist Theodor Schwann (1810–1882)] —metabolic adj.

metabolite n. a substance necessary for, involved in, or produced by METABOLISM.

metabotropic receptor a neurotransmitter RECEPTOR that does not itself contain an ION CHANNEL but may use a G PROTEIN to open a nearby ion channel. See GLUTAMATE RECEPTOR. Compare IONOTROPIC RECEPTOR.

metachromatic leukodystrophy an autosomal recessive disorder (see RECESSIVE ALLELE) characterized by deficiency or absence of the enzyme arylsulfatase A, which results in loss of myelin in the nervous system and accu-
mulation of cerebroside sulfate (a type of myelin lipid) within the white matter of the central nervous system. Loss of motor function and deterioration in mental ability most commonly develop after the 1st year of life (late infantile form), but symptoms may also appear between 3 and 10 years of age (juvenile form) or around age 30 (adult form).

**metacognition** *n.* awareness of one’s own cognitive processes, often involving a conscious attempt to control them. The *tip-of-the-tongue phenomenon*, in which one struggles to retrieve something that one knows one knows, provides an interesting and common example of metacognition. —**metacognitive** adj.

**metacognitive model of attitudes (MCM)** a model postulating that people associate an **attitude object** not only with positive and negative evaluations but also with true or false assessments known as **validity tags**. The model proposes that responses to deliberative attitude measures (i.e., **explicit attitude measures**) are influenced by these tags, whereas responses to nondeliberative attitude measures (i.e., **implicit attitude measures**) are relatively uninfluenced by them. [proposed by U.S. psychologist Richard E. Petty (1951– ). Spanish psychologist Pablo Brinol, and U.S. psychologist Kenneth G. DeMarree]

**metacomunication** *n.* auxiliary or covert messages, usually conveyed in the form of subtle gestures, movements, and facial expressions, about the procedural aspects or the dynamics (rather than the actual content) of communication between two or more parties. For example, a manager may respond to an employee’s request for help by looking annoyed, thus indicating displeasure that the employee could not handle the situation alone.

**metacontrast** *n.* a form of backward masking in which the perception of a visible stimulus (the target) is altered by the subsequent presentation of a second visual stimulus (the mask) in a different spatial location. The target is often a small dot, while the mask is a ring that surrounds it. Each stimulus is presented very briefly (10–100 ms), at intervals that are varied systematically, and the quality of the target’s percept is measured. Compare **paracontrast**.

**metacriterion** *n.* a suggested criterion, proposed by Hungarian-born philosopher Imre Lakatos (1922–1974), for evaluating competing understandings of science. Lakatos derived his metacriterion from the use of similar criteria in the evaluation of competing philosophical theories and proposed it as an alternative to both the Falsificationism of Austrian-born British philosopher Karl Popper (1902–1994) and the historical theories of science of U.S. philosopher Thomas Kuhn (1922–1996). According to the metacriterion, a theory of science should be preferred to its competitors if it (a) makes more rational sense of the history of scientific practice and findings and (b) can be shown to lead to the discovery of more novel historical facts.

**Metadata** *n.* a trade name for **methylphenidate**.

**metaemotion** *n.* one’s awareness of and attitude toward one’s own and others’ emotions. For example, some people have negative attitudes toward anger in themselves or anyone else; others like to encourage anger. Some are ashamed of being too happy; others strive for such a state.

**metaesthetic range** the range of weak pain sensations just below the level of obvious, unmistakable pain.

**metaethics** *n.* see **ethics**.

**metaevaluation** *n.* in evaluation research, an attempt to make judgments on the worth of an evaluation process with regard to its value and usefulness and its reliance on accepted evaluation standards. This involves a systematic evaluation that focuses on assessing methodological rigor, utility, cost, relevance, scope, importance, credibility, timeliness, and pervasiveness of dissemination.

**metagnomy** *n.* the divination of knowledge of the past or present by means other than the five senses, such as **extraneous perception**.

**metalanguage** *n.* 1. a language or set of symbols that is used to describe another language or set of symbols. Examples are English words used in teaching a foreign language, the instructions that accompany a computer program, and the use of mathematical symbols to analyze the logic of an argument (see **symbolic logic**). Also called **second-order language**. 2. any use of language to discuss or analyze language, as in formal linguistic study, literary criticism, or the attempts of speakers to make sure that they understand one another correctly (e.g., “When you said the book was unreadable, were you referring to the print quality or the author’s style?”). (The *metalanguage* here refers to the language used to discuss the language used to discuss the book.)

**metalinguistic awareness** a conscious awareness of the formal properties of language as well as its functional and semantic properties. It is associated with a mature stage in language and metacognitive development (see **metacognition**) and does not usually develop until around age 8. The arrival of metalinguistic awareness is often signaled by an interest in **puns** and word games. Also called **linguistic awareness**.

**metamemory** *n.* awareness of one’s own memory processes, often involving a conscious attempt to direct or control them. It is an aspect of **metacognition**.

**metamorphosis** *n.* a change in form or structure, typically from one developmental stage to another. See also **sexual metamorphosis**. —**metamorphose** vb.

**metamotivation** *n.* in the humanistic psychology of Abraham Maslow, those motives that propel an individual toward “character growth, character expression, maturation, and development,” operating on the level of **self-actualization** and transcendence in the hierarchy of needs (see Maslow’s **motivational hierarchy**). In Maslow’s view, metamotivation is distinct from the motivation operating in the lower level needs, which he calls **deficiency motivation**, and it emerges after the lower needs are satisfied. Also called **being motivation**: B-motivation; **growth motivation**. See also Maslow’s **theory of human motivation**.

**metaneed** *n.* in the humanistic psychology of Abraham Maslow, the highest level of need that comes into play primarily after the lower level needs have been met. Metaneeds constitute the goals of self-actualizers and include the needs for knowledge, beauty, and creativity. In Maslow’s view, the inability to fulfill them results in **metaanalysis**. Also called **being value**: B-value. See also Maslow’s **motivational hierarchy**; Maslow’s **theory of human motivation**.
metaphysics n. the branch of philosophy that deals with the question of the nature of ultimate reality; as such, it is considered to be the most abstract and speculative branch of philosophy. Metaphysics was the founding project of Greek philosophy and thus of the Western intellectual tradition as a whole. The term derives from the Greek, meaning "above (or beyond) the physical." Early metaphysical philosophy most notably that of PLATO, suggested a reality above the physical world that accounts for and gives rise to physical reality (see PLATONIC IDEALISM). Later metaphysical conceptions have emphasized, as the ultimate foundation of reality, constructs as varied as mind, spirit, abstract principles, and physical matter. Since the time of René DESCARTES, the main focus of Western philosophy has shifted from metaphysics to EPistemology, the study of the nature and limitations of knowledge; this shift is largely owing to a recognition that meaningful answers to questions of ultimate reality depend upon the working out of criteria (an epistemology) by which such answers can be judged as true. Nevertheless, any scholarly discipline, including psychology, that makes a claim of discovering or explaining the ultimate nature or origin of a phenomenon may be said to be engaged in metaphysics. —metaphys-
cal adj.

metapsychics n. 1. the study of purported mental phenomena and abilities that are beyond the limits of orthodox psychological understanding, such as TELEPATHY and the survival of the human psyche after death. The term has now generally been superseded byparapsychology. 2. people who are or appear to be exceptionally gifted in one or more paranormal abilities. See PSYCHIC.

metapsychological profile in psychoanalysis, a systematic profile of a patient’s intrapsychic functioning, in contrast to a mere list of symptoms; such a profile offers a picture of his or her entire personality. The technique was developed by Anna FREUD in 1965.

