SAMIR S. SHAH, MD, MSCE

Professor of Pediatrics
University of Cincinnati College of Medicine
Director, Division of Hospital Medicine
Chief Metrics Officer
James M. Ewell Endowed Chair
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

ROBERT C. TASKER, MBBS, MD

Professor of Neurology
Professor of Anesthesia
Harvard Medical School
Senior Associate, Critical Care Medicine
Director, Pediatric NeuroCritical Care Program
Boston Children's Hospital
Boston, Massachusetts

KAREN M. WILSON, MD, MPH

Professor of Pediatrics
Debra and Leon Black Division Chief of General Pediatrics
Vice-Chair for Clinical and Translational Research
Kravis Children's Hospital at the Icahn School of Medicine at Mount Sinai
New York, New York

*Editor Emeritus*
RICHARD E. BEHRMAN, MD

Volume 1

Part I The Field of Pediatrics

Chapter 1 Overview of Pediatrics

Vital Statistics About Children's Health Globally

The Changing Pediatric World
The New Morbidities

Chronic Illness and Children With Special Health Care Needs

Systems of Care

Bibliography

Chapter 2 Child Health Disparities

Determinants of Health and Health Disparities

Disparities in Child Health and Healthcare:

Approaches to Eradicating Disparities: Interventions

Keywords

Racism as Social Determinant

Explaining Racial Disparities: A Taxonomy of Racism

Opportunities to Address Racism

Bibliography

Bibliography

Chapter 3 Global Child Health

Global Burden and Trends in Child Health

Social Determinants of Child Health

Evidence-Based Interventions and Innovations to Address Child Health Inequities

Challenges in Global Health
Chapter 4 Quality and Value in Healthcare for Children

The Need for Improvement in Quality and Value

What Is Quality?

Framework for Quality

Developing Guidelines to Establish the Standard for Quality

Improving Quality

Measuring Quality

Analyzing Quality Data

Comparing and Reporting Quality

Implications of the U.S. Healthcare Reform for Quality

Information Technology and Quality Improvement

Expanding Individual Quality Improvement Initiatives to Scale

Chapter 5 Safety in Healthcare for Children

Error vs Harm

Safety Frameworks

Identifying and Analyzing Harm, Errors, and Latent Threats

Safety Culture

Reliability Science and High-Reliability Organizations
Serious Harm Events and Healthcare-Associated Conditions

Safety Opportunities and Gaps

Emerging Areas of Safety Research and Improvement

Bibliography

Chapter 6 Ethics in Pediatric Care

Assent and Parental Permission

Treatment of Critically Ill Children

Neonatal Ethics

Declaring Death and Organ Donation

Religious or Cultural Objections to Treatment

Pediatric Ethics Committees and Ethics Consultation

Newborn Screening

Genetics, Genomics, and Precision Medicine

Adolescent Healthcare

Research

Balancing Maternal and Fetal Interests

Justice and Pediatric Ethics

Emerging Issues

Bibliography

Chapter 7 Pediatric Palliative Care
Care Settings

Communication, Advance Care Planning, and Anticipatory Guidance

Bibliography

Chapter 8 Domestic and International Adoption

Domestic Adoption

Intercountry Adoption

Role of Pediatricians

Bibliography

Chapter 9 Foster and Kinship Care

Epidemiology

Legislation in the United States

Early Childhood Trauma Leads to Poor Health Outcomes

Health Issues

Healthcare for Children and Adolescents in Foster Care

Bibliography

Chapter 10 Medical Evaluation of the Foreign-Born Child

Commonly Encountered Infections

Immunizations

Bibliography
Chapter 11 Cultural Issues in Pediatric Care

What Is Culture?

Culturally Informed Care

Bibliography

Chapter 12 Maximizing Children's Health

Periodicity Schedule and Guidelines

Tasks of Well-Child Care

Infancy and Early Childhood

Middle Childhood and Adolescence

Office Intervention for Behavioral and Mental Health Issues

Evidence

Caring for the Child and Youth in the Context of the Family and Community

Bibliography

Chapter 13 Injury Control

Scope of the Problem

Principles of Injury Control

Risk Factors for Childhood Injuries

Mechanisms of Injury

Psychosocial Consequences of Injuries
Chapter 14 Impact of Violence on Children

Impacts of Violence

Keywords

Bullying and Cyberbullying

School Violence

Treatment and Prevention of Bullying and School Violence

Bibliography

Resources

Keywords

Screening

Recommendations (see Table 14.1)

Bibliography

Resources

Keywords

Susceptibility of Children in Times of War

Psychological Impact of War

Efforts to Protect Children From the Effects of War

Role of Pediatricians and Allied Health Professionals

Bibliography
Chapter 15 Child Trafficking for Sex and Labor

Clinical Presentation
Approach to the Potentially Trafficked Child
Examination and Diagnostic Testing
Referrals and Resources

Chapter 16 Abused and Neglected Children

Definitions
Incidence and Prevalence
Etiology
Clinical Manifestations
General Principles for Assessing Possible Abuse and Neglect
General Principles for Addressing Child Maltreatment
Outcomes of Child Maltreatment
Prevention of Child Abuse and Neglect
Advocacy

Keywords

Presentation of Sexual Abuse
Role of General Pediatrician in Assessment and Management of Possible Sexual Abuse

Physical Examination of the Child With Suspected Sexual Abuse

Additional Management

Sexual Abuse Prevention

Bibliography

Keywords

Clinical Manifestations

Diagnosis

Treatment

Bibliography

Bibliography

Chapter 17 Strategies for Health Behavior Change

Unified Theory of Behavior Change

Transtheoretical Model of Health Behavior Change

Common Factors Approach

Motivational Interviewing

Shared Decision-Making

Bibliography

Part II Growth, Development, and Behavior
Chapter 18 Developmental and Behavioral Theories

Biopsychosocial Model and Ecobiodevelopmental Framework: Models of Development

Bibliography

Chapter 19 Positive Parenting and Support

The Importance of Parenting

The Role of the Family

Parenting Styles

Child Temperament

Child Behavioral Problems

Defining Positive Parenting

Parenting as an Intervention

The Role of the Pediatrician

Bibliography

Chapter 20 Assessment of Fetal Growth and Development

Somatic Development

Neurologic Development

Behavioral Development

Psychologic Changes in Parents

Threats to Fetal Development
Chapter 21 The Newborn

Parental Role in Mother–Infant Attachment

The Infant's Role in Mother–Infant Attachment

Implications for the Pediatrician

Bibliography

Chapter 22 The First Year

Age 0-2 Months

Age 2-6 Months

Age 6-12 Months

Bibliography

Chapter 23 The Second Year

Age 12-18 Months

Age 18-24 Months

Bibliography

Chapter 24 The Preschool Years

Structural Development of the Brain

Physical Development

Language, Cognition, and Play
Chapter 25 Middle Childhood

Physical Development
Cognitive Development
Social, Emotional, and Moral Development

Chapter 26 Adolescence

Chapter 27 Assessment of Growth

Techniques to Measure Growth
Growth Curves
Other Growth Considerations

Chapter 28 Developmental and Behavioral Surveillance and Screening

Developmental and Behavioral Surveillance
Developmental and Behavioral Screening
Beyond Surveillance and Screening

Chapter 29 Childcare
Provision, Regulation, and Use of Childcare in America

Childcare's Role in Child Health and Development

Role of Pediatric Providers in Childcare

Bibliography

Chapter 30 Loss, Separation, and Bereavement

Separation and Loss

Divorce

Move/Family Relocation

Separation Because of Hospitalization

Military Families

Parental/Sibling Death

Grief and Bereavement

Developmental Perspective

Role of the Pediatrician in Grief

Treatment

Spiritual Issues

Bibliography

Chapter 31 Sleep Medicine

Basics of Sleep and Chronobiology

Developmental Changes in Sleep
Common Sleep Disorders
Health Supervision
Evaluation of Pediatric Sleep Problems
Bibliography

Part III Behavioral and Psychiatric Disorders

Chapter 32 Psychosocial Assessment and Interviewing

Aims of Assessment
Presenting Problems
General Principles of the Psychosocial Interview
Indications for Referral
Psychiatric Diagnostic Evaluation
Special Considerations in the Diagnostic Evaluation of Infants and Young Children
Bibliography

Chapter 33 Psychopharmacology

Stimulants and Other ADHD Medications
Antidepressants
Antipsychotics
Mood Stabilizers
Medication Use in Physical Illness
Chapter 34 Psychotherapy and Psychiatric Hospitalization

Psychotherapy

Psychiatric Hospitalization

Bibliography

Chapter 35 Somatic Symptom and Related Disorders

Epidemiology

Risk Factors

Assessment

Management

Bibliography

Chapter 36 Rumination and Pica

Epidemiology

Etiology and Differential Diagnosis

Treatment

Bibliography

Epidemiology

Etiology and Differential Diagnosis

Treatment
Chapter 38 Anxiety Disorders

Anxiety Associated With Medical Conditions

Safety and Efficacy Concerns About SSRIs

Bibliography

Chapter 39 Mood Disorders

Description

Epidemiology

Clinical Course

Differential Diagnosis

Comorbidity

Sequelae

Etiology and Risk Factors

Prevention

Screening/Case Finding

Early Intervention

Treatment

Level of Care

Bibliography

Description
Chapter 40 Suicide and Attempted Suicide

Epidemiology
Risk Factors
Assessment and Intervention
Prevention
Bibliography

Chapter 41 Eating Disorders

Definitions
Epidemiology
Chapter 42 Disruptive, Impulse-Control, and Conduct Disorders

Description

Epidemiology

Clinical Course

Differential Diagnosis

Comorbidity

Sequelae

Etiology and Risk Factors

Prevention

Screening/Case Finding

Early Intervention
Chapter 43 Tantrums and Breath-Holding Spells

Chapter 44 Lying, Stealing, and Truancy

Chapter 45 Aggression

Chapter 46 Self-Injurious Behavior

Chapter 47 Childhood Psychoses
Differential Diagnosis
Comorbidity
Sequelae
Etiology and Risk Factors
Neuroanatomic Abnormalities
Prevention
Screening/Case Finding
Assessment
Treatment
Bibliography
Bibliography
Bibliography
Diagnosis and Treatment
Bibliography
Clinical Manifestations
Diagnosis and Differential Diagnosis
Treatment
Bibliography

**Part IV Learning and Developmental Disorders**

Chapter 48 Neurodevelopmental and Executive Function and Dysfunction

Terminology and Epidemiology
Chapter 49 Attention-Deficit/Hyperactivity Disorder

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis and Differential Diagnosis

Treatment

Prognosis

Prevention

Bibliography

Chapter 50 Dyslexia

Etiology

Epidemiology

Pathogenesis
Chapter 51 Math and Writing Disabilities

Keywords
Math Learning Disability Defined
Epidemiology
Causes of Math Learning Disability
Treatment and Interventions
Bibliography
Keywords
Epidemiology
Skill Deficits Associated With Impaired Writing
Treatment
Bibliography

Chapter 52 Language Development and Communication Disorders

Normal Language Development
Language and Communication Disorders
Chapter 53 Developmental Delay and Intellectual Disability

Definition

Etiology
Epidemiology
Pathology and Pathogenesis
Clinical Manifestations
Diagnostic Evaluation
Differential Diagnosis
Diagnostic Psychologic Testing
Complications
Prevention
Treatment
Supportive Care and Management
Prognosis
Bibliography

Chapter 54 Autism Spectrum Disorder
Definition
Diagnostic Criteria and Symptoms
Epidemiology
Etiology
Differential Diagnosis
Comorbid Conditions
Screening
Part V Nutrition

Chapter 55 Nutritional Requirements

Dietary Reference Intakes

Energy

Fat

Protein

Carbohydrates

Fiber

Micronutrients

Water

Measuring Nutritional Adequacy

Bibliography

Chapter 56 Feeding Healthy Infants, Children, and Adolescents

Feeding During the First Year of Life

Cow's Milk Protein–Based Formulas
Soy Formulas

Protein Hydrolysate Formulas

Amino Acid Formulas

Milk and Other Fluids in Infants and Toddlers

Complementary Feeding

Feeding Toddlers and Preschool-Age Children

Feeding School-Age Children and Adolescents

Nutrition Issues of Importance Across Pediatric Ages

Bibliography

Chapter 57 Nutrition, Food Security, and Health

Malnutrition as the Intersection of Food Insecurity and Health

Insecurity

Food Security

Undernutrition

Severe Acute Malnutrition

Bibliography

Chapter 58 Refeeding Syndrome

Bibliography

Chapter 59 Malnutrition

Clinical Manifestations
Etiology and Diagnosis

Treatment

Prognosis

Bibliography

Chapter 60 Overweight and Obesity

Epidemiology

Body Mass Index

Etiology

Comorbidities

Identification

Evaluation

Intervention

Prevention

Keywords

Clinical Manifestations

Diagnosis

Management

Etiology: Studies and Hypotheses

Differential Diagnosis

Bibliography
Chapter 61 Vitamin A Deficiencies and Excess

Overview of Vitamin A
Metabolism of Vitamin A
Functions of Vitamin A and Mechanisms of Action
Vitamin A Deficiency
Hypervitaminosis A

Chapter 62 Vitamin B Complex Deficiencies and Excess

Keywords
Thiamine Deficiency
Thiamine Toxicity

Keywords
Riboflavin Deficiency
Riboflavin Toxicity

Keywords
Niacin Deficiency
Niacin Toxicity
Chapter 63 Vitamin C (Ascorbic Acid) Deficiency and Excess

Dietary Needs and Sources of Vitamin C

Vitamin C Deficiency

Vitamin C Toxicity

Bibliography
Chapter 64 Vitamin D Deficiency (Rickets) and Excess

Rickets

Vitamin D Disorders

Calcium Deficiency

Phosphorus Deficiency

Rickets of Prematurity

Distal Renal Tubular Acidosis

Hypervitaminosis D

Bibliography

Chapter 65 Vitamin E Deficiency

Pathogenesis

Clinical Manifestations

Laboratory Findings

Diagnosis and Differential Diagnosis

Treatment

Prognosis

Prevention

Bibliography

Chapter 66 Vitamin K Deficiency

Pathogenesis
Clinical Manifestations

Diagnosis and Differential Diagnosis

Treatment

Prevention

Bibliography

Chapter 67 Micronutrient Mineral Deficiencies

Bibliography

**Part VI Fluid and Electrolyte Disorders**

Chapter 68 Electrolyte and Acid-Base Disorders

Keywords

Total Body Water

Fluid Compartments

Electrolyte Composition

Osmolality

Point-of-Care Testing

Bibliography

Keywords

Regulation of Osmolality

Regulation of Volume
Keywords

Sodium Metabolism

Hypernatremia

Hyponatremia

Potassium Metabolism

Hyperkalemia

Hypokalemia

Magnesium Metabolism

Hypomagnesemia

Hypermagnesemia

Phosphorus Metabolism

Hypophosphatemia

Hyperphosphatemia
Keywords

Acid-Base Physiology

Normal Acid-Base Balance

Clinical Assessment of Acid-Base Disorders

Metabolic Acidosis

Metabolic Alkalosis

Respiratory Acidosis

Respiratory Alkalosis

Chapter 69 Maintenance and Replacement Therapy

Maintenance Therapy

Maintenance Water

Intravenous Solutions

Glucose

Selection of Maintenance Fluids

Variations in Maintenance Water and Electrolytes

Replacement Fluids

Chapter 70 Deficit Therapy
Clinical Manifestations
Laboratory Findings
Calculation of the Fluid Deficit
Approach to Severe Dehydration
Monitoring and Adjusting Therapy
Hyponatremic Dehydration
Hypernatremic Dehydration
Bibliography

Chapter 71 Fluid and Electrolyte Treatment of Specific Disorders

Acute Diarrhea
Pyloric Stenosis
Perioperative Fluids

Part VII Pediatric Drug Therapy

Chapter 72 Pediatric Pharmacogenetics, Pharmacogenomics, and Pharmacoproteomics

Definition of Terms
Developmental or Pediatric Pharmacogenetics and Pharmacogenomics
Drug Biotransformation: Applications to Pediatric Therapy
Pharmacogenetics of Drug Transporters
Polymorphisms in Drug Receptors

Current and Future Applications in Pediatrics

Bibliography

Chapter 73 Principles of Drug Therapy

General Pharmacokinetic and Pharmacodynamic Principles

Impact of Ontogeny on Drug Disposition

Impact of Ontogeny on Pharmacodynamics

Additional Considerations in Pediatric Therapeutics

Drug Formulation and Administration

Adherence and Compliance

Drug-Drug Interactions

Adverse Drug Reactions

Personalized Medicine

Bibliography

Chapter 74 Anesthesia and Perioperative Care

Preanesthetic Evaluation

Preoperative Preparation

General Anesthesia

Induction of General Anesthesia

Maintenance of Anesthesia
Postanesthesia Care Unit

Postoperative Pain Management

Keywords

Bibliography

Bibliography

Chapter 75 Procedural Sedation

Bibliography

Chapter 76 Pediatric Pain Management

Definition and Categories of Pain
Assessment and Measurement of Pain in Children
Conceptual Framework for Treatment of Pediatric Pain
Unconventional Medications in Pediatric Pain
Nonpharmacologic Treatment of Pain
Invasive Interventions for Treating Pain
Intrathecal Analgesia
Nerve Ablation and Destruction
Considerations for Special Pediatric Populations
Chronic and Recurrent Pain Syndromes
Managing Complex Chronic Pain Problems
Bibliography
Chapter 77 Poisoning

Prevention

Approach to the Poisoned Patient

Principles of Management

Select Compounds in Pediatric Poisoning

Bibliography

Chapter 78 Complementary Therapies and Integrative Medicine

Dietary Supplements

Dietary Supplement Safety

Dietary Supplement Efficacy

Massage and Chiropractic

Mind-Body Therapies

Acupuncture

Cannabis

Bibliography

Part VIII Emergency Medicine and Critical Care

Chapter 79 Emergency Medical Services for Children

Primary Care Physician and Office Preparedness

Pediatric Prehospital Care
The Emergency Department
Keywords
Communications and Dispatch Center
Medical Control Physician
Transport Team
Ground vs Air Ambulance
Transport Physiology
Safety
Family-Centered Care
Referring Hospital Responsibilities
Educational Outreach
Bibliography
Keywords
Outcome Measures in Emergency Medical Services for Children
Risk Adjustment
Bibliography
Keywords
Continuum-of-Care Model
Humanitarian Disasters
Bibliography
Chapter 80 Triage of the Acutely Ill Child

Assessment of Vital Signs

History

Physical Examination

Management

Disposition

Chapter 81 Pediatric Emergencies and Resuscitation

Approach to the Emergency Evaluation of a Child

Recognition and Treatment of Respiratory Distress and Failure

Recognition and Management of Shock

Recognition of Bradyarrhythmias and Tachyarrhythmias

Recognition and Management of Cardiac Arrest

Vascular Access

Nonvascular Emergency Procedures

Postresuscitation Care

Chapter 82 Acute Care of Multiple Trauma
Epidemiology
Regionalization and Trauma Teams
Primary Survey
Secondary Survey
Psychological and Social Support
Bibliography

Chapter 83 Spinal Cord Injuries in Children
Clinical Manifestations
Clearing the Cervical Spine in Children
Treatment
Prevention
Bibliography

Chapter 84 Care of Abrasions and Minor Lacerations
Lacerations and Cuts
Abrasions
Bibliography

Chapter 85 Neurologic Emergencies and Stabilization
Neurocritical Care Principles
Traumatic Brain Injury
Chapter 88 Shock

Epidemiology

Types of Shock

Pathophysiology

Clinical Manifestations

Diagnosis

Laboratory Findings

Treatment

Prognosis

Bibliography

Chapter 89 Respiratory Distress and Failure

Respiratory Distress

Respiratory Failure

Monitoring a Child in Respiratory Distress and Respiratory Failure

Management

Keywords

Basic Concepts of Ventilator Management

Noninvasive Mechanical Ventilation

Invasive Mechanical Ventilation

Additional Ventilatory Modalities
Conventional Ventilator Settings

Patient-Ventilator Asynchrony

Monitoring Respiratory Mechanics

Ventilator-Induced Lung Injury

Bibliography

Bibliography

Chapter 90 Altitude-Associated Illness in Children (Acute Mountain Sickness)

Etiology

General Effects of Hypobaric Hypoxia

Acute Mountain Sickness

High-Altitude Cerebral Edema

High-Altitude Pulmonary Edema

Special Considerations

Bibliography

Chapter 91 Drowning and Submersion Injury

Etiology

Epidemiology

Pathophysiology

Management

Prognosis
Chapter 92 Burn Injuries

Epidemiology

Prevention

Acute Care, Resuscitation, and Assessment

Treatment

Electrical Burns

Bibliography

Chapter 93 Cold Injuries

Pathophysiology

Etiology

Clinical Manifestations

Cold-Induced Fat Necrosis (Panniculitis)

Bibliography

Part IX Human Genetics

Chapter 94 Integration of Genetics Into Pediatric Practice

Diagnostic Testing

Predictive Testing
Chapter 95 The Genetic Approach in Pediatric Medicine

The Burden of Genetic Disorders in Childhood

The Changing Paradigm of Genetics in Medicine

Ethics Issues

Bibliography

Chapter 96 The Human Genome

Fundamentals of Molecular Genetics

Genetic Variation

Genotype-Phenotype Correlations in Genetic Disease

Human Genome Project

Bibliography

Chapter 97 Patterns of Genetic Transmission
Family History and Pedigree Notation
Mendelian Inheritance
Y-Linked Inheritance
Inheritance Associated With Pseudoautosomal Regions
Digenic Inheritance
Pseudogenetic Inheritance and Familial Clustering
Nontraditional Inheritance
Multifactorial and Polygenic Inheritance
Bibliography

Chapter 98 Cytogenetics
Bibliography
Aneuploidy and Polyploidy
Down Syndrome
Bibliography
Translocations
Inversions
Deletions and Duplications
Insertions
Isochromosomes
Marker and Ring Chromosomes
Bibliography

Turner Syndrome
Klinefelter Syndrome
47, XYY

Bibliography

Pallister-Killian Syndrome
Hypomelanosis of Ito
Uniparental Disomy
Imprinting

Bibliography

Chapter 99 Genetics of Common Disorders

Linkage Mapping
Genetic Association

Bibliography

Chapter 100 Epigenome-Wide Association Studies and Disease

Epigenetic Mechanisms of Disease: Viable Yellow Mouse Model
Epigenetics and Regulation of Gene Expression
Pediatric Diseases Involving Epigenetic Processes
Epigenome-Wide Association Studies: DNA Methylation
Cell Fate Variability as Model for Epigenetics and Disease

Epigenetic Disease and Therapeutic Interventions

Bibliography

Chapter 101 Genetic Approaches to Rare and Undiagnosed Diseases

Scope of Genetic Disease

Clinical Evaluation

Single Nucleotide Polymorphism Arrays

Exome Sequencing

Gene Function Studies

Pediatric Issues

The Diagnostic Spectrum

Bibliography

Part X Metabolic Disorders

Chapter 102 An Approach to Inborn Errors of Metabolism

Newborn Screening

Clinical Manifestations of Genetic Metabolic Diseases

Treatment

Bibliography

Chapter 103 Defects in Metabolism of Amino Acids
Keywords

Severe Phenylalanine Hydroxylase Deficiency (Classic Phenylketonuria)

Hyperphenylalaninemia Caused by Deficiency of the Cofactor Tetrahydrobiopterin

Tetrahydrobiopterin Defects Without Hyperphenylalaninemia

Bibliography

Keywords

Tyrosinemia Type I (Fumarylacetoacetate Hydrolase Deficiency, Hepatorenal Tyrosinemia)

Tyrosinemia Type II (Tyrosine Aminotransferase Deficiency, Richner-Hanhart Syndrome, Oculocutaneous Tyrosinemia)

Tyrosinemia Type III (Primary Deficiency of 4-Hydroxyphenylpyruvate Dioxygenase)

Hawkinsinuria

Transient Tyrosinemia of the Newborn

Alkaptonuria

Tyrosine Hydroxylase Deficiency

Albinism

Bibliography

Keywords

Homocystinuria (Homocystinemia)

Hypermethioninemia
Primary Cystathioninemia (Cystathioninuria)

Bibliography

Keywords

Sulfite Oxidase Deficiency and Molybdenum Cofactor Deficiency

Bibliography

Keywords

Hartnup Disorder

Bibliography

Keywords

Maple Syrup Urine Disease

Branched-Chain α-Ketoacid Dehydrogenase Kinase Deficiency

Branched-Chain Amino Acid Transporter Deficiency

Isovaleric Acidemia

Multiple Carboxylase Deficiencies (Defects of Biotin Cycle)

3-Methylcrotonyl-CoA Carboxylase Deficiency

3-Methylglutaconic Acidurias

β-Ketothiolase (3-Oxothiolase) Deficiency (Mitochondrial Acetoacetyl-CoA Thiolase \([T_2]\) Deficiency)

Cytosolic Acetoacetyl-CoA Thiolase Deficiency

Mitochondrial 3-Hydroxy-3-Methylglutaryl-CoA Synthase Deficiency

3-Hydroxy-3-Methylglutaryl-CoA Lyase Deficiency (3-Hydroxy-3-
Methylglutaric Aciduria
Succinyl-CoA:3-Oxoadid-CoA Transferase Deficiency
Mevalonate Kinase Deficiency
Propionic Acidemia (Propionyl-CoA Carboxylase Deficiency)
Isolated Methylmalonic Acidemias
Isolated Homocystinuria
Combined Malonic and Methylmalonic Aciduria (*ACSF3* -Related Disorder)
Bibliography
Hypoglycinemia
Hyperglycinemia
Nonketotic Hyperglycinemia (Glycine Encephalopathy)
Sarcosinemia
Primary Trimethylaminuria
Hyperoxaluria and Oxalosis
Bibliography
Keywords
3-Phosphoglycerate Dehydrogenase Deficiency
Phosphoserine Aminotransferase Deficiency
3-Phosphoserine Phosphatase Deficiency

Bibliography

Keywords

Hyperprolinemia Type I
Hyperprolinemia Type II
Prolidase Deficiency
Disorders of De Novo Proline Synthesis

Bibliography

Keywords

Glutathione Synthetase Deficiency

γ-Glutamyl Transpeptidase Deficiency (Glutathionemia)

Genetic Disorders of Metabolism of γ-Aminobutyric Acid

Bibliography

Keywords

Tyrosine Hydroxylase Deficiency (Infantile Parkinsonism, Autosomal Recessive Dopa-Responsive Dystonia, Autosomal Recessive Segawa Syndrome)

Aromatic l-Amino Acid Decarboxylase Deficiency

Tetrahydrobiopterin Deficiency

Dopamine β-Hydroxylase Deficiency

Monoamine Oxidase a Deficiency
Disorders of γ-Aminobutyric Acid (GABA) Metabolism

Defects in Neurotransmitter Transporter Proteins

Histidine Decarboxylase Deficiency

Hyperprolinemia

3-Phosphoglycerate Dehydrogenase Deficiency

Phosphoserine Aminotransferase Deficiency

Nonketotic Hyperglycinemia

Bibliography

Keywords

Genetic Causes of Hyperammonemia

Clinical Manifestations of Hyperammonemia

Diagnosis

Treatment of Acute Hyperammonemia

Carbamoyl Phosphate Synthetase 1 and N-Acetylglutamate Synthase Deficiencies

Ornithine Transcarbamylase Deficiency

Citrullinemia

Argininosuccinate Lyase Deficiency (Argininosuccinic Aciduria)

Arginase 1 Deficiency (Hyperargininemia)

Transient Hyperammonemia of the Newborn

Disorders of Ornithine Metabolism
Congenital Glutamine Deficiency

Bibliography

Keywords

Pyridoxine (Vitamin B₆)–Dependent Epilepsy

Glutaric Aciduria Type 1 (Glutaryl-CoA Dehydrogenase Deficiency)

Lysinuric Protein Intolerance (Familial Protein Intolerance)

Bibliography

Keywords

Etiology and Pathology

Clinical Manifestations

Atypical Canavan Disease

Diagnosis

Treatment and Prevention

Bibliography

Chapter 104 Defects in Metabolism of Lipids

Keywords

Defects in the β-Oxidation Cycle

Defects in the Carnitine Cycle
Defects in the Electron Transfer Pathway
Defects in the Ketone Synthesis Pathway
Defects in Ketone Body Utilization
Bibliography
Keywords
Peroxisomal Disorders
Adrenoleukodystrophy
Bibliography
Keywords
Epidemiology of Blood Lipids and Cardiovascular Disease
Blood Lipids and Atherogenesis
Plasma Lipoprotein Metabolism and Transport
Hyperlipoproteinemias
Bibliography
Keywords
GM\textsubscript{1} Gangliosidosis
The GM\textsubscript{2} Gangliosidoses
Gaucher Disease
Niemann-Pick Disease
Fabry Disease
Fucosidosis
Schindler Disease
Metachromatic Leukodystrophy
Multiple-Sulfatase Deficiency
Krabbe Disease
Farber Disease
Wolman Disease and Cholesterol Ester Storage Disease

Chapter 105 Defects in Metabolism of Carbohydrates

Keywords
Liver Glycogenoses
Muscle Glycogenoses

Bibliography

Keywords
Galactose-1-Phosphate Uridyl Transferase Deficiency Galactosemia
Galactokinase Deficiency
Uridine Diphosphate Galactose-4-Epimerase Deficiency

Bibliography

Keywords

Deficiency of Fructokinase (Essential or Benign Fructosuria)

Deficiency of Fructose-1,6-Bisphosphate Aldolase (Aldolase B, Hereditary Fructose Intolerance)

Bibliography

Keywords

Disorders of Gluconeogenesis

Disorders of Pyruvate Metabolism

Bibliography

Keywords

Essential Pentosuria

Transaldolase Deficiency

Ribose-5-Phosphate Isomerase Deficiency

Bibliography

Sialidosis and Galactosialidosis

Aspartylglucosaminuria

α-Mannosidosis

Bibliography

Keywords
Congenital Disorders of Protein N-Glycosylation

Congenital Disorders of Protein O-Glycosylation

Defects in Lipid Glycosylation and in Glycosylphosphatidylinositol Anchor Biosynthesis

Defects in Multiple Glycosylation Pathways and in Other Pathways, Including Dolicholphosphate Biosynthesis Defects

Congenital Disorders of Deglycosylation

Therapeutic Summary

Bibliography

Chapter 106 Mitochondrial Disease Diagnosis

Overview of Mitochondrial Disease

When to Suspect Mitochondrial Disease

Mitochondrial Disease Inheritance

Diagnostic Testing for Mitochondrial Disease

Treatment Principles for Mitochondrial Disease

Bibliography

Chapter 107 Mucopolysaccharidoses

Disease Entities

Diagnosis and Differential Diagnosis

Treatment
Chapter 108 Disorders of Purine and Pyrimidine Metabolism

Gout
Abnormalities in Purine Salvage
Disorders Linked to Purine Nucleotide Synthesis
Disorders Resulting From Abnormalities in Purine Catabolism
Disorders of Pyrimidine Metabolism

Chapter 109 Hutchinson-Gilford Progeria Syndrome (Progeria)

Clinical Manifestations
Laboratory Findings
Molecular Pathogenesis
Diagnosis and Differential Diagnosis
Treatment and Prognosis
Patient Resources

Chapter 110 The Porphyrias

The Heme Biosynthetic Pathway
Classification and Diagnosis of Porphyrias
δ-Aminolevulinic Acid Dehydratase Deficient Porphyria

Acute Intermittent Porphyria

Congenital Erythropoietic Porphyria

Porphyria Cutanea Tarda

Hepatoerythropoietic Porphyria

Hereditary Coproporphyria

Variegate Porphyria

Erythropoietic Protoporphyria and X-Linked Protoporphyria

Dual Porphyria

Porphyria Resulting From Tumors

Bibliography

Chapter 111 Hypoglycemia

Definition

Significance and Sequelae

Substrate, Enzyme, and Hormonal Integration of Glucose Homeostasis

Clinical Manifestations

Classification of Hypoglycemia in Infants and Children

Diagnosis and Differential Diagnosis

Treatment
Prognosis

Bibliography

Part XI The Fetus and the Neonatal Infant

Chapter 112 Overview of Morbidity and Mortality

Infant Mortality

Major Causes of Infant Death

Infant Mortality Reduction

Bibliography

Chapter 113 The Newborn Infant

General Appearance

Skin

Skull

Face

Neck

Chest

Lungs

Heart

Abdomen

Genitals
Anus
Extremities
Neurologic Examination
Bibliography
Maintenance of Body Heat
Antiseptic Skin and Cord Care
Newborn Prophylaxis and Screening
Bibliography
Bibliography
Rooming-in and Breastfeeding
Bibliography

Chapter 114 High-Risk Pregnancies
Genetic Factors
Maternal Factors
Bibliography

Chapter 115 The Fetus
Bibliography
Bibliography
Infectious Diseases
Noninfectious Diseases (see Table 114.2)
Chapter 116 Fetal Intervention and Surgery

Fetal Therapy Ethics
Obstructive Uropathy
Nonobstructive Renal Disease
Congenital Diaphragmatic Hernia
Congenital Pulmonary Airway Malformation
Myelomeningocele
Other Indications
Fetal Centers

Chapter 117 The High-Risk Infant

Keywords
Monozygotic vs Dizygotic Twins
Incidence
Etiology
Atypical Twinning

Complications

Twin Syndromes (TRAP, TTTS)

Diagnosis

Prognosis

Treatment

Bibliography

Keywords

Incidence

Etiology

Assessment of Gestational Age

Nursery Care

Immaturity of Drug Metabolism

Morbidity and Mortality

Bibliography

Keywords

Moderate Preterm Infant

Late Preterm Infant

Bibliography

Keywords
Small for Gestational Age and IUGR
Large-for-Gestational-Age Infants
Postterm Infants
Bibliography
Keywords
Discharge From the Hospital
Postdischarge Follow-Up
Bibliography

Chapter 118 Transport of the Critically Ill Newborn
Regionalized Care of Newborns
Levels of Neonatal Care
Transport of the Critically Ill Neonate
Bibliography

Chapter 119 Clinical Manifestations of Diseases in the Newborn Period
Abnormal Movements
Altered Mental Status
Apnea
Congenital Anomalies
Cyanosis
Gastrointestinal Disturbances
Chapter 120 Nervous System Disorders

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Prognosis

Prevention

Treatment

Bibliography

Etiology

Pathophysiology and Pathology
Clinical Manifestations

Diagnosis

Treatment

Prognosis

Bibliography

Bibliography

Brachial Palsy

Phrenic Nerve Paralysis

Facial Nerve Palsy

Bibliography

Chapter 121 Neonatal Resuscitation and Delivery Room Emergencies

Neonatal Resuscitation

Resuscitation of the Preterm Infant

Special Circumstances in the Delivery Room

Injury During Delivery

Ongoing Care After Resuscitation

Bibliography

Chapter 122 Respiratory Tract Disorders

Keywords

The First Breath
Breathing Patterns in Newborns

Keywords

Apnea of Prematurity

Treatment

Prognosis

Apnea of Prematurity and Sudden Infant Death Syndrome

Bibliography

Keywords

Incidence

Etiology and Pathophysiology

Clinical Manifestations

Diagnosis

Prevention

Treatment

Complications

Bibliography

Keywords

Incidence

Etiology and Pathophysiology

Clinical Manifestations
Meconium Plugs
Meconium Ileus
Meconium Peritonitis
Bibliography
Keywords
Pathology and Pathogenesis
Clinical Manifestations
Diagnosis
Treatment
Prognosis
Prevention
Bibliography
Keywords
Etiology
Clinical Manifestations
Differential Diagnosis
Physiologic Jaundice (Icterus Neonatorum)
Pathologic Hyperbilirubinemia
Jaundice Associated With Breastfeeding
Neonatal Cholestasis
Congenital Atresia of the Bile Ducts

Bibliography

Keywords

Clinical Manifestations

Incidence and Prognosis

Prevention

Treatment of Hyperbilirubinemia

Bibliography

Chapter 124 Blood Disorders

Keywords

Normal Hematocrit and Hemoglobin Concentrations in Newborn Infants

Classification of Anemia and Diagnostic Evaluation

Treatment Options for Neonatal Anemia

Bibliography

Keywords

Hemolytic Disease Caused by Rh Incompatibility

Hemolytic Disease Caused by Blood Group A and B Incompatibility

Other Forms of Hemolytic Disease

Bibliography
Keywords

Bibliography

Keywords

Vitamin K Deficiency Bleeding
Disseminated Intravascular Coagulopathy
Neonatal Thrombocytopenia

Bibliography

Keywords

Bibliography

Chapter 125 The Umbilicus

Umbilical Cord
Hemorrhage
Granuloma
Infections
Umbilical Hernia
Congenital Omphalocele
Tumors

Bibliography

Chapter 126 Abstinence Syndromes

Keywords
Chapter 127 The Endocrine System

Keywords

Pathophysiology

Clinical Manifestations

Treatment

Prognosis

Bibliography
Chapter 128 Dysmorphology

Classification of Birth Defects

Molecular Mechanisms of Malformations

Approach to the Dysmorphic Child

Bibliography

Chapter 129 Epidemiology of Infections

Incidence and Epidemiology

Pathogenesis

Clinical Manifestations

Laboratory Findings

General Approach to Management

Prevention

Bibliography

Chapter 130 Healthcare-Acquired Infections

Incidence

Epidemiology

Pathogenesis

Types of Infection

Prevention

Bibliography
Chapter 131 Congenital and Perinatal Infections

General Approach
Pathogenesis
Clinical Manifestations
Diagnosis
Specific Infectious Agents

Part XII Adolescent Medicine

Chapter 132 Adolescent Physical and Social Development

Physical Development
Neurologic, Cognitive, and Moral Development
Psychosocial Development
Implications for Providers, Parents, and Policymakers
Bibliography
Chapter 133 Gender and Sexual Identity

Terms and Definitions

Factors That Influence Sexual Identity Development

Nonconformity in Gender Expression Among Children and Adolescents

Transgender and Gender-Nonconforming Identities Among Children and Adolescents

Bibliography

Chapter 134 Gay, Lesbian, and Bisexual Adolescents

Prevalence of Homosexuality and Bisexuality in Youth

Development of Sexual Orientation in Childhood and Adolescence

Stigma, Risk, and Resilience

Health

Recommendations for Care

Bibliography

Chapter 135 Transgender Care

Cultural and Clinical Competence

Gender Literacy

Assessment

Treatment
Families

Bibliography

Chapter 136 The Epidemiology of Adolescent Health Problems

Access to Healthcare

Bibliography

Chapter 137 Delivery of Healthcare to Adolescents

Bibliography

Interviewing the Adolescent

Psychosocial Assessment

Physical Examination

Bibliography

Bibliography

Chapter 138 Transitioning to Adult Care

Bibliography

Chapter 139 Violent Behavior

Epidemiology

Etiology

Clinical Manifestations

Diagnosis
Chapter 140 Substance Abuse

Etiology

Epidemiology

Clinical Manifestations

Screening for Substance Abuse Disorders

Diagnosis

Complications

Treatment

Prognosis

Prevention

Pharmacology and Pathophysiology

Clinical Manifestations

Diagnosis

Treatment

Bibliography

Keywords

Cigarettes
Pharmacology
Clinical Manifestations
Electronic Cigarettes (E-Cigarettes)
Hookah
Treatment
Bibliography
Keywords
Clinical Manifestations
Synthetic Marijuana
Bibliography
Keywords
Clinical Manifestations
Complications
Diagnosis
Treatment
Bibliography
Keywords
Lysergic Acid Diethylamide
Methylenedioxymethamphetamine
Phencyclidine
Chapter 142 Menstrual Problems

Normal Menstruation

Menstrual Irregularities

Keywords

History and Physical Examination

Laboratory Studies

Treatment

Bibliography

Keywords

Irregular Menstrual Bleeding

Heavy and Prolonged Menstrual Bleeding

Laboratory Findings

Treatment

Bibliography

Keywords

Bibliography

Keywords
Chapter 143 Contraception

Contraceptive Effectiveness

Keywords

Sexual Activity

Use of Contraception Among Teens

Bibliography

Keywords

Intrauterine Devices

Implants

Bibliography

Keywords

Depo-Provera

Progestin-Only Pills

Bibliography

Keywords

Combined Oral Contraceptives
Transdermal Patch
Vaginal Ring
Contraindications
Bibliography
Keywords
Copper IUD
Ulipristal Acetate
Levonorgestrel
Bibliography
Keywords
Condoms
Bibliography
Keywords
Diaphragm, Cervical Cap, and Sponge
Keywords
Spermicides
Withdrawal
Fertility Awareness–Based Methods
Lactational Amenorrhea Method
Bibliography
Chapter 144 Adolescent Pregnancy

Epidemiology
Etiology
Clinical Manifestations
Diagnosis
Pregnancy Counseling and Initial Management
Adolescent Fathers
Medical Complications of Mothers and Babies
Psychosocial Outcomes/Risks for Mother and Child
Prevention of Teen Pregnancies
Bibliography

Chapter 145 Adolescent Sexual Assault

Epidemiology
Types of Rape
Clinical Manifestations
Interview and Physical Examination
Laboratory Data
Treatment
Prevention
Bibliography
Chapter 146 Sexually Transmitted Infections

Etiology
Epidemiology
Pathogenesis
Screening
Common Infections and Clinical Manifestations
Diagnosis
Treatment
Prevention
Bibliography

Chapter 147 Chronic Overlapping Pain Conditions

Prevalence
Symptom/Disorder Overlap
Psychiatric Comorbidities
Predisposing Factors
Natural History
Proposed Pathophysiology
Treatment
Keywords
Epidemiology
Part XIII Immunology

Section 1 Evaluation of the Immune System

Chapter 148 Evaluation of Suspected Immunodeficiency

Advanced Testing

Bibliography

Section 2 The T-, B-, and NK-Cell Systems

Chapter 149 Lymphocyte Development and Function

Lymphopoiesis in the Fetus

Postnatal Lymphocyte Behavior

Inheritance of Abnormalities in T-, B-, and NK-Cell Development
Bibliography

Chapter 150 Primary Defects of Antibody Production

X-Linked Agammaglobulinemia
Common Variable Immunodeficiency
Selective IgA Deficiency
IgG Subclass Deficiencies
Immunoglobulin Heavy- and Light-Chain Deletions
Transient Hypogammaglobulinemia of Infancy
Class Switch Defects
X-Linked Lymphoproliferative Disease
Bibliography

Chapter 151 Primary Defects of Cellular Immunity

Chromosome 22Q11.2 Deletion Syndrome
T-Cell Activation Defects
Chronic Mucocutaneous Candidiasis
Autoimmune Polyendocrinopathy-Candidiasis–Ectodermal Dysplasia
Bibliography

Chapter 152 Immunodeficiencies Affecting Multiple Cell Types
Keywords
Pathogenesis
Clinical Manifestations
Treatment
Genetics
Bibliography

Keywords
Cartilage-Hair Hypoplasia
Wiskott-Aldrich Syndrome
Ataxia-Telangiectasia
Autosomal Dominant Hyper-IgE Syndrome
DOCK8 Deficiency

Bibliography

Keywords
Interferon-γ Receptors 1 and 2, IL-12 Receptor β1, and IL-12P40 Defects
IL-1R–Associated Kinase 4 Deficiency and Myeloid Differentiation Factor 88
Natural Killer Cell Deficiency

Defects in Innate Responses to Viral Infection
Defects in Innate Responses to Fungi
Section 3 The Phagocytic System

Chapter 153 Neutrophils

The Phagocytic Inflammatory Response

Hematopoiesis

Neutrophil Maturation and Kinetics
Neutrophil Function

Bibliography

Chapter 154 Monocytes, Macrophages, and Dendritic Cells

Development

Activation

Functional Activities

Dendritic Cells

Abnormalities of Monocyte-Macrophage or Dendritic Cell Function

Bibliography

Chapter 155 Eosinophils

Diseases Associated With Eosinophilia

Bibliography

Chapter 156 Disorders of Phagocyte Function

Leukocyte Adhesion Deficiency

Treatment

Prognosis

Chédiak-Higashi Syndrome

Myeloperoxidase Deficiency

Chronic Granulomatous Disease
Section 4 The Complement System

Chapter 159 Complement Components and Pathways

Classical and Lectin Pathways

Alternative Pathway

Membrane Attack Complex

Control Mechanisms

Participation in Host Defense

Bibliography
Chapter 160 Disorders of the Complement System

Keywords

Bibliography

Keywords

Bibliography

Keywords

Section 5 Hematopoietic Stem Cell Transplantation

Chapter 161 Principles and Clinical Indications of Hematopoietic Stem Cell Transplantation

HSCT From an HLA-Identical Sibling Donor

Acute Lymphoblastic Leukemia

Acute Myeloid Leukemia

Chronic Myelogenous Leukemia

Juvenile Myelomonocytic Leukemia
Myelodysplastic Syndromes Other Than Juvenile Myelomonocytic Leukemia

Non-Hodgkin Lymphoma and Hodgkin Disease

Acquired Aplastic Anemia

Inherited Bone Marrow Failure Syndromes

Thalassemia

Sickle Cell Disease

Immunodeficiency Disorders

Inherited Metabolic Diseases

Bibliography

Chapter 162 Hematopoietic Stem Cell Transplantation From Alternative Sources and Donors

Unrelated Donor Transplants

Umbilical Cord Blood Transplants

Haploidentical Transplants

Donor Versus Recipient NK-Cell Alloreactivity

Autologous Hematopoietic Stem Cell Transplantation

Bibliography

Chapter 163 Graft-Versus-Host Disease, Rejection, and Venoocclusive Disease

Acute Graft-Versus-Host Disease
Chronic Graft-Versus-Host Disease

Graft Failure

Venoocclusive Disease

Bibliography

Chapter 164 Infectious Complications of Hematopoietic Stem Cell Transplantation

Bibliography

Chapter 165 Late Effects of Hematopoietic Stem Cell Transplantation

Endocrine Effects

Cardiovascular Effects

Secondary Malignancy

Graft-Versus-Host Disease

Other Effects

Special Considerations

Bibliography

Part XIV Allergic Disorders

Chapter 166 Allergy and the Immunologic Basis of Atopic Disease

Key Elements of Allergic Diseases

Mechanisms of Allergic Tissue Inflammation
Genetic Basis of Atopy

Bibliography

Chapter 167 Diagnosis of Allergic Disease

Allergy History

Physical Examination

Diagnostic Testing

Bibliography

Chapter 168 Allergic Rhinitis

Etiology and Classification

Pathogenesis

Clinical Manifestations

Differential Diagnosis

Complications

Laboratory Findings

Treatment

Prognosis

Bibliography

Chapter 169 Childhood Asthma

Etiology
Chapter 170 Atopic Dermatitis (Atopic Eczema)

Etiology

Pathology

Pathogenesis

Clinical Manifestations

Laboratory Findings

Diagnosis and Differential Diagnosis

Treatment

Avoiding Triggers

Complications

Prognosis
Chapter 171 Insect Allergy

Etiology
Pathogenesis
Clinical Manifestations
Diagnosis
Treatment
Prevention

Chapter 172 Ocular Allergies

Clinical Manifestations
Diagnosis
Treatment

Chapter 173 Urticaria (Hives) and Angioedema

Etiology and Pathogenesis
Physical Urticaria
Chronic Idiopathic Urticaria and Angioedema
Chapter 174 Anaphylaxis

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Laboratory Findings

Diagnosis

Treatment

Prevention

Bibliography

Chapter 175 Serum Sickness

Etiology

Pathogenesis

Clinical Manifestations

Differential Diagnosis

Diagnosis

Treatment
Prevention

Bibliography

Chapter 176 Food Allergy and Adverse Reactions to Foods

Genetics

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 177 Adverse Reactions to Drugs

Epidemiology

Pathogenesis and Clinical Manifestations

Diagnosis

Treatment

Bibliography

Part XV Rheumatic Diseases of Childhood (Connective Tissue Disease, Collagen Vascular Diseases)
Chapter 178 Evaluation of Suspected Rheumatic Disease

Symptoms Suggestive of Rheumatic Disease

Signs Suggestive of Rheumatic Disease

Laboratory Testing

Imaging Studies

Bibliography

Chapter 179 Treatment of Rheumatic Diseases

Pediatric Rheumatology Teams and Primary Care Physicians

Therapeutics

Bibliography

Chapter 180 Juvenile Idiopathic Arthritis

Epidemiology

Etiology

Pathogenesis

Clinical Manifestations

Diagnosis

Differential Diagnosis

Laboratory Findings

Treatment

Prognosis
Chapter 181 Ankylosing Spondylitis and Other Spondyloarthritides

Epidemiology

Etiology and Pathogenesis

Clinical Manifestations and Diagnosis

Laboratory Findings

Differential Diagnosis

Treatment

Prognosis

Bibliography

Chapter 182 Reactive and Postinfectious Arthritis

Pathogenesis

Clinical Manifestations and Differential Diagnosis

Diagnosis

Treatment

Complications and Prognosis

Bibliography

Chapter 183 Systemic Lupus Erythematosus

Etiology
Chapter 184 Juvenile Dermatomyositis

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Differential Diagnosis

Laboratory Findings

Treatment

Complications

Prognosis

Keywords

Bibliography
Chapter 185 Scleroderma and Raynaud Phenomenon

Etiology and Pathogenesis

Classification

Epidemiology

Clinical Manifestations

Diagnosis

Differential Diagnosis

Laboratory Findings

Treatment

Prognosis

Bibliography

Chapter 186 Behçet Disease

Epidemiology

Etiology and Pathogenesis

Clinical Manifestations and Diagnosis
Chapter 191 Kawasaki Disease

Etiology
Epidemiology
Pathology
Clinical Manifestations
Laboratory and Radiology Findings
Diagnosis
Differential Diagnosis
Treatment
Complications
Prognosis
Bibliography

Chapter 192 Vasculitis Syndromes

Epidemiology
Pathology
Pathogenesis
Clinical Manifestations
Diagnosis
Laboratory Findings
Treatment
Chapter 193 Musculoskeletal Pain Syndromes

Clinical Manifestations
Diagnosis and Differential Diagnosis

Treatment

Complications and Prognosis

Bibliography

Chapter 194 Miscellaneous Conditions Associated With Arthritis

Relapsing Polychondritis

Mucha-Habermann Disease/Pityriasis Lichenoides Et Varioliformis Acuta

Sweet Syndrome

Hypertrophic Osteoarthropathy

Plant Thorn Synovitis

Pigmented Villonodular Synovitis

Bibliography

Part XVI Infectious Diseases
Section 1 General Considerations

Chapter 195 Diagnostic Microbiology

Specimen Collection

Laboratory Diagnosis of Bacterial and Fungal Infections

Antimicrobial Susceptibility Testing

Point-of-Care Diagnostics

Laboratory Detection of Parasitic Infections

Serologic Diagnosis

Laboratory Diagnosis of Viral Infections

Bibliography

Chapter 196 The Microbiome and Pediatric Health

Measuring the Microbiome

Early Childhood Development of the Microbiome

The Microbiome and Physiologic Development

Contributions of Microbiome to Disease

Therapeutic Manipulation of the Microbiome

Bibliography

Section 2 Preventive Measures
Chapter 197 Immunization Practices

Passive Immunity

Active Immunization

Vaccination System in the United States

Recommended Immunization Schedule

Vaccines Recommended in Special Situations

Precautions and Contraindications

Medical Exemptions

Improving Immunization Coverage

Vaccine Hesitancy

Bibliography

Bibliography

Chapter 198 Infection Prevention and Control

Hand Hygiene

Standard Precautions

Isolation

Additional Measures

Surgical Prophylaxis

Employee Health
Chapter 199 Childcare and Communicable Diseases

Epidemiology

Respiratory Tract Infections

Gastrointestinal Tract Infections

Skin Diseases

Invasive Organisms

Herpesviruses

Bloodborne Pathogens

Antibiotic Use and Bacterial Resistance

Prevention

Standards

Bibliography

Chapter 200 Health Advice for Children Traveling Internationally

The Pediatric Travel Medicine Consultation

Safety and Preventive Counseling Topics

Routine Childhood Vaccinations Required for Pediatric Travel

Specialized Pediatric Travel Vaccinations

Traveler's Diarrhea

Insect-Borne Infections
Malaria Chemoprophylaxis
The Returning Traveler
The Adolescent Traveler
Bibliography

Chapter 201 Fever
Pathogenesis
Etiology
Clinical Features
Evaluation
Management
Bibliography

Chapter 202 Fever Without a Focus in the Neonate and Young Infant
Etiology and Epidemiology
Clinical Manifestations
Diagnosis
Laboratory Diagnosis
Treatment
Prognosis
Bibliography
Chapter 203 Fever in the Older Child

Diagnosis

General Approach

Evaluation

Management

Bibliography

Chapter 204 Fever of Unknown Origin

Etiology

Diagnosis

Management

Prognosis

Bibliography

Chapter 205 Infections in Immunocompromised Persons

Abnormalities of the Phagocytic System

Defective Splenic Function, Opsonization, or Complement Activity

B Cell Defects (Humoral Immunodeficiencies)

T Cell Defects (Cell-Mediated Immunodeficiencies)

Combined B Cell and T Cell Defects

Bibliography

Acquired Immunodeficiency From Infectious Agents
Malignancies

Fever and Neutropenia

Fever Without Neutropenia

Transplantation

Bibliography

Bibliography

Chapter 206 Infection Associated With Medical Devices

Intravascular Access Devices

Cerebrospinal Fluid Shunts

Urinary Catheters

Peritoneal Dialysis Catheters

Orthopedic Prostheses

Bibliography

Section 3 Antibiotic Therapy

Chapter 207 Principles of Antibacterial Therapy

Age- and Risk-Specific Use of Antibiotics in Children

Antibiotics Commonly Used in Pediatric Practice

Bibliography
Section 4 Gram-Positive Bacterial Infections

Chapter 208 Staphylococcus

Chapter 308 Giardiasis and Balantidiasis

Etiology

Epidemiology

Clinical Manifestations

Diagnosis

Treatment

Prognosis

Prevention

Bibliography

Bibliography
Chapter 309 Cryptosporidium, Cystoisospora, Cyclospora, and Microsporidia

Cryptosporidium
Diagnosis
Cystoisospora
Cyclospora
Microsporidia
Bibliography

Chapter 310 Trichomoniasis (Trichomonas vaginalis)
Epidemiology
Pathogenesis
Clinical Manifestations
Diagnosis
Complications
Treatment
Prevention
Bibliography

Chapter 311 Leishmaniasis (Leishmania)
Etiology
Epidemiology
Pathology
Chapter 312 African Trypanosomiasis (Sleeping Sickness; *Trypanosoma brucei* Complex)

Etiology

Life Cycle

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 313 American Trypanosomiasis (Chagas Disease; *Trypanosoma cruzi*)
Etiology
Life Cycle
Epidemiology
Pathogenesis
Clinical Manifestations
Diagnosis
Treatment
Prevention
Bibliography

Chapter 314 Malaria (*Plasmodium*)

Etiology
Epidemiology
Pathogenesis
Clinical Manifestations
Diagnosis
Treatment
Complications of *Plasmodium Falciparum* MALARIA
Prevention
Bibliography

Chapter 315 Babesiosis (*Babesia*)
Chapter 316 Toxoplasmosis (*Toxoplasma gondii*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Systemic Signs

Diagnosis

Treatment

Prognosis

Prevention

Acknowledgment
Section 16 Helminthic Diseases

Chapter 317 Ascariasis (*Ascaris lumbricoides*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 318 Hookworms (*Necator americanus* and *Ancylostoma* spp.)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Bibliography
Chapter 319 Trichuriasis (*Trichuris trichiura*)

Etiology

Epidemiology

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 320 Enterobiasis (*Enterobius vermicularis*)

Etiology

Epidemiology
Chapter 321 Strongyloidiasis (*Strongyloides stercoralis*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 322 Lymphatic Filariasis (*Brugia malayi, Brugia timori, and Wuchereria bancrofti*)

Etiology

Epidemiology

Clinical Manifestations
Diagnosis
Treatment
Bibliography

Chapter 323 Other Tissue Nematodes

Onchocerciasis *(Onchocerca Volvulus)*

Loiasis *(Loa Loa)*

Infection With Animal Filariae

*Angiostrongylus Cantonensis*

*Angiostrongylus Costaricensis*

Dracunculiasis *(Dracunculus Medinensis)*

*Gnathostoma Spinigerum*

Bibliography

Chapter 324 Toxocariasis (Visceral and Ocular Larva Migrans)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention
Chapter 325 Trichinellosis (*Trichinella spiralis*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography

Chapter 326 Schistosomiasis (*Schistosoma*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prevention

Bibliography
Chapter 327 Flukes (Liver, Lung, and Intestinal)

Liver Flukes
Lung Flukes
Intestinal Flukes

Bibliography

Chapter 328 Adult Tapeworm Infections

Etiology
Epidemiology
Pathogenesis
Clinical Manifestations
Diagnosis
Treatment
Prevention
Diphyllobothriasis (*Diphyllobothrium Spp.*)
Hymenolepiasis (*Hymenolepis*)
Dipylidiasis (*Dipylidium Caninum*)

Bibliography

Chapter 329 Cysticercosis

Etiology
Epidemiology
Chapter 330 Echinococcosis (*Echinococcus granulosus* and *Echinococcus multilocularis*)

Etiology

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis

Treatment

Prognosis

Prevention

Bibliography

**Volume 2**

**Part XVII The Digestive System**
Section 1 Clinical Manifestations of Gastrointestinal Disease

Chapter 331 Normal Digestive Tract Phenomena

Bibliography

Chapter 332 Major Symptoms and Signs of Digestive Tract Disorders

Dysphagia
Regurgitation
Anorexia
Vomiting
Diarrhea
Constipation
Abdominal Pain
Gastrointestinal Hemorrhage
Abdominal Distention and Abdominal Masses

Bibliography

Section 2 The Oral Cavity

Chapter 333 Development and Developmental Anomalies of the Teeth
Development of Teeth

Bibliography

Chapter 334 Disorders of the Oral Cavity Associated With Other Conditions

Chapter 335 Malocclusion

Variations in Growth Patterns
Crossbite
Open and Closed Bites
Dental Crowding
Digit Sucking

Chapter 336 Cleft Lip and Palate

Incidence and Epidemiology
Clinical Manifestations
Treatment
Postoperative Management
Sequelae
Velopharyngeal Dysfunction
Bibliography

Chapter 337 Syndromes With Oral Manifestations

Bibliography
Chapter 338 Dental Caries

Etiology

Epidemiology

Clinical Manifestations

Complications

Treatment

Prevention

Bibliography

Chapter 339 Periodontal Diseases

Gingivitis

Aggressive Periodontitis in Children (Prepubertal Periodontitis)

Aggressive Periodontitis in Adolescents

Cyclosporine- or Phenytoin-Induced Gingival Overgrowth

Acute Pericoronitis

Necrotizing Periodontal Disease (Acute Necrotizing Ulcerative Gingivitis)

Bibliography

Chapter 340 Dental Trauma

Injuries to Teeth

Injuries to Periodontal Structures
Chapter 341 Common Lesions of the Oral Soft Tissues

Oropharyngeal Candidiasis

Aphthous Ulcers

Herpetic Gingivostomatitis

Recurrent Herpes Labialis

Parulis

Cheilitis

Ankyloglossia

Geographic Tongue

Fissured Tongue

Developmental (Normal) Variations

Chapter 342 Diseases of the Salivary Glands and Jaws

Parotitis

Ranula

Mucocele

Congenital Lip Pits
Chapter 346 Obstructing and Motility Disorders of the Esophagus

Extrinsic

Intrinsic

Chapter 347 Dysmotility

Upper Esophageal and Upper Esophageal Sphincter Dysmotility (Striated Muscle)

Lower Esophageal and Lower Esophageal Sphincter Dysfunction (Smooth Muscle)

Chapter 348 Hiatal Hernia
Chapter 349 Gastroesophageal Reflux Disease

Pathophysiology

Epidemiology and Natural History

Clinical Manifestations

Diagnosis

Management

Keywords

Esophageal: Esophagitis and Sequelae—Stricture, Barrett Esophagus, Adenocarcinoma

Nutritional

Extraesophageal: Respiratory (“Atypical”) Presentations

Apnea and Stridor

Bibliography

Bibliography

Chapter 350 Eosinophilic Esophagitis, Pill Esophagitis, and Infective Esophagitis

Eosinophilic Esophagitis

Infective Esophagitis

Pill Esophagitis

Bibliography
Chapter 351 Esophageal Perforation

Bibliography

Chapter 352 Esophageal Varices

Bibliography

Chapter 353 Ingestions

Bibliography

Keywords

Bibliography

Section 4 Stomach and Intestines

Chapter 354 Normal Development, Structure, and Function of the Stomach and Intestines

Development

Digestion and Absorption

Chapter 355 Pyloric Stenosis and Other Congenital Anomalies of the Stomach

Etiology

Clinical Manifestations

Differential Diagnosis

Treatment
Chapter 356 Intestinal Atresia, Stenosis, and Malrotation

Clinical Manifestations and Diagnosis

Treatment

Bibliography

Clinical Manifestation and Diagnosis
Chapter 357 Intestinal Duplications, Meckel Diverticulum, and Other Remnants of the Omphalomesenteric Duct

Clinical Manifestations

Diagnosis

Bibliography

Chapter 358 Motility Disorders and Hirschsprung Disease

Clinical Manifestations

Diagnosis

Treatment

Bibliography

Bibliography

Clinical Manifestations

Diagnosis
Chapter 359 Ileus, Adhesions, Intussusception, and Closed-Loop Obstructions
Prognosis

Bibliography

Chapter 360 Foreign Bodies and Bezoars

Bibliography

Chapter 361 Peptic Ulcer Disease in Children

Pathogenesis

Clinical Manifestations

Diagnosis

Primary Ulcers

Secondary Ulcers

“Stress” Ulceration

Treatment

Bibliography

Chapter 362 Inflammatory Bowel Disease

Keywords

Clinical Manifestations
Differential Diagnosis
Diagnosis
Treatment
Prognosis
Bibliography

Clinical Manifestations
Differential Diagnosis
Diagnosis
Treatment
Prognosis
Bibliography
Keywords
Bibliography

Chapter 363 Eosinophilic Gastroenteritis

Bibliography

Chapter 364 Disorders of Malabsorption

Clinical Approach
Keywords
Investigations for Carbohydrate Malabsorption
Investigations for Fat Malabsorption

Investigations for Protein-Losing Enteropathy

Investigations for Exocrine Pancreatic Function

Investigations for Intestinal Mucosal Disorders

Imaging Procedures

Bibliography

Keywords

Etiology and Epidemiology

Genetics and Pathogenesis

Clinical Presentation and Associated Disorders

Diagnosis

Treatment

The Spectrum of Gluten-Related Disorders

Bibliography

Keywords

Defects of Enterocyte Differentiation and Polarization

Microvillus Inclusion Disease (Congenital Microvillus Atrophy)

Tufting Enteropathy (Congenital Tufting Enteropathy)

Tricho-Hepato-Enteric Syndrome (Syndromic Diarrhea)

Defects in Enteroendocrine Cells Differentiation
Enteric Anendocrinosis
Proprotein Convertase 1/3 Deficiency
Mitchell-Riley Syndrome
Aristaless-Related Homeobox Gene Mutations
Autoimmune Enteropathy
Autoimmune Polyglandular Syndrome Type 1
Abetalipoproteinemia
Homozygous Hypobetalipoproteinemia
Chylomicron Retention Disease (Anderson Disease)
DGAT1 Mutation
Wolman Disease
Tangier Disease
Sitosterolemia
Bile Acid Malabsorption
Protein-Losing Enteropathy
Bibliography
Keywords
Postinfectious Diarrhea
Proximal Intestinal Bacterial Overgrowth
Environmental Enteropathy (Tropical Sprue)
Whipple Disease