metapsychology n. the study of, or a concern for, the fundamental underlying principles of any psychology. The term was used by Sigmund FREUD to denote his own psychological theory, emphasizing its ability to offer comprehensive explanations of psychological phenomena on a fundamental level. Freud’s criteria for a metapsychology were that it should explain a psychical phenomenon in terms of (a) its dynamics, (b) its topology, and (c) its economic aspects. Although these specific criteria apply most clearly to Freud’s own theory, the notion of metapsychology as explanation at a fundamental and comprehensive level continues to be a useful construct. —metapsycho-
logical adj.

metastasis n. see CANCER.

metatheory n. a higher order theory about theories, allowing one to analyze, compare, and evaluate competing bodies of ideas. The concept of a metatheory suggests that theories derive from other theories, so that there are always prior theoretical assumptions and commitments behind any theoretical formulation. It follows that these prior assumptions and commitments are worthy of study in their own right, and an understanding of them is essential to a full understanding of derivative theories. —metatheoretical adj.

metathetic adj. 1. denoting a stimulus dimension in which a change of magnitude can cause a qualitative change in the psychological experience produced. For example, a faint smell may be quite pleasing, whereas an increase in intensity may cause revulsion. Compare PROTHETIC. 2. relating to a change in place or condition, particularly the transposition of two PHONEMES in a word or the exchange of elements between chemical compounds to create different kinds of compounds. —metathesis n.

metaworry n. 1. persistent worry about one’s own thoughts and cognitive processes. 2. a negative metacognitive process in which one worries about one’s own worrying and about its potentially harmful effects on oneself. According to British psychologist Adrian Wells, who first described this process in 1994, it contributes to the development of GENERALIZED ANXIETY DISORDER.

metempirical adj. describing or pertaining to knowledge that is not subject to verification by experience and thus cannot be established by the methods of science. As described by British writer George Henry Lewes (1817–1878), the metempirical is roughly equivalent to the notion of the transcendent developed by German philosopher Immanuel KANT (see noumenon; TRANSCENDENCE). metempsychosis n. transmigration of the soul, whereby upon death a soul takes up residence in another body, human or animal. The belief is inherent in the doctrine of samsara, the cycle of birth, life, death, and rebirth, that is central to HINDUISM and BUDDHISM. An important and unanswerable issue attends the doctrine: the extent to which the reincarnated soul retains its memories and personality. In the ancient Western world, a similar belief in multiple lives was taught by Greek philosophers Pythago-
ras (c. 569–c. 475 BCE) and Empedocles (c. 493–c. 453 BCE). See also REINCARNATION.

metencephalon n. the portion of the BRAINSTEM that includes the PONS and CEREBELIUM. With the medulla ob-
longata, the metencephalon forms the HINDBRAIN. —met-
encephalic adj.

meth n. slang for METHAMPHETAMINE.

methadone n. a synthetic OPIOID ANALGESIC that is used for pain relief and as a substitute for heroin and other opioids in METHADONE MAINTENANCE THERAPY. It is quite effective when orally ingested and has a long duration of action, both preventing withdrawal symptoms and blocking the reinforcing effects of these opioids. U.S. trade name (among others): Dolophine.
methadone maintenance therapy, a drug-rehabilitation therapy in which those with dependence on heroin and other opiates are prescribed a daily oral dose of methadone to blunt craving for these drugs and to diminish withdrawal symptoms. A controversial treatment, it is nonetheless widely considered the most effective approach to heroin addiction. The use of an opioid partial agonist, BUPRENORPHINE, particularly in combination with NALOXONE, is increasing as an alternative to methadone maintenance therapy.

methamphetamine n. A CNS STIMULANT whose chemical structure is similar to that of amphetamine. It is used for treating attention-deficit/hyperactivity disorder in children and as a short-term aid to obesity treatment in adults. Like all AMPHETAMINES, methamphetamine is prone to abuse and dependence. It can be smoked, snorted, ingested orally, or injected. After the initial rush—it increases activity levels and induces a general sense of well-being—a state of high agitation that can lead to violence is experienced by some users. Long-term abuse is associated with nerve damage and behavioral and mental status changes, including psychosis. U.S. trade name: Desoxyn.

methaqualone n. A synthetic drug with sedative and hypnotic effects, unrelated chemically to other sedatives and having a potency roughly equal to that of PENTOBARBITAL. It is used to treat patients who are unable to tolerate barbiturate drugs. In small doses, the drug depresses the sensory cortex; in larger doses, it affects the spinal reflexes. Its clinical use peaked during the 1960s and 1970s, but due to its potential for abuse—it became a popular recreational drug (street name: lude)—it was classified as a Schedule I controlled substance in 1984, which ended its legal availability in the United States. Trade name (among others): Quaalude. See SEDATIVE, HYPNOTIC, AND ANXIOLYTIC DRUG.

methocarbamol n. A member of a group of centrally acting MUSCLE RELAXANTS used as an adjunctive agent in the management of musculoskeletal pain. Because methocarbamol does not directly reduce skeletal muscle tension, its therapeutic action is thought to be due to its sedative or CNS DEPRESSANT properties. It is available in tablet and injectable forms. U.S. trade name: Robaxin.

method of absolute judgment a psychophysical procedure in which stimuli are presented in random order to a participant, whose task is to place each stimulus in a particular category. The stimuli usually vary along one or two dimensions, such as brightness or loudness. Also called absolute-judgment method.

method of adjustment a psychophysical technique in which the participant adjusts a variable stimulus to match a constant or standard. For example, the observer is shown a standard visual stimulus of a specific intensity and is asked to adjust a comparison stimulus to match the brightness of the standard. Also called adjustment method: error method; method of average error; method of equivalents.

method of agreement and difference the third of the five canons of empirical science laid down by John Stuart MILL. It enables the discovery of necessary and sufficient conditions for a phenomenon by combining the first two of MILL’S CANONS: the METHOD OF AGREEMENT and the METHOD OF DIFFERENCE.

method of average error see METHOD OF ADJUSTMENT.

method of choice a psychophysical procedure in which the participant is presented with several arrays of stimuli, one of which contains the target stimulus. The participant’s task is to choose the array that contains the target stimulus.

method of concomitant variation the fifth of the five canons of empirical science laid down by John Stuart MILL. It is meant to establish the causal relationship between phenomena. It holds that if there is a functional relationship between a condition C1 and an effect E1. It may be inferred that there is a causal relationship between one or more of the elements that make up C1 and the resultant E1. Which element of C1 is causal can be established by implementing the rest of MILL’S CANONS. This strategy is essentially the foundation of modern approaches to experimentation in psychology and is directly related to the problems of inferring causality from correlation.

method of constant adjustment see METHOD OF LIMITS.

method of constant stimuli a psychophysical procedure for determining the sensory threshold by randomly presenting several stimuli known to be close to the threshold. The threshold is the stimulus value that was detected 50% of the time. Also called constant stimulus method: method of right and wrong cases. See also METHOD OF LIMITS.

method of difference the second of the five canons of empirical science laid down by John Stuart MILL. It is meant to establish sufficient conditions for a phenomenon. For example, if under one condition, C1, an effect, E1, does not occur, and as C1 is changed to C2 the effect E1 does occur, it may be concluded that C2 is a sufficient cause of E1. The method of difference is applied when it is known that the effect E1 occurs on all conditions of C1 and on none of C2, and the cause E1 is eliminated. Thus, the effect is attributed to the “difference” between conditions C1 and C2. Also called difference canon.

method of equal and unequal cases in psychophysics, a variation of the METHOD OF CONSTANT STIMULI requiring judgment of paired stimuli as equal or unequal.

method of equal-appearing intervals in psychophysics, a procedure in which magnitudes between pairs of stimuli are adjusted so that the differences between stimuli within each pair are perceived as equal. Also called method of equal sense differences; method of mean gradations.

method of equivalents see METHOD OF ADJUSTMENT.