Bibliography

Keywords

Bibliography

Keywords

Treatment

Complications

Bibliography

Keywords

Bibliography

Keywords

Carbohydrate Malabsorption

Lactase Deficiency

Fructose Malabsorption

Sucrase-Isomaltase Deficiency

Glucose-Galactose Malabsorption

Exocrine Pancreatic Insufficiency

Enterokinase (Enteropeptidase) Deficiency
Trehalase Deficiency
Trypsinogen Deficiency
Bibliography
Keywords
Keywords
Disorders of Carbohydrate Absorption
Disorders of Amino Acid and Peptide Absorption
Disorders of Fat Transport
Disorders of Vitamin Absorption
Disorders of Electrolyte and Mineral Absorption
Bibliography

Chapter 365 Intestinal Transplantation in Children With Intestinal Failure
Indications for Intestinal Transplant
Transplantation Operation
Postoperative Management
Bibliography

Chapter 366 Acute Gastroenteritis in Children
Burden of Childhood Diarrhea
Pathogens
Epidemiology in the United States and Other Middle- and High-
Chapter 367 Chronic Diarrhea

Definition of Epidemiology

Pathophysiology

Etiology

Evaluation of Patients

Investigations

Treatment
Chapter 368 Functional Gastrointestinal Disorders

Functional Gastrointestinal Disorders in Children and Adolescents
Functional Abdominal Pain Disorders
Functional Defecation Disorders

Chapter 369 Cyclic Vomiting Syndrome

Chapter 370 Acute Appendicitis

Epidemiology
Pathophysiology
Appendicitis Risk Scoring Systems
Laboratory Findings
Imaging Studies
Diagnosis and Treatment
Differential Diagnosis
Antibiotics
Surgical Intervention

Perforated Appendicitis

Nonoperative Management of Uncomplicated Appendicitis

Recurrent Appendicitis

Interval Appendectomy

Incidental Appendicoliths

Bibliography

Chapter 371 Surgical Conditions of the Anus and Rectum

Keywords

Embryology

Associated Anomalies

Manifestations and Diagnosis

Approach to the Patient

Operative Repair

Outcome

Bibliography

Keywords

Clinical Manifestations

Treatment

Chapter 372 Tumors of the Digestive Tract

Hamartomatous Tumors
Adenomatous Tumors
Other Gastrointestinal Tumors

Bibliography

Chapter 373 Inguinal Hernias
Embryology and Pathogenesis

Evaluation of Acute Inguinal–Scrotal Swelling

Direct Inguinal Hernia

Femoral Hernia

Complications

Bibliography

Section 5 Exocrine Pancreas

Chapter 374 Embryology, Anatomy, and Physiology of the Pancreas

Bibliography

Bibliography

Bibliography

Chapter 375 Pancreatic Function Tests

Direct Test

Bibliography

Chapter 376 Disorders of the Exocrine Pancreas

Disorders Associated With Pancreatic Insufficiency

Cystic Fibrosis (see Chapter 432)

Shwachman-Diamond Syndrome (see Chapter 157)
Pearson Syndrome

Johanson-Blizzard Syndrome

Isolated Enzyme Deficiencies

Other Syndromes Associated With Pancreatic Insufficiency

Bibliography

Chapter 377 Treatment of Pancreatic Insufficiency

Bibliography

Chapter 378 Pancreatitis

Keywords

Clinical Manifestations

Diagnosis

Treatment

Prognosis

Bibliography

Keywords

Bibliography

Chapter 379 Pancreatic Fluid Collections

Treatment of Fluid Collections and Necrosis

Bibliography
Chapter 380 Pancreatic Tumors

Bibliography

Section 6 The Liver and Biliary System

Chapter 381 Morphogenesis of the Liver and Biliary System

Hepatic Ultrastructure

Metabolic Functions of the Liver

Bibliography

Chapter 382 Manifestations of Liver Disease

Pathologic Manifestations

Clinical Manifestations

Keywords

Biochemical Tests

Liver Biopsy

Hepatic Imaging Procedures

Diagnostic Approach to Infants With Jaundice

Bibliography

Bibliography

Chapter 383 Cholestasis
Mechanisms
Evaluation
Intrahepatic Cholestasis
Bile Acid-Coenzyme a Ligase Deficiency
Disorders of Embryogenesis
Biliary Atresia
Management of Chronic Cholestasis
Prognosis
Bibliography

Chapter 384 Metabolic Diseases of the Liver

Crigler-Najjar Syndrome Type I (Glucuronyl Transferase Deficiency)
Crigler-Najjar Syndrome Type II (Partial Glucuronyl Transferase Deficiency)
Inherited Conjugated Hyperbilirubinemia
Dubin-Johnson Syndrome
Bibliography
Pathogenesis
Clinical Manifestations
Pathology
Diagnosis
Chapter 385 Viral Hepatitis

Issues Common to All Forms of Viral Hepatitis

Hepatitis A
Hepatitis B
Hepatitis C
Hepatitis D
Hepatitis E

Approach to Acute or Chronic Hepatitis

Bibliography

Chapter 386 Liver Abscess

Bibliography
Chapter 387 Liver Disease Associated With Systemic Disorders

Inflammatory Bowel Disease

Bacterial Sepsis

Celiac Disease

Cardiac Disease

Cholestasis Associated With Chronic Total Parenteral Nutrition

Cystic Fibrosis

Bone Marrow Transplantation

Hemoglobinopathies

Histiocytic Disorders

Bibliography

Bibliography

Chapter 388 Mitochondrial Hepatopathies

Epidemiology

Clinical Manifestations

Primary Mitochondrial Hepatopathies

Diagnostic Evaluation

Treatment of Mitochondrial Hepatopathies

Bibliography

Chapter 389 Autoimmune Hepatitis
Autoimmune Hepatitis

Etiology

Pathology

Clinical Manifestations

Laboratory Findings

Diagnosis

Treatment

Prognosis

Bibliography

Chapter 390 Drug- and Toxin-Induced Liver Injury

Treatment

Prognosis

Prevention

Bibliography

Chapter 391 Acute Hepatic Failure

Etiology

Pathology

Pathogenesis

Clinical Manifestations

Laboratory Findings
Chapter 392 Cystic Diseases of the Biliary Tract and Liver

Choledochal Cysts

Autosomal Dominant Polycystic Kidney Disease

Autosomal Dominant Polycystic Liver Disease

Chapter 393 Diseases of the Gallbladder

Anomalies

Acute Hydrops

Cholecystitis and Cholelithiasis

Biliary Dyskinesia

Chapter 394 Portal Hypertension and Varices

Etiology

Pathophysiology

Clinical Manifestations

Diagnosis
Chapter 395 Liver Transplantation

Indications

Technical Innovations

Immunosuppression

Complications

Outcomes

Bibliography

Section 7 Peritoneum

Chapter 396 Peritoneal Malformations

Acknowledgment

Bibliography

Chapter 397 Ascites

Bibliography

Chapter 398 Peritonitis
History

Physical Examination

Blood Gas Analysis

Transillumination of the Chest

Radiographic Techniques

Pulmonary Function Testing

Microbiology: Examination of Lung Secretions

The Microbiome (see Chapter 196)

Airway Visualization and Lung Specimen–Based Diagnostic Tests

Bibliography

Chapter 401 Chronic or Recurrent Respiratory Symptoms

Judging the Seriousness of Chronic Respiratory Complaints

Recurrent or Persistent Cough

Frequently Recurring or Persistent Stridor

Recurrent or Persistent Wheeze

Recurrent and Persistent Lung Infiltrates

Evaluation

Bibliography

Bibliography

Chapter 402 Sudden Infant Death Syndrome
Chapter 403 Brief Resolved Unexplained Events and Other Acute Events in Infants

Background
Section 2 Disorders of the Respiratory Tract

Chapter 404 Congenital Disorders of the Nose

Normal Newborn Nose

Physiology

Congenital Disorders

Choanal Atresia

Congenital Defects of the Nasal Septum

Pyriform Aperture Stenosis

Congenital Midline Nasal Masses

Diagnosis and Treatment

Bibliography

Chapter 405 Acquired Disorders of the Nose

Keywords

Etiology
Chapter 406 Nasal Polyps

Etiology

Clinical Manifestations

Diagnosis and Differential Diagnosis

Treatment

Bibliography

Chapter 407 The Common Cold

Etiology
Chapter 408 Sinusitis

Etiology
Epidemiology
Pathogenesis
Clinical Manifestations

Chapter 484 Definitions and Classification of Hemolytic Anemias
Bibliography

Chapter 485 Hereditary Spherocytosis
Etiology
Clinical Manifestations
Diagnosis
Differential Diagnosis
Treatment
Bibliography

Chapter 486 Hereditary Elliptocytosis, Hereditary Pyropoikilocytosis, and Related Disorders

Etiology

Clinical Manifestations

Laboratory Findings

Treatment

Bibliography

Chapter 487 Hereditary Stomatocytosis

Hereditary Xerocytosis

Hereditary Hydrocytosis

Intermediate Syndromes and Other Variants

Other Disorders Associated With Stomatocytosis

Bibliography

Chapter 488 Paroxysmal Nocturnal Hemoglobinuria and Acanthocytosis

Paroxysmal Nocturnal Hemoglobinuria

Acanthocytosis

Bibliography

Chapter 489 Hemoglobinopathies
Hemoglobin Disorders
Pathophysiology
Diagnosis and Epidemiology
Clinical Manifestations and Treatment of Sickle Cell Anemia (HbSS)
Therapeutic Considerations
Other Sickle Cell Syndromes
Anticipatory Guidance
Bibliography

Hemoglobin C
Hemoglobin E
Hemoglobin D
Epidemiology
Pathophysiology
Homozygous β-Thalassemia (Thalassemia Major, Cooley Anemia)
Other β-Thalassemia Syndromes
α-Thalassemia Syndromes
Bibliography

Chapter 490 Enzymatic Defects
Keywords
Etiology

Clinical Manifestations and Laboratory Findings

Treatment

Keywords

Deficiencies of Enzymes of Hexose Monophosphate Pathway

Keywords

Episodic or Induced Acute Hemolytic Anemia

Chronic Hemolytic Anemias Associated With Deficiency of G6PD or Related Factors

Bibliography

Chapter 491 Hemolytic Anemias Resulting from Extracellular Factors—Immune Hemolytic Anemias

Immune Hemolytic Anemias

Autoimmune Hemolytic Anemias Associated With “Warm” Antibodies

Autoimmune Hemolytic Anemias Associated With “Cold” Antibodies

Bibliography

Chapter 492 Hemolytic Anemias Secondary to Other Extracellular Factors

Fragmentation Hemolysis

Thermal Injury

Renal Disease
Section 4 Polycythemia (Erythrocytosis)

Chapter 493 Polycythemia

Clonal (Primary) Polycythemia (Polycythemia Vera)

Bibliography

Chapter 494 Nonclonal Polycythemia

Pathogenesis

Diagnosis

Treatment

Bibliography

Section 5 The Pancytopenias

Chapter 495 Inherited Bone Marrow Failure Syndromes With Pancytopenia

Fanconi Anemia

Shwachman-Diamond Syndrome
Dyskeratosis Congenita

Congenital Amegakaryocytic Thrombocytopenia

Other Inherited Aplastic Anemias

Other Inherited Syndromes With Occasional Significant Bone Marrow Failure

Unclassified Inherited Bone Marrow Failure Syndromes

Bibliography

Chapter 496 The Acquired Pancytopenias

Etiology and Epidemiology

Pathology and Pathogenesis

Clinical Manifestations, Laboratory Findings, and Differential Diagnosis

Treatment

Complications

Prognosis

Pancytopenia Caused by Marrow Replacement

Bibliography

Section 6 Blood Component Transfusions

Chapter 497 Red Blood Cell Transfusions and Erythropoietin Therapy
RBC Transfusion in Children and Adolescents

RBC Transfusion in Preterm Infants and Neonates

RBC Product and Dose

Storage Age of RBC Units

Bibliography

Chapter 498 Platelet Transfusions

Children and Adolescents

Infants and Neonates

Platelet Products and Dosing

Bibliography

Chapter 499 Neutrophil (Granulocyte) Transfusions

Granulocyte Transfusions for Children

Granulocyte Transfusion for Neonates

Granulocyte Product

Bibliography

Chapter 500 Plasma Transfusions

Plasma Products and Patient Testing

Plasma Transfusion in Children

Plasma Transfusion in Neonates
**Section 7 Hemorrhagic and Thrombotic Diseases**

Etiology

Pathogenesis

Clinical Manifestations
Chapter 551 Renal Transplantation

Incidence and Etiology of End-Stage Renal Disease

Indications for Renal Transplantation

Characteristics of Kidney Donors and Recipients

Evaluation and Preparing for Kidney Transplantation

Immunosuppression

Fluid Management in Infants and Small Children Following Kidney Transplantation

Rejection of Kidney Transplant

Graft Survival of Kidneys

Complications of Immunosuppression

Long-Term Outcome of Kidney Transplantation

Bibliography

Part XXIII Urologic Disorders in Infants and Children
Chapter 552 Congenital Anomalies and Dysgenesis of the Kidneys

Embryonic and Fetal Development
Renal Agenesis
Renal Dysgenesis: Dysplasia, Hypoplasia, and Cystic Anomalies
Renal Cysts in Children
Anomalies in Shape and Position
Associated Physical Findings
Bibliography

Chapter 553 Urinary Tract Infections
Prevalence and Etiology
Clinical Manifestations and Classification
Pathogenesis and Pathology
Diagnosis
Imaging Findings
Treatment
Imaging Studies in Children With a Febrile UTI
Prevention of Recurrences
Bibliography

Chapter 554 Vesicoureteral Reflux
Classification
Clinical Manifestations

Diagnosis

Natural History

Treatment

Current Vesicoureteral Reflux Guidelines

Bibliography

Chapter 555 Obstruction of the Urinary Tract

Etiology

Clinical Manifestations

Diagnosis

Physical Findings

Imaging Studies

Specific Types of Urinary Tract Obstruction and Their Treatment

Bibliography

Chapter 556 Anomalies of the Bladder

Bladder Exstrophy

Other Exstrophy Anomalies

Bladder Diverticula

Urachal Anomalies

Bibliography
Chapter 557 Neuropathic Bladder

Neural Tube Defects

Associated Disorders

Bibliography

Chapter 558 Enuresis and Voiding Dysfunction

Normal Voiding and Toilet Training

Diurnal Incontinence

Overactive Bladder (Diurnal Urge Syndrome)

Nonneurogenic Neurogenic Bladder (Hinman Syndrome)

Infrequent Voiding (Underactive Bladder)

Vaginal Voiding

Other Causes of Incontinence in Females

Voiding Disorders Without Incontinence

Nocturnal Enuresis

Bibliography

Chapter 559 Anomalies of the Penis and Urethra

Hypospadias

Chordee Without Hypospadias

Phimosis and Paraphimosis

Circumcision
Penile Torsion

Inconspicuous Penis

Micropenis

Priapism

Other Penile Anomalies

Meatal Stenosis

Other Male Urethral Anomalies

Urethral Prolapse (Female)

Other Female Urethral Lesions

Bibliography

Chapter 560 Disorders and Anomalies of the Scrotal Contents

Undescended Testis (Cryptorchidism)

Scrotal Swelling

Testicular (Spermatic Cord) Torsion

Torsion of the Appendix Testis/Epididymis

Epididymitis

Varicocele

Spermatocele

Hydrocele

Inguinal Hernia
Testicular Microlithiasis
Testicular Tumor
Bibliography

Chapter 561 Trauma to the Genitourinary Tract
Etiology
Diagnosis
Treatment
Bibliography

Chapter 562 Urinary Lithiasis
Stone Formation
Clinical Manifestations
Diagnosis
Metabolic Evaluation
Pathogenesis of Specific Renal Calculi
Treatment
Stone Prevention
Bibliography

Part XXIV Gynecologic Problems of Childhood

Chapter 563 Gynecologic History and Physical Examination
Chapter 564 Vulvovaginitis

Etiology

Epidemiology

Clinical Manifestations

Diagnosis and Differential Diagnosis

Treatment and Prevention

Bibliography

Chapter 565 Vaginal Bleeding in the Prepubertal Child

Part XXV The Endocrine System
Section 1 Disorders of the Hypothalamus and Pituitary Gland

Chapter 572 Hormones of the Hypothalamus and Pituitary

Anatomy

Embryology

Vascular Supply

Anterior Pituitary Cell Types

Posterior Pituitary Cell Types

Bibliography

Chapter 573 Hypopituitarism

Multiple Pituitary Hormone Deficiency

Isolated Growth Hormone Deficiency and Insensitivity

Growth Hormone Insensitivity

Clinical Manifestations

Laboratory Findings

Radiologic Findings

Differential Diagnosis

Treatment

Complications and Adverse Effects of Growth Hormone Treatment
Bibliography

Chapter 574 Diabetes Insipidus

Physiology of Water Balance

Approach to the Patient With Polyuria, Polydipsia, and Hypernatremia

Causes of Hypernatremia

Treatment of Central Diabetes Insipidus

Treatment of Nephrogenic Diabetes Insipidus

Bibliography

Chapter 575 Other Abnormalities of Arginine Vasopressin Metabolism and Action

Causes of Hyponatremia

Treatment

Bibliography

Chapter 576 Hyperpituitarism, Tall Stature, and Overgrowth Syndromes

Hyperpituitarism

Tall Stature

Sotos Syndrome (Cerebral Gigantism)

Treatment of Normal Variant Tall Stature

Excess Growth Hormone Secretion and Pituitary Gigantism
Hypersecretion of Other Pituitary Hormones

Bibliography

Chapter 577 Physiology of Puberty

Chapter 586 Autoimmune Polyglandular Syndromes

Monogenic Autoimmune Polyglandular Syndromes

Autoimmune Polyglandular Syndrome Type 1

Immune Dysregulation-Polyendocrinopathy-Enteropathy X-Linked

Other Monogenic Immune Dysregulation Disorders

Polygenic Autoimmune Polyglandular Syndrome (APS-2)

Chromosomal Abnormalities Associated With Autoimmune Polyglandular Syndrome

Nongenetic Autoimmune Causes of Multiple Endocrinopathy

Bibliography

Chapter 587 Multiple Endocrine Neoplasia Syndromes
Multiple Endocrine Neoplasia Type 1
Multiple Endocrine Neoplasia Type 2
Multiple Endocrine Neoplasia Type 2A
Multiple Endocrine Neoplasia Type 2B
Familial Medullary Thyroid Carcinoma
Management of Multiple Endocrine Neoplasia Type 2

Bibliography

Section 3 Disorders of the Parathyroid Gland

Chapter 588 Hormones and Peptides of Calcium Homeostasis and Bone Metabolism

Parathyroid Hormone
Parathyroid Hormone–Related Peptide
Vitamin D
Calcitonin

Bibliography

Chapter 589 Hypoparathyroidism

Etiology
Aplasia or Hypoplasia of the Parathyroid Glands
X-Linked Recessive Hypoparathyroidism
Autosomal Recessive Hypoparathyroidism With Dysmorphic Features

Hypoparathyroidism, Sensorineural Deafness, and Renal Anomaly Syndrome

Suppression of Neonatal Parathyroid Hormone Secretion Because of Maternal Hyperparathyroidism

Autosomal Dominant Hypoparathyroidism

Hypoparathyroidism Associated With Mitochondrial Disorders

Surgical Hypoparathyroidism

Autoimmune Hypoparathyroidism

Idiopathic Hypoparathyroidism

Bibliography

Chapter 590 Pseudohypoparathyroidism

Type Ia

Type Ib

Acrodysostosis With Hormone Resistance

Bibliography

Chapter 591 Hyperparathyroidism

Etiology

Clinical Manifestations

Laboratory Findings
Differential Diagnosis

Treatment

Prognosis

Familial Hypocalciuric Hypercalcemia (Familial Benign Hypercalcemia)

Granulomatous Diseases

Hypercalcemia of Malignancy

Miscellaneous Causes of Hypercalcemia

Diagnostic Evaluation
Part XXVII Neuromuscular Disorders

Chapter 625 Evaluation and Investigation of Neuromuscular Disorders

- Genetic Testing
- Clinical Manifestations
- Laboratory Findings
- Imaging of Muscles and the Central Nervous System
- Muscle Biopsy
- Nerve Biopsy
- Cardiac Assessment

Chapter 626 Developmental Disorders of Muscle

- Myogenic Regulatory Genes and Genetic Loci of Inherited Diseases of Muscle
- Treatment of Congenital Myopathies
- Pathogenesis
- Clinical Manifestations
- Laboratory Findings
- Diagnosis

Clinical Manifestations
Laboratory Findings
Genetics
Treatment and Prognosis
Chapter 627 Muscular Dystrophies

Clinical Manifestations
Chapter 628 Endocrine and Toxic Myopathies

Thyroid Myopathies
Steroid-Hormone Induced Myopathy
Statin-Induced Rhabdomyolysis With Myoglobinuria
Mitochondrial Dysfunction in Toxic Myopathies
Critical Illness Myopathy

Chapter 629 Metabolic Myopathies and Channelopathies

Treatment
Other Muscle Channelopathies

Investigations
Chapter 630 Disorders of Neuromuscular Transmission and of Motor Neurons

Autoimmune Myasthenia Gravis

Clinical Manifestations

Congenital Myasthenic Syndromes

Rare Other Causes of Myasthenia

Laboratory Findings and Diagnosis

Treatment

Complications

Prognosis

Other Causes of Neuromuscular Blockade

Bibliography

Etiology

Clinical Manifestations and Course

Laboratory Findings

Diagnosis

Genetics
Chapter 631 Hereditary Motor-Sensory Neuropathies

Clinical Manifestations

Laboratory Findings and Diagnosis

Treatment

Chapter 632 Toxic Neuropathies

Bibliography
Chapter 633 Autonomic Neuropathies

Pathology

Clinical Manifestations

Laboratory Findings

Diagnosis

Treatment

Prognosis

Bibliography

Congenital Insensitivity to Pain and Anhidrosis

Allgrove Syndrome (Triple a Syndrome)

Bibliography

Chapter 634 Guillain-Barré Syndrome

Clinical Manifestations

Laboratory Findings and Diagnosis

Treatment

Prognosis

Bibliography

Chapter 635 Bell Palsy

Clinical Manifestations

Treatment
Prognosis

Facial Palsy at Birth

Bibliography

Part XXVIII Disorders of the Eye

Chapter 636 Growth and Development of the Eye

Bibliography

Chapter 637 Examination of the Eye

Visual Acuity

Visual Field Assessment

Color Vision Testing

Pupillary Examination

Ocular Motility

Binocular Vision

External Examination

Biomicroscopy (Slit-Lamp Examination)

Fundus Examination (Ophthalmoscopy)

Refraction

Tonometry

Bibliography
Chapter 638 Abnormalities of Refraction and Accommodation

Hyperopia
Myopia
Astigmatism
Anisometropia
Accommodation
Bibliography

Chapter 639 Disorders of Vision

Amblyopia
Diplopia
Suppression
Amaurosis
Nyctalopia
Psychogenic Disturbances
Dyslexia
Bibliography

Chapter 640 Abnormalities of Pupil and Iris

Aniridia
Coloboma of the Iris
Microcoria
Congenital Mydriasis
Dyscoria and Corectopia
Anisocoria
Dilated Fixed Pupil
Tonic Pupil
Marcus Gunn Pupil
Horner Syndrome
Paradoxical Pupil Reaction
Persistent Pupillary Membrane
Heterochromia
Other Iris Lesions
Leukocoria
Bibliography

Chapter 641 Disorders of Eye Movement and Alignment
Strabismus
Congenital Ocular Motor Apraxia
Nystagmus
Other Abnormal Eye Movements
Bibliography

Chapter 642 Abnormalities of the Lids
Ptosis
Epicanthal Folds
Lagophthalmos
Lid Retraction
Ectropion, Entropion, and Epiblepharon
Blepharospasm
Blepharitis
Hordeolum (Stye)
Chalazion
Coloboma of the Eyelid
Tumors of the Lid
Bibliography

Chapter 643 Disorders of the Lacrimal System

The Tear Film
Dacryostenosis
Alacrima and “Dry Eye”
Bibliography

Chapter 644 Disorders of the Conjunctiva

Conjunctivitis
Bibliography
Chapter 645 Abnormalities of the Cornea

Megalocornea
Microcornea
Keratoconus
Neonatal Corneal Opacities
Sclerocornea
Peters Anomaly
Corneal Dystrophies
Dermoids
Dendritic Keratitis
Corneal Ulcers
Phlyctenules
Interstitial Keratitis
Corneal Manifestations of Systemic Disease

Bibliography

Chapter 646 Abnormalities of the Lens

Cataracts
Ectopia Lentis
Other Disorders of the Lens

Bibliography
Chapter 647 Disorders of the Uveal Tract

Uveitis (Iritis, Cyclitis, Chorioretinitis)

Bibliography

Chapter 648 Disorders of the Retina and Vitreous

Retinopathy of Prematurity

Persistent Fetal Vasculature

Retinoblastoma

Retinitis Pigmentosa

Stargardt Disease (Fundus Flavimaculatus)

Best Vitelliform Degeneration

Cherry-Red Spot

Phakomas

Retinoschisis

Retinal Detachment

Coats Disease

Familial Exudative Vitreoretinopathy

Hypertensive Retinopathy

Diabetic Retinopathy

Subacute Bacterial Endocarditis

Blood Disorders
Trauma-Related Retinopathy
Myelinated Nerve Fibers
Coloboma of the Fundus
Bibliography

Chapter 649 Abnormalities of the Optic Nerve
Optic Nerve Aplasia
Optic Nerve Hypoplasia
Optic Nerve Coloboma
Morning Glory Disc Anomaly
Tilted Disc
Drusen of the Optic Nerve
Papilledema
Optic Neuritis
Leber Optic Neuropathy
Optic Atrophy
Optic Nerve Glioma
Traumatic Optic Neuropathies
Bibliography

Chapter 650 Childhood Glaucoma
Clinical Manifestations
Diagnosis and Treatment

Bibliography

Chapter 651 Orbital Abnormalities

Hypertelorism and Hypotelorism
Exophthalmos and Enophthalmos
Orbital Inflammation
Tumors of the Orbit
Bibliography

Chapter 652 Orbital Infections

Dacryoadenitis
Dacryocystitis
Preseptal Cellulitis
Orbital Cellulitis
Bibliography

Chapter 653 Injuries to the Eye

Ecchymosis and Swelling of the Eyelids
Lacerations of the Eyelids
Superficial Abrasions of the Cornea
Foreign Body Involving the Ocular Surface
Hyphema
Open Globe
Optic Nerve Trauma
Chemical Injuries
Orbital Fractures
Penetrating Wounds of the Orbit
Child Abuse
Fireworks-Related Injuries
Sports-Related Ocular Injuries and Their Prevention
Handheld Laser Retinal Injury
Bibliography

Part XXIX The Ear

Chapter 654 General Considerations and Evaluation of the Ear
Clinical Manifestations
Facial Paralysis
Physical Examination
Bibliography

Chapter 655 Hearing Loss
Incidence and Prevalence
Chapter 656 Congenital Malformations of the Ear

Pinna Malformations

Congenital Stenosis or Atresia of the External Auditory Canal

Congenital Middle-Ear Malformations

Congenital Inner Ear Malformations

Congenital Cholesteatoma

Bibliography

Chapter 657 External Otitis (Otitis Externa)

Etiology

Clinical Manifestations

Diagnosis
Chapter 658 Otitis Media

Epidemiology
Etiology
Pathogenesis
Clinical Manifestations
Examination of the Tympanic Membrane
Prevention
Immunoprophylaxis and Vaccination Status
Treatment
Antimicrobial Prophylaxis
Management of Otitis Media With Effusion
Intracranial Complications
Possible Developmental Sequelae
Bibliography

Chapter 659 Acute Mastoiditis

Anatomy
Epidemiology
Microbiology
Clinical Manifestations
Imaging
Management
Special Situations
Bibliography

Chapter 660 The Inner Ear and Diseases of the Bony Labyrinth

Other Diseases of the Inner Ear

Bibliography

Chapter 661 Traumatic Injuries of the Ear and Temporal Bone

Auricle and External Auditory Canal
Tympanic Membrane and Middle Ear
Temporal Bone Fractures
Acoustic Trauma
Bibliography

Chapter 662 Tumors of the Ear and Temporal Bone

Bibliography

Part XXX The Skin
Chapter 663 Morphology of the Skin

Epidermis

Dermis

Subcutaneous Tissue

Appendageal Structures

Bibliography

Chapter 664 Dermatologic Evaluation of the Patient

History and Physical Examination

Biopsy of Skin

Wood Lamp

Potassium Hydroxide Preparation

Tzanck Smear

Immunofluorescence Studies

Connective Tissue Diseases

Vasculitides

Gastrointestinal Diseases

Cutaneous Manifestations of Malignancy

Cutaneous Reactions in the Setting of Immunosuppression

Drug Rash With Eosinophilia and Systemic Symptoms (DRESS Syndrome)
Serum Sickness–Like Reaction

Acute Generalized Exanthematous Pustulosis

Bibliography

Chapter 665 Principles of Dermatologic Therapy

Wet Dressings

Bath Oils, Colloids, Soaps

Lubricants

Shampoos

Shake Lotions

Powders

Pastes

Keratolytic Agents

Tar Compounds

Antifungal Agents

Topical Antibiotics

Topical Corticosteroids

Topical Nonsteroidal Antiinflammatory Agents

Sunscreens

Laser Therapy

Bibliography
Chapter 666 Dermatologic Diseases of the Neonate

Sebaceous Hyperplasia

Milia

Sucking Blisters

Cutis Marmorata

Harlequin Color Change

Nevus Simplex (Salmon Patch)

Dermal Melanocytosis (Mongolian Spots)

Erythema Toxicum

Transient Neonatal Pustular Melanosis

Infantile Acropustulosis

Eosinophilic Pustular Folliculitis

Bibliography

Chapter 667 Cutaneous Defects

Skin Dimples

Redundant Skin

Amniotic Constriction Bands

Preauricular Sinuses and Pits

Accessory Tragi

Branchial Cleft and Thyroglossal Cysts and Sinuses
Supernumerary Nipples

Aplasia Cutis Congenita (Congenital Absence of Skin)

Focal Facial Dermal Dysplasias

Focal Dermal Hypoplasia (Goltz-Gorlin Syndrome)

Dyskeratosis Congenita (Zinsser-Engman-Cole Syndrome)

Cutis Verticis Gyrata

Bibliography

Chapter 668 Ectodermal Dysplasias

Hypohidrotic Ectodermal Dysplasia

Hidrotic Ectodermal Dysplasia (Clouston Syndrome)

Bibliography

Chapter 669 Vascular Disorders

Vascular Malformations

Lymphatic Malformations

Arteriovenous Malformation

Klippel-Trenaunay and Parkes-Weber Syndromes

Phakomatosis Pigmentovascularis

Nevus Anemicus

Vascular Tumors

Bibliography
Chapter 670 Cutaneous Nevi

Acquired Melanocytic Nevus
Atypical Melanocytic Nevus
Congenital Melanocytic Nevus
Melanoma
Halo Nevus
Spitz Nevus (Spindle and Epithelioid Cell Nevus)
Zosteriform Lentiginous Nevus (Agminated Lentigines)
Nevus Spilus (Speckled Lentiginous Nevus)
Nevus of Ota and Nevus of Ito
Blue Nevi
Nevus Depigmentosus (Achromic Nevus)
Epidermal Nevi
Nevus Comedonicus
Connective Tissue Nevus
Smooth Muscle Hamartoma

Chapter 671 Hyperpigmented Lesions

Disorders of Pigment
Ephelides (Freckles)
Lentigines

Café-Au-Lait Spots

Incontinentia Pigmenti (Bloch-Sulzberger Disease)

PostInflammatory Pigmentary Changes

Bibliography

Chapter 672 Hypopigmented Lesions

Albinism

Melanoblast Migration Abnormalities

Bibliography

Chapter 673 Vesiculobullous Disorders

Keywords

Etiology

Clinical Manifestations

Bibliography

Keywords

Etiology

Bibliography

Keywords

Epidemiology and Etiology

Clinical Manifestations
Chapter 674 Eczematous Disorders

Irritant Contact Dermatitis

Diaper Dermatitis

Allergic Contact Dermatitis

Bibliography

Etiology

Clinical Manifestations

Differential Diagnosis

Treatment
Chapter 675 Photosensitivity

Acute Sunburn Reaction
Photosensitive Reactions
Porphyrias
Colloid Milium
Hydroa Vacciniforme
Solar Urticaria
Polymorphous Light Eruption
Actinic Prurigo
Cockayne Syndrome
Xeroderma Pigmentosum
Rothmund-Thomson Syndrome
Bloom Syndrome
Hartnup Disease