method of exclusion a principle by which empirical observation can eliminate (or exclude) possible causes for a phenomenon and thereby reach conclusions about the true cause. The principle is attributed to Francis BACON, who proposed an inductive method (see INDUCTION) in which the observer lists both positive and negative instances of a phenomenon and then attempts to infer a common factor that is present in the positive instances and absent in the negative instances. Thus, the cause of the phenomenon is established by a method of exclusion of
method of just noticeable differences  a psychophysical procedure to determine the smallest difference between stimuli that can be perceived. A standard stimulus is presented together with a variable stimulus whose magnitude is increased in some trials and decreased in others until a just perceptible difference between the stimuli is reported. The average of the two series is taken, and the threshold is calculated as the point where the difference can be recognized 50% of the time. Also called method of serial exploration.

method of limits  a psychophysical procedure for determining the sensory threshold by gradually increasing or decreasing the magnitude of the stimulus presented in discrete steps. That is, a stimulus of a given intensity is presented to a participant; if it is perceived, a stimulus of lower intensity is presented on the next trial, until the stimulus can no longer be detected. If it is not perceived, a stimulus of higher intensity is presented, until the stimulus is detected. The threshold is the average of the stimulus values at which there is a detection-response transition (from yes to no, or vice versa). An alternative procedure, the method of constant adjustment, allows the participant to adjust a stimulus continuously until it can no longer be perceived. See also METHOD OF CONSTANT STIMULI.

method of loci  a mnemonic technique in which the items to be remembered are converted into mental images and associated with specific positions or locations. For instance, to remember a shopping list, each product could be imagined at a different location along a familiar street.

method of moments  an alternative to maximum likelihood estimation in which values describing basic characteristics of a sample (known as moments) are used to approximate the corresponding values for the larger population. For example, a researcher could use the method of moments to estimate the mean or variance for a population by inserting the appropriate sample value into an equation that calculates one from the other. Although simpler than maximum likelihood, the method of moments is less accurate.

method of opposition  see process-dissociation procedure.

method of ratio estimation  a psychophysical procedure in which two stimuli of different intensity are presented, and the observer estimates the ratio of the perceived intensities.

method of residues  the fourth of the five canons of empirical science laid down by John Stuart Mill. It is meant to establish sufficient conditions for a phenomenon through the elimination of alternative potential causes on the basis of previous experiments or already known laws. For example, if the phenomena E1 and E2 occur together having antecedents C1 and C2, and if it is known by prior research or established law that C1 cannot cause E2 but causes E1, one may conclude that C2 is the cause of E2. Also called residue method.

method of right and wrong cases  see method of constant stimuli.

method of selective adaptation  a psychophysical procedure in which repeated exposure to a stimulus produces sensory adaptation that influences perception of a subsequent stimulus.

method of serial exploration  see method of just noticeable differences.

method of single stimuli  any psychophysical procedure in which items in a series are presented one at a time, and the participant is required to respond to each in the absence of any comparison point or standard.

method of successive approximations  a method of shaping operant behavior by reinforcing responses similar to the desired behavior. Initially, responses roughly approximating the desired behavior are reinforced. Later, only responses closely approximating the desired behavior are reinforced. The process gradually leads to the desired behavior. Also called successive-approximations method.

method of successive intervals  a psychophysical procedure in which respondents place stimuli into categories defined by their diminishing degree of possession of an attribute. Thus, the first category would contain all stimuli judged to have the most of the attribute, the second category would contain those stimuli judged to have slightly less of the attribute, and so forth.

method of triads  any psychophysical procedure in which three stimuli are presented, and the observer must choose one of the three based on some property (e.g., its dissimilarity from the other two).

methodological behaviorism  a form of behaviorism that concedes the existence and reality of conscious events but contends that the only suitable means of studying them scientifically is via their expression in behavior. Compare radical behaviorism. See neobehaviorism.

methodological individualism  a theory that emphasizes the importance of each person in determining his or her own circumstances and minimizes any possible influence from larger societal groups or structures. For example, a researcher who endorsed methodological individualism would be less apt to consider how socioeconomic status might contribute to the level of achievement for a sample of individuals, preferring instead to investigate variables believed to be under each person’s control, such as motivation, determination, or ability.

methodological objectivism versus methodological subjectivism  a prescriptive dimension along which psychological theories can be evaluated. Methodological objectivism is the position that methods of investigation can be, and should be able to be, repeated and verified by another investigator. Methodological subjectivism is the position that methods cannot be repeated and thus cannot be verified by another. See also CONTENTUAL OBJECTIVISM versus CONTENTUAL SUBJECTIVISM. [introduced by U.S. psychologist Robert L. Watson (1909–1980)]

methodological pluralism  the belief that various approaches to conducting research, qualitative and quantitative, each have their respective strengths and weaknesses such that no one method is inherently superior to any other and no single method is best overall.

methodological solipsism  the adoption of solipsism as a philosophical position because of the belief that no other position is tenable.

methodological triangulation  the use of multiple quantitative and qualitative procedures to collect data so as to generate converging evidence on the topic of study. For example, a researcher studying alcohol consumption
might employ methodological triangulation by measuring participants’ blood alcohol levels, collecting self-reports on quantity of alcohol consumed, and obtaining input from peers on quantity of alcohol consumed.

**methodology** n. 1. the science of method or orderly arrangement; specifically, the branch of logic concerned with the application of the principles of reasoning to scientific and philosophical inquiry. 2. the system of methods, principles, and rules of procedure used within a particular discipline. For example, in research and experimental design the term refers to the techniques used to collect information, and in statistics it refers to the procedures used to analyze such data.

**methods analysis** in ergonomics, the development of improved ways of performing a task, through analysis of the particular operation and its component tasks, techniques, factors, and resources. This typically involves use of process charts and micromotion studies and application of the principles of motion economy. See also task analysis.

**methotrimeprazine** n. a low-potency antipsychotic of the aliphatic phenothiazine class. In the United States, it is currently used only for the treatment of pain. Also called levomepromazine. U.S. trade name: Levoprome.

**metoxyhydroxyphenylglycol** (MHPG) n. a product of the synthesis in vitro of endogenous epinephrine and norepinephrine levels. MHPG is found in the brain, blood, cerebrospinal fluid, and urine; its concentration reflects catecholamine levels.

**methyldopa** n. a drug used for treating hypertension. It acts as an agonist at alpha-adrenergic receptors in brainstem centers that control the vascular system. When stimulated by methyldopa, these receptors, which act via norepinephrine levels, stimulate the release of catecholamines from the sympathetic nervous system and elevate blood pressure. U.S. trade name: Aldomet.

3,4-methylenedioxymethamphetamine **n.** see MDA.

3,4-methylenedioxamphetamine **n.** see MDMA.

**methylphenidate** n. a stimulant related to the amphetamine and with a similar mechanism of action. It is an indirect agonist of dopamine neurotransmission, blocking the reuptake of catecholamines from the synaptic cleft and stimulating presynaptic release of norepinephrine. Unlike amphetamine, methylphenidate is more potent as a reuptake blocker than as a releasing agent. Methylphenidate is used as an adjunct to antidepressant therapy and to increase concentration and alertness in patients with brain injuries, brain cancer, or dementia. It is approved by the U.S. Food and Drug Administration for the treatment of attention-deficit/hyperactivity disorder (ADHD) and narcolepsy in both children and adults. In children with ADHD, methylphenidate increases attention and decreases impulsivity and physical overactivity, leading to improvement in academic and social functioning, at least while the drug is being administered. Potential long-term side effects include growth suppression, which may occur at least transiently in some children taking these drugs. It is not recommended to use methylphenidate or other stimulants in children without concurrent behavioral therapy or counseling. Methylphenidate has been used off-label by students and long-haul drivers to enhance attention and decrease fatigue. It is classified by the U.S. Drug Enforcement Administration as a Schedule II controlled substance (see scheduled drug). U.S. trade names (among others): Concerta; Metadate; Ritalin.

**methylphenyl-tetrahydrodropyrindine** n. see MPTP.

**methylxanthine** n. any of a group of methylated derivatives of xanthenes (stimulant plant alkaloids) with similar pharmacological actions. The most common are caffeine (1,3,7-trimethylxanthine), the active ingredient in coffee; theobromine (1,3,7-trimethylxanthine), the active ingredient in cocoa; and theophylline (1,3-dimethylxanthine), the active ingredient in tea. At low doses, methylxanthines cause CNS stimulation and arousal; at high doses, anxiety, agitation, and coma may result. Methylxanthines also relax bronchial muscles: Some (e.g., theophylline) have been used in the medical management of reactive airway disease, although they have now largely been supplanted by newer agents.

**methysergide** n. an ergot derivative used in the treatment of migraine headaches. It reduces the frequency and intensity of migraine attacks in most individuals and is thought to act by opposing the action of serotonin (see serotonin antagonist). Methysergide is closely related to LSD and has similar effects at some tissue sites. Side effects of methysergide include light-headedness or dizziness, nausea or vomiting, euphoria, insomnia, and unsteadiness. U.S. trade name: Sansert.

**metonymy** n. 1. a figure of speech in which not the literal word but one associated with it is used, as the sword for war. Synecdoche is the form of metonymy in which a whole is represented by a part or vice versa, as in referring to a laborer as a hand or a police officer as the police. 2. in speech pathology, a disturbance in which imprecise or inappropriate words and expressions are used. —metonymic adj.

**metrazol shock treatment** a form of shock therapy involving the intravenous injection of Metrazol, a trade name for pentylentetrazol, a powerful CNS stimulant that induces convulsions and coma. Because the incidence of mortality from this procedure was high, it was discontinued in the 1940s. Also called Metrazol therapy. Metrazol treatment. [introduced in 1934 by Hungarian psychiatrist Ladislas von Meduna (1896–1964)].

**metric** n. a scale or system used to express amount or quantity. For example, the Fahrenheit scale is a metric for assessing temperature and the system of IQ points is a metric for assessing intelligence.

**metronomic pacing** a technique of auditory feedback to improve speaking performance, in which a portable device containing an electronic metronome is typically set between 50 and 150 beats per minute and the speaker receives pacing feedback through headphones as he or she speaks. Among those who benefit most are stutterers and those with motor speech disorders.

**Meyer’s loop** see optic radiations. [Adolf Meyer]

**Meyer’s theory** the theory proposed by Adolf Meyer that mental disorders result from behavior patterns that develop as faulty responses to specific situations. He advocated a holistic approach (see psychobiology) to diagnosis and treatment of mental disorders.

**Meynert’s nucleus** see basal nucleus of Meynert. [Theodor Il. Meynert (1833–1892), Austrian neurologist]

**MFF** abbreviation for matching familiar figures test.

**MHA** abbreviation for mental health america.
MHC abbreviation for MAJOR HISTOCOMPATIBILITY COMPLEX.

MHPG abbreviation for METHOXYPHENYLGLYCINE.

MHV abbreviation for MILL HILL VOCABULARY SCALE.

mianserin n. an antidepressant with a mechanism of action similar to that of the related compound MIRTAZAPINE. Mianserin is marketed in several countries (e.g., under the trade name "Tolvon") but not in the United States.

Michelangelo phenomenon a process in which relationship partners support each other’s efforts toward achieving personally desired goals and particularly toward attaining an IDEAL SELF. Because committed partners must reconcile their personal goals with the needs and goals of their partners, partner encouragement or discouragement represents an important factor in how a person pursues a goal, as well as the likelihood of its attainment. [first identified in a 1999 article, “Close Partner as Sculptor of the Ideal Self,” by U.S. social psychologists Stephen M. Drigotas (1966—), Caryl E. Rusbult (1952–2010), and colleagues; their coinage refers to the artist Michelangelo’s description of his sculptural work as releasing the beautiful form already present in a block of marble].

Michigan Alcoholism Screening Test (MAST) a widely used measure designed to provide a rapid screening for problematic alcohol consumption, alcohol abuse, and alcoholism. It comprises 25 yes-no questions, such as “Do you ever feel guilty about your drinking?” or “Are you able for problematic alcohol consumption, alcohol abuse, and other chromosomal syndromes; neurometabolic syndromes; maternal PkU; and prenatal exposure to drugs or alcohol, cytomegalovirus, rubella (German measles), varicella (chicken pox) virus, and certain toxic chemicals. Depending on the severity of their accompanying syndrome, children with microcephaly may have intellectual disability, delayed motor functions and speech, facial distortions, dwarfism or short stature, hyperactivity, seizures, difficulties with coordination and balance, and other brain or neurological abnormalities. Some children with microcephaly will have normal intelligence and a head that will grow bigger, although it will still be below the normal growth curves for head circumference. See also PRIMARY MICROCEPHALY. Compare MACROCEPHALY. —microcephalic adj.

microcounseling n. a concentrated training approach originally designed to teach basic counseling skills to trainees in the helping professions (e.g., counseling, clinical psychology). Trainees apply specific, single skills (e.g., attending behavior, basic listening) in 5-minute videotaped sessions with volunteer clients, then view the video while receiving didactic instruction and feedback from a trainer, and then undergo a second round of videotaped skills application and subsequent review and instruction. The approach became a formal training program in the 1960s, founded on several principles, among them OBSERVATIONAL LEARNING and REHEARSAL. It has since evolved to become a professional training paradigm for teaching techniques in specific types of therapies (e.g., cognitive behavior therapy, multicultural therapy), a conceptual framework for understanding the counseling process itself, and a method for teaching effective communication skills directly to clients (e.g., in CONJUNCT THERAPY). Also called microteaching: microtraining. [developed by U.S. counseling psychologist Allen E. Ivey (1933—)].

microdata pl. n. 1. scores or other information collected on individual participants or units. In many research studies, microdata are consolidated into total scores, scale scores, or summary statistics known as AGGREGATE DATA. 2. terms or codes used to elucidate the content of webpages, particularly ones based on hypertext markup language (HTML). Microdata help search engines identify webpage information relevant to the topic of interest and present it to users.

microdialysis n. a method for measuring the concentration of chemicals in a tissue or organ (e.g., a small region of brain) by allowing the chemicals to pass through a membrane into a small tube implanted in the interstitial space.

microelectrode n. an electrode with a tip no larger than a few micrometers in diameter that can be inserted into a single cell. In the microelectrode technique, used in studies of neurophysiology and disorders of the nervous system, intracellular microelectrodes with tips less than 1 μm in diameter are able to stimulate and record activity within a single neuron (single-cell or single-unit recording). Compare MACROELECTRODE.

microergonomics n. an approach to ERGONOMICS that focuses on the detailed examination of individual operator–machine interfaces or combinations. Compare MACROERGONOMICS.

microfilament n. a very small protein filament (7 nm in diameter) found within all cells. Microfilaments are key components of the cell’s internal scaffolding (cytoskeleton) and help to determine cell shape.

microgenetic development the series of changes that occur over relatively brief periods of time—in seconds,
minutes, or days—as distinct from the larger scale changes that are conventionally studied in ontogenetic development (see ONTOGENY). [postulated by Lev Vygotsky in his sociocultural theory]

**microgenetic method** a research methodology for studying cognitive developmental change, involving (a) observations of individual children throughout a period of change, (b) a high density of observations relative to the rate of change within that period, and (c) intensive trial-by-trial analyses intended to infer the processes that gave rise to the change. [developed by U.S. developmental psychologist Robert S. Siegler (1949– )]

**microgia** n. an extremely small type of nonneuronal central nervous system cell (GLIA) that removes cellular debris from injured or dead cells. —microglial adj.