Chapter 676 Diseases of the Epidermis

Etiology/Pathogenesis
Clinical Manifestations
Differential Diagnosis
Chapter 677 Disorders of Keratinization

Disorders of Cornification

Collodion Baby

Nonsyndromic Ichthyoses

Autosomal Recessive Congenital Ichthyoses

Keratinopathic Ichthyoses

Other Nonsyndromic Ichthyoses

Syndromic Ichthyoses

Other Syndromes With Ichthyosis

Bibliography

Chapter 678 Diseases of the Dermis

Keloid

Striae Cutis Distensae (Stretch Marks)

Corticosteroid-Induced Atrophy

Granuloma Annulare

Necrobiosis Lipoidica

Lichen Sclerosus

Morphea

Scleredema (Scleredema Adulorum, Scleredema of Buschke)
Lipoid Proteinosis (Urbach-Wiethe Disease, Hyalinosis Cutis Et Mucosae)

Macular Atrophy (Anetoderma)

Cutis Laxa (Dermatomegaly, Generalized Elastolysis)

Pseudoxanthoma Elasticum

Elastosis Perforans Serpiginosa

Reactive Perforating Collagenosis

Xanthomas

Fabry Disease

Mucopolysaccharidoses

Mastocytosis

Keywords

Bibliography

Chapter 679 Ehlers-Danlos Syndrome

Classification of the 6 Most Common Subtypes of Ehlers-Danlos Syndrome

Differential Diagnosis

General Approach to Management

Bibliography
Chapter 680 Diseases of Subcutaneous Tissue

Corticosteroid-Induced Atrophy

Erythema Nodosum

Post-Steroid Panniculitis

Lupus Erythematosus Profundus (Lupus Erythematosus Panniculitis)

Alpha\textsubscript{1} -Antitrypsin Deficiency

Pancreatic Panniculitis

Subcutaneous Fat Necrosis

Sclerema Neonatorum

Cold Panniculitis

Chilblains (Pernio)

Factitial Panniculitis

Bibliography

Partial Lipodystrophy

Generalized Lipodystrophy

Bibliography

Chapter 681 Disorders of the Sweat Glands

Anhidrosis

Hyperhidrosis

Miliaria
Bromhidrosis

Hidradenitis Suppurativa

Fox-Fordyce Disease

Bibliography

Chapter 682 Disorders of Hair

Hypertrichosis

Hypotrichosis and Alopecia

Traumatic Alopecia (Traction Alopecia, Hair Pulling, Trichotillomania)

Alopecia Areata

Acquired Diffuse Hair Loss

Congenital Diffuse Hair Loss

Bibliography

Chapter 683 Disorders of the Nails

Abnormalities in Nail Shape or Size

Changes in Nail Color

Nail Separation

Nail Changes Associated With Skin Disease

Trachyonychia (20-Nail Dystrophy)

Nail Infection

Paronychial Inflammation
Paronychial Tumors

Bibliography

Chapter 684 Disorders of the Mucous Membranes

Angular Cheilitis

Aphthous Stomatitis (Canker Sores)

Fordyce Spots

Epstein Pearls (Gingival Cysts of the Newborn)

Mucocele

Fissured Tongue

Geographic Tongue (Benign Migratory Glossitis)

Black Hairy Tongue

Oral Hairy Leukoplakia

Acute Necrotizing Ulcerative Gingivitis (Vincent Stomatitis, Fusospirochetal Gingivitis, Trench Mouth)

Noma

Cowden Syndrome (Multiple Hamartoma Syndrome)

Bibliography

Chapter 685 Cutaneous Bacterial Infections

Etiology/Pathogenesis

Clinical Manifestations
Erythrasma

Erysipeloid

Tuberculosis of the Skin

Bibliography

Chapter 686 Cutaneous Fungal Infections

Tinea Versicolor

Dermatophytoses

Candidal Infections (Candidosis, Candidiasis, and Moniliasis)

Bibliography

Chapter 687 Cutaneous Viral Infections

Wart (Verruca)

Molluscum Contagiosum

Bibliography

Chapter 688 Arthropod Bites and Infestations

Clinical Manifestations

Treatment

Bibliography

Etiology and Pathogenesis

Clinical Manifestations
Differential Diagnosis

Treatment

Norwegian (Crusted) Scabies

Canine Scabies

Other Types of Scabies

Bibliography

Chapter 689 Acne

Acne Vulgaris

Drug-Induced Acne

Halogen Acne

Chloracne

Neonatal Acne

Infantile Acne

Mid-Childhood Acne

Tropical Acne

Acne Conglobata

Acne Fulminans (Acute Febrile Ulcerative Acne)

Bibliography

Chapter 690 Tumors of the Skin
Epidermal Inclusion Cyst (Epidermoid Cyst)

Milium

Fibrofolliculomas

Pilar Cyst (Trichilemmal Cyst)

Pilomatrixcoma (Pilomatrixoma)

Trichoepithelioma

Eruptive Vellus Hair Cysts

Steatocystoma Multiplex

Syringoma

Infantile Digital Fibroma

Dermatofibroma (Histiocytoma)

Juvenile Xanthogranuloma

Lipoma

Basal Cell Carcinoma

Nevoid Basal Cell Carcinoma Syndrome (Basal Cell Nevus Syndrome, Gorlin Syndrome)

Melanoma

Mucosal Neuroma Syndrome (Multiple Endocrine Neoplasia Type lib)

Bibliography

Chapter 691 Nutritional Dermatoses
Acrodermatitis Enteropathica

Essential Fatty Acid Deficiency

Kwashiorkor

Cystic Fibrosis

Pellagra

Scurvy (Vitamin C or Ascorbic Acid Deficiency)

Vitamin a Deficiency

Bibliography

Part XXXI Bone and Joint Disorders

Section 1 Orthopedic Problems

Chapter 692 Growth and Development

   In Utero Positioning

   Growth and Development

   Centers of Ossification

   Gait/Functional Maturation

   Bibliography

Chapter 693 Orthopedic Evaluation of the Child

   History
Physical Examination
Limping
Back Pain
Neurologic Evaluation
Radiographic Assessment
Laboratory Studies
Bibliography

Chapter 694 The Foot and Toes
Clinical Manifestations
Radiographic Evaluation
Treatment

Spondylolysis, Spondylolisthesis, and Facet Syndrome

Lumbar Disk Herniation, Strain, and Contusion

Other Causes

Bibliography

Bibliography

Initial Treatment of Acute Knee Injuries

Chronic Injuries
Chapter 708 Sports-Related Traumatic Brain Injury (Concussion)

Epidemiology
Pathophysiology
Assessment of the Injured Player
Management and Treatment
Prevention
Bibliography

Chapter 709 Cervical Spine Injuries

Soft Tissue Injury
Spear Tackler's Spine
Cervical Fractures
Stingers (Burners)
Transient Quadripareisis

Congenital Spinal Stenosis

Spinal Cord Injury

Bibliography

Chapter 710 Heat Injuries

Bibliography

Chapter 711 Female Athletes

Bibliography

Chapter 712 Performance-Enhancing Aids

Bibliography

Chapter 713 Specific Sports and Associated Injuries

Sports Participation, Early Specialization, Injury Risk and Burnout

Football

Baseball/Softball

Basketball/Volleyball

Tennis

Lacrosse

Swimming/Diving

Soccer
Section 3 The Skeletal Dysplasias

Chapter 714 General Considerations in Skeletal Dysplasias

   Clinical Manifestations
   Diagnosis
   Molecular Genetics
   Pathophysiology
   Treatment
Chapter 715 Disorders Involving Cartilage Matrix Proteins

Spondyloepiphyseal Dysplasias/Type 2 Collagenopathies
Kniest Dysplasia
Late-Onset Spondyloepiphyseal Dysplasia
Aggrecan-Related Spondyloepiphyseal Dysplasias
Stickler Syndrome/Dysplasia (Hereditary Osteoarthroophthalmopathy)
Schmid Metaphyseal Dysplasia
Pseudoachondroplasia and Multiple Epiphyseal Dysplasia

Chapter 716 Disorders Involving Transmembrane Receptors

Achondroplasia Group
Jansen Metaphyseal Dysplasia

Chapter 717 Disorders Involving Ion Transporters

Autosomal Recessive Multiple Epiphyseal Dysplasia

Chapter 718 Disorders Involving Transcription Factors
Campomelic Dysplasia
Cleidocranial Dysplasia
Nail-Patella Syndrome
Bibliography

Chapter 719 Disorders Involving Defective Bone Resorption

Osteopetrosis
Clinical Manifestations
Treatment
Pyknodysostosis
Bibliography

Chapter 720 Other Inherited Disorders of Skeletal Development

Ellis–Van Creveld Syndrome
Asphyxiating Thoracic Dystrophy (See Also Chapter 445.3)
Short-Rib Polydactyly Syndromes
Cartilage-Hair Hypoplasia–Anauxetic Spectrum Disorders
Metatropic Dysplasia
Spondylometaphyseal Dysplasia, Kozlowski Type
Disorders Involving Filamins
Juvenile Osteochondroses
Caffey Disease (Infantile Cortical Hyperostosis)
Chapter 721 Osteogenesis Imperfecta

Etiology

Epidemiology

Pathology

Pathogenesis

Clinical Manifestations

Other Genes for Osteogenesis Imperfecta

Laboratory Findings

Complications

Treatment

Prognosis

Genetic Counseling

Bibliography

Chapter 722 Marfan Syndrome

Epidemiology

Pathogenesis

Clinical Manifestations

Diagnosis
Section 4 Metabolic Bone Disease

Chapter 723 Bone Structure, Growth, and Hormonal Regulation

Chapter 724 Hypophosphatasia

Chapter 725 Hyperphosphatasia

Chapter 726 Osteoporosis
Part XXXII Rehabilitation Medicine

Chapter 727 Evaluation of the Child for Rehabilitative Services

Child Characteristics

Family Characteristics

The Physical Environment

The Previously Healthy Child

Chapter 728 Rehabilitation for Severe Traumatic Brain Injury

Pathophysiology

Severity

Medical Complications

Spasticity

Bibliography

Chapter 729 Spinal Cord Injury and Autonomic Dysreflexia Management

Clinical Manifestations

Prognosis

Bibliography

Chapter 730 Spasticity

Oral Medications
Chapter 731 Birth Brachial Plexus Palsy

Physical Examination
Evaluation
Treatment

Chapter 732 Meningomyelocele (Spina Bifida)

Etiology
Prevention
Prenatal Screening
Clinical Implications
Adolescence and Transition to Adulthood

Chapter 733 Ambulation Assistance

Orthoses
Prostheses
Assistive Mobility Devices
Wheelchair
Bibliography

Chapter 734 Health and Wellness for Children With Disabilities

Health Promotion Definitions and Background for Disability

Anticipatory Guidance, Counseling, and Preventive Care

Physical Activity and Exercise

Nutrition and Obesity

Emotional Health and Leisure Activities

Dental Care

Role of Healthcare Providers

Keywords

Preparation

Community Resources

Subacute Care

Emergency and Acute Care

Quality of Life

Bibliography

Part XXXIII Environmental Health

Chapter 735 Overview of Environmental Health and Children
Global Climate Change

Localized Environmental Hazards

Toxins Versus Toxicants

Mycotoxins

Food-Borne Diseases Caused by Environmental Exposures

Bibliography

Chapter 736 Biologic Effects of Ionizing Radiation on Children

Basic Principles

Biologic Effects of Radiation

Radiation Exposure in Diagnostic Imaging of Children

Decreasing Unnecessary Diagnostic Radiation in Children While Still Obtaining Diagnostic Images

Radiation Therapy—Acute and Late Effects

Whole-Body Irradiation

Internal Contamination

External Contamination

Bibliography

Chapter 737 Chemical Pollutants

Synthetic Chemicals and Human Health

Children's Unique Susceptibility to Synthetic Chemicals
Safety Testing of Synthetic Chemicals

Synthetic Chemicals and Disease in Children

Chemical Pollutants of Major Concern

Health Hazards of Unconventional Natural Gas Development (Fracking)

The Physician's Role

Keywords

Composition of Second-Hand Smoke and Toxicities

Tobacco Use and Exposure Is A Health Risk Disparity

Maternal Smoking During Pregnancy and Tobacco Smoke Exposure During Pregnancy

Postnatal Second-Hand Smoke Exposure—Effects on the Child

Treatment for Second-Hand Tobacco Smoke Exposure

Bibliography

Chapter 738 Heavy Metal Intoxication

Arsenic

Mercury

Treatment of Arsenic and Mercury Intoxication

Bibliography
Chapter 739 Lead Poisoning

Public Health History
Sources of Exposure
Metabolism
Clinical Effects
Clinical Symptoms
Diagnosis
Treatment
Bibliography

Chapter 740 Nonbacterial Food Poisoning

Keywords
Gastrointestinal: Delayed Onset
Renal: Delayed Onset
Autonomic Nervous System: Rapid Onset
Central Nervous System: Rapid Onset
Gastrointestinal: Rapid Onset

Notices
Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary. Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility. With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of
each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions. To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein. Dedication

To the Child’s Physician who through their expressed confidence in past editions of this book have provided the stimulus for this revision. May we continue to be a resource of helpful information for clinicians who care for all of our children.

R.M. Kliegman
Contributors

Nadia Y. Abidi MD
Resident Physician
Department of Dermatology
University of Missouri School of Medicine
Columbia, Missouri

*Cutaneous Defects*

*Ectodermal Dysplasias*

Mark J. Abzug MD
Professor of Pediatrics
Vice Chair for Academic Affairs

Childcare and Communicable Diseases
Joanna S. Cohen MD
Associate Professor of Pediatrics and Emergency Medicine
George Washington University School of Medicine
Division of Pediatric Emergency Medicine
Children's National Medical Center
Washington, DC

Care of Abrasions and Minor Lacerations

Mitchell B. Cohen MD
Katharine Reynolds Ireland Endowed Chair in Pediatrics
Professor and Chair, Department of Pediatrics
University of Alabama at Birmingham School of Medicine
Physician-in-Chief
Children's of Alabama
Birmingham, Alabama

Clostridium difficile Infection

Michael Cohen-Wolkowiez MD
Professor of Pediatrics
Duke Clinical Research Institute
Duke University Medical Center
Durham, North Carolina

Principles of Antifungal Therapy

Robert A. Colbert MD, PhD
Acting Clinical Director
National Institute of Arthritis and Musculoskeletal and Skin Diseases
Chief, Pediatric Translational Branch
National Institutes of Health
Bethesda, Maryland

Ankylosing Spondylitis and Other Spondylarthritides
Reactive and Postinfectious Arthritis

F. Sessions Cole III, MD
Inherited Disorders of Surfactant Metabolism
Pulmonary Alveolar Proteinosis

J. Michael Collaco MD, MS, MBA, MPH, PhD
Associate Professor of Pediatrics
Eudowood Division of Pediatric Respiratory Sciences
Johns Hopkins University School of Medicine
Baltimore, Maryland

Bronchopulmonary Dysplasia

John L. Colombo MD
Professor of Pediatrics
University of Nebraska College of Medicine
Division of Pediatric Pulmonology
Nebraska Regional Cystic Fibrosis Center
University of Nebraska Medical Center
Omaha, Nebraska

Aspiration Syndromes
Chronic Recurrent Aspiration

Joseph A. Congeni MD
Director, Sports Medicine Center
Akron Children's Hospital
Akron, Ohio;
Associate Professor of Pediatrics and Sports Medicine
Northeast Ohio Medical University
Rootstown, Ohio;
Clinical Associate Professor of Pediatrics and Sports Medicine
Ohio University College of Osteopathic Medicine
Athens, Ohio

Sports-Related Traumatic Brain Injury (Concussion)
Cervical Spinal Spine Injuries

Lindsay N. Conner MD, MPH
Department of Obstetrics and Gynecology
Benefis Health System
Great Falls, Montana

Breast Concerns

Sarah M. Creighton MBBS
Professor and Consultant Gynaecologist
Department of Women's Health
University College London Hospitals
London, United Kingdom

Female Genital Mutilation

James E. Crowe Jr, MD
Ann Scott Carell Chair and Professor of Pediatrics
Division of Pediatric Infectious Diseases
Professor of Pathology, Microbiology, and Immunology
Director, Vanderbilt Vaccine Center
Vanderbilt University School of Medicine
Nashville, Tennessee

Respiratory Syncytial Virus
Human Metapneumovirus

Steven J. Czinn MD
Professor and Chair
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland

Peptic Ulcer Disease in Children

Aarti S. Dalal DO
Assistant Professor of Pediatrics
Washington University School of Medicine in St. Louis
Division of Pediatric Cardiology
St Louis Children's Hospital
St. Louis, Missouri

Syncope

Disturbances of Rate and Rhythm of the Heart
Sudden Death

Josep O. Dalmau MD, PhD
Research Professor ICREA-IDIBAPS
Service of Neurology
Hospital Clinic
University of Barcelona
Barcelona, Spain;
Adjunct Professor of Neurology
University of Pennsylvania Perelman School of Medicine
Philadelphia, Pennsylvania

Autoimmune Encephalitis

Lara A. Danziger-Isakov MD, MPH
Professor of Pediatrics
University of Cincinnati College of Medicine
Director, Immunocompromised Host Infectious Disease
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Histoplasmosis (Histoplasma capsulatum)

Toni Darville MD
Professor of Pediatrics and Microbiology and Immunology
Neisseria gonorrhoeae (Gonococcus)

Robert S. Daum MD, CM, MSc  
Professor of Medicine  
Center for Vaccine Development and Global Health  
University of Maryland School of Medicine  
Baltimore, Maryland

Haemophilus influenzae

Loren T. Davidson MD  
Clinical Professor  
Department of Physical Medicine and Rehabilitation  
University of California, Davis School of Medicine  
Davis, California;  
Director, Spinal Cord Injury  
Shriners Hospital for Children  
Sacramento, California

Spasticity

Richard S. Davidson MD  
Emeritus Professor of Orthopaedic Surgery  
University of Pennsylvania Perelman School of Medicine  
Attending Orthopaedic Surgeon  
Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

The Foot and Toes  
Leg-Length Discrepancy  
Arthrogryposis
H. Dele Davies MD, MS, MHCM
Vice-Chancellor for Academic Affairs
Dean for Graduate Studies
University of Nebraska Medical Center
Omaha, Nebraska

*Chancroid (Haemophilus ducreyi)*
*Syphilis (Treponema pallidum)*
*Nonvenereal Treponemal Infections*
*Leptospira*
*Relapsing Fever (Borrelia)*

Najat C. Daw MD
Professor
Division of Pediatrics
University of Texas MD Anderson Cancer Center
Houston, Texas

*Neoplasms of the Kidney*

Shannon L. Dean MD, PhD
Instructor in Neurology and Pediatrics
University of Rochester Medical Center
Rochester, New York

*Dystonia*

Helen M. Oquendo Del Toro, MD
Pediatric and Adolescent Gynecology
Clinical Assistant Professor
University of New Mexico
Department of Obstetrics and Gynecology
Albuquerque, New Mexico

*Vulvovaginitis*

David R. DeMaso MD
Psychiatrist-in-Chief
The Leon Eisenberg Chair in Psychiatry
Boston Children's Hospital;
George P. Gardner and Olga E. Monks Professor of Child Psychiatry
Professor of Pediatrics
Harvard Medical School
Boston, Massachusetts

Psychosocial Assessment and Interviewing
Psychopharmacology
Psychotherapy and Psychiatric Hospitalization
Somatic Symptom and Related Disorders
Rumination and Pica
Motor Disorders and Habits
Anxiety Disorders
Mood Disorders
Suicide and Attempted Suicide
Disruptive, Impulse-Control, and Conduct Disorders
Tantrums and Breath-Holding Spells
Lying, Stealing, and Truancy
Aggression
Self-Injurious Behavior
Childhood Psychoses

Mark R. Denison MD
Craig-Weaver Professor of Pediatrics
Professor of Pathology, Microbiology, and Immunology
Vanderbilt University Medical Center
Monroe Carell Jr Children's Hospital at Vanderbilt
Nashville, Tennessee

Coronaviruses
Arlene E. Dent MD, PhD
Associate Professor of Pediatrics
Center for Global Health and Diseases
Case Western Reserve University School of Medicine
Cleveland, Ohio

Ascariasis (*Ascaris lumbricoides*)
Trichuriasis (*Trichuris trichiura*)
Enterobiasis (*Enterobius vermicularis*)
Strongyloidiasis (*Strongyloides stercoralis*)
Lymphatic Filariasis (*Brugia malayi*, *Brugia timori*, and *Wuchereria bancrofti*)
Other Tissue Nematodes
Toxocariasis (*Visceral and Ocular Larva Migrans*)
Trichinellosis (*Trichinella spiralis*)

Robert J. Desnick MD, PhD
Dean for Genetics and Genomic Medicine
Professor and Chair Emeritus, Genetics and Genomic Sciences
Professor, Departments of Pediatrics, Oncological Sciences, and Obstetrics, Gynecology and Reproductive Science
Kravis Children's Hospital at the Icahn School of Medicine at Mount Sinai
New York, New York

Lipidoses (*Lysosomal Storage Disorders*)
Mucolipidoses
Disorders of Glycoprotein Degradation and Structure
The Porphyrias

Robin R. Deterding MD
Professor of Pediatrics
University of Colorado School of Medicine
Chief, Pediatric Pulmonary Medicine
Director, Breathing Institute
Co-Chair, Children's Interstitial and Diffuse Lung Disease Research Network
Medical Director, Children's Colorado Innovation Center
Children's Hospital Colorado
Aurora, Colorado

**Fibrotic Lung Disease**

**Prasad Devarajan MD, FAAP**
Louise M. Williams Endowed Chair
Professor of Pediatrics and Developmental Biology
University of Cincinnati College of Medicine
Director of Nephrology and Hypertension
CEO, Dialysis Unit
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Daren A. Diiorio MD
Resident Physician
Department of Dermatology
Medical College of Wisconsin
Milwaukee, Wisconsin

Principles of Dermatologic Therapy
Cutaneous Bacterial Infections
Cutaneous Fungal Infections
Cutaneous Viral Infections
Arthropod Bites and Infestations

Linda A. DiMeglio MD, MPH
Professor
Department of Pediatrics
Indiana University School of Medicine
Indiana University Clinical and Translational Science Institute
Riley Hospital for Children
Indianapolis, Indiana
Hypophosphatasia
Hyperphosphatasia

Bradley P. Dixon MD, FASN
Associate Professor of Pediatrics and Medicine
Renal Section, Department of Pediatrics
University of Colorado School of Medicine
Kidney Center
Children's Hospital Colorado
Aurora, Colorado

Tubular Function
Renal Tubular Acidosis
Nephrogenic Diabetes Insipidus
Inherited Tubular Transport Abnormalities

Nomazulu Dlamini MBBS, PhD
Assistant Professor of Pediatrics
University of Toronto Faculty of Medicine
Staff Physician in Neurology
Director, Children's Stroke Program
Hospital for Sick Children
Toronto, Ontario, Canada

Pediatric Stroke

Sonam N. Dodhia MD
Resident Physician
New York-Presbyterian Hospital
New York, New York

Congenital Disorders of the Nose
Acquired Disorders of the Nose
Nasal Polyps
General Considerations and Evaluation of the Ear
Hearing Loss
Congenital Malformations of the Ear
External Otitis (Otitis Externa)
The Inner Ear and Diseases of the Bony Labyrinth
Traumatic Injuries of the Ear and Temporal Bone
Tumors of the Ear and Temporal Bone

Patricia A. Donohoue MD
Professor of Pediatrics
Chief, Pediatric Endocrinology
Medical College of Wisconsin
Medical Director, Pediatric Endocrinology
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Development and Function of the Gonads
Hypofunction of the Testes
Pseudoprecocity Resulting from Tumors of the Testes
Gynecomastia
Hypofunction of the Ovaries
Pseudoprecocity Resulting from Lesions of the Ovary
Disorders of Sex Development

Kevin J. Downes MD
Assistant Professor of Pediatrics
University of Pennsylvania Perelman School of Medicine
Attending Physician, Division of Infectious Diseases
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Tularemia (Francisella tularensis)
Brucella
Alexander J. Doyle MBBS, MDRes, FRCA  
William Harvey Research Institute  
Barts and The London School of Medicine

New York-Presbyterian Komansky Children's Hospital
New York, New York

Strategies for Health Behavior Change

Michael Green MD, MPH
Professor of Pediatrics, Surgery, and Clinical and Translational Science
Infections in Immunocompromised Persons

Larry A. Greenbaum MD, PhD
Marcus Professor of Pediatrics
Director, Division of Pediatric Nephrology
Emory University School of Medicine
Children's Healthcare of Atlanta
Atlanta, Georgia

Vitamin D Deficiency (Rickets) and Excess
Vitamin E Deficiency
Vitamin K Deficiency
Micronutrient Mineral Deficiencies
Electrolyte and Acid-Base Disorders
Maintenance and Replacement Therapy
Deficit Therapy

V. Jordan Greenbaum MD
International Centre for Missing and Exploited Children
Alexandria, Virginia

Child Trafficking for Sex and Labor

James M. Greenberg MD
Professor of Pediatrics
Director, Division of Neonatology
University of Cincinnati College of Medicine
Co-Director, Perinatal Institute
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio
Overview of Morbidity and Mortality
Clinical Manifestations of Diseases in the Newborn Period

Anne G. Griffiths MD
Pediatric Pulmonologist
Children's Respiratory and Critical Care Specialists
Director, Primary Ciliary Dyskinesia Center
Children's Minnesota
Minneapolis, Minnesota

Chronic or Recurrent Respiratory Symptoms

Kenneth L. Grizzle PhD
Associate Professor of Pediatrics
Medical College of Wisconsin
Child Development Center
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Math and Writing Disabilities
Child-Onset Fluency Disorder

Judith A. Groner MD
Clinical Professor of Pediatrics
The Ohio State University College of Medicine
Section of Ambulatory Pediatrics
Nationwide Children's Hospital
Columbus, Ohio

Tobacco

Alfredo Guarino MD
Professor of Pediatrics
Department of Translational Medical Sciences
University of Naples Federico II
Napoli, Italy
Intestinal Infections and Infestations Associated with Malabsorption

Juan P. Gurria MD
Fellow in Pediatric Trauma
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Meconium Ileus, Peritonitis, and Intestinal Obstruction

Anat Guz-Mark MD
Attending Physician
Institute of Gastroenterology, Nutrition and Liver Disease
Schneider Children's Medical Center of Israel
Petah Tikva, Israel;
Sackler Faculty of Medicine
Tel Aviv University
Tel Aviv, Israel;

Chronic Diarrhea

Gabriel G. Haddad MD
Distinguished Professor of Pediatrics and Neuroscience
Chairman, Department of Pediatrics
University of California, San Diego School of Medicine
Physician-in-Chief and Chief Scientific Officer
Rady Children's Hospital–San Diego

Diagnostic Approach to Respiratory Disease

Joseph Haddad Jr, MD
Lawrence Savetsky Professor Emeritus
Columbia University Irving Medical Center
New York, New York

Congenital Disorders of the Nose
Acquired Disorders of the Nose
Nasal Polyps
General Considerations and Evaluation of the Ear
Hearing Loss
Congenital Malformations of the Ear
External Otitis (Otitis Externa)
The Inner Ear and Diseases of the Bony Labyrinth
Traumatic Injuries of the Ear and Temporal Bone
Tumors of the Ear and Temporal Bone

Joseph F. Hagan Jr, MD, FAAP
Clinical Professor
Department of Pediatrics
The Robert Larner College of Medicine at the University of Vermont College of Medicine
Hagan, Rinehart, and Connolly Pediatricians, PLLC
Burlington, Vermont

Maximizing Children's Health: Screening, Anticipatory Guidance, and Counseling

James S. Hagood MD
Professor of Pediatrics (Pulmonology)
Director, Program in Rare and Interstitial Lung Disease
University of North Carolina at Chapel Hill
Chapel Hill, North Carolina

Diagnostic Approach to Respiratory Disease

Suraiya K. Haider MD
Sleep Physician
Fairfax Neonatal Associates
Fairfax, Virginia

Pleurisy, Pleural Effusions, and Empyema
Goknur Haliloglu MD
Professor of Pediatrics
Department of Pediatric Neurology
Hacettepe University Children's Hospital
Ankara, Turkey

* Nemaline Rod Myopathy
* Core Myopathies
* Myofibrillar Myopathies
* Brain Malformations and Muscle Development
* Arthrogryposis
* Spinal Muscular Atrophies
* Other Motor Neuron Diseases

Scott B. Halstead MD
Adjunct Professor
Department of Preventive Medicine and Biostatistics
Uniformed Services University of the Health Sciences
Bethesda, Maryland

* Arboviral Infections
* Dengue Fever, Dengue Hemorrhagic Fever, and Severe Dengue
* Yellow Fever
* Ebola and Other Viral Hemorrhagic Fevers
* Hantavirus Pulmonary Syndrome

Allison R. Hammer MSN, APRN, CPNP-PC
Advanced Practice Nurse
Department of Otolaryngology – Head and Neck Surgery
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

* Foreign Bodies in the Airway
Margaret R. Hammerschlag MD  
Professor of Pediatrics and Medicine  
Director, Pediatric Infectious Disease Fellowship Program  
SUNY Down State Medical Center  
Brooklyn, New York

**Chlamydia pneumoniae  
Chlamydia trachomatis  
Psittacosis (Chlamydia psittaci)**

Aaron Hamvas MD  
Raymond and Hazel Speck Barry Professor of Neonatology  
Northwestern University Feinberg School of Medicine  
Head, Division of Neonatology  
Ann & Robert H. Lurie Children's Hospital of Chicago  
Chicago, Illinois

**Inherited Disorders of Surfactant Metabolism  
Pulmonary Alveolar Proteinosis**

James C. Harris MD  
Professor of Pediatrics, Psychiatry and Behavioral Sciences, Mental Health, and History of Medicine  
Division of Child and Adolescent Psychiatry  
Director, Developmental Neuropsychiatry  
Johns Hopkins University School of Medicine  
Baltimore, Maryland

**Disorders of Purine and Pyrimidine Metabolism**

Douglas J. Harrison MD, MS  
Associate Professor of Pediatrics  
Director of Patient Care and Programs  
Co-Chair Pediatric Solid Tumor and Sarcoma Team  
The Children's Cancer Hospital of MD Anderson  
The University of Texas MD Anderson Cancer Center  
Houston, Texas
Neuroblastoma

Corina Hartman MD
Pediatric Gastroenterology and Nutrition Unit
Lady Davis Carmel Medical Center
Haifa, Israel

Other Malabsorptive Syndromes

Mary E. Hartman MD, MPH
Assistant Professor of Pediatrics
Washington University School of Medicine in St. Louis
Division of Pediatric Critical Care Medicine
St. Louis Children's Hospital
St. Louis, Missouri

Pediatric Emergencies and Resuscitation

David B. Haslam MD
Associate Professor of Pediatrics
University of Cincinnati College of Medicine
Director, Antimicrobial Stewardship Program
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Epidemiology of Infections
Healthcare-Acquired Infections
Non–Group A or B Streptococci
Enterococcus

H. Hesham Abdel-Kader Hassan MD, MSc
Professor of Pediatrics
Chief, Division of Pediatric Gastroenterology and Nutrition
The University of Arizona College of Medicine
Tucson, Arizona

Cholestasis
Fern R. Hauck MD, MS
Spencer P. Bass MD Twenty-First Century Professor of Family Medicine
Departments of Family Medicine and Public Health Sciences
University of Virginia School of Medicine
Charlottesville, Virginia

**Sudden Infant Death Syndrome**

Fiona P. Havers MD, MHS
Medical Epidemiologist
Epidemiology and Prevention Branch, Influenza Division
National Center for Immunization and Respiratory Diseases
Centers for Disease Control and Prevention
Atlanta, Georgia

Ericka V. Hayes MD
Associate Professor
Department of Pediatrics
Division of Infectious Diseases
Washington University School of Medicine in St. Louis
Medical Director, Pediatric and Adolescent HIV Program
Medical Director, Infection Prevention
St. Louis Children's Hospital
St. Louis, Missouri

**Campylobacter**

**Yersinia**

**Nontuberculous Mycobacteria**

**Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome**

Jacqueline T. Hecht PhD
Professor and Division Head
Pediatric Research Center
Vice-Chair for Research
General Considerations in Skeletal Dysplasias
Disorders Involving Cartilage Matrix Proteins
Disorders Involving Transmembrane Receptors
Disorders Involving Ion Transporters
Disorders Involving Transcription Factors
Disorders Involving Defective Bone Resorption
Other Inherited Disorders of Skeletal Development

Sabrina M. Heidemann MD
Professor
Department of Pediatrics
Wayne State University School of Medicine
Director, Intensive Care Unit
Co-Director of Transport
Children's Hospital of Michigan
Detroit, Michigan

Respiratory Distress and Failure

Jennifer R. Heimall MD
Assistant Professor of Clinical Pediatrics
University of Pennsylvania Perelman School of Medicine
Attending Physician
Division of Allergy and Immunology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Immunodeficiencies Affecting Multiple Cell Types
Cheryl Hemingway MBChB, PhD
Consultant Pediatric Neurologist
Great Ormond Street Hospital for Children
London, United Kingdom

*Demyelinating Disorders of the Central Nervous System*

J. Owen Hendley MD †
Professor of Pediatric Infectious Diseases
University of Virginia School of Medicine
Charlottesville, Virginia

*Sinusitis*

*Retropharyngeal Abscess, Lateral Pharyngeal (Parapharyngeal) Abscess, and Peritonsillar Cellulitis/Abscess*

Michelle L. Hernandez MD
Associate Professor of Pediatrics
University of North Carolina School of Medicine
Chief Medical Officer
UNC Center for Environmental Medicine, Asthma, and Lung Biology
Chapel Hill, North Carolina

*Hypersensitivity Pneumonia*

*Occupational and Environmental Lung Disease*

Andrew D. Hershey MD, PhD, FAAN, FAHS
Professor of Pediatrics
University of Cincinnati College of Medicine
Endowed Chair and Director, Division of Neurology
Headache Medicine Specialist
Cincinnati Children's Medical Center
Cincinnati, Ohio

*Headaches*
Cynthia E. Herzog MD  
Professor of Pediatrics  
University of Texas MD Anderson Cancer Center  
Houston, Texas

Boston, Massachusetts

Group B Streptococcus

Stephan Ladisch MD
Professor of Pediatrics and Biochemistry/Molecular Biology
George Washington University School of Medicine
Center for Cancer and Immunology Research and
Center for Cancer and Blood Disorders
Children's Research Institute
Children's National Medical Center
Washington, DC

Histiocytosis Syndromes of Childhood

Oren J. Lakser MD
Assistant Professor of Pediatrics
Northwestern University Feinberg School of Medicine
Associate Clinician Specialist
Division of Pulmonary Medicine
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois
Bronchiectasis
Pulmonary Abscess

Philip J. Landrigan MD, MSc, FAAP
Director, Global Public Health Program
Schiller Institute for Integrated Science and Society
Professor of Biology
Boston College
Chestnut Hill, Massachusetts

Chemical Pollutants

Gregory L. Landry MD
Professor Emeritus
Department of Pediatrics
University of Wisconsin – Madison
School of Medicine and Public Health
Madison, Wisconsin

Epidemiology and Prevention of Injuries
Heat Injuries
Female Athletes: Menstrual Problems and the Risk of Osteopenia
Performance-Enhancing Aids

Wendy G. Lane MD, MPH, FAAP
Associate Professor
Department Epidemiology and Public Health
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland

Abused and Neglected Children

A. Noelle Larson MD
Associate Professor, Orthopedic Surgery
**Benign Tumors and Tumor-Like Processes of Bone**

**Phillip S. LaRussa MD**  
Professor of Pediatrics  
Columbia University College of Physicians and Surgeons  
Division of Pediatric Infectious Diseases  
NewYork-Presbyterian Morgan Stanley Children's Hospital  
New York, New York

**Varicella-Zoster Virus**

**Oren J. Lakser MD**  
Assistant Professor of Pediatrics  
Northwestern University Feinberg School of Medicine  
Division of Pulmonary Medicine  
Ann & Robert H. Lurie Children's Hospital of Chicago  
Chicago, Illinois

**Bronchiectasis**  
**Pulmonary Abscess**

**J. Todd R. Lawrence MD, PhD**  
Assistant Professor  
Department of Orthopaedic Surgery  
University of Pennsylvania Perelman School of Medicine  
Attending Orthopaedic Surgeon  
Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**The Knee**

**Brendan Lee MD, PhD**  
Robert and Janice McNair Endowed Chair in Molecular and Human Genetics
Integration of Genetics into Pediatric Practice
The Genetic Approach in Pediatric Medicine
The Human Genome
Patterns of Genetic Transmission
Cytogenetics
Genetics of Common Disorders

K. Jane Lee MD, MA
Associate Professor
Department of Pediatrics
Medical College of Wisconsin
Division of Pediatric Special Needs
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Brain Death

J. Steven Leeder PharmD, PhD
Marion Merrell Dow / Missouri Endowed Chair in Pediatric Pharmacology
Chief, Division of Pediatric Pharmacology and Medical Toxicology
Children's Mercy Hospitals and Clinics
Kansas City, Missouri;
Adjunct Professor
Department of Pharmacology, Toxicology, and Therapeutics
Kansas University School of Medicine
Kansas City, Kansas

Pediatric Pharmacogenetics, Pharmacogenomics, and Pharmacoproteomics

Jennifer W. Leiding MD
Assistant Professor of Pediatrics  
University of South Florida College of Medicine  
St. Petersburg, Florida

**Immunodeficiencies Affecting Multiple Cell Types**

**Michael J. Lentze MD**  
Professor Emeritus of Pediatrics  
Zentrum für Kinderheilkunde  
Universitätsklinikum Bonn  
Bonn, Germany

**Enzyme Deficiencies**

**Steven O. Lestrud MD**  
Assistant Professor of Pediatrics  
Northwestern University Feinberg School of Medicine  
Medical Director, Respiratory Care  
Ann & Robert H. Lurie Children's Hospital of Chicago  
Chicago, Illinois

**Bronchopulmonary Dysplasia**  
**Chronic Respiratory Failure and Long-Term Mechanical Ventilation**

**Donald Y.M. Leung MD, PhD**  
Edelstein Family Chair of Pediatric Allergy-Immunology  
National Jewish Health  
Professor of Pediatrics  
University of Colorado School of Medicine  
Denver, Colorado

**Atopic Dermatitis (Atopic Eczema)**

**Michael N. Levas MD**  
Associate Professor of Pediatrics  
Medical College of Wisconsin  
Division of Pediatric Emergency Medicine
Violent Behavior

Rona L. Levy MSW, PhD, MPH
Professor and Director
Behavioral Medicine Research Group
Assistant Dean for Research
School of Social Work
University of Washington
Seattle, Washington

Pediatric Pain Management

B U.K. Li MD
Clinical Professor of Pediatrics
Medical College of Wisconsin
Division of Pediatric Gastroenterology
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Cyclic Vomiting Syndrome

Chris A. Liacouras MD
Professor of Pediatrics
University of Pennsylvania Perelman School of Medicine
Co-Director, Center for Pediatric Eosinophilic Disorders
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Normal Digestive Tract Phenomena
Major Symptoms and Signs of Digestive Tract Disorders
Normal Development, Structure, and Function of the Stomach and Intestines
Pyloric Stenosis and Other Congenital Anomalies of
the Stomach
Intestinal Atresia, Stenosis, and Malrotation
Intestinal Duplications, Meckel Diverticulum, and
Other Remnants of the Omphalomesenteric Duct
Motility Disorders and Hirschsprung Disease
Ileus, Adhesions, Intussusception, and Closed-Loop
Obstructions
Foreign Bodies and Bezoars
Functional Abdominal Pain
Cyclic Vomiting Syndrome
Malformations
Ascites
Peritonitis

Christopher W. Liebig MD
Clinical Assistant Professor of Pediatrics
Northeast Ohio Medical University
Rootstown, Ohio;
Director, Sports Medicine in Mahoning Valley
Akron Children's Hospital
Boardman, Ohio

Sports-Related Traumatic Brain Injury (Concussion)

Paul H. Lipkin MD
Associate Professor of Pediatrics
Director, Medical Informatics
Director, Interactive Autism Network
Kennedy Krieger Institute
Johns Hopkins University School of Medicine
Baltimore, Maryland

Developmental and Behavioral Surveillance and
Screening

Deborah R. Liptzin MD, MS
Assistant Professor of Pediatrics
University of Colorado School of Medicine
Associate Director, Colorado chILD
Children's Hospital Colorado
Aurora, Colorado

Fibrotic Lung Disease

Andrew H. Liu MD
Professor
Department of Pediatrics
Children's Hospital Colorado
University of Colorado School of Medicine
Aurora, Colorado

Childhood Asthma

Lucinda Lo MD
Clinical Assistant Professor of Pediatrics
Physician Advisor, CDI and CM
University of Pennsylvania Perelman School of Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Malnutrition

Stanley F. Lo PhD
Associate Professor of Pathology
Medical College of Wisconsin
Technical Director, Clinical Chemistry, POCT, and Biochemical Genetics
Director, Reference Standards Library
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Laboratory Testing in Infants and Children
Reference Intervals for Laboratory Tests and Procedures

Kathleen A. Long MD
Department of Child Health
University of Missouri School of Medicine
Columbia, Missouri

Dermatologic Diseases of the Neonate

Sarah S. Long MD
Professor of Pediatrics
Drexel University College of Medicine
Division of Infectious Diseases
St. Christopher's Hospital for Children
Philadelphia, Pennsylvania

Pertussis (Bordetella pertussis and Bordetella parapertussis)

Anna Lena Lopez MD, MPH
Director, Institute of Child Health and Human Development
Research Associate Professor
University of the Philippines Manila–National Institutes of Health
Manila, Philippines

Cholera

Santiago M.C. Lopez MD
Assistant Professor of Pediatrics
University of South Dakota School of Medicine
Pediatric Infectious Diseases
Sanford Children's Hospital/Specialty Clinic
Sioux Falls, South Dakota

The Common Cold

Steven V. Lossef MD
Associate Professor of Radiology
George Washington University School of Medicine and Health Sciences
Head, Pediatric Interventional Radiology
Division of Diagnostic Imaging and Radiology
Children's National Medical Center
Washington, DC

Pertussis (*Bordetella pertussis* and *Bordetella parapertussis*)
Pleurisy, Pleural Effusions, and Empyema

Jennifer A. Lowry MD
Professor of Pediatrics
University of Missouri – Kansas City School of Medicine
Director, Division of Clinical Pharmacology, Toxicology, and Therapeutic Innovation
Children's Mercy
Kansas City, Missouri

Principles of Drug Therapy

Ian R. Macumber MD, MS
Assistant Professor of Pediatrics
University of Connecticut School of Medicine
Division of Nephrology
Connecticut Children's Medical Center
Hartford, Connecticut

Systemic Hypertension

Mark R. Magnusson MD, PhD
Co-Director, Diagnostic and Complex Care Center
Medical Director, Spina Bifida Program
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Chronic Fatigue Syndrome
Pilar L. Magoulas MS
Assistant Professor, Clinical Program
Department of Molecular and Human Genetics
Baylor College of Medicine
Houston, Texas

**Genetic Counseling**

Prashant V. Mahajan MD, MPH, MBA
Professor of Emergency Medicine and Pediatrics
Vice-Chair, Department of Emergency Medicine
Division Chief, Pediatric Emergency Medicine
University of Michigan
Ann Arbor, Michigan

**Heavy Metal Intoxication**

Joseph A. Majzoub MD
Thomas Morgan Rotch Professor of Pediatrics
Harvard Medical School
Division of Endocrinology
Boston Children's Hospital
Boston, Massachusetts

**Diabetes Insipidus**

**Other Abnormalities of Arginine Vasopressin Metabolism and Action**

Robert J. Mann MD
The Karl and Patricia Betz Family
Endowed Director of Research
Helen DeVos Children's Hospital
Grand Rapids, Michigan

**Deformational Plagiocephaly**

Irini Manoli MD, PhD
National Human Genome Research Institute
Nutritional Requirements
Normal Digestive Tract Phenomena
Major Symptoms and Signs of Digestive Tract Disorders
Normal Development, Structure, and Function of the Stomach and Intestines
Pyloric Stenosis and Other Congenital Anomalies of the Stomach
Intestinal Atresia, Stenosis, and Malrotation
Intestinal Duplications, Meckel Diverticulum, and Other Remnants of the Omphalomesenteric Duct

Peritonitis

Ashley M. Maranich MD
Program Director, Pediatrics Residency
Tripler Army Medical Center
Honolulu, Hawaii

Malassezia

Nicole Marcantuono MD
Associate Professor
Department of Pediatrics
Thomas Jefferson Medical College
Philadelphia, Pennsylvania;
Attending Physician
Alfred I. du Pont Hospital for Children
Wilmington, Delaware

Evaluation of the Child for Rehabilitative Services

David Margolis MD
Professor and Associate Chair
Department of Pediatrics
Medical College of Wisconsin
Program Director, Bone Marrow Transplantation
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Principles and Clinical Indications of Hematopoietic Stem Cell Transplantation
Hematopoietic Stem Cell Transplantation from Alternative Sources and Donors
Graft-Versus-Host Disease, Rejection, and Venoocclusive Disease
Late Effects of Hematopoietic Stem Cell
Transplantation

Mona Marin MD
Division of Viral Diseases
National Center for Immunization and Respiratory Diseases
Centers for Disease Control and Prevention
Atlanta, Georgia

Varicella-Zoster Virus

Joan C. Marini MD, PhD
Chief, Bone and Extracellular Matrix Branch
National Institute for Child Health and Development
National Institutes of Health
Bethesda, Maryland

Osteogenesis Imperfecta

Thomas C. Markello MD, PhD
Associate Staff Clinician,
Medical Genetics Branch
National Human Genome Research Institute
National Institutes of Health
Bethesda, Maryland

Genetic Approaches to Rare and Undiagnosed Diseases

Morri Markowitz MD
Professor of Pediatrics and Medicine
Albert Einstein College of Medicine
Director, Lead Poisoning Prevention and Treatment Program
The Children's Hospital at Montefiore
Bronx, New York

Lead Poisoning

Stacene R. Maroushek MD, PhD, MPH
Assistant Professor of Pediatrics  
Divisions of Pediatric Infectious Diseases and General Pediatrics  
University of Minnesota Medical School  
Hennepin County Medical Center  
Minneapolis, Minnesota

Medical Evaluation of the Foreign-Born Child  
Principles of Antimycobacterial Therapy

Justin D. Marsh MD  
Assistant Professor of Pediatric Ophthalmology  
University of Missouri-Kansas City School of Medicine  
Kansas City, Missouri

Growth and Development of the Eye  
Examination of the Eye  
Abnormalities of Refraction and Accommodation  
Disorders of Vision  
Abnormalities of Pupil and Iris  
Disorders of Eye Movement and Alignment  
Abnormalities of the Lids  
Disorders of the Lacrimal System

New York, New York

Altitude-Associated Illness in Children (Acute Mountain Sickness)

Judith A. Owens MD, MPH
Professor of Neurology
Harvard Medical School
Director of Sleep Medicine
Boston Children's Hospital
Boston, Massachusetts

Sleep Medicine

Seza Özen MD
Professor of Paediatrics
Divisions of Paediatric Rheumatology
Hacettepe University
Ankara, Turkey

Behçet Disease

Lee M. Pachter DO
Overview of Pediatrics

Child Health Disparities

Cultural Issues in Pediatric Care

Amruta Padhye MD
Assistant Professor of Clinical Child Health
Division of Pediatric Infectious Diseases
University of Missouri School of Medicine
Columbia, Missouri

Diphtheria (Corynebacterium diphtheriae)

Suzinne Pak-Gorstein MD, PhD, MPH
Associate Professor of Pediatrics
Adjunct Associate Professor of Global Health
University of Washington School of Medicine
Seattle, Washington

Global Child Health

Jennifer Panganiban MD
Assistant Professor of Clinical Pediatrics
University of Pennsylvania Perelman School of Medicine
Director, Non Alcoholic Fatty Liver Disease Clinic
Division of Gastroenterology, Hepatology, and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Nutritional Requirements

Diane E. Pappas MD, JD
Professor of Pediatrics
Director of Child Advocacy
University of Virginia School of Medicine
Charlottesville, Virginia

Sinusitis
\textit{Retropharyngeal Abscess, Lateral Pharyngeal (Parapharyngeal) Abscess, and Peritonsillar Cellulitis/Abscess}

John J. Parent MD, MSCR
Assistant Professor of Pediatrics
Indiana University School of Medicine
Section of Cardiology
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

Diseases of the Myocardium
Diseases of the Pericardium
Tumors of the Heart

Alasdair P.J. Parker MBBS (Lond), MRCP, MD, MA (Camb)
Consultant in Pediatric Neurology
Addenbrooke's Hospital
Associate Lecturer
University of Cambridge School of Clinical Medicine
Cambridge, United Kingdom

\textit{Idiopathic Intracranial Hypertension (Pseudotumor Cerebri)}

Elizabeth Prout Parks MD, MSCE
Assistant Professor of Pediatrics
Nutritional Requirements
Feeding Healthy Infants, Children, and Adolescents

Briana C. Patterson MD, MS
Associate Professor of Pediatrics
Division of Pediatric Endocrinology
Director, Pediatric Endocrine Fellowship Program
Emory University School of Medicine
Atlanta, Georgia

Hormones of the Hypothalamus and Pituitary
Hypopituitarism

Maria Jevitz Patterson MD, PhD
Professor Emeritus of Microbiology and Molecular Genetics
Michigan State University College of Human Medicine
East Lansing, Michigan

Syphilis (Treponema pallidum)

Anna L. Peters MD, PhD
Clinical Fellow
Division of Gastroenterology, Hepatology, and Nutrition
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Metabolic Diseases of the Liver

Timothy R. Peters MD
Professor of Pediatrics
Wake Forest School of Medicine
Division of Pediatric Infectious Diseases
Wake Forest Baptist Medical Center
Streptococcus pneumoniae (Pneumococcus)

Rachel A. Phelan MD, MPH
Assistant Professor of Pediatrics
Medical College of Wisconsin
Division of Hematology/Oncology/BMT
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Principles and Clinical Indications of Hematopoietic
Stem Cell Transplantation
Hematopoietic Stem Cell Transplantation from
Alternative Sources and Donors
Graft-Versus-Host Disease, Rejection, and
Venoocclusive Disease
Late Effects of Hematopoietic Stem Cell
Transplantation

Anna Pinto MD, PhD
Lecturer of Neurology
Harvard Medical School
Co-Director, Sturge Weber Clinic
Department of Neurology
Boston Children's Hospital
Boston, Massachusetts

Neurocutaneous Syndromes

Brenda B. Poindexter MD, MS
Professor of Pediatrics
University of Cincinnati College of Medicine
Director of Clinical and Translational Research
Perinatal Institute
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

The High-Risk Infant
Transport of the Critically Ill Newborn

Andrew J. Pollard FRCPCH, PhD, FMedSci
Professor of Paediatric Infection and Immunity
Department of Paediatrics
University of Oxford
Children's Hospital
Oxford, United Kingdom

Neisseria meningitidis (Meningococcus)

Diego Preciado MD, PhD
Professor of Pediatrics, Surgery, and Integrative Systems Biology
George Washington University School of Medicine and Health Sciences
Vice-Chief, Division of Pediatric Otolaryngology
Children's National Health System
Washington, DC

Otitis Media

Mark R. Proctor MD
Franc D. Ingraham Professor of Neurosurgery
Harvard Medical School
Neurosurgeon-in-Chief
Boston Children's Hospital
Boston, Massachusetts

Spinal Cord Injuries in Children
Spinal Cord Disorders

Howard I. Pryor II, MD
Instructor of Surgery
Division of Pediatric Surgery
Johns Hopkins University School of Medicine
Johns Hopkins Children's Center
Baltimore, Maryland

**Acute Care of Multiple Trauma**

Lee A. Pyles MD, MS  
Associate Professor of Pediatrics  
Division of Pediatric Cardiology  
West Virginia University School of Medicine  
Morgantown, West Virginia

**Disorders of Lipoprotein Metabolism and Transport**

Molly Quinn MD  
Fellow, Reproductive Endocrinology and Infertility  
Department of Obstetrics, Gynecology, and Reproductive Sciences  
University of California, San Francisco  
San Francisco, California

**Polycystic Ovary Syndrome and Hirsutism**

Elisabeth H. Quint MD  
Professor of Obstetrics and Gynecology  
Director, Fellowship in Pediatric and Adolescent Gynecology  
University of Michigan Medical School  
Ann Arbor, Michigan

**Gynecologic Care for Girls with Special Needs**

Amy E. Rabatin MD  
Fellow, Pediatric Rehabilitation and Board Certified Sports Medicine  
Department of Physical Medicine and Rehabilitation  
Mayo Clinic Children's Center  
Rochester, Minnesota

**Specific Sports and Associated Injuries**

C. Egla Rabinovich MD, MPH  
Professor of Pediatrics  
Duke University School of Medicine
Evaluation of Suspected Rheumatic Disease
Treatment of Rheumatic Diseases
Juvenile Idiopathic Arthritis
Scleroderma and Raynaud Phenomenon
Sjögren Syndrome
Miscellaneous Conditions Associated With Arthritis

Leslie J. Raffini MD
Associate Professor
Department of Pediatrics
University of Pennsylvania Perelman School of Medicine
Division of Hematology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Hemostasis
Hereditary Predisposition to Thrombosis
Thrombotic Disorders in Children
Disseminated Intravascular Coagulation

Shawn L. Ralston MD, MS
Associate Professor and Vice Chair for Clinical Affairs
Department of Pediatrics
Geisel School of Medicine at Dartmouth
Chief, Section of Pediatric Hospital Medicine
Children's Hospital at Dartmouth-Hitchcock
Hanover, New Hampshire

Wheezeing in Infants: Bronchiolitis

Sanjay Ram MD
Neisseria gonorrhoeae (Gonococcus)

Octavio Ramilo MD
Professor of Pediatrics
Henry G. Cramblett Chair in Medicine
The Ohio State University College of Medicine
Chief, Division of Infectious Diseases
Nationwide Children's Hospital
Columbus, Ohio

Mycoplasma pneumoniae

Kacy A. Ramirez MD
Assistant Professor of Pediatrics
Wake Forest School of Medicine
Division of Pediatric Infectious Diseases
Wake Forest Baptist Medical Center
Winston-Salem, North Carolina

Streptococcus pneumoniae (Pneumococcus)

Casey M. Rand BS
Project Manager, Center for Autonomic Medicine in Pediatrics
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Rapid-Onset Obesity with Hypothalamic Dysfunction, Hypoventilation, and Autonomic Dysregulation (ROHHAD)
Congenital Central Hypoventilation Syndrome

Adam J. Ratner MD, MPH
Associate Professor of Pediatrics and Microbiology
New York University School of Medicine
Chief, Division of Pediatric Infectious Diseases
New York University Langone Medical Center
New York, New York

Aeromonas and Plesiomonas

Lee Ratner MD, PhD
Professor of Medicine
Professor of Molecular Microbiology and of Pathology and Immunology
Washington University School of Medicine in St. Louis
St. Louis, Missouri

Human T-Lymphotropic Viruses (1 and 2)

Gerald V. Raymond MD
Professor of Neurology
University of Minnesota School of Medicine
Chief of Pediatric Neurology
University of Minnesota Medical Center, Fairview
Minneapolis, Minnesota

Disorders of Very-Long-Chain Fatty Acids and Other Peroxisomal Functions

Ann M. Reed MD
Professor of Pediatrics
Chair, Department of Pediatrics
Physician-in-Chief
Duke Children's
Duke University
Durham, North Carolina

Juvenile Dermatomyositis

Shimon Reif MD
Chairman, Department of Pediatrics
Diarrhea From Neuroendocrine Tumors

Megan E. Reller MD, PhD, MPH
Associate Professor of Medicine
Associate Research Professor of Global Health
Duke University Medical Center
Durham, North Carolina

Spotted Fever Group Rickettsioses
Scrub Typhus (Orientia tsutsugamushi)
Typhus Group Rickettsioses
Ehrlichioses and Anaplasmosis
Q Fever (Coxiella burnetii)

Caroline H. Reuter MD, MSCI
Associate Medical Director, Pharmacovigilance
Bioverativ
Waltham, Massachusetts

Group A Streptococcus

Jorge D. Reyes MD
Professor and Roger K. Giesecke Distinguished Chair
Department of Surgery
University of Washington School of Medicine
Chief, Division of Transplant Surgery
Seattle Children’s Hospital
Seattle, Washington

Intestinal Transplantation in Children with Intestinal Failure
Liver Transplantation
Firas Rinawi MD  
Attending Physician  
Institute of Gastroenterology, Nutrition, and Liver Diseases  
Schneider Children's Medical Center of Israel  
Petah Tikva, Israel

*Evaluation of Children with Suspected Intestinal Malabsorption*

A. Kim Ritchey MD  
Professor and Vice-Chair of International Affairs  
Department of Pediatrics  
University of Pittsburgh School of Medicine  
Division of Hematology/Oncology  
UPMC Children's Hospital of Pittsburgh  
Pittsburgh, Pennsylvania

*Principles of Cancer Diagnosis*  
*Principles of Cancer Treatment*  
*The Leukemias*

Frederick P. Rivara MD, MPH  
Seattle Children's Guild Endowed Chair in Pediatrics  
Professor and Vice-Chair, Department of Pediatrics  
University of Washington School of Medicine  
Seattle, Washington

*Injury Control*

Eric Robinette MD  
Attending Physician in Infectious Diseases  
Akron Children's Hospital  
Akron, Ohio

*Osteomyelitis*  
*Septic Arthritis*
Angela Byun Robinson MD, MPH
Associate Professor
Cleveland Clinic Lerner College of Medicine
Staff, Pediatrics Institute
Cleveland Clinic Children's
Cleveland, Ohio

*Juvenile Dermatomyositis*

*Miscellaneous Conditions Associated with Arthritis*

Kristine Knuti Rodrigues MD, MPH
Assistant Professor of Pediatrics
University of Colorado School of Medicine
Department of Pediatrics
Denver Health Medical Center
Denver, Colorado

*Acute Inflammatory Upper Airway Obstruction*  
*(Croup, Epiglottitis, Laryngitis, and Bacterial Tracheitis)*

David F. Rodríguez-Buritica MD
Assistant Professor
Department of Pediatrics
Division of Medical Genetics
McGovern Medical School at UTHealth
Houston, Texas

*Disorders Involving Ion Transporters*
*Disorders Involving Transcription Factors*
*Disorders Involving Defective Bone Resorption*

Rosa Rodríguez-Fernández MD, PhD
Hospital General Universitario Gregorio Marañón
Instituto de Investigación Sanitaria Gregorio Marañón (IISGM)
Madrid, Spain;
Genital Mycoplasmas (Mycoplasma hominis, Mycoplasma genitalium, and Ureaplasma urealyticum)

Genie E. Roosevelt MD, MPH
Professor of Emergency Medicine
University of Colorado School of Medicine
Department of Emergency Medicine
Denver Health Medical Center
Denver, Colorado

Acute Inflammatory Upper Airway Obstruction (Croup, Epiglottitis, Laryngitis, and Bacterial Tracheitis)

David R. Rosenberg MD
Chair, Department of Psychiatry and Behavioral Neurosciences
Chief of Child Psychiatry and Psychology
Wayne State University School of Medicine
Detroit, Michigan

Anxiety Disorders

Cindy Ganis Roskind MD
Program Director
Pediatric Emergency Medicine Fellowship
Children's Hospital of New York–Presbyterian
Associate Professor of Pediatrics
Columbia University Irving Medical Center
Columbia University College of Physicians and Surgeons
New York, New York
Acute Care of Multiple Trauma

A. Catharine Ross PhD
Professor and Dorothy Foehr Huck Chair
Department of Nutritional Sciences
The Pennsylvania State University
College of Health and Human Development
University Park, Pennsylvania

Vitamin A Deficiencies and Excess

Joseph W. Rossano MD, MS
Chief, Division of Cardiology
Co-Executive Director, The Cardiac Center
Jennifer Terker Endowed Chair in Pediatric Cardiology
Associate Professor of Pediatrics
Children's Hospital of Philadelphia
University of Pennsylvania Perelman School of Medicine
Philadelphia, Pennsylvania

Heart Failure

Pediatric Heart and Heart-Lung Transplantation

Jennifer A. Rothman MD
Associate Professor
Department of Pediatrics
Division of Pediatric Hematology/Oncology
Duke University Medical Center
Durham, North Carolina

Iron-Deficiency Anemia

Other Microcytic Anemias

Ranna A. Rozenfeld MD
Professor of Pediatrics
The Warren Alpert Medical School
Brown University
Division of Pediatric Critical Care Medicine
Hasbro Children's Hospital
Providence, Rhode Island

**Atelectasis**

Colleen A. Ryan MD
Instructor in Psychiatry
Harvard Medical School
Boston Children's Hospital
Boston, Massachusetts

**Motor Disorders and Habits**

Monique M. Ryan M Med BS, FRACP
Professor of Paediatric Neurology
Director, Department of Neurology
Honorary Fellow, Murdoch Children's Research Institute
University of Melbourne
Royal Children's Hospital
Parkville, Victoria, Australia

**Autonomic Neuropathies**

*Guillain-Barré Syndrome*

*Bell Palsy*

Julie Ryu MD
Professor of Pediatrics
University of California, San Diego School of Medicine
Interim Chief, Division of Respiratory Medicine
Chief Research Informatics Officer
Department of Pediatrics
Rady Children's Hospital–San Diego
San Diego, California

**H.P.S. Sachdev MD, FIAP, FAMS, FRCPCH**
Senior Consultant
Departments of Pediatrics and Clinical Epidemiology
Sitaram Bhartia Institute of Science and Research
New Delhi, India

**Vitamin B Complex Deficiencies and Excess Vitamin C (Ascorbic Acid)**

**Manish Sadarangani MRCPCH, DPHIL, BM.BCh, MA**
Assistant Professor of Pediatrics
Sauder Family Chair in Pediatric Infectious Diseases
University of British Columbia Faculty of Medicine
Director, Vaccine Evaluation Center
British Columbia Children's Hospital
Vancouver, British Columbia, Canada

**Neisseria meningitidis (Meningococcus)**

**Rebecca E. Sadun MD, PhD**
Assistant Professor of Adult and Pediatric Rheumatology
Departments of Medicine and Pediatrics
Duke University School of Medicine
Durham, North Carolina

**Systemic Lupus Erythematosus**

**Mustafa Sahin MD, PhD**
Professor of Neurology
Harvard Medical School
Director, Translational Neuroscience Center
Boston Children's Hospital
Boston, Massachusetts

**Neurocutaneous Syndromes**

**Nina N. Sainath MD**
Division of Gastroenterology, Hepatology, and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

**Feeding Healthy Infants, Children, and Adolescents**
Robert A. Salata MD
Professor and Chairman, Department of Medicine
Case Western Reserve University School of Medicine
Physician-in-Chief
University Hospitals Case Medical Center
Cleveland, Ohio

Amebiasis
Trichomoniasis (Trichomonas vaginalis)
African Trypanosomiasis (Sleeping Sickness; Trypanosoma brucei complex)
American Trypanosomiasis (Chagas Disease; Trypanosoma cruzi)

Edsel Maurice T. Salvana MD
Clinical Associate Professor of Medicine
University of the Philippines College of Medicine
Director, Institute of Molecular Biology and Biotechnology
National Institutes of Health
Manila, The Philippines;
Adjunct Professor of Global Health
University of Pittsburgh School of Medicine
Pittsburgh, Pennsylvania