**microgliosis** n. the condition of having an abnormally small tongue. Although relatively rare, the condition may occur during prenatal development and result in speech that sounds muffled.

**micrographia** n. a disorder characterized by very small, often unreadable writing and associated most often with PARKINSON’S DISEASE.

**micromastia** n. abnormally small size of one or both testicles, as in KLINEFELTER’S SYNDROME. Also called microorchidism.

**microphonia** n. a disorder characterized by extremely small tongue. Although relatively rare, the condition may occur during prenatal development and result in speech that sounds muffled.

**micrographia** n. a disorder characterized by very small, often unreadable writing and associated most often with PARKINSON’S DISEASE.

**micromastia** n. abnormally small size of one or both testicles, as in KLINEFELTER’S SYNDROME. Also called microorchidism.

**microphonia** n. see HYPOPHONIA.

**micropolygyria** n. see LISENCEPHALY.

**micropsia** n. a VISUAL ILLUSION in which an object appears to be smaller than it is in reality. See also METAMORPHOPSIA. Compare MACROPSIA.

**micropsychosis** n. psychotic episodes of very brief duration (minutes to hours) that occur during times of stress. Micropsychoses have been observed primarily in BORDERLINE PERSONALITY DISORDER and PSEUDONEUROTIC SCHIZOPHRENIA, although the latter is no longer a valid diagnostic entity.

**micropolygyria** n. see LISENCEPHALY.

**micropsia** n. a VISUAL ILLUSION in which an object appears to be smaller than it is in reality. See also METAMORPHOPSIA. Compare MACROPSIA.

**micropsychosis** n. psychotic episodes of very brief duration (minutes to hours) that occur during times of stress. Micropsychoses have been observed primarily in BORDERLINE PERSONALITY DISORDER and PSEUDONEUROTIC SCHIZOPHRENIA, although the latter is no longer a valid diagnostic entity.

**micropolygyria** n. see LISENCEPHALY.

**micropsia** n. a VISUAL ILLUSION in which an object appears to be smaller than it is in reality. See also METAMORPHOPSIA. Compare MACROPSIA.

**micropsychosis** n. psychotic episodes of very brief duration (minutes to hours) that occur during times of stress. Micropsychoses have been observed primarily in BORDERLINE PERSONALITY DISORDER and PSEUDONEUROTIC SCHIZOPHRENIA, although the latter is no longer a valid diagnostic entity.

**microptic hallucination** see LILIPUTIAN HALLUCINATION.

**microsaccades** pl. n. small rapid eye movements that occur during attempted fixation of a target and cease when fixation is achieved.

**microscopic level** an investigatory approach that focuses on the smallest recognizable units of analysis. Microscopic psychology is sometimes associated with physiologically cellular level of analysis.

**microsleep** n. a momentary loss of awareness when a person is fatigued or sleep-deprived, especially during monotonous tasks, such as driving, looking at a computer, or passively monitoring machinery. Microsleep episodes may be noticed when the head literally drops forward and can last from less than 1 second to minutes. They are more likely to occur in the predawn and midafternoon hours and can be a major risk factor for traffic and industrial accidents.

**microsomia** n. see HYPOSOMIA.

**microsocial engineering** a technique of conflict resolution among family members in which a BEHAVIOR CON-
midpoint

midrange n. the average of the lowest and highest scores in a set of data. The midrange is a measure of central tendency more prone to bias than the mean, median, and mode because it relies solely upon the two most extreme scores, which potentially are outliers. For example, consider the following hours per week spent using a computer for five individuals: 6, 10, 15, 21, and 35. The midrange is 20.5, the mean is 17.4, and the median is 15. The midrange score thus is larger than the mean or median due to the influence of the outlier of 35 hours.

midspread n. see interquartile range.

midwife n. a professionally trained and licensed health care provider of primary medical services for women, including perinatal (prenatal, delivery, and postpartum) care for pregnant women and new mothers and most family planning and gynecological services for healthy women of all ages. Midwives work together with obstetrics and gynecology (OB/GYN) doctors. They either consult with or refer to other health care providers in cases that are outside of their expertise (e.g., high-risk pregnancies, pregnant women with a chronic illness). Compare doula. —mid-wifery n.

Mignon delusion a variation of the family-romance fantasy in which children believe that their parents are actually foster parents and their own families are of distinguished lineage. The name is derived from the child character in the novel Wilhelm Meister’s Apprenticeship (1796) by Johann Wolfgang von Goethe (1749–1832).

migraine headache a headache that is recurrent, usually severe, usually limited to one side of the head, and likely to be accompanied by nausea, vomiting, and photophobia. Migraine headaches may be preceded by an aura of flickering or flashing light, blacking out of part of the visual field, or illusions of colors or patterns. They are much more common in women than in men. Also called sick headache.

Migranal a trade name for dihydroergotamine.

migration n. 1. travel by nonhuman animals over relatively long distances to or from breeding areas. Migration is observed in birds, fish, and some mammals and insects (among others). In some species, it is seasonal, involving movement from a breeding area to an overwintering area; in others, particularly the salmon, it is observed only once in the lifetime of an individual. Factors influencing migratory behavior include chemical cues, pituitary or other hormones, relative change in day length, and temperature. See also migratory restlessness. Navigation. 2. in the development of the nervous system, the movement of nerve cells from their origin in the ventricular zone to establish distinctive cell populations, such as brain nuclei and layers of the cerebral cortex.

migratory restlessness increased activity that occurs prior to the period of migration. Migratory restlessness in captive animals is an index of responsiveness to cues indicating annual cycles. Also called Zugunruhe.

MII abbreviation for müllerian-inhibiting hormone.

mild cognitive impairment (MCI) a decline in cognitive function that is small but detectable and that represents a transitional condition between the cognitive changes typically associated with normal aging and those changes that meet the criteria for dementia. One or more
cognitive domains may be impaired but not significantly enough to affect everyday functioning. At least two subtypes of MCI have been identified. One is amnestic MCI, or clinically significant memory loss experienced by individuals whose other cognitive capacities (e.g., executive function, language use) are largely intact; such individuals are at increased risk for developing dementia due to Alzheimer’s disease. The other subtype, nonamnestic MCI, is characterized by impairments in visuospatial skills, language use, or other cognitive functions besides memory; individuals with this subtype may be at risk for other forms of dementia (e.g., dementia due to Lewy body disease).

mild mental retardation an older diagnostic and classification category applying to those with IQs of 50 to 69, comprising 85% of people with mental retardation. These individuals usually develop good communication skills and reach a sixth-grade level of academic performance in their late teens, but they may not develop beyond the social skill levels typical of adolescents. Usually, they are able to learn life and vocational skills adequate for basic self-support and independent living.

milieu n. (pl. milieux) 1. the environment in general. 2. in psychology and psychiatry, the social environment, especially the atmosphere and character of the home, neighborhood, school, workplace, and so on as they affect the personality and adjustment of the individual.

milieu therapy psychotherapeutic treatment based on modification or manipulation of the client’s life circumstances or immediate environment. Milieu therapy attempts to organize the social and physical setting in which the client lives or is being treated in such a way as to promote healthier, more adaptive cognitions, emotions, and behavior. See also environmental therapy; therapeutic community.

military environment factors that affect human performance in military operations. Performance may be compromised by exposure to extreme weather conditions (ranging from excessive heat to extreme cold); other factors include the effects of clothing and equipment in different environments, motivational and attitudinal factors, acclimatization, the size of the unit involved, and the quality of its leadership.

military officer selection the selection and assessment of military personnel considered suitable to carry the special responsibilities associated with being an officer. The assessment techniques used by applied psychologists involve evaluation of an individual’s academic qualifications, use of psychological instruments in recognized assessment centers, and construct-oriented psychological assessment.

military peacekeeping military operations that, with the consent of the belligerent parties in a conflict, are conducted to maintain a negotiated truce and to facilitate a diplomatic resolution. Peacekeeping operations may include withdrawal and disengagement, ceasefire, prisoner-of-war exchanges, arms control, demilitarization, and demobilization. Military peacekeeping is frequently carried out on a multinational basis.