Amebiasis
Trichomoniasis (Trichomonas vaginalis)
African Trypanosomiasis (Sleeping Sickness; Trypanosoma brucei complex)
American Trypanosomiasis (Chagas Disease; Trypanosoma cruzi)

Hugh A. Sampson MD
Kurt Hirschhorn Professor of Pediatrics
Jaffé Food Allergy Institute
Anaphylaxis
Food Allergy and Adverse Reactions to Foods

Chase B. Samsel MD
Instructor in Psychiatry
Harvard Medical School
Boston Children's Hospital
Boston, Massachusetts

Rumination and Pica

Thomas J. Sandora MD, MPH
Associate Professor of Pediatrics
Harvard Medical School
Hospital Epidemiologist
Division of Infectious Diseases
Boston Children's Hospital
Boston, Massachusetts

Community-Acquired Pneumonia

Tracy L. Sandritter PharmD
Division of Clinical Pharmacology, Toxicology, and Therapeutic Innovation
Children's Mercy
Adjunct Clinical Professor
University of Missouri – Kansas City School of Pharmacy
Kansas City, Missouri

Principles of Drug Therapy

Wudbhav N. Sankar MD
Associate Professor
Department of Orthopaedic Surgery
University of Pennsylvania Perelman School of Medicine
Attending Orthopaedic Surgeon
The Hip

Eric J. Sarkissian MD
Resident Physician
Department of Orthopaedic Surgery
Stanford University School of Medicine
Stanford, California

Osgood-Schlatter Disease and Sinding-Larsen-Johansson Syndrome

Ajit A. Sarnaik MD
Associate Professor of Pediatrics
Wayne State University School of Medicine
Director, Pediatric Critical Care Medicine Fellowship Program
Children's Hospital of Michigan
Detroit, Michigan

Mechanical Ventilation

Ashok P. Sarnaik MD
Professor and Former Interim Chair
Department of Pediatrics
Wayne State University School of Medicine
Former Pediatrician-in-Chief
Children's Hospital of Michigan
Detroit, Michigan

Respiratory Distress and Failure

Harvey B. Sarnat MD, MS, FRCPC
Professor of Pediatrics, Pathology (Neuropathology), and Clinical Neurosciences
University of Calgary Cumming School of Medicine
Division of Pediatric Neurology
Alberta Children's Hospital Research Institute
Calgary, Alberta, Canada

Evaluation and Investigation of Neuromuscular Disorders
Developmental Disorders of Muscle
Endocrine and Toxic Myopathies
Metabolic Myopathies
Hereditary Motor-Sensory Neuropathies
Toxic Neuropathies

Joshua K. Schaffzin MD, PhD
Assistant Professor of Pediatrics
University of Cincinnati College of Medicine
Director, Infection Prevention and Control
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Liver Abscess

Laura E. Schanberg MD
Professor of Pediatrics
Duke University School of Medicine
Division of Pediatric Rheumatology
Duke University Medical Center
Durham, North Carolina

Systemic Lupus Erythematosus
Musculoskeletal Pain Syndromes

Michael S. Schechter MD, MPH
Professor of Pediatrics
Virginia Commonwealth University School of Medicine
Chief, Division of Pulmonary Medicine
Director, Cystic Fibrosis Center
Director, UCAN Community Asthma Program
Children's Hospital of Richmond at VCU
Richmond, Virginia

Cystic Fibrosis

Mark R. Schleiss MD
Professor of Pediatrics
American Legion and Auxiliary Heart Research Foundation Endowed Chair
Division of Pediatric Infectious Diseases and Immunology
University of Minnesota Medical School
Minneapolis, Minnesota

Principles of Antibacterial Therapy
Botulism (Clostridium botulinum)
Tetanus (Clostridium tetani)
Principles of Antiviral Therapy
Principles of Antiparasitic Therapy

Nina F. Schor MD, PhD
Deputy Director
National Institute of Neurological Disorders and Stroke
National Institute of Health
Bethesda, Maryland

Neurologic Evaluation

James W. Schroeder Jr, MD, FACS, FAAP
Associate Professor
Department of Otolaryngology – Head and Neck Surgery
Northwestern University Feinberg School of Medicine
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Congenital Anomalies of the Larynx, Trachea, and Bronchi
Foreign Bodies in the Airway
Laryngotracheal Stenosis and Subglottic Stenosis
Neoplasms of the Larynx, Trachea, and Bronchi

Elaine E. Schulte MD, MPH
Professor of Pediatrics
Albert Einstein College of Medicine
Vice Chair, Academic Affairs and Faculty Development
Division of Academic General Pediatrics
The Children's Hospital at Montefiore
Bronx, New York

Domestic and International Adoption

Mark A. Schuster MD, PhD
Founding Dean and CEO
Professor
Kaiser Permanente School of Medicine
Pasadena, California

Gay, Lesbian, and Bisexual Adolescents

Daryl A. Scott MD, PhD
Assistant Professor
Department of Molecular and Human Genetics
Baylor College of Medicine
Houston, Texas

The Genetic Approach in Pediatric Medicine
The Human Genome
Patterns of Genetic Transmission

J. Paul Scott MD
Professor
Department of Pediatrics
Division of Pediatric Hematology/Oncology
Medical College of Wisconsin
Blood Center of Southeastern Wisconsin
Milwaukee, Wisconsin

von Willebrand Disease
Hereditary Predisposition to Thrombosis
Thrombotic Disorders in Children
Postneonatal Vitamin K Deficiency
Liver Disease
Acquired Inhibitors of Coagulation
Disseminated Intravascular Coagulation
Platelet and Blood Vessel Disorders

John P. Scott MD
Associate Professor of Anesthesiology and Pediatrics
Divisions of Pediatric Anesthesiology and Pediatric Critical Care
Medical College of Wisconsin
Children's Hospital of Wisconsin
Milwaukee, Wisconsin

Anesthesia and Perioperative Care
Procedural Sedation

Patrick C. Seed MD, PhD, FAAP, FIDSA
Children's Research Fund Chair in Basic Science
Professor of Pediatrics, Microbiology and Immunology
Northwestern University Feinberg School of Medicine
Division Head, Pediatric Infectious Diseases
Associate Chief Research Officer of Basic Science
Stanley Manne Children's Research Institute
Director, Host-Microbial Interactions, Inflammation, and Immunity (HMI3) Program
Ann & Robert H. Lurie Children's Hospital
Chicago, Illinois
The Microbiome and Pediatric Health

Shigella

Escherichia coli

Janet R. Serwint MD
Professor
Department of Pediatrics
Johns Hopkins University School of Medicine
Baltimore, Maryland

Loss, Separation, and Bereavement

Apurva S. Shah MD, MBA
Assistant Professor
Department of Orthopedic Surgery
University of Pennsylvania Perelman School of Medicine
Attending Orthopaedic Surgeon
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Common Fractures

Dheeraj Shah MD, FIAP, MAMS
Professor
Department of Pediatrics
University College of Medical Sciences
Guru Teg Bahadur Hospital
New Delhi, India

Vitamin B Complex Deficiencies and Excess

Vitamin C (Ascorbic Acid)

Samir S. Shah MD, MSCE
Professor of Pediatrics
University of Cincinnati College of Medicine
Director, Division of Hospital Medicine
Chief Metrics Officer
Quality and Value in Healthcare for Children
Fever Without a Focus in the Neonate and Young Infant
Osteomyelitis
Septic Arthritis

Ala Shaikhkhalil MD
Pediatric Nutrition Fellow
Division of Gastroenterology, Hepatology, and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Nutritional Requirements
Feeding Healthy Infants, Children, and Adolescents

Impact of Violence on Children
† Deceased
Preface

Whoever saves one life it is considered as if they saved an entire world.
— Babylonian Talmud

The 21st edition of *Nelson Textbook of Pediatrics* continues its tradition of being an essential resource for general pediatric providers and pediatric subspecialists as they diagnose and treat infants, children, and adolescents throughout the world. The 21st edition has been thoroughly revised, updated, and edited to keep up with the huge advances in clinical care derived from basic, clinical, and population-based research. The promise that translational medicine will improve the lives of children has become a daily reality for most but not all children. Knowledge of human development, behavior, and diseases from the molecular to sociologic levels has led to greater understanding of health and illness in children and substantial improvements in health quality for those who have access to health care. These exciting scientific advances also provide hope to effectively address prevention and treatment of new and emerging diseases threatening children and their families.

The field of pediatrics encompasses advocacy for all children throughout the world and must address societal inequalities of important resources required for normal development, as well as protection from natural and man-made disasters. Unfortunately, many children throughout the world have not benefited from the significant advances in the prevention and treatment of health-related problems. For our increasing knowledge to benefit all children and youth, medical advances and good clinical practice must always be coupled with effective advocacy to overcome unconscious bias, lack of political will, and misplaced priorities.

This new edition of *Nelson Textbook of Pediatrics* attempts to provide the essential information that practitioners, house staff, medical students, and all other care providers involved in pediatric health care throughout the world need to understand to effectively address the enormous range of biologic, psychologic, and social problems that our children and youth face. In addition,
pediatric subspecialists will benefit from the details of coexisting disorders often seen in their patients. Our goal is to be comprehensive yet concise and reader friendly, embracing both new advances in clinical science and the time-honored art of pediatric practice.

The 21st edition is reorganized and revised from the previous edition. There are many additions of new diseases and new chapters, as well as substantial expansion or significant modification of others. In addition, many more tables, photographs, imaging studies, and illustrative figures, as well as up-to-date references, have been added. This new edition has greatly benefited by the addition of four new associate editors with an extremely broad base of clinic experiences: Dr. Nathan Blum, Chief, Division of Developmental and Behavioral Pediatrics at the Children's Hospital of Philadelphia; Dr. Samir S. Shah, Director, Division of Hospital Medicine and Chief Metrics Officer, Cincinnati Children's Hospital Medical Center; Dr. Robert Tasker, Director, Pediatric NeuroCritical Care Medicine, Boston Children's Hospital; and Dr. Karen Wilson, Division Chief of General Pediatrics, Vice-Chair for Clinical and Translational Research, Kravis Children's Hospital at the Icahn School of Medicine at Mount Sinai, have all contributed to the planning and editing of the 21st edition.

Although, to an ill child and their family and physician, even the rarest disorder is of central importance, all health problems cannot possibly be covered with the same degree of detail in one general textbook of pediatrics. Thus, leading articles and subspecialty texts are referenced and should be consulted when more information is desired. In addition, as new recommendations or policies are developed, they will be updated on our website.

The outstanding value of the 21st edition of the textbook is due to its many expert and authoritative contributors. We are all indebted to these dedicated authors for their hard work, knowledge, thoughtfulness, and good judgment. Our sincere appreciation also goes to Jennifer Shreiner and Sarah Barth at Elsevier and to Carolyn Redman in the Pediatric Department of the Medical College of Wisconsin. We have all worked hard to produce an edition that will be helpful to those who provide care for children and youth and to those desiring to know more about children's health worldwide.

In this edition we have had informal assistance from many faculty and house staff of the department of pediatrics at the Medical College of Wisconsin, University of Pennsylvania Perelman School of Medicine, University of Cincinnati College of Medicine, Harvard Medical School, and the Kravis
Children's Hospital at the Icahn School of Medicine at Mount Sinai. The help of these individuals and of the many practicing pediatricians from around the world who have taken the time to offer thoughtful feedback and suggestions is always greatly appreciated and helpful.

Last and certainly not least, we especially wish to thank our families for their patience and understanding about the great time commitment we as editors have spent reading and editing this edition.

The Field of Pediatrics

## OUTLINE

- Chapter 1 Overview of Pediatrics
- Chapter 2 Child Health Disparities
- Chapter 3 Global Child Health
- Chapter 4 Quality and Value in Healthcare for Children
- Chapter 5 Safety in Healthcare for Children
- Chapter 6 Ethics in Pediatric Care
- Chapter 7 Pediatric Palliative Care
- Chapter 8 Domestic and International Adoption
- Chapter 9 Foster and Kinship Care
- Chapter 10 Medical Evaluation of the Foreign-Born Child
- Chapter 11 Cultural Issues in Pediatric Care
- Chapter 12 Maximizing Children's Health Screening, Anticipatory Guidance, and Counseling
- Chapter 13 Injury Control
- Chapter 14 Impact of Violence on Children
- Chapter 15 Child Trafficking for Sex and Labor
- Chapter 16 Abused and Neglected Children
- Chapter 17 Strategies for Health Behavior Change
Pediatrics is the only discipline dedicated to all aspects of the care and well-being of infants, children, and adolescents, including their health—their physical, mental, social, and psychological growth and development—and their ability to achieve full potential as adults. Pediatricians must be concerned not only with specific organ systems, genetics, and biologic processes, but also with environmental, psychosocial, cultural, and political influences, all of which may have major impacts on the health and well-being of children and their families.

Children cannot advocate wholly for themselves. As the professionals whose purpose is to advance the well-being of children, pediatricians must be advocates for the individual child and for all children, irrespective of culture, religion, gender, sexual orientation, race, or ethnicity or of local, state, or national boundaries. The more politically, economically, or socially disenfranchised a population is, the greater the need for advocacy for its children and for those who support children. Youth are often among the most vulnerable persons in society, and thus their needs require special attention. As segmentation between nations blur through advances in media, transportation, technology, communication, and economics, a global, rather than a national or local, perspective for the field of pediatrics becomes both a reality and a necessity. The interconnectedness of health issues across the world has achieved widespread recognition in the wake of the Zika, Ebola, SARS, and AIDS epidemics; war and bioterrorism; the tsunami of 2004; the earthquake in Haiti in 2010; the displacement of families during the Syrian refugee crisis in 2016–2018; and the growing severity of drought, hurricanes, and cyclones brought about by climate change.

More than a century ago, pediatrics emerged as a medical specialty in response to increasing awareness that the health problems of children differ from
those of adults, and that a child's response to disease and stress varies with age and development. In 1959 the United Nations issued the Declaration of the Rights of the Child, articulating the universal presumption that children everywhere have fundamental needs and rights. Today, an affirmation of those rights and an effort to satisfy those needs are more important than ever.

**Vital Statistics About Children's Health Globally**

From 1990 to 2010, the world population grew at an annual rate of 1.3% per year, down from 1.8% during the prior 20 yr. This rate continues to decline; in 2016 the growth rate was 1.13%. Worldwide, there are 2.34 billion children 18 yr and younger, which accounts for approximately one third (32%) of the world's population of 7.4 billion persons. In 2016 the average birthrate in the world was 18.5 births per 1,000 population, with a high of 44.8/1,000 in Niger to the lowest in Monaco at 6.6/1,000. The most populous countries—China, India, and the United States—have rates of 12.4, 19.3, and 12.5 per 1,000 population, respectively.

Despite global interconnectedness, the health of children and youth varies widely between and within regions and nations of the world, depending on several interrelated factors. These include (1) economic conditions; (2) educational, social, and cultural considerations; (3) health and social welfare infrastructure; (4) climate and geography; (5) agricultural resources and practices, which account for nutritional resources; (6) stage of industrialization and urbanization; (7) gene frequencies for certain disorders; (8) the ecology of infectious agents and their hosts; (9) social stability; and (10) political focus and stability. Although genetics, biology, and access to affordable and quality healthcare are important determinants, it has been shown that the social determinants of health—the physical environment, political and economic conditions, social and cultural considerations, and behavioral psychology—play as great a role, if not greater, in health outcomes.

To ensure that the needs of children and adults worldwide were not obscured by local needs, in 2000 the international community established 8 Millennium Development Goals (MDGs) to be achieved by 2015. Although all 8 MDGs impact child well-being, MDG 4 was exclusively focused on children: to reduce the under-five mortality rate (U5MR) by two-thirds between 1990 and 2015. It
was estimated that poor nutrition contributed to more than one third of the deaths worldwide in children <5 yr old, so many of the efforts to reach this goal centered on increasing household food security. Increasing measles vaccination, particularly in sub-Saharan Africa, was another strategy to reduce the U5MR.

There was some progress in achieving MDG 4; the worldwide U5MR decreased by 50% between 1990 and 2015. Although the goal of a two-thirds reduction was not achieved, deaths in children under5 dropped from 12.7 million in 1990 to about 6 million in 2015, despite growth in world population during the same period.

The U5MR can be further divided into neonatal (<1 mo of age), infant (<1 yr of age), and after infancy (1-5 yr of age) (Fig. 1.1). The leading causes of worldwide U5MR are preterm birth complications, pneumonia, perinatal asphyxia, diarrheal diseases, and malaria. Many of these causes are linked to malnutrition. Children in sub-Saharan Africa are 14 times more likely to die before age 5 yr than children in the developed areas of the world.

Causes of under-5 mortality differ greatly between developed and developing nations. In developing countries, 66% of deaths in children <5 yr old resulted from infectious and parasitic diseases. Among the 42 countries having 90% of childhood deaths, diarrheal disease accounted for 22% of deaths, pneumonia 21%, malaria 9%, AIDS 3%, and measles 1%. Neonatal causes contributed 33%. In the United States, pneumonia (and influenza) accounted for only 2% of under-5 deaths, with only negligible contributions from diarrheal diseases and malaria. Unintentional injury is the most common cause of death among U.S. children age 1-4 yr, accounting for approximately 33% of deaths, followed by congenital anomalies (11%), homicides (9%), and malignant neoplasms (8%). Other causes accounted for <5% of total mortality within this age-group (Table 1.1). Violence is a significant contributor to injury-related mortality in all child age-groups (Tables 1.2 and 1.3). Although unintentional injuries in developing countries are proportionately less important causes of mortality than in developed countries, the absolute rates and contributions of these injuries to morbidity are substantially greater.

</table>

The infant mortality rate (deaths of children <1 yr old) accounts for 85% of the U5MR in industrialized countries, but only 70% in the least developed nations. Neonatal (<1 mo) death contributes substantially as well, growing in proportion as the U5MR decreases. Globally, the neonatal mortality rate of 19/1,000 live births represents 60% of the infant mortality rate and 45% of the U5MR. The neonatal mortality rate is responsible for 56% of the U5MR in industrialized nations, 45% in developing countries, but only 38% in the least-developed countries. More children <5 yr old in developing countries die from non–birth-related causes.

Across the globe, there are significant variations in child mortality rates by nation, by region, by economic status, and by level of industrial development, the categorizations employed by the World Bank (http://wdi.worldbank.org/table/2.18). As of 2015, 8 nations have a U5MR of ≥100 per 1,000 live births (all in the WHO African region) (Fig. 1.2). The
average U5MR in low-income countries was 76/1,000 live births, and in high-income countries, 6/1,000. Income and wealth, however, are not the only determinants of mortality. For example, the United States has the 10th highest gross national income per capita, but ranked 57th in lowest infant mortality rate in 2016.

In addition to mortality rates, causes of death vary by developmental status of the nation. In the United States the 3 leading causes of death among children <5 yr old were congenital anomalies, disorders related to gestation and low birthweight, and unintentional injuries. By contrast, in developing countries, most infant deaths are caused by pneumonia, diarrheal disease, and malaria.

The Changing Pediatric World

A profound improvement in child health within industrialized nations occurred in the 20th century with the introduction of vaccines, antibiotic agents, and improved hygienic practices. Efforts to control infectious diseases were
complemented by better understanding of the role of nutrition in preventing illness and maintaining health. In the United States, Canada, and parts of Europe, new and continuing discoveries in these areas led to establishment of publicly funded well-child clinics for low-income families. Although the timing of infectious disease control was uneven around the globe, this focus on control was accompanied by significant decreases in morbidity and mortality in all countries.

In the later 20th century, with improved control of infectious diseases through more effective prevention and treatment (including the eradication of polio in the Western hemisphere), pediatric medicine in industrialized nations increasingly turned its attention to a broad spectrum of noninfectious acute and chronic conditions. These included potentially lethal conditions as well as temporarily or permanently handicapping conditions. Advances occurred in the diagnosis, care, and treatment of leukemia and other neoplasms, cystic fibrosis, sickle cell disease, diseases of the newborn infant, congenital heart disease, genetic defects, rheumatic diseases, renal diseases, and metabolic and endocrine disorders.

Until the 1970s and early 1980s, children affected with sickle cell disease often died within the 1st 3 yr of life often from overwhelming sepsis caused by encapsulated bacteria. In the 1980s a multicenter study showed that early initiation of penicillin prophylaxis led to an 84% risk reduction for pneumococcal sepsis. Life expectancy for those with sickle cell disease increased when penicillin prophylaxis was initiated early in life. The use of prophylactic penicillin became the standard of care, increasing the importance of early detection of sickle cell disease (which led to expanding universal newborn screening) and paving the way for advances in the chronic management of the disease, including transfusion therapy, radiographic screening for silent cerebral infarctions, and hydroxyurea as a disease-modifying therapy. The success of penicillin prophylaxis likely led to a more rapid rate of innovation in the diagnosis and management of the disease, since children with the condition now had increased life expectancy. Whereas in the preprophylaxis era children often died by age 3, now 95% of individuals born with sickle cell disease will live to their 18th birthday, and most will survive until their 5th decade.

The treatment of acute lymphoblastic leukemia (ALL), the most common pediatric malignancy, has also shown amazing advances. Five-year survival rates have increased from <10% in the 1960s to >90% in 2000–2005. Cystic fibrosis has shown improvements in survival as well. In the 1960s, most children with cystic fibrosis did not live until school age. With advances in pulmonary and
nutritional therapies, as well as earlier initiation of these therapies secondary to earlier identification through newborn screening, a child born with cystic fibrosis in 2010 has a projected life expectancy of 39-56 yr.

These major advances in the management of chronic diseases of childhood were accomplished when significant improvement occurred in the prevention and treatment of acute infectious diseases, at least in industrial countries. This allowed human and economic resources to shift toward addressing chronic disease.

The New Morbidities

Given the advances in public health aimed at decreasing morbidity and mortality in infectious diseases (immunization, hygiene, antibiotics), along with the rise of technologic advances in clinical care, attention was given to the new morbidities—behavioral, developmental, and psychosocial conditions and problems shown to be increasingly associated with suboptimal health outcomes and quality of life. The American Academy of Pediatrics (AAP) Committee on Psychosocial Aspects of Child and Family Health asserted that the prevention, early detection, and management of these types of child health problems should be a central focus of the field of pediatrics, and that it would require an expansion in the knowledge base regarding (1) physical and environmental factors affecting behavior, (2) normal child behavior and development, (3) health behaviors as they pertain to child health, and (4) mild, moderate, and severe behavioral and developmental disorders. Accomplishing this would require reconceptualizing professional training, improving clinical communication and interviewing skills, expanding mental health resources for children, and shifting time allocation during child health supervision visits to address these concerns. In 2001 the Committee revisited this issue and reemphasized the need to address environmental and social aspects in addition to developmental and behavioral issues (Table 1.4). These included violence, firearms, substance use, and school problems, as well as poverty, homelessness, single-parent families, divorce, media, and childcare. Although this expanding list seems daunting and beyond the scope of what pediatricians typically addressed (i.e., physical health and development), many of these behavioral, environmental, and psychosocial issues (which fall under the category of social determinants of health) account for a large proportion of variance in health outcomes in children and youth. The role of pediatrics and the boundaries of clinical practice needed to change in order to
address these salient contributors to child health and well-being. Newer models of clinical care that rely on close collaboration and coordination with other professionals committed to child welfare (e.g., social workers, psychologists, mental health providers, educators) were developed. As this model expanded, so did the role of the family, in particular the child's caregiver, from a passive recipient of professional services to a more equitable and inclusive partner in identifying the issues that needed to be addressed, as well as helping decide which therapeutic options had the “best fit” with the child, the family, and the condition.

The framing of salient child health issues under the “new morbidity” concept acknowledges that the determinants of health are heterogeneous but interconnected. Biology, genetics, healthcare, behaviors, social conditions, and environmental influences should not be viewed as mutually exclusive determinants; they exert their influences through complex interactions on multiple levels. For example, epigenetic changes that result from specific social and environmental conditions illustrate the influence of context on gene
expression.

Studies have demonstrated that while each of these interrelated determinants are important for optimal health, development, and well-being, the greatest contributions to health outcomes occur in the behavioral, social, and environmental domains—the social determinants of health. From 40% to 70% of the relative variation in certain health outcomes is caused by social and economic conditions, health behaviors, and environmental factors. Whereas traditional medical education and clinical practice emphasized the biologic, genetic, and healthcare-related determinants of health, the recognition of the new morbidities as a focus of child healthcare provision reinforced the need to address social determinants as a key component of pediatric care, training, and research.

The “New” New Morbidities

The new morbidities concept brought into perspective the importance of addressing the social determinants of health, as well as the increasing prevalence and salience of chronic physical and behavioral health conditions in pediatric healthcare. Since then, advances in epidemiology, physiology, and epigenetics have expanded the scope of inquiry into the effects of a broad range of health determinants and provided more sophisticated explanatory models for the mechanisms that explain their effects (Table 1.4).

Adverse Childhood Experiences

Adverse childhood experiences (ACEs) are stressful events experienced during childhood that can have profound health consequences in childhood and throughout the life course into adulthood. ACEs were initially defined as abuse (physical, emotional, sexual), neglect (physical and emotional), and household challenges/family dysfunction (parental spousal abuse, mental illness in household, household substance abuse, incarceration of household member, parental separation or divorce). Retrospective studies have shown a graded dose-response effect of ACEs experienced in childhood on the future adult health of the child who experience the ACEs. For example, more childhood adversity was associated with significantly increased risk in later life of ischemic heart disease, chronic obstructive pulmonary disease, liver disease, depression, obesity, and cancer. People who suffered ≥6 ACEs as a child died almost 20 yr earlier than those who experienced no ACEs.
While the original conceptualization of ACEs included family-level psychosocial trauma, recent attempts have been made to expand the concept to include “macro” level stressors, such as those encountered in the neighborhood and community (Table 1.5). These include witnessing violence in the community, poverty, bullying and peer victimization, peer isolation, living in unsafe neighborhoods, low neighborhood social capital, living in foster care, and experiencing discrimination or racism.

ACEs and other psychosocial traumas may influence health through a number of mechanisms. ACEs are associated with adoption of risky behaviors such as substance use and early initiation of sexual activity, which in turn may increase the risk of chronic diseases such as lung cancer, liver disease, obesity, human papillomavirus (HPV) infection and cervical cancer, chronic lung disease, and premature mortality. Childhood trauma can also disrupt neurodevelopment during critical stages and contribute to social, emotional, and cognitive impairment. Finally, ACEs can result in toxic stress and lead to the dysregulation of normal physiologic processes.
Toxic Stress and Allostatic Load

The effects of stress are moderated by the intensity of the stress, the biologic response to the stress, and the social and physical environment in which the stress is experienced. **Toxic stress** occurs when a child experiences stressful events that are chronic, intense, or prolonged and are inadequately buffered by the child's social support system (most importantly, parents and adult caregivers). Toxic psychosocial stress influences physical health by producing **allostatic load**, or pathophysiologic dysregulation of normal regulatory systems. Allostatic load is the “wear and tear” that the body and its regulatory mechanisms experience in response to chronic, unbuffered stress. The systems that can be affected through allostatic load include the neuroendocrine, cardiovascular, immune, and metabolic systems. Dysregulation of stress hormones in the hypothalamic-pituitary-adrenal (HPA) and sympathetic-adrenal-medullary (SAM) systems, inflammatory cytokines, hormones (e.g., insulin), immune factors (e.g., fibrinogen, C-reactive protein), and cardiovascular biomarkers (e.g., blood pressure) can occur from chronic stress and result in pathophysiologic conditions associated with chronic diseases. Chronic stress can also have effects at the genetic level. Studies of cellular aging have shown that chronic stress decreases telomere length, a determinant of aging on the cellular level. Epigenetic changes, including differential immune system DNA methylation, have been shown to occur after child abuse and posttraumatic stress disorder (PTSD), contributing to inflammatory and immune dysregulation.

Pediatrics, developmental psychology, basic sciences, and public health have contributed significant advances to the study of the behavioral, developmental, and social determinants of child health. The influence of psychosocial stress brought about by environmental challenges, while always acknowledged as important, has taken on a new level of salience as epidemiologists have linked its occurrence to significant morbidities throughout the life course, and as basic and clinical neuroscience has provided a multilevel framework for understanding how behavioral and psychosocial issues “get under the skin” to cause physiologic dysfunction and dysregulation.

Ecobiodevelopmental Framework

An ecobiodevelopmental framework has been proposed to integrate the environmental, biologic, and developmental factors into a model of health and illness (**Fig. 1.3**). This model posits that the ecology (or the physical and social
environment) effects biology through the epigenetic and allostatic load mechanisms discussed above. The environment also influences development through life course science, which includes the effects of toxic exposures and childhood adversity on cognitive, behavioral, and physical health throughout the life course. Biology influences development though brain maturation and neuroplasticity, which in turn are also affected by inputs from the social and physical environment. The ecobiodevelopmental framework is consistent with the biopsychosocial model while adding a life course developmental dimension.

**FIG. 1.3** New proposed biologic pathways that mediate effects of selected stressful or adversarial poverty-associated risks to neurocognitive outcomes in children. Complex interactions among key poverty-related risk factors, focusing on primary biologic pathways related to malnutrition, infection and inflammation, and neuroendocrine responses to stress. (From Jensen SKG, Berens AE, Nelson CA: Effects of poverty on interacting biological systems underlying child development, Lancet 1:225–238, 2017, Fig 1, p 228.)
Chronic Illness and Children With Special Health Care Needs

The care of children with chronic conditions has become an increasingly larger part of clinical pediatrics, for both the pediatric subspecialist and the general pediatrician. **Children and youth with special health care needs (CSHCN)** are defined by the U.S. Maternal and Child Health Bureau as “those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally.” According to the 2011/12 **National Survey of Children's Health (NSCH)**, >14.5 million, or 20% of U.S. children, have a special health need. The 2009–2010 **National Survey of Children with Special Health Care Needs (NS-CSHCN)** reports that almost one quarter (23%) of U.S. households with children have a child with a special need. The conditions these children have are extremely heterogeneous and include cerebral palsy, asthma, obesity, sickle cell disease, diabetes, learning disability, communication disorders, Down syndrome, heart conditions, migraine headaches, depression, conduct disorder, autism, and attention-deficit/hyperactivity disorder (Table 1.6). Most of these children need specialty care in addition to primary care. In the United States, 0.4–0.7% of children fall into the category of “highest medical complexity”; these children account for 15–33% of all healthcare spending for children. Children with medical complexity account for >70% of hospital readmissions.

* List is not comprehensive and does not include all conditions that CSHCN may have.  

Adapted from Child and Adolescent Health Measurement Initiative (2012).  
2009/10 NS-CSHCN: Health Conditions and Functional Difficulties, Data Resource Center, supported by Cooperative Agreement 1-U59-MC06980-01 from the US Department of Health and Human Services, Health Resources and Services Administration (HRSA), Maternal and Child Health Bureau (MCHB).  

Nine of 10 CSHCN have functional difficulties in the sensory, cognitive, movement, emotional, or behavioral domains (Table 1.7). More than 65% (7.2 million) of CSHCN have conditions that affect their daily activities, and >2.3 million families experience financial difficulties because of their children's special health needs. The fact that 25% of family members of CSHCN cut back work hours or stop working because of their child's special needs highlights the social and economic impact of child chronic illness, at both the individual and the national economic level.

**Table 1.7**

Functional Difficulties in Children With
**Special Health Care Needs (CSHCN)**

**Experiencing Difficulty With …**

- Breathing, or respiratory problem
- Swallowing, digesting food, or metabolism
- Blood circulation
- Repeated or chronic physical pain, including headaches
- Seeing, even when wearing glasses or contact lenses
- Hearing, even when using a hearing aid or other devise
- Taking care of self, such as eating, dressing, or bathing
- Coordination or moving around
- Using his/her hands
- Learning, understanding, or paying attention
- Speaking, communicating, or being understood
- Feeling anxious or depressed
- Behavior problems such as acting out, fighting, bullying, or arguing
- Making and keeping friends

* List is not comprehensive and does not include all functional difficulties that CSHCN may have.