Military Personnel Management a strategic global framework proposed by the U.S. Department of Defense for achieving an accurate accounting of deployed personnel. It concentrates on identifying and eliminating waste, avoiding duplication, and reducing costs in military establishments.

military psychology the application of psychological principles, theories, and methods to the evaluation, selection, assignment, and training of military personnel, as well as to the design of military equipment. This field of applied psychology also includes the application of clinical and counseling techniques to the maintenance of morale and mental health in military settings and covers human functioning in a variety of environments during times of peace and war.

military stress factors circumstances that potentially affect the number of military personnel that become stress casualties, including the nature of the operation in which they are involved; the intensity of the conflict; the number of battle casualties occurring; and the size, cohesion, and leadership of the unit in which they are serving.

Military Testing Association see international military testing association.

milk letdown reflex in mothers who are nursing, an automatic release of milk from sacs within the mammary glands in response to infant suckling or associated stimuli (e.g., the infant’s cry). The milk letdown reflex is regulated by the hormone oxytocin: Suckling stimulates the production of oxytocin, which in turn stimulates contractions of the smooth muscle myoepithelial cells surrounding the mammary glands, leading to the expulsion of milk from the sacs into ducts that converge on the nipples. The actual production of milk by the mammary glands is regulated by the hormone prolactin. Also called milk ejection reflex.

millenarianism n. 1. belief in the imminent end of human history, to be followed by a thousand-year period of peace and blessedness (often associated with the Second Coming of Christ). Such beliefs were current in the early Christian church and appeared sporadically, primarily from the 11th through the 17th centuries, in periods of political or intellectual crisis and among marginalized groups. Some groups proclaim similar beliefs but without the language and imagery of Christianity. 2. by extension, any belief that rapid and violent change can lead to a golden age of justice and peace. —millenarian adj.

Miller Analogies Test (MAT) a test designed to measure the ability to understand relationships between ideas and to think analytically. It has been used since 1926 to predict scholastic ability at the graduate school level as well as in hiring and promotion decisions in the workplace. The MAT is composed of 120 partial analogies that require knowledge in many different areas, including sciences, literature, the arts, history, and vocabulary. Participants complete the analogies, only 100 of which are scored, by choosing the appropriate answer from among four options. [Wilford Stanton Miller (1883–1960), U.S. psychologist]

Miller–Morrow shuttle box an apparatus for studying escape and avoidance learning. It consists of a straight alley with a guillotine door at its midpoint and a grid floor that can be electrified independently in each half. The experimental animal can avoid the aversive stimulus (an electric shock) by moving to the opposite end of the box but must do so within a given time. [Neal E. Miller and O. Hobart Morrow]

Mill Hill Vocabulary Scale (MHV) a measure of crystallized abilities (see Cattell–Horn theory of intelligence) designed to be administered in conjunction with Raven’s Progressive Matrices. It consists of 88 words and is available in three forms: one requiring participants to define all words, one requiring participants to recognize the meanings of all words by choosing the correct synonym for
Mimicry

Mimicry is the faithful, behavioral, perceptual, and cognitive systems; that phenomena of an organism, encompassing motivational, affective, behavioral, perceptual, and cognitive systems; that is, the organized totality of an organism’s mental and psychical processes and the structural and functional cognitive components on which they depend. The term, however, is also used more narrowly to denote only cognitive activities and functions, such as perceiving, attending, thinking, problem solving, language, learning, and memory. The nature of the relationship between the mind and the body, including the brain and its mechanisms or activities, has been, and continues to be, the subject of much debate. See Mind–Body Problem; Philosophy of Mind.

Mill’s canons

Mill’s canons is a set of five principles of sound experimental science proposed by John Stuart Mill. These principles outline the logical conditions under which observations can establish necessary and sufficient causal relationships between events. Because each of the principles enables the observer to eliminate potential causes, the general approach is often referred to as eliminative induction. Mill’s work in this area is related to both the Method of Exclusion described by Francis Bacon and the work on the logic of causality of David Hume. It also presages the falsificationism of Austrian-born British philosopher Karl Popper (1902–1994). Mill’s five canons are (a) the Method of Agreement, (b) the Method of Difference, (c) the Method of Residues, and (d) the Method of Concomitant Variation.

Milling crowd

Milling crowd is an aggregation of individuals, usually gathered in a public area (e.g., a street or concourse), whose members seem to be moving restlessly or aimlessly about the area.

Millon Clinical Multiaxial Inventory (MCMI) is a true–false questionnaire, consisting of 175 items, that is widely used to assess clinical conditions and personality disorders in psychiatric patients in the United States. First published in 1977, it has been revised twice; the most recent version, MCMI–III, includes 24 scales arranged into four groups: clinical personality patterns, severe personality pathology, clinical syndromes, and severe clinical syndromes. Additionally, there are four corrections scales to help detect random or dishonest responding. Base rate scores are used in interpreting results. [Theodore Millon]

Mindblindness

Mindblindness is a deficit in Theory of Mind that is characteristic of people with autism. A person with mindblindness cannot “read the minds” of others—that is, understand their behavior in terms of belief–desire reasoning. [described by British psychologist Simon Baron-Cohen (1958– )]

Mind-body intervention

Mind-body intervention is a therapeutic approach that focuses on harnessing the power of the mind to bring about change in the body or achieve reduction of symptoms of disease or disorder. The various techniques used include relaxation training (e.g., autogenic training, progressive relaxation), meditation, prayer, and creative arts therapy. See also Complementary and Alternative Medicine.

Mind-body problem

Mind-body problem is the problem of accounting for and describing the relationship between mental and physical processes (psyche and soma). Solutions to this problem fall into six broad categories: (a) Interactionism, in which mind and body are separate processes that nevertheless exert mutual influence (see Cartesian Dualism); (b) Parallelism, in which mind and body are separate processes with a point-to-point correspondence but no causal connection (see Occasionalism; freestanding harmony); (c) Idealism, in which only mind exists and the soma is a function of the psyche; (d) Double-aspect theory, in which body and mind are both functions of a common entity (see Neutral Monism); (e) Epiphenomenalism, in which mind is a by-product of bodily processes; and (f) Materialism, in which body is the only reality and the psyche is nonexistent. Categories (a) and (b) are varieties of Monism. In the context of psychopathology, two central questions arising from the mind–body problem are which sphere takes precedence in the genesis and development of illness and how does each sphere affect the other. Also called body–mind problem.

Mind–brain education (MBE) is Neuroeducation.

Mind control

Mind control is an extreme form of social influence used to indoctrinate an individual in the attitudes and beliefs of a group, usually one that is religious or political in nature. See Brainwashing; Coercive Persuasion.
Minimal intergroup situation

nomic functions, by mental processes. See AUTONOMIC 
TRAINING; BIOFEEDBACK. See also MIND–BODY INTERVENTION.

Mindfulness n. awareness of one’s internal states and 
surroundings. The concept has been applied to various 
therapeutic interventions—for example, mindfulness-
based COGNITIVE BEHAVIOR THERAPY, mindfulness-based 
stress reduction, and MINDFULNESS MEDITATION—to help 
people avoid destructive or automatic habits and responses 
by learning to observe their thoughts, emotions, and other 
present-moment experiences without judging or reacting 
to them. —Mindful adj.

Mindfulness meditation a type of MEDITATION in 
which a person focuses attention on his or her breathing 
and thoughts, feelings, and sensations are experienced 
freely as they arise. Mindfulness meditation is intended to 
enable individuals to become highly attentive to sensory 
information and to focus on each moment as it occurs. See 
also TRANSCENDENTAL MEDITATION. Compare CONCENTRA-
TIVE MEDITATION.

Mind reading a form of alleged EXTRASENSORY PERCEP-
TION in which an individual claims to have access to the 
thoughts of another person. With THOUGHT TRANSFER-
ENCE, it is one of the two main forms of TELEPATHY.

Mind-set n. a state of mind that influences how people 
think about and then enact their goal-directed activities 
in ways that may systematically promote or interfere with 
optimal functioning. German psychologist Peter Gollwitzer 
(1950– ) identified two types: (a) a deliberate mind-set, 
in which a person debates the merits and drawbacks of 
various courses of action (or inaction) when choosing a 
goal to pursue from a set of possible goals; and (b) an im-
personal mind-set, in which a person has made the choice 
and execution of particular actions to realize chosen goals. Mind-sets sometimes generalize from one activity to later, 
unrelated activities.

Mind’s eye the mind’s capacity to recall or create images 
based on visual experience. See VISUAL IMAGERY.

Mindsight n. a proposed but controversial mode of non-
conscious or semiconscious vision that may permit visual 
decision making in the absence of fully conscious visual 
perception. Research on mindsight has arisen out of 
work on CHANGE BLINDNESS. [proposed by Canadian psychologist and 
computer scientist Ronald A. Rensink]

Mind stuff in the philosophy of British mathematician 
William K. Clifford (1845–1879), the single substance that 
constitutes reality; this consists internally of mind but ap-
pears externally in the form of matter. His argument, from 
evolution, was that since consciousness exists in humankind, 
and humankind evolved from matter, matter must also possess consciousness. Clifford’s position is often taken to be one of PANPSYCHISM.

Mind wandering a condition in which thoughts do not 
remain focused on the task at hand but range widely and 
spontaneously across other topics. It tends to occur during 
tasks that do not require sustained attention. Mind wanding 
cannot be scientifically quantified but has been studied using THOUGHT SAMPLING and questionnaires. Re-
search questions include how much mind wandering is a 
stable personality trait, how much it is linked to mood and 
situation, and how it relates to processing capacity and 
working memory. The contents of mind wandering are 
often referred to as task-unrelated thoughts (TUTs), task-
related images and thoughts (TUTs), or stimulus-inde-
pendent and task-unrelated thoughts (SITUTs). See also ABSENT-MINDEDNESS; INTRUSIVE THOUGHTS.

Mineralocorticoid n. any CORTICOSTEROID hormone 
that affects ion concentrations in body tissues and helps to 
regulate the excretion of salt and water. In humans, the 
principal mineralocorticoid is ALDOSTERONE.

MINERVA 2 a GLOBAL MEMORY MODEL that describes, in 
mathematical form, memory for both individual experi-
ences (see EPISODIC MEMORY) and abstract generic facts (see 
SEMANTIC MEMORY). The model postulates that each experi-
ence leaves a MEMORY TRACE, and repetition creates multi-
ple copies rather than strengthening a single trace. Memory retrieval activates the sum of all relevant traces. [proposed by Douglas L. Hintzman (1941– )]

Miniature end-plate potential see END PLATE.

Miniature system the organized, integrated knowl-
edge, including facts, assumptions, and theories or hypoth-
eses, relating to a restricted area of study. An example is 
the theory that explains a particular perceptual phenome-
non, such as the MÜLLER-LYER ILLUSION.

Minimal audible field (MAF) the threshold for a tone 
presented in a sound field to a participant who is not wear-
ing headphones. The participant faces the sound source, 
and the threshold intensity is measured at the midpoint of 
the head. In this procedure, the sound pressure is presented 
in an open space free of echoes, rather than directly at the 
eardrum. Also called minimum audible field.

Minimal audible pressure (MAP) the level of a tone 
presented via headphones at the threshold of audibility. 
The level (in decibels sound-pressure level) is the inferred 
or measured pressure at the tympanic membrane. Also 
called minimum audible pressure.

Minimal brain dysfunction (MBD) 1. a relatively 
mild impairment of brain function that is presumed to ac-
count for a variety of soft signs seen in certain learning or 
behavioral disabilities. These signs include short attention 
span, distractibility, impulsivity, hyperactivity, emotional 
unstability, poor motor coordination, visual-perceptual distur-
bance, and language difficulties. Also called minimal 
brain damage: minimal cerebral dysfunction. 2. an 
obsolete name for ATTENTION-DEFICIT/HYPERACTIVITY DIS-
ORDER.

Minimal group 1. a group lacking interdependence, 
GROUP COHESION, structure, and other characteristics typi-
cally found in social groups. An example is a group of peo-
ple disembarking from a bus. 2. a type of zero-history 
NOMINAL GROUP assembled and studied in the MINIMAL IN-
TERGROUP SITUATION. It has been found that individuals in 
such groups respond in biased ways when allocating re-
sources to INGROUP and OUTGROUP members, even though 
the groups are not psychologically or interpersonally 
meaningful. [introduced by Polish-born British social psy-
chologist Henri Tajfel (1919–1982)]

Minimal intergroup situation 1. any situation in-
volving contact between two or more MINIMAL GROUPS, as 
when a group of individuals disembarking from a bus min-
gles with a group of individuals getting on the bus. 2. a re-
search procedure, used mainly in studies of INTERGROUP CONFLICT, that involves creating temporary groupings of 
anonymous people whose interdependence is virtually nil. 
Also called minimal group paradigm. [developed by Pol-
ish-born British social psychologist Henri Tajfel (1919–1982)]
minimally conscious state (MCS) a condition in which a person who has experienced severe brain injury or deterioration retains a limited awareness of self and environment through residual cognitive functions. The individual is awake and occasionally able to communicate and do simple voluntary activities that demonstrate an engagement with surroundings. For example, he or she may produce intelligible verbalizations (e.g., saying yes or no) follow simple commands (e.g., blinking when asked), gesture, track moving targets, grasp objects, or otherwise purposefully respond to stimuli. Given that diagnosis is based on observations by clinicians of subtle, functionally useful behaviors over an extended period of time, MCS is difficult to distinguish from a vegetative state (wakefulness without any awareness). Despite the similar clinical presentations of the two conditions, research using brain imaging and event-related potentials reveals them to be quite different neurologically. Formerly called minimally responsive state; quasi-vegetative state.

minimal pair in linguistics, two forms that differ in just one phonological feature, thereby illustrating the critical contrastive role played by that feature. In English, for example, the spoken forms [pin] and [bin] are a minimal pair that serve to identify /p/ and /b/ as distinct phonemes. See binary feature;emic–etic distinction.

minimax strategy in game theory or decision making, a tactic in which individuals attempt either to minimize their own maximum losses or to reduce the most an opponent will gain. For example, a health researcher may propose an intervention that would be the least aversive treatment for a serious disease, thereby minimizing the adverse effects patients may expect to experience as a result of the disease. Compare Maximin strategy.