Pediatricians are typically the “point persons” in the professional care of these children and provide data and expert opinion to procure needed services and resources to the child in the clinic, home, schools, and community. Such demands require an efficient model of chronic care.
**Systems of Care**

**Population Health Approach**

Because pediatric practice is increasingly spent working with patients and families who have chronic issues and conditions, new approaches to healthcare services delivery have been proposed. Whereas traditional practice models concentrate efforts toward the preventive and therapeutic needs of those patients who present for care, a **population health** approach to care refocuses efforts to emphasize the need to address health from a community- or population-level perspective, with emphasis on identifying and addressing the needs of individuals and families who do not seek regular care, or whose care is episodic and suboptimal from a prevention or management standpoint. Effectiveness of such a system would increase with advances in collaboration between healthcare providers and payers (insurance companies) to identify gaps in care, data surveillance systems, and electronic health records (EHRs), and with an expanded cadre of health care personnel such as care coordinators, nurse practitioners and physician assistants, social workers, health navigators, and community health workers. Healthcare reimbursement modifications, such as incorporating value-based and quality-of-care–based models, if implemented correctly, may further advance a population health approach to care.

**Medical Home**

The concept of the **patient and family–centered medical home (PFCMH)** approach to providing care has its origins in pediatrics in the late 20th century. As defined by AAP, a medical home provides care that is accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. Patients and family members are key active participants, working with clinicians to identify priorities for and approaches to care. A key aspect of the PFCMH is care coordination. According to AAP, **care coordination** “addresses interrelated medical, social, developmental, behavioral, educational and financial needs to achieve optimal health and wellness outcomes.” A **care coordinator** in the “point person” on the team who prospectively identifies the patient's and family's needs, concerns, and priorities for the healthcare visit, gathers pertinent information (lab results, consultations, educational plans, screening/testing results), communicates with subspecialists, and relays all important information to the clinical team before the patient/family visit. After a healthcare visit, the
care coordinator works with the family to address any ongoing concerns, directs efforts to schedule follow up appointments and referrals, and communicates information to all necessary parties. The care coordinator typically is not a physician. The intended result of care coordination is an efficient and comprehensive interaction between the pediatric team and the family, between primary care and specialty care, between ambulatory and inpatient care teams, and between the pediatric care team and the community-based supports on which the patient and family depend.

Provision of care consistent with the elements of a medical home has been associated with more accurate and early diagnosis, fewer emergency department visits and inpatient hospitalizations, lower costs, fewer unmet needs, lower out-of-pocket medical costs, less impact on parental employment, fewer school absences, and better patient satisfaction. According to the 2011/12 National Survey of Children's Health, 54.4% of U.S. children received coordinated, comprehensive care within a medical home.

### Medical and Health Neighborhood

While the medical home concept relates to practice transformation specific to primary care, a broadening of this concept has been proposed along 2 separate dimensions. The **medical neighborhood** expands the medical home concept and refers to coordinated and efficient integration between primary care pediatricians and the subspecialists, including integrated EHRs, efficient coordinated appointment scheduling, and enhanced communication. Such a system has the potential to provide a less stressful patient and family experience and could also lead to cost reduction and a decrease in medical errors.

Another expansion and modification of the medial home is the **health neighborhood** concept. The health neighborhood is based on the recognition of the importance of coordination with community-based and nonmedical providers to address comprehensively and efficiently the social determinants of health. Health neighborhoods include the healthcare providers (consistent with the medical home and neighborhood) but also involves services such as early intervention programs, the education system, childcare, community-based behavioral and mental health services, legal services, nutritional support services, and other clinical and community-based services that the patient and family need to access. The health neighborhood team helps families identify the needs of the patient, assists with referrals to appropriate agencies outside the
healthcare system, and coordinates care.

Some nonmedical services may be co-located at the medical office. **Medical-legal partnerships** (MLPs) are collaborations between the healthcare and legal systems and embed legal aid personnel in the medical clinic. These lawyers and legal paraprofessionals can provide direct services to patients and families who have legal issues that may be affecting the child's health (e.g., housing code violations, utility shutoff, food insecurity, immigration issues, educational accommodations, guardianship). In addition to providing direct services, MLPs also train healthcare personnel in the legal and social determinants of health and work with physicians and others to advocate for policy change. Other nonmedical health neighborhood services that could be co-located in the medical center include supplemental nutrition assistance programs, parenting programs, behavioral health services, and family financial counseling.

Many, if not most, other services are located in the community. The health neighborhood model links families to these services and provides efficient ongoing coordination and communication. Community health workers or health navigators are paraprofessional team members who are community and culturally informed and serve as a coordinating link between the family, the medical home, and needed community services. Community health workers and health navigators can also provide patient and family education.

Expanded care models such as these have the potential to achieve what the Institute for Healthcare Improvement calls the “triple aim” for healthcare, focusing on **care** (improving the patient experience with healthcare, quality care, and satisfaction), **health** (improving the health of populations), and **cost** (reducing per-capita healthcare costs) (**Fig. 1.4**).

Millenium Development Goals.

Health and illness are not distributed equally among all members in most societies. Differences exist in risk factors, prevalence and incidence, manifestations, severity, and outcome of health conditions, as well as in the availability and quality of healthcare. When these differences are modifiable and avoidable, they are referred to as disparities or inequities. The U.S. Department of Health and Human Services (DHHS) Healthy People 2020 report defines health disparity as “a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage. Health disparities adversely affect groups of people who have systematically experienced greater obstacles to health based on their racial or ethnic group; religion; socioeconomic status; gender; age; mental health; cognitive, sensory, or physical disability; sexual orientation or gender identity; geographic location; or other characteristics historically linked to discrimination or exclusion.” The U.S. Centers for Disease Control and Prevention (CDC) define health disparities as “preventable differences in the burden of disease, injury, violence, or opportunities to achieve optimal health that are experienced by socially disadvantaged populations.” Health and healthcare disparities occur by nature of unequal distribution of resources that are inherent in societies that exhibit social stratification, which occurs in social systems that rank and categorize people into a hierarchy of unequal status and power. There exists a hierarchy of “haves and have nots” based on group classifications.

Although there are many differences regarding health status, not all these differences are considered disparities. The increased prevalence of sickle cell disease in people of African descent, or the increased prevalence of cystic fibrosis in white individuals of Northern European descent, would not be considered a disparity because—at least at present—the genetic risk is not easily
modifiable. However, in 2003, funding was 8-fold greater per patient for cystic fibrosis than for sickle cell disease, which could be considered a disparity because it is modifiable.

Health and healthcare disparities have existed for centuries. A critical mass of research building in the mid-2000s corresponded to the U.S. Institute of Medicine's 2003 book, *Unequal Treatment: Confronting Racial and Ethnic Disparities in Healthcare*. It reviewed the literature on racial and ethnic disparities in health and healthcare and found 600 citations.

**Determinants of Health and Health Disparities**

Fig. 2.1 displays a categorization of the multiple determinants of health and well-being. Applying this categorization to health disparities, conceptualizations of the root causes of health disparities emphasize the most modifiable determinants of health: the physical and social environment, psychology and health behaviors, socioeconomic position and status, and access to and quality of healthcare. Differential access to these resources result in differences in *material* resources (e.g., money, education, healthcare) or *psychosocial* factors (e.g., locus of control, adaptive or risky behaviors, stress, social connectedness) that may contribute to differences in health status.
Fig. 2.2 illustrates the complex relationships among multileveled factors and health outcomes. **Social stratification** factors such as socioeconomic status (SES), race, and gender have profound influences on environmental resources available to individuals and groups, including neighborhood factors (e.g., safety, healthy spaces), social connectedness and support, work opportunities, and family environment. Much of the differential access to these resources results from discrimination, on a systematic or interpersonal level. **Discrimination** is defined as negative beliefs, attitudes, or behaviors resulting from categorizing individuals based on perceived group affiliation, such as gender (sexism) or race/ethnicity (racism).
SES, race/ethnicity, gender, and other social stratification factors also have effects on psychological functioning, including sense of control over one's life, expectations, resiliency, negative affect, and perceptions of and response to discrimination. Environmental and psychological context then have influence over more proximal determinants of health, including health-promoting or risk-promoting behaviors; access to and quality of healthcare and health education; exposure to pathogens, toxins, and carcinogens; pathophysiologic (biologic) and epigenetic response to stress; and the resources available to support optimal child development. Variability in these factors in turn results in differential health outcomes.

Psychosocial Stress and Allostatic Load

An understanding has emerged that helps explain how psychosocial stress influences disease and health outcomes (Fig. 2.3). This theory, allostatic load, provides insight into the processes and mechanisms that may contribute to health disparities. Allostasis refers to the normal physiologic changes that occur when individuals experience a stressful event. These internal reactions to an external stressor includes activation of the stress-response systems, such as increases in cortisol and epinephrine, changes in levels of inflammatory and immune mediators, cardiovascular reactivity, and metabolic and hormone activation. These are normal and adaptive responses to stress and result in physiologic
stability in the face of an external challenge. After an acute external stress or challenge, these systems revert to normal baseline states. However, when the stressor becomes chronic and unbuffered by social supports, dysregulation of these systems may occur, resulting in pathophysiologic alterations to these responses, such as hyperactivation of the allostatic systems, or burnout. Over time this dysregulation contributes to increased risk of disease and dysfunction. This pathophysiologic response is called allostatic load.

![Percentage of children age 6-17 yr who are obese by race and Hispanic origin, selected years 1976–2014](https://www.childstats.gov/americaschildren/health_fig.asp#health7)

Given the systems affected (e.g., metabolic, immune, inflammatory, cardiovascular), allostatic load may contribute to increase incidence of chronic diseases such as cardiovascular disease, stroke, diabetes, asthma, and depression. It is notable that these specific chronic diseases have increased prevalence in racial and ethnic minority groups. Racial and ethnic minorities experience significantly higher degrees of chronic psychosocial stress (see Fig. 2.2), which over time contributes to allostatic load and the resultant disparities in these chronic diseases. Many of these conditions are noted to occur in adulthood, demonstrating the life course consequences of chronic psychosocial stress and adversity that begins in childhood.

The allostatic load model provides a pathophysiologic mechanism through which social determinants of health contribute to health disparities. It
complements other mechanisms noted in Fig. 2.2, such as differential access to healthcare, increase in health risk behaviors, and increased exposure to pathogens, toxins, and other unhealthy agents.

**The Hispanic Paradox**

Whereas data suggest that minority racial and ethnic groups typically have worse health outcomes than the majority white group, this is not always the case. This finding demonstrates the complex interrelationship among race/ethnicity, minority status, and other factors that contribute to disparities, such as social class and SES.

Studies suggest that for many health outcomes, Hispanic/Latino populations do significantly better than other minority racial/ethnic groups and sometimes as well as the majority non-Hispanic white population. This finding has been called the *Hispanic Paradox* (also known as the Latino Paradox, Epidemiologic Paradox, Immigrant Paradox, and Health Immigrant Effect). Hispanic life expectancy is about 2 yr higher than for non-Hispanic whites, and mortality rates are lower for 7 of the 10 leading causes of death. Among child health issues, Hispanics in general have lower rates of prematurity and low birthweight than African Americans, and Mexican Americans have lower rates of asthma than African Americans and non-Hispanic whites.

Several hypotheses may explain these epidemiological findings. First, the relative advantages seen in Hispanic health are greatest for non–U.S.-born Hispanics, and many of the health advantages become nonsignificant in second- or third-generation U.S. Hispanics (as individuals spend more time in the United States). Thus, indigenous cultural beliefs and lifestyles brought over by Hispanic immigrants may provide a selective health advantage, including low rates of tobacco and illicit drug use, strong family support and community ties, and healthy eating habits. Health advantages disappear as immigrants become more acculturated to U.S. standards—poorer nutritional habits and tobacco, alcohol, and illicit drug use—supporting this theory. It is also hypothesized that those who immigrate to the United States are younger and healthier than those Hispanics who do not immigrate and stay in their country of origin, so there may be a selection bias; Hispanic immigrants may start out healthier on arrival. Recent immigrants also tend to reside in ethnic enclaves, and socially supportive residential environments are associated with better health outcomes. When immigrants acculturate to U.S. lifestyles, not only do they acquire unhealthy
behaviors, but they also tend to lose the protective aspects of their original culture and lifestyle.

There are also differences in outcomes among different Hispanic/Latino subgroups. Selective advantages in Hispanics are usually found among Hispanics from Mexico or South/Central America. Puerto Rican Hispanics typically have worse outcomes, compared to other Hispanic groups and non-Hispanic whites. Puerto Rico is a U.S. territory (Puerto Ricans are not immigrants) and has many of the negative health profiles seen in the mainland (e.g., high rates of tobacco rates and other health risk behaviors), which further supports the importance of indigenous, healthy, cultural behaviors and lifestyle as an explanation for the healthy immigrant profile seen in Central and South American Hispanics.

Disparities in Child Health and Healthcare:

Tables 2.1 and 2.2 display some of the known disparities in child health and healthcare. As previously noted, health disparities may occur as a result of race/ethnicity, socioeconomic status (often operationalized through family income, sometimes using insurance status as a proxy), and residency patterns, such as urban and rural locale.

HPV, Human papillomavirus.

Child Health Disparities

Asthma

Disparities in asthma prevalence are seen by racial/ethnic group and SES. According to the 2015 U.S. National Health Interview Survey (NHIS), American Indian/Alaskan Native, Mainland Puerto Rican, and African American children have the highest prevalence of childhood asthma (14.4%, 13.9%, and 13.4%, respectively), followed non-Hispanic white (7.4%) and Asian (5.4%). The prevalence of childhood asthma in Hispanics is 8%, but when the Hispanic category is disaggregated, Mexican Americans have a prevalence of 7.3%, which is lower than that for non-Hispanic whites; Puerto Rican children have
among the highest rates of asthma. The cause of this difference among Hispanic/Latino subgroups is debatable, but some data suggest that bronchodilator response may be different in the 2 groups, possibly based on genetic variants. Data also suggest that within the Mexican American population, differences in prevalence exist based on birthplace or generation (see earlier, The Hispanic Paradox): immigrant and first-generation Mexican American children have lower prevalence of asthma than Mexican American children who have lived in the United States longer. This may reflect the changes that occur as Latinos become more acculturated to U.S. behavioral norms the longer they reside in the United States (e.g., tobacco use, dietary patterns, environmental exposures).

Regarding SES, children living at <100% the federal poverty level have a childhood asthma prevalence of 10.7%, whereas those living at ≥200% the poverty level have a prevalence of 7.2%.

**Obesity**

In 2014 the percentage of Hispanic/Latino children in the National Health and Nutrition Examination Survey (NHANES) age 6-17 yr who were obese was 24.3%. The percentage of African American children who were obese was 22.5%. This compares to non-Hispanic whites (17.1%) and Asian (9.8%) (see Fig. 2.3). Dietary patterns, access to nutritious foods, and differing cultural norms regarding body habitus may account for some of these differences. The relationship between SES and childhood obesity is less clear. Some studies suggest that the racial and ethnic differences in childhood obesity become nonsignificant when factoring in family income, whereas other national survey studies suggest a relationship between family income and obesity rates in non-Hispanic whites but not among black or Mexican American children.

**Infant Mortality**

Highest rates of infant mortality are seen in non-Hispanic black infants. According to data from the 2007–2008 National Center for Health Statistics (NCHS)–linked Live Birth–Infant Death Cohort Files, the odds ratio for non-Hispanic black infant mortality is 2.32, compared to non-Hispanic white rates, and remains significant after controlling for maternal age, education, marital status, parity, plurality, nativity, tobacco use, hypertension, and diabetes. Compared with non-Hispanic whites, higher infant mortality is also seen in
Hispanic black and Hispanic white infants as well.

In 2012 the infant mortality rate for black, non-Hispanic (11.2/1,000 live births) and American Indian/Alaskan Native (8.4/1,000) infants was higher than for white, non-Hispanic (5.0/1,000), Hispanic (5.1/1,000), and Asian/Pacific Islander (4.1/1,000) (Fig. 2.4). There was variation in the U.S. Hispanic population: the Puerto Rican infant mortality rate was 6.9/1,000, compared to 5.0/1,000 for Mexican Americans and 4.1/1,000 for Central and South American origin.

![Fig. 2.4](https://www.childstats.gov/americaschildren/health_fig.asp#health2)  

**Prematurity and Low Birthweight**

There are significant black-white differences in preterm birth and low birthweight (LBW) (Fig. 2.5). According to the 2014 NCHS National Vital Statistics System, LBW births (<2500 g) were significantly higher among black non-Hispanic women (13.2%) than white non-Hispanic (7.0%), American Indian/Alaskan Native (7.6%), Asian/Pacific Islander (8.1%), or Hispanic (7.1%) women. Among Hispanics, Puerto Rican women had higher rates of LBW births than Mexican Americans (9.5% vs 6.6%).
Regarding preterm births (<37 wk), the black non-Hispanic rate was 13.2%, compared to 8.9% for white non-Hispanics, 8.5% for Asian/Pacific Islanders, 10.2% for American Indian/Alaskan Native, and 9% for Hispanics. Within the Hispanic group, the Puerto Rican preterm rate was higher than for Mexican Americans (11% vs 8.8%).

There are many hypotheses for the increased rates of preterm birth and LBW in black births. Risk factors such as inadequate prenatal care, genitourinary tract infections, increased exposure to environmental toxins, and increased tobacco use may account for some of the disparity, but not all, and neither do SES differences, since high-SES black women still have higher rates of premature and LBW births.

Increased stress has been presented as a potential mechanism. Studies have shown that minority women who experience perceptions of racism and discrimination have higher odds of delivering a preterm or LBW child than do minority women who have not perceived experiences with discrimination. Residential segregation is also a potential source of differences in preterm and LBW outcomes. Living in hypersegregated neighborhoods can decrease access to prenatal care, increased exposure to environmental pollutants, and increase psychosocial stress, all of which may contribute to increased risk.

Increased age at delivery in African American women does not lessen the risk of preterm or LBW delivery (as it does in white mothers). This has led to the
theory that cumulative stress in black women, related to chronic exposure to factors such as socioeconomic deprivation and racial discrimination, leads to declining health at an earlier age compared with white women, and thus increases the risk for poor pregnancy outcomes. Called the weathering hypothesis, this has been proposed as an explanation for racial variations in pregnancy outcomes.

**Oral Health**

Significant differences exist in oral health status as well as preventive oral healthcare according to race/ethnicity, SES, and residency locale. Data from the 1994–2004 NHANES show that compared to non-Hispanic white children, black and Mexican American children had higher rates of caries and untreated caries and lower rates of receiving dental sealants. Children living at or below the federal poverty level also had higher rates of caries and untreated caries and lower rates of dental sealant applications, compared with nonpoor children.

Preventive oral healthcare may improve rates of caries and treat caries before further impairment ensues. Data from the 2004 Medical Expenditure Panel Survey revealed that only 34.1% of black and 32.9% of Hispanic children had a yearly visit to a dentist, compared to 52.5% of white children. Likewise, only 33.9% of low-income children had dentist visits, compared to 46.5% of middle-income children and 61.8% of high-income children.

According to the 2011/12 National Survey of Children’s Health (NSCH), parents reported fair to poor teeth condition at a higher rate in Asian non-Hispanic children (8.5%), black non-Hispanic children (7.6%), and Hispanic children (15.2%), compared to white children (4.2%). Hispanic and black non-Hispanic children had higher rates of oral health problems than white non-Hispanic and Asian non-Hispanic children as well.

**Hearing Care**

No data suggest that the prevalence of hearing loss (either congenital or acquired) is different among racial/ethnic or SES categories, but follow-up care after diagnosis of a hearing problem has been shown to be worse in certain groups. Higher “lost to follow-up” rates have been noted in children living in rural areas as well as with publically insured and nonwhite children. Much of this disparity is reduced when families have access to specialists.
Vision Problems
The parent-reported 2011/12 NSCH found no differences in the prevalence of correctable vision problem among white non-Hispanic, black non-Hispanic, Hispanic, and “other” racial/ethnic groups, or with regard to SES or urban/rural residence.

Immunization
Immunization against infectious agents was one of the major clinical and public health successes of the 20th century. Rates of life-threatening infectious diseases plummet after effective vaccines are introduced. The primary series of childhood immunizations against diphtheria, tetanus, pertussis, polio, rotavirus, measles, mumps, rubella, hepatitis A and B, Haemophilus influenzae type b, varicella, and Streptococcus pneumoniae have significantly decreased the incidence of illness caused by these agents.

Disparities in immunization rates had been noted regarding household income status, insurance status, and residential location. In response to these socioeconomic disparities, as well as higher rates of measles cases in the 1980s among racial and ethnic minority groups, a number of interventions were initiated, including the creation of the Vaccines for Children program (VFC), which eliminated the financial barrier to immunization by providing free immunizations to at-risk groups (Medicaid-eligible, uninsured, American Indian/Alaskan Native, or underinsured and vaccinated at a federally qualified health center or rural health clinic). Since VFC inception, disparities in immunization rates have either been eliminated or have significantly narrowed, showing that targeted public health programs can successfully eliminate health disparities.

Although rates of initial primary vaccine series demonstrate no or decreasing disparities, other vaccination rates do show differences. For example, black and Hispanic adolescent females have lower human papillomavirus (HPV) vaccination rates than whites. Reasons for this disparity include parental concerns about safety and no provider recommendation. Of interest, studies of HPV vaccination in adolescent males show that black and Hispanic male adolescents have higher rates of HPV vaccine coverage than whites.

Adolescent Suicide
In 2014 the highest rate of suicide for male adolescents was seen in American
Indian (20 per 100,000 population) and white (17/100,000) teens, compared to Hispanic (9/100,000), black (7/100,000), and Asian/Pacific Islander (6/100,000) teens. For female adolescents, highest suicide rates were seen in American Indian (12/100,000), compared to white (5/100,000), Asian/Pacific Islander (5/100,000), Hispanic (3/100,000), and Black (2/100,000) teens.

Hispanic female students in grades 9-12 were more likely to consider suicide (26%), report attempting suicide (15%), and require medical attention for a suicide attempt (5%), compared to black (19%, 10%, 4%) or White (23%, 10%, 3%) female students. Among male students, Hispanic and black students, compared to white students, were more likely to attempt suicide (8% and 7% vs 4%, respectively) and require medical attention for a suicide attempt (4% and 3% vs 1%).

**Child Maltreatment**

In 2014, reports of child abuse and neglect were higher in black (15.3 per 1,000 children), American Indian/Alaskan Native (13.4/1,000), and multiracial (10.6/1,000) children, compared to Hispanic (8.8/1,000), Pacific Islander (8.6/1,000), white (8.4/1,000), and Asian (1.7/1,000) children. Poverty, measured at the family as well as community level, is also a significant risk factor for maltreatment. Counties with high poverty concentration had >3 times the rate of child abuse deaths than counties with the lowest concentration of poverty. Nonetheless, race itself *should not be a marker* for child abuse or neglect.

**Behavioral Health Disparities**

**Attention-Deficit/Hyperactivity Disorder (ADHD)**

White and black children are more often diagnosed with ADHD (10.7% and 8.4%, respectively) than are Hispanic children (6.3%), according to NHIS data. Other studies have shown that both black and Hispanic children have lower odds of having an ADHD diagnosis than white children. Children reared in homes that are below the federal poverty level are diagnosed more often (11.6%) than those at or above the FPL (8.1%).

Children diagnosed with ADHD have different medication practices. Hispanic (43.8%) and black (40.9%) children with ADHD are more likely than white children (25.5%) *not* to be taking medication. The causes of this disparity are
unknown but may include different patient and parental beliefs and perceptions about medication side effects and different prescribing patterns by clinicians.

**Depression and Anxiety Disorders**

According to the 2011/12 NSCH, there were no parent-reported differences in rates of childhood depression (2-17 yr) among racial/ethnic groups. Children living in poverty, as well as children living in rural areas, had higher rates of parent-reported depression. According to the 2015 *Youth Risk Behavior Survey* of adolescent in grades 9-12, Hispanic students had higher rates of reporting that they felt sad or hopeless (35.3%) compared to white (28.6%) and black (25.2%) students. This relationship existed for both male and female students.

The NSCH data noted that white children ages 2-17 yr had higher rates of anxiety than black or Hispanic children. “Poor” children had higher rates of anxiety than “not poor” children.

**Autism Spectrum Disorder (ASD)**

Compared with white children, black and Hispanic children are less likely to be diagnosed with ASD, and when diagnosed, are typically diagnosed at a later age and with more severe symptoms. This disparity in diagnosis and timing of diagnosis is concerning given that early diagnosis provides access to therapeutic services that are best initiated as early as possible. Reasons for these disparities may include differences in cultural behavioral norms, stigma, differences in parental knowledge of typical and atypical child development, poorer access to quality healthcare and screening services, differences in the quality of provider–patient communication, trust in providers, as well as differential access to specialists.

**Behavioral or Conduct Problems**

According to the 2011/12 NSCH, black children age 2-17 yr have higher rates of oppositional defiant disorder (ODD) or conduct disorder than white and Hispanic children. Children living in poverty have higher rates than those not living in poverty.

**Developmental Delay**

The 2011/12 NSCH found that black and white children age 2-17 yr had higher
rates of developmental delay than Hispanic children (4.5% and 3.8% vs 2.7%, respectively). However, when parents of children age 4 mo to 5 yr were asked if they had concerns about their child's development (highly correlated with risk of developmental, behavioral, or social delays), Hispanic children had higher rates of moderate or high risk for developmental delay (32.5%) than did black (29.7%) or white (21.2%) children. This discrepancy may result from either overestimation of concerns in Hispanic mothers or underdiagnosis of Hispanic children by clinicians.

Children living below the poverty level have higher rates of developmental delay as well.

**Disparities in Healthcare**

In almost all areas, minority children have been identified as having worse access to needed healthcare, including receipt of any type of medical care within the past 12 mo, well-child or preventive visits, delay in care, having an unmet need due to healthcare cost, lack of care in a medical home, problems accessing specialist care when needed, lack of preventive dental care, vision screening, mental health counseling, and recommendations for adolescent immunizations (see Table 2.2). In addition, many of these healthcare indicators are found to be worse for children living in poverty, as well as those living in a rural area, compared to urban-dwelling children.

**Approaches to Eradicating Disparities: Interventions**

Much of the information regarding health disparities over the past 10-20 yr has focused on the identification of areas where health disparities exist. Additional work has expanded on simple description and acknowledged the multivariable nature of disparities. This has provided a more nuanced understanding of the complex interrelationships among factors such as race/ethnicity, socioeconomic status, social class, generation, acculturation, gender, and residency.

An example of a successful intervention that closed the disparity gap is the implementation of the VFC program, which, as noted earlier, significantly decreased the disparity in underimmunization rates noted among racial/ethnic groups and poor/underinsured children. This is an example of a public health
policy approach to intervention.

Interventions need to occur at the clinical level as well. The almost universal use of electronic health records (EHR) provides a unique opportunity for collecting clinical and demographic data that can be helpful in identify disparities and monitor the success of interventions. All EHR platforms should use a standardized approach to gathering information on patient race/ethnicity, SES, primary language preferences, and health literacy. The Institute of Medicine's 2009 report *Race, Ethnicity, and Language Data: Standardization for Health Care Quality Improvement* provides best practices information about capturing these data in the health record.

The advancing science of clinical quality improvement can also provide a framework for identifying clinical strategies to reduce disparities in care. Use of PDSA (Plan-Do-Study-Act) cycles targeting specific clinical issues where health disparities exist can result in practice transformation and help reduce differential outcomes.

Another practice-level intervention that has the potential to reduce disparities in care and outcomes is the medical home model, providing care that is accessible, family centered, continuous, comprehensive, compassionate, coordinated, and culturally effective. The use of care coordinators and community-based health navigators is an effective tool in helping to break down the multiple social and health system barriers that contribute to disparities.

Population health strategies have the advantage of addressing the determinants of disparities at both the clinic and the community levels. Techniques such as “hotspotting,” “cold-casing” (finding patients and families lost to follow up and not receiving care), and “geocoding,” combined with periodic community health needs assessments, identify the structural, systemic, environmental, and social factors that contribute to disparities and help guide interventions that are tailored to the local setting.

When developing strategies to address disparities, it is imperative to include patients and community members from the beginning of any process aimed at identification and intervention. Many potential interventions seem appropriate and demonstrate efficacy under ideal circumstances. However, if the intervention does not address the concerns of the end users—patients and communities—or fit the social or cultural context, it will likely be ineffective in the “real world.” Only by involving the community from the beginning, including defining the issues and problems, can the likelihood of success be optimized.

Health disparities are a consequence of the social stratification mechanisms
inherent in many modern societies. Health disparities mirror other societal disparities in education, employment opportunities, and living conditions. While society grapples with the broader issues contributing to disparities, healthcare and public health can work to understand the multiple causes of these disparities and develop interventions that address the structural, clinical, and social root causes of these inequities.

2.1 Racism and Child Health

Mary T. Bassett, Zinzi D. Bailey, Aletha Maybank

Keywords

- adverse childhood experiences
- cultural humility
- cultural safety
- doll experiment
- equity
- implicit bias
- infant mortality rate
- institutional racism
- internalized racism
- interpersonal racism
- microaggression
- racial disparities
- residential segregation
- social determinants
- stereotype threat
- structural competency
- structural racism
Racism as Social Determinant

An emerging body of evidence supports the role of racism in a range of adverse physical, behavioral, developmental, and mental health outcomes. Racial/ethnic patterning of health in the United States is long-standing, apparent from the first collection of vital statistics in the colonial period. However, the extensive data that document racial disparities have not settled the question of why groups of people, particularly of African and Native American Indian ancestry, face increased odds of shorter lives and poorer health (Table 2.3). The role of societal factors, not only factors related to the individual, is increasingly recognized in determining population health, but often omits racism among social determinants of health. This oversight occurs in the face of a long history of racial and ethnic subjugation in the United States that has been justified both explicitly and implicitly by racism. From the early 18th century, colonial America established racial categories that enshrined the superiority of whites, conferring rights specifically on white men, while denying these rights to others. Similar, perhaps less explicit, discrimination has continued through the centuries and remains a primary contributor to racial inequities in children's health.

</table>
For generations, racial/ethnic disparities have been documented beginning at birth and extending across life. In 2014, life expectancy at birth for blacks was almost 4 yr shorter than life expectancy of non-Hispanic whites, influenced heavily by disparities starting at birth (Table 2.3). The infant mortality rate (IMR), arguably the most important measure of national health, has shown a persistent relative black-white gap. Despite the substantial decline in U.S. IMR for all racial/ethnic groups, there is still at least a 2-fold higher risk of death in the 1st yr of life for black infants than for white infants (Table 2.3). NCHS data in 2014 showed a double-digit IMR only among non-Hispanic blacks, with 11.8 deaths per 1,000 live births, compared to 4.89/1,000 for non-Hispanic whites. In 2016 the black IMR slightly increased after many years of progressive decline, which may portend a further rise in the relative black-white gap. A troubling stagnation in IMR, with no recent decline, is found among Alaska Natives and American Indians. The 2005 IMR in American Indian or Alaskan Native women, 8.06 deaths/1000 live births, has remained essentially unchanged for a
decade, with the 2014 IMR at 7.59/1,000.

Exposures that affect infant survival occur before birth. Prenatal maternal exposures to pesticides, lead, and other environmental toxins vary by race. Additionally, a higher prevalence of maternal obesity, diabetes, and substance/alcohol use before conception also adversely affects birth outcomes. A California study of maternal obesity based on claims data and vital records found that 22.3% of pregnant black women and 20.3% of Latina women had a body mass index (BMI) of 30-40, compared to 14.9% of white and 5.6% of Asian women. BMI >40 was more than twice as prevalent in black (5.7%) than white (2.6%) women.

The effects of racism are also stressful and toxic to the body, and evidence supports biologic effects of discrimination across the life span, especially for pregnant women. Racism can increase cortisol levels and lead to a cascade of effects, including impaired cell function, altered fat metabolism, increased blood glucose and blood pressure, and decreased bone formation (see Chapter 1, Fig. 1.3). This can affect a growing fetus, leading to increased infant cortisol levels, lower birthweight (LBW), and prematurity. In New York City, white women had lower rates of adverse birth outcomes: 1.3% had preeclampsia, less than half the rate for black women (2.9%).