Mini-Mental State Examination (MMSE) an instrument used extensively to provide a quick screening assessment of cognitive status. The patient is asked simple questions relating to time and place orientation and required to perform simple tasks (e.g., write an intelligible sentence) assessing memory, attention, calculation, and language. Lower scores suggest that the patient should be evaluated for a cognitive impairment, such as dementia. Also called Folstein Mini-Mental State Examination. [developed in 1975 by U.S. psychiatrists Marshal F. Folstein (1941– ), Susan E. Folstein (1944– ), and Paul R. McHugh (1931– ).]

minimization n. cognitive distortion consisting of a tendency to present events to oneself or others as insignificant or unimportant. Minimization often involves being unclear or nonspecific, so the listener does not have a complete picture of all the details and may be led to draw inaccurate or incomplete conclusions.

minimum power theory an analysis of coalition formation processes that assumes that (a) all members who control sufficient resources to turn a winning coalition into a losing one or a losing coalition into a winning one are equal in terms of power; and (b) individuals’ expectations concerning the division of the coalition’s pay-offs will conform to an equity norm (see equity theory), but one based on power rather than resources. This theory predicts that the most likely coalition to form in a group will be one that wins but comprises the individuals with the smallest amounts of power consistent with this outcome. Compare minimum resource theory.

minimum resource theory an analysis of coalition formation processes that assumes that (a) people in group situations will behave hedonistically and thus will be motivated to maximize their power, outcomes, and pay-offs by forming coalitions; and (b) individuals’ expectations concerning the division of the coalition’s pay-off will conform to an equity norm (see equity theory). The minimum resource theory predicts that the most likely coalition to form in a group will be the one that contains those individuals whose total, combined resources are the fewest needed to control the outcome of the entire group. Compare minimum power theory.

minimum separable the minimum distance that can be detected between two adjacent high-contrast visual stimuli. This distance, 1 minute of arc at the fovea, is about 60 times greater than the minimum detectable width of a line that appears alone. Compare minimum visible.

minimum visible the narrowest visual stimulus that can be detected when it appears alone in the visual field. Compare minimum separable.

Minnesota Multiphasic Personality Inventory (MMPI) a personality inventory first published in 1940 and now one of the most widely used self-report tools for assessing personality. It has broad applications across a range of mental health, medical, substance abuse, forensic, and personnel screening settings as a measure of psychological maladjustment. The original inventory consisted of 550 true–false items grouped into nine scales reflecting common clinical problems: hypochondria, depression, hysteria, psychopathic deviate, masculine–feminine interest, paranoia, psychasthenia (i.e., anxiety), schizophrenia, and hypomania. The results were scored by the examiner or by computer to determine the participant’s personality profile as well as any tendency to lie or to fake good or bad. The version currently in use, the MMPI–2 (1989), features 567 true–false questions that assess symptoms, attitudes, and beliefs that relate to emotional and behavioral problems, including substantial revisions of the original items and the addition of new scales.

The early 1990s saw the publication of a version of the instrument, the MMPI–A, with content items specifically relevant to adolescents ages 14 to 18. The instrument’s 478 items help identify personal, social, and behavioral problems (e.g., family issues, eating disorders, chemical dependency). In 2008, a substantially shorter version of the MMPI–2, the MMPI–2–RF (Restructured Form), was published with 338 true–false items for individuals 18 years and older. [originally developed by Starke Rosecrans Hathaway and U.S. psychiatrist John Charnley McKinley (1891–1950) at the University of Minnesota]

Minnesota Satisfaction Questionnaire (MSQ) a measure of job satisfaction, developed at the University of Minnesota, in which employees rate the extent to which they are satisfied or dissatisfied with each of several intrinsic factors (e.g., the work itself) and extrinsic factors (e.g., pay) relating to the job.

minor n. a person who is not legally an adult. See also emancipated minor.

minor depression see dysthymia.

minor depressive disorder in an appendix to DSM–IV–TR, a proposed diagnosis of a mood disorder in which an individual experiences persistent sadness or anhedonia and other symptoms similar to major depressive disorder or dysthymic disorder but without meeting the full criteria for either diagnosis. These other symptoms may include
appetite, weight, or sleep changes; psychomotor agitation or psychomotor retardation; fatigue or loss of energy; feelings of worthlessness or guilt; difficulty concentrating or making decisions; and recurrent thoughts of death or suicide.

**minority group** a population subgroup with social, religious, ethnic, racial, or other characteristics that differ from those of the majority of the population. The term is sometimes extended to cover any group that is the subject of oppression and discrimination, whether or not it literally comprises a minority of the population. When members of groups historically considered minorities make up more than 50% of an area’s population, that jurisdiction is described as majority-minority. See also ETHNIC GROUP; SUBCULTURE.

**minority influence** social pressure exerted on the majority of a group by a smaller faction of the group. Studies suggest that minorities who argue consistently prompt the majority of a group by a smaller faction of the group. Studies described as well-learned patterns of hand–eye coordination. In the test, the participant traces an image while looking into a mirror that shows only the image and the pencil.

**minority stress** the physiological and psychological effects associated with the adverse social conditions experienced by ethnic and racial minorities, lesbians, gay men, bisexual and transgender individuals, and others who are members of stigmatized social groups. Common sources of minority stress include experiencing prejudice, discrimination, harassment, or verbal or physical violence; experiencing rejection by others; concealing one’s minority identity; and internalizing negative societal attitudes about one’s social group that results in a negative self-view. The concept is frequently invoked by researchers to explain the increased rates of depression, suicide, anxiety, substance abuse, workplace problems, body image problems, eating disorders, high blood pressure, cardiovascular disease, and other mental and physical conditions among members of minority or marginalized groups. Conversely, researchers have hypothesized certain protective factors that help ameliorate the adverse health outcomes of minority stress. These include personal characteristics, such as resilience and an effective coping strategy, and social support mechanisms, such as group solidarity, group cohesion, and collective self-esteem. [coined in 1995 by Israeli-born U.S. social psychologist Ilan H. Meyer—mirrored by the mirror neuron] mirror sign

**minor security** a motor-skill test of the ability to alter well-learned patterns of hand–eye coordination. In the test, the participant traces an image while looking into a mirror that shows only the image and the pencil.

**minor imaging** 1. a type of reversed asymmetry of characteristics often found between twins, particularly monozygotic twins. Examples include handedness, fingerprints, and hair whorls. 2. see MIRROR NEURON.

**minor strategy** an arithmetic strategy in which children faced with an addition problem start with the largest addend and count up from there. For example, for the problem, 3 + 2 = 7, a child would say “3... 4... 5.”

**minty adj.** denoting one of the seven classes of odorants in the STEROIC SMELL THEORY. mirroring

**miosis (myosis)** n. contraction of the pupil of the eye. —miotic adj.

**Miriad warning** a warning given in the United States by police officers to suspects during an arrest to make them aware of their rights against self-incrimination. Suspects must be told they have the right to remain silent and the right to have an attorney present during questioning: an attorney will be provided if suspects cannot afford one. They must also be informed that anything they say can be used as evidence against them in court. It is named for the defendant in Miranda v. Arizona, a case that was ultimately decided in 1966 by the U.S. Supreme Court. Also called Miranda rights.

**mirror-box technique** a rehabilitation method in which an individual who has lost the use of a limb due to stroke places both affected and unaffected limbs (e.g., left arm and right arm) into slots of a box containing two mirrors in the center that each face outward, reflecting the respective limb. The person moves the intact limb and watches its reflection in the corresponding mirror, which gives the illusion that the other, paralyzed limb is moving in response to the brain’s commands. Research has shown that the technique aids recovery of limb function following stroke, perhaps by tapping into former MIRROR NEURON circuits that have only been partially damaged. The technique is also used, in modified form, with individuals who have lost a limb to amputation and has been effective in reducing or alleviating their PHANTOM LIMB pain. [developed by neurologist Vilayanur S. Ramachandran (1951–)"

**mirror draws** a motor-skill test of the ability to alter well-learned patterns of hand–eye coordination. In the test, the participant traces an image while looking into a mirror that shows only the image and the pencil.

**mirror imaging** 1. a type of reversed asymmetry of characteristics often found between twins, particularly monozygotic twins. Examples include handedness, fingerprints, and hair whorls. 2. see MIRROR NEURON.