Although infant deaths occur more frequently among low-income groups of all race/ethnicities, these birth outcome disparities by race/ethnicity are found also in blacks with higher socioeconomic status (SES). College-educated black women are more likely than white high school–educated women to have a LBW infant, a principal risk factor for infant death. Another study examined California birth certificates of pregnant Arab American women after the September 11, 2001, terrorist attacks and found that those who experienced discrimination immediately after the 9/11 attacks had a higher relative risk of giving birth to an LBW infant in the following 6 mo than seen in births before this date.

The increased risk for populations of color continues from infancy into childhood; racial/ethnic disparities are seen across almost all health indicators, with most relative gaps remaining stagnant or worsening over the last 2 decades. Black children are about twice as likely to be diagnosed with asthma, more likely to be hospitalized for its treatment, and more likely to have fatal attacks. The black-white disparity in asthma has grown steadily over time. Native American children and youth (≤19 yr) also experience negative health outcomes, with the highest rates of unintentional injury and mortality rates at least twice as high as for other racial/ethnic groups. Additionally, according to a 2015
NCHS brief, Latino youth age 2-19 have the highest rates of obesity, defined as a BMI ≥95th percentile in the 2000 CDC sex/age-specific growth charts. The NCHS data show that 21.9% of Latino (followed by black) children qualified as obese from 2011 to 2014. Black children are more likely to be exposed to witnessed, personal, or family violence and have several-fold higher prevalence of psychiatric distress than their white counterparts, a racial difference that continues into adulthood.

Explaining Racial Disparities: A Taxonomy of Racism

Explanations of these ubiquitous racial gaps have focused on individual factors, including variation in individual genetic constitution, behavioral risks, poverty, and access to (and use of) healthcare services. Scientists agree that “race” is a social construct that is not based on biology, despite the persistence of the idea that racial categories reflect a racially distinctive genetic makeup that has a bearing on health. In fact, the genetic variation between individuals within a particular racial/ethnic group is far greater than the variability between “races.” Despite the genetic data, many groups have been “racialized” over time. Notably, the U.S. Census Bureau's demographic classifications reflect this process. In the mid-late 1800s the census counted “mulattos,” those of white and black ancestry, as another race. Starting in the late 19th century, Eastern European immigrants and Jews were considered different races. As early as 1961, the U.S. Census identified Mexicans and Puerto Ricans as “white,” even as racial classification varied by geography. All states collected birth records by 1919, but there was little uniformity on how race was collected, if at all, across states. It was not until 1989, when the National Center for Health Statistics (NCHS) recommended assigning “infant race” as that of the mother, that standard guidance and categories were issued for states on collecting racial data at birth. Existing categories were changed and continue to change based on the economic, cultural, or political utility of the time, rather than actual genetic distinction.

Defining Racism

Racism has consistently structured U.S. society and is based on “white
supremacy,” a hierarchical idea that whites, the dominant group, are intrinsically superior to other groups who are not classified as “white.” No single definition of racism exists, but one useful description is racial prejudice backed by power and resources. This conceptualization asserts that not only must there be prejudice, but also an interlocking system of institutions to produce and reproduce inequities in access to and utilization of resources and decision-making power. Even when considering variations in health behavior, lifestyles, economic status, and healthcare utilization, individual-level behavioral factors do not capture how broader shared social experiences shape outcomes. Racial domination or racism contributes to variation in the population's access to resources and exposure to disease, as well as the group experience of fair treatment and opportunity. Although many groups in the United States may encounter discrimination based on race/ethnicity, most of the modest literature on health effects of racism has focused on people of African descent, leaving a need to better understand the impact of racism on other nonwhite groups. Table 2.4 describes various pathways through which racism affects health.

| Targeted marketing of health-harming substances |
Legal: cigarettes; sugar sweetened beverages
Illegal: heroin; illicit opioids

**Inadequate healthcare**
- Inadequate access to health insurance and healthcare facilities
- Inadequate treatment caused by implicit or explicit racial bias

**State-sanctioned violence and alienation from property and traditional lands**
- Police violence
- Forced urban “renewal” (use of eminent domain to force relocation of urban communities of color)
- Genocide and forced removal of Native Americans

**Political exclusion**
- Voter restrictions (e.g. for ex-felons, ID requirements)

**Maladaptive coping behaviors**
- Increased tobacco and alcohol consumption

**Stereotype threat**
- Stigma of inferiority leading to physiologic arousal
- Impaired patient-provider relationship

* Small, often unintentional racial slights/insults (e.g., a judge asking a black defense attorney, “Can you wait outside until your attorney gets here?”)

While the empirical data on disparities for nonblack populations of color deserve greater research, useful frameworks exist to understand the disparities that public health has documented to date. A useful taxonomy of how racism operates in society has 4 categories: internalized racism, interpersonal racism, institutional racism, and structural racism. Each is relevant in considering the impact of racism on child health.

**Internalized Racism**
When the larger society characterizes marginalized racialized groups as “inferior,” these negative assessments may be accepted by members of those groups themselves, either consciously or unconsciously. The result is *devaluation* of personal abilities and intrinsic worth, as well as the capacity, of others also classified as being a part of a marginalized racialized group. The best-known documentation of *internalized racism* comes from the study of Kenneth and Mamie Clark known as the **doll experiment**, conducted in the 1940s. Black children, both boys and girls, were asked to choose between a black doll and a white doll according to attributes described by the interviewer. In response to positive attributes (e.g., *pretty, good, smart*), most children chose the white doll. The Clarks interpreted this finding to mean that black children had internalized the societal views of black inferiority and white superiority, even at the expense of their personal self-image. Repeated by a New York City high school student several decades later, the findings were much the same, with 15 of 21 children endorsing positive attributes to light-skinned dolls. Multiple studies confirm that racial identity is established in young children, both black and white, along with negative views of blackness. Developmentally, however, nonwhite youth often explore racial identity earlier than their white counterparts.

In terms of health outcomes, depending on perceived inferiority or superiority of the group, racial identification is associated with self-esteem, mastery, and depressive symptoms. Low self-esteem is independently implicated in mental health disorders and may contribute to the phenomenon of **stereotype threat**, in which personal expectation of underperformance correlates with prevailing social stereotypes and adversely affects actual performance.

### Interpersonal Racism

How racial beliefs affect interactions between individuals has been the most studied aspect of racism. **Interpersonal racism** refers to situations where one person from society's privileged racial group acts in a discriminatory manner that adversely affects another person or group of people. Such actions may be based on explicit beliefs or on implicit beliefs of which the perpetrating individual is not consciously aware. A burgeoning field is examining how experience of unfair treatment has *biologic* consequences, reflected in measurable increases in stress responses.

Such effects of interpersonal racism are best documented for **mental health**, where perceived unfair treatment serves as psychosocial stressors, and are
weaker for physical health outcomes. A 2009 study of 5,147 5th-grade students found that compared to only 7% of whites who reported experiencing racial discrimination, 15% of Latinos and 20% of blacks self-reported enduring racial discrimination. Furthermore, discriminatory experiences have been strongly and consistently linked to greater risk for anxiety, depression, conduct disorder, psychological distress, ADHD, ODD, self-esteem, self-worth, and psychological adaptation and adjustment. Perceived racial discrimination can affect behavioral, mental, and physical health outcomes and is associated with: increased alcohol and drug use among Native Americans (age 9-16 yr), increased tobacco smoking for black youth (11-19 yr), higher depressive symptoms among Puerto Rican children, and insulin resistance among young females.

Understanding the enduring impact of childhood experience on adult health has increased with the study of adverse childhood experiences (ACEs) (see Chapter 1). ACEs have well-documented cumulative negative health effects that occur across the life span and are patterned by race/ethnicity. Early experience of racism is a proxy measure for toxic stress. The question, “Was [child's name] ever treated or judged unfairly because of [his/her] race or ethnic group?” is included in the U.S. Census Bureau's National Survey of Children's Health, a random sample of 91,000-102,000 households (depending on the year) to assess the health of children up to 17 yr old. Children of color from low-income households, especially Latino children, were reported to have the lowest level of health. However, exposure to racism among higher SES did not protect children from experiencing relatively poorer health. Children exposed to racism were also more likely (by 3.2%) to have a diagnosis of ADHD. Children exposed to racism were 2 times more likely to experience anxiety and depression.

Toxic stress increases cortisol levels in the body, increasing the risk of chronic disease. A 2010 study revealed that Mexican adolescents who perceived racism experienced greater cortisol output, after controlling for other stressors. Adolescents who experience racism with no support have been shown to have higher levels of blood pressure and obesity than those with emotional support, which can be protective.

Medical practice has not been exempt from these occurrences of interpersonal racism. Using variation in adherence to established clinical standards in diagnostic and treatment decisions across racialized groups, researchers have been assessing interpersonal racism in physician–patient interactions. The most comprehensive review of such bias in clinical care remains the 2003 study by the U.S. Institute of Medicine, in which the discriminatory treatment was inferred
from examination of clinical decision-making rather than from directly observed interactions. For virtually every condition studied, black patients were less likely to receive recommended care. Such racial bias has been most extensively established in adults but also extends to children. A study conducted in an emergency department found pediatric patients (<21 yr) were less likely to receive medically indicated pain medication if they were black, mirroring the historical misconception of reduced pain sensitivity among blacks. Within this context, it is unsurprising that perceived interpersonal racism has been linked to healthcare utilization, including delays in seeking care or filling prescriptions and distrust of the health system.

**Institutional Racism**

Interpersonal racism clearly inflicts harms, but even if completely eliminated, racial inequities would persist because of institutional and structural racism. Broadly, *institutional racism* refers to patterns of discrimination based on policy, culture, or practice and carried out by state and nonstate institutions (e.g., corporations, universities, legal systems, cultural institutions) within various sectors (e.g., housing, education, criminal justice). Key to current residential segregation are banking practices dating to the post-Depression era. As an institution, the education system has been another tragic case of how racism impacts children's health. In addition, mass incarceration by the criminal justice system has dramatically increased in the United States while remaining relatively flat in other developed countries (Fig. 2.6). Over a lifetime, approximately 30% of African American men have been imprisoned.

![FIG. 2.6 Trends in incarceration prevalence in developed democracies, 1981–2007.](image)

(Adapted from Wilderman C, Wang EA: Mass incarceration, public health, and widening inequality in the USA, *Lancet* 389:1464–1472, 2017, Fig 1.)
In school, children of color can experience not only individual racism but also institutional racism, as documented by higher rates of disciplinary actions such as suspensions, and at younger ages than white children. According to a 2016 U.S. Department of Education civil rights survey, black children, who represent only 19% of national preschool students, account for a staggering 47% of at least 1 out-of-school suspension. Black preschoolers are 3.6 times more likely to be suspended than their white peers. Black females, representing 20% of female preschool population, account for 54% of out-of-school suspensions.

Unfortunately, this disparity persists as children continue through the school system: for kindergarten to grade 12 (K-12) students, black children are 3.8 times more likely to face out-of-school suspension than white peers. This inequity is particularly harmful because the educational system feeds into the criminal justice system. Black students are 2.2 times more likely to have either school-related arrests or law enforcement referrals than their white peers. The U.S. Department of Education survey also reveals racial inequities among children with disabilities. For K-12 children with disabilities covered under the Individuals with Disability in Education Act, 21% of multiracial females were issued with at least 1 out-of-school suspension, compared to 5% of white females.

In addition to the threat to educational and employment prospects, school suspensions also risk children's health. A 2016 brief from the Yale Child Study Center states that early suspensions and expulsions of children harm behavioral and social-emotional development, weakening a child's overall development. Furthermore, these forms of punishment may prevent the treatment of underlying health issues, such as mental health issues or disabilities, and cause increased stress for the entire family.

Institutional racism can function without apparent individual involvement and has powerful repercussions that persist centuries later. Both medical professional organizations and educational institutions have legacies of racial discrimination rooted in scientific racism. In 2008 the American Medical Association (AMA) issued a formal apology for its long history, dating to the 1870s, of endorsing explicitly racist practices, including exclusion of black physicians, silence on civil rights, and refusal to make any public statement on federally sponsored hospital segregation. Despite a focus on medical school desegregation in the 1960s and 1970s, the presence of black students in medical schools is actually declining. Low enrollment has become especially critical for black men, who in
2014 accounted for about 500 of the 20,000 medical students nationwide. If physicians hold stereotyped views about race that affect their clinical decision-making, the declining diversity of medical student bodies may well have consequences for the quality of medical care. This history of institutional racism on people of color contributes to the mistrust, apprehension, and fear projected toward the entire medical establishment.

**Structural Racism**

The institutional racism within medical institutions reinforces institutional racism in other sectors, creating a larger system of discrimination, *structural racism*. Structural racism can be described as “the totality of ways in which societies foster racial discrimination via mutually reinforcing systems of housing, education, employment, earnings, benefits, credit, media, healthcare, and criminal justice. These patterns and practices in turn reinforce discriminatory beliefs, values, and distribution of resources, which together affect risk of adverse health outcomes.” Institutional racism and structural racism are sometimes used interchangeably, but structural racism refers to overarching patterns beyond a single or even collection of institutions. Historically, government policies and practices have been largely responsible for the creation of these structures.

De facto and de jure urban residential segregation serves as a case study for how the mechanisms of structural racism operate across multiple sectors and can impact child health and development across the life course. In the 20th century, urban residential racial segregation was reinforced by the government-sanctioned policy and practice of *redlining*. This now-illegal practice was initiated by the U.S. Federal Housing Administration in 1934. Surveyors literally demarcated city maps with red ink to indicate those urban neighborhoods to be made ineligible for home loans. *Racial composition* was the most important driver of this categorization, and thus black neighborhoods were excluded from the federally financed, post-Depression home ownership boom and remained segregated. Through this segregation, existing resources were systematically removed (*disinvestment*) and led to further impoverished communities of color.

The effects of residential segregation were not restricted to the banking or housing sectors. **Residential segregation** ties together multiple systems, driving children's access to and quality of healthcare, education, and justice, as follows
Residential segregation and the healthcare system. Healthcare institutions were explicitly racially segregated by law and inequitably resourced until passage of the 1964 Civil Rights Act. Vestiges of this segregation continue in recent hospital-level segregation and racial composition by hospital. In addition, institutions that provide mainly for uninsured or underserved residents are often financially unstable, leading to higher risk of closure in disinvested neighborhoods of color. On the provider level, fewer primary care and specialty physicians practice in disinvested, segregated neighborhoods, and those who are present are less likely to participate in Medicaid.

Residential segregation and the education system. Schools have a similar history of racial segregation and, after a brief respite of integration peaking in 1980, the rates of segregation now resemble pre–Civil Rights levels of segregation. School segregation is related to high-risk health behaviors. Within these schools and in their neighborhoods, black children experience disproportionate penalization and criminalization in the educational and criminal justice systems, reinforcing institutional racism in other sectors and other forms of racism. A low-income black child is much more likely than a low-income white child to live in a segregated neighborhood. The
result is that the black child will face not only the cumulative disadvantage in both family and neighborhood resources and experiences over time, but also the initiation of chains of disadvantage during sensitive periods of childhood key for development and adult transition (e.g., early childhood, adolescence).

- **Residential segregation and the criminal justice system.** Incarceration is concentrated in overpoliced and criminalized black communities. In the NCHS, almost 13% of black children had a parent imprisoned during their childhood (to age 17 yr), compared to about 6% of white children. Parental incarceration, which may start with a traumatic arrest in the home and later disrupt caregiving, create social stigma, deepen financial disadvantage, disconnect parents emotionally from children, and disrupt children's psychological development, has been independently associated with higher risk of children's antisocial behavior.

Most notably, experiences directly related to institutional and structural racism, operating through residential segregation (including financial hardship, parental imprisonment, and neighborhood violence), result in higher levels of ACEs for blacks and Latinos than whites. There has been growing, consistent evidence of the lifelong association between ACEs and a range of negative physical and mental health outcomes across the life course.

Structural racism, shown here with the example of residential segregation, affects child health through various direct and indirect, overlapping pathways,
including the concentration of dilapidated housing, inferior quality of the social and built environment, exposure to pollutants and toxins, limited access to high-quality primary and secondary education, few well-paying jobs, overpolicing and criminalization, adverse experiences, and limited access to quality healthcare.

Opportunities to Address Racism

Racism as a determinant of health has strong empirical support, and there is promising evidence for community-wide approaches to its mitigation. Less is known about effective interventions in clinical settings. Most medical schools and subsequent training will not have prepared practitioners to examine the role of racism in their patients’ lives or clinical care settings. Nonetheless, it is reasonable to expect that pediatricians can help address racism and promote racial justice in at least 3 ways: during individual patient encounters and at their practice sites, as members of institutions that provide medical care and training, and as respected community members.

Clinical Settings

A first step is understanding that racism affects everyone and personally assessing implicit bias. Such biases reflect reflexive patterns of thinking often using racial stereotypes stemming from living in a racially stratified society. The Project Implicit Race Implicit Association Test (https://implicit.harvard.edu/implicit/takeatest.html) is available online, and its results are confidential. The purpose of such tests is to create awareness, not apportion blame. Nonetheless, results are usually jarring for all participants, no matter their racial identity, many of whom will uncover negative racial biases of which they were unaware. Such individual assessments may contribute to addressing interpersonal racism as it triggers self-reflection. Further, a growing number of organizations offer training in understanding common behaviors associated with implicit bias, including microaggressions (see later) and inequitable hiring practices. Recognizing and undoing personal biases as pediatricians requires training to challenge existing thought processes and actions that are often difficult to see.

Pediatricians and other health workers have an entrusted role in families that requires a partnership. Recognizing the strengths of families and valuing their
lived experiences of internalized and interpersonal racism as expertise fosters a more collaborative clinical interaction and relationship. This expertise cannot be readily captured by pedagogy or acquired by a pediatrician in training or clinical practice. Such an approach emphasizes respect for the expertise that caregivers bring to raising their child and begins with the presumption that caregivers want to do what is best for the child. By doing this, physicians can form a collaborative relationship, rather than one based on racial stereotypes and blame. Cultural competence is a widespread concept recognizing that other cultures exist that the dominant culture must learn to decode. In contrast, the concept of cultural humility, for which training is increasingly available, considers equality among cultures and a partnership approach to differences.

During clinical encounters with children and families, healthcare workers can use their authority to acknowledge racism. Pediatricians should broach “The Talk” with their patients who are black, young adolescent, and male. “The Talk” is the conversation that black parents typically initiate with their sons regarding interactions with police. In doing so, the pediatrician affirms the need for such conversations to promote safety and may provide opportunities to connect families to community resources. For all young children and youth of color, pediatricians should ask patients if they have they been treated unfairly because of their race, recognizing this can by a form of bullying. The experience of racism at all levels can be traumatic. Trauma consists of experiences or situations that are emotionally painful and distressing, and that overwhelm people's ability to cope, leaving them powerless. Pediatricians must consider adopting trauma-informed care practices that shift the paradigm from, “What is wrong with you?” to, “What has happened to you?”

In addition, healthcare providers must strive for structural competency, which is the “trained ability to discern how a host of issues defined clinically as symptoms, attitudes, or diseases also represent the downstream implications of a number of upstream decisions,” according to Johnathan M. Metzl and Helena Hansen. Consequently, it is helpful to ensure that clinical practices are aware of other social services that may enhance health and engagement with clinical care, such as need for legal counsel to address substandard housing, counter landlord harassment, or negotiate threatened evictions (http://medical-legalpartnership.org/), or the support of literacy by prescribing or distributing children's books in order to encourage parents to read to children (http://www.reachoutandread.org/).
Institutional Settings

The healthcare institution more broadly is also a setting where racial dynamics occur. Introducing conversations about race may uncover experiences that would not otherwise be apparent. A common outcome of implicit racial bias is microaggressions, actions and attitudes that may seem trivial or unimportant to the perpetrators but create a cumulative burden for those who perceive them. A physician of color might be asked for identification on entering a hospital, while white colleagues are not so queried. These microaggressions occur in interactions among staff as well with patients and may contribute to an unspoken and uncomfortable racial climate. While such interactions rarely would violate federal discrimination standards, interaction between co-workers shapes an entire practice and can be perceived by families.

Encouraging institutions to assess the impact of race among patients and staff is a first step. Healthcare delivery institutional settings can use both data and patient accounts to examine racial effects in the practice and experience by routinely disaggregating assessment measures by race/ethnicity. Patient-reported satisfaction or quality of care might be disaggregated by race. In addition, it is important to consider racial equity within the practice's employment structure: Are there discrepancies in hiring, retention, and salaries by race? Are there proper supervision and grievance procedures, particularly around issues related to racial microaggressions? Also, consider the images and language used to discuss and represent both patients and staff, particularly when alluding to race/ethnicity. Organizations such as Race Forward (https://www.raceforward.org) and organizational assessment tools developed by the Race Matters Institute can help to guide institutional assessments and internal change processes. Several local health departments have already incorporated antiracism training into staff professional development and introduced internal reforms to drive organizational change. Since institutional reform is closely associated with other models of productive practices, including quality improvement, collective impact, community engagement, and community mobilization, application of an antiracism lens should be judged by its contributions to organizational effectiveness as well as on its moral merits.

Education or training institutions have a special role in ensuring a workforce that is both diverse and informed. Patterns of student admissions should be scrutinized, as should the curriculum. Although many medical schools now include diversity training and provide instruction on cultural competency, such
instruction is often brief (and sometimes delivered online). By contrast, approaches based on structural competency, cultural humility, and cultural safety have been implemented in health professionals’ training in such countries as Canada and New Zealand. These approaches emphasize the value of gaining knowledge about structural racism, internalized scripts of racial superiority and inferiority, and the cultural and power contexts of health professionals and their patients or clients. Health professionals benefit from the scholarship of diverse disciplines about the origins and perpetuation of, as well as remedies to counter, racism. Finding class time for these topics encounters a biomedical bias that is widespread in medical education, although arguably successful medical practice also requires a host of skills in addition a firm grounding in pathophysiology and recommended treatments. Racism results in damaging disparities that cause ill health and shorten lives, which justifies the teaching hours committed to its understanding.

Pediatricians as Advocates for Antiracist Practices and Systems

Physicians are respected members of communities and wield the power, privilege, and responsibility for dismantling structural racism. A conceptual review of structural racism highlights the promise of place-based interventions that target geographically defined communities, to engage residents and a range of institutions (across sectors) in order to ensure equitable access to resources and services, remediating the processes set in motion decades earlier. Clinicians play a role in linking patients to services, programming, and other resources and advocating for responsiveness in addressing gaps. Over time, concentrated efforts across sectors in targeted areas have shown improvement in a host of social outcomes, including health outcomes. Similarly, providing access to higher-quality housing, either with housing vouchers or housing lotteries, had unexpected positive health impacts. These findings are encouraging, as are the social policy interventions and systemic change, including legislation such as the Civil Rights Act, the advent of Medicare and Medicaid, and tenement regulations, associated with the narrowing of racial gaps.

Global Burden and Trends in Child Health

The **under-five mortality rate** (U5MR), also known as the **child mortality rate**, serves as a reliable gauge of child well-being. It measures the outcome of a country's health system and reflects a nation's social and economic development. The global U5MR fell by 53% between 1990 and 2015. Despite these gains, in 2016 an estimated 5.6 million children <5 yr old died worldwide, equivalent to **41 deaths per 1,000 live births**, or almost **15,000 child deaths each day**. The burden of the world's child mortality disproportionately falls on low- and middle-income regions of Africa and Asia ([Fig. 3.1](#)), with 86% of child deaths occurring in these regions and <1% in high-income countries. Consequently, a child born in sub-Saharan Africa is >15 times more likely to die by age 5 yr than a child born in a high-income country.
Improvements in child mortality have been uneven globally, regionally, and nationally. Rates of change in U5MR range from a decrease of 8.9% in the Maldives to an increase of 2.5% in Syria during 2000–2016. Significant disparities in child mortality persist and have become increasingly concentrated in specific regions of Africa and Asia, with one third of these deaths occurring in South Asia and half in sub-Saharan Africa.

While the number of child deaths has decreased dramatically over the past 2 decades, the early years of life remain one of a child's most vulnerable periods. Among the under-5 child deaths, almost half occurred within the 1st mo of life (2.7 million deaths in 2016). This estimate of neonatal deaths (<1 mo) translates into 19 per 1,000 live births. Declines in neonatal mortality occurred at slower rates, so that in 2015 the neonatal deaths made up 46% of all under-5 deaths (Fig. 3.2).
Neonatal deaths account for a smaller percentage of child mortality in low- and middle-income countries compared to high-income countries (Fig. 3.3), but the absolute risk of death remains significantly higher. A child in sub-Saharan Africa or South Asia is 9 times more likely to die in the 1st mo of life than a child born in a high-income country.
An estimated 1.7 million stillborn deaths (≥28 completed wk of gestation) burden families worldwide every year, which correlates to 13.1 deaths per 1,000 births. Global and national estimates of stillbirths vary widely because of inadequate data collection, reflecting the low prioritization of this vulnerable age-group. Progress to reduce stillbirth rates during the MDG era (UN Millennium Development Goals) has been slow, with the annual rate of reduction estimated to be half that for neonatal deaths between 2000 and 2015. Almost all stillbirths occur in low- and middle-income countries (98%), with three-quarters in sub-Saharan Africa and South Asia.

Most childhood deaths are caused by conditions that could be prevented or managed through improved access to simple, low-cost interventions. The most common causes of child death are pneumonia (13%), diarrhea (9%), and malaria (5%), which account for almost one third of all under-5 deaths and about 40% of under-5 deaths in sub-Saharan Africa (see Chapter 1, Fig. 1.1). Neonatal deaths are caused by prematurity (16%), intrapartum-related complications such as birth asphyxia (11%), and neonatal sepsis (7%). In contrast, child deaths from infections in developed countries are less common, and injuries and congenital malformations account for higher proportions of
under-5 deaths. **Undernutrition**, including fetal growth restriction, stunting and wasting, and micronutrient deficiencies, contributes up to 45% of under-5 deaths and leads to poor childhood development in low- and middle-income countries. Undernutrition has an enormous impact on child mortality because of the vicious cycle between nutrition and infection. Lowered immunity and mucosal damage from inadequate dietary intake leads to increased susceptibility to pathogen invasion. Recurrent infections and immature microbiome impairs the child's ability to absorb nutrients.

Infants who start out life with a **low birthweight** (LBW) are at high risk of death, contributing 60–80% of all neonatal deaths. Most of these infants are premature (<37 wk of pregnancy) or had fetal growth restriction. About half of stillbirths take place during labor, ranging from 10.0% in developed regions to 59.3% in South Asia, which reflects the extent that timely, high-quality care at delivery can prevent many of these deaths.

Mortality among older children (5-14 yr) is low compared with the younger cohort, although 1 million children in this age-group died in 2016, equivalent to 3,000 children dying every day. Infectious diseases play a smaller role in deaths among these older children, with injuries from external causes such as drowning and motor vehicle crashes accounting for more than one quarter of the deaths and noncommunicable diseases for another quarter.

Child health should not be assessed based on mortality rates alone. Children surviving illness are often left with **lifelong disabilities**, burdening their families and impacting their economic productivity. Approximately 1 in 10 children are born with or acquire a disability, and 80% of these disabled children live in low- or middle-income countries. Neonatal disorders, infectious diseases, protein-energy and micronutrient deficiencies, hemoglobinopathies, and injuries are leading causes of disability in children. Child deaths can also lead to disability in the surviving mother. A woman who has a stillbirth is at risk of an obstetric fistula or death, with an estimated 78–98% of women with obstetric fistula having had a stillbirth. Also, perinatal loss with child death is a psychological trauma. Stillbirth, neonatal death, and child loss can lead to posttraumatic stress disorder, depression, anxiety, guilt, and in some settings, shame and social stigma, particularly in the mother, with significant impact on the health and well-being of the family.

Adolescents age 10-19 yr, who have benefited from the gains in child survival, grow up to find themselves in social settings where less attention and fewer resources are devoted to their well-being compared to their earlier years of
growth. The paucity of support during this time of transition into adulthood diminishes the impact that child survival can have on their lives. Adolescents make up 18% of the world's population, approximately 1.8 billion in 2010, which is expected to increase to >2 billion by 2050. The vast majority of adolescents, 88%, live in low- and middle-income countries. In 2050, sub-Saharan Africa is projected to have more adolescents than any other region. While adolescent mortality rates are much lower than their younger-age cohorts, in low-income countries they face a lack of educational and employment opportunities, risk of injuries and violence, HIV/AIDS, mental health problems, marriage, and teenage pregnancy, preventing them from attaining their potential as they transition into adulthood. The decade of adolescence is a critical period when poverty and inequity frequently transfer to the next generation. The intergenerational transmission of poverty is most apparent among undereducated adolescent females. In many parts of the world, poor teenage females are likely to be married early, risking premature childbearing and higher rates of maternal mortality, and leading to infant and child undernutrition.

**Social Determinants of Child Health**

The gross national income level accounts for much of the difference in child mortality observed between countries, but other significant factors impact child health. Although the wealth of the United States places it in the 8th position with respect to gross domestic product (GDP) per capita (2016) in the world, the U.S. child mortality rate is ranked 56th in the world, at 5.8 deaths per 1,000 live births, which is higher than the United Kingdom (4.3), Cuba (4.4), Canada (4.5), Czech Republic (2.6), and Japan (2.0). *National estimates of mortality mask differences in health status among subpopulations within the same country.* In Burkina Faso the child mortality rate is 43.7/1,000 live births among children born to mothers with no education, whereas it is 16.7 per 1,000 among children born to mothers with at least secondary education. Similarly, in 2013, the infant mortality rate in the Dominican Republic was 14.0/1,000 live births for children in the highest wealth quintile, but 40.0/1,000 for children living in the lowest quintile.

Child health is influenced by socioeconomic factors that operate at multiple levels of the society. Disparities in these socioeconomic factors translate into child health inequities, as reflected by high rates of disease, poor nutrition, and disability. Fig. 3.4 outlines the immediate, underlying, and basic structural
determinants of disease, malnutrition, and disability. Preventive and curative medical interventions focus on the immediate causes of poor health. However, inequities in child mortality and morbidity will persist unless the basic and underlying determinants of health are addressed.

Socioeconomic and Political Roots of Disparities in Global Health

The root causes of a child's health lie in the economic and political environments in which the child is born (Fig. 3.4). Growth of economies during the 1st half of the 20th century was associated with dramatic health improvements with falling mortality rates and rising life expectancy across all regions. However, the 2nd half observed significant disparities in global economies and health among and within many countries.

Between 1980 and 2016, the richest 1% of the world reaped twice as much of the world's income as the poorest 50% of the world (27% of income growth vs 12%) (World Inequality Report, 2018, http://wir2018.wid.world/). Almost all countries report income inequalities among its population, but a few countries, such as the United States, have seen income disparities at historical proportions (Fig. 3.5). Since 1980 the bottom half of Americans captured only 3% of the total growth. Growing income inequalities translates into greater differences in health outcomes, such as life expectancy, between the rich and the poor in the
United States (Fig. 3.6). More aggressive redistribution of wealth through taxes and transfers has spared Europe from such glaring disparities.

**FIG. 3.5** Inflation-adjusted annual household income at selected percentiles, 1967–2014. All series show percentiles of the distribution except for top 1%, which shows the mean of the top 1%. All income series except for the top 1% are plotted against the left vertical axis, displaying incomes from $0 to $200,000. The top 1% is plotted against the right vertical axis, displaying incomes from $200,000 to $1,000,000. Income is expressed in 2014 US$. (Data from US Census Bureau Current Population Survey, 1968–2015, Annual Social and Economic Supplements and World Wealth and Income Database. From Bor J, Cohen GH, Galea S: Population health in an era of rising income inequality: USA, 1980–2015, Lancet 389:1475–1490, 2017, Fig 1.)

Evidence supports that income inequality is not just a human rights issue, but also detrimental to economic growth. Wealthier households spend a smaller percentage of their own income, thereby dampening demand and slowing down economies. Poorer households face greater challenges to invest in health and educational opportunities, translating into less human capital, and obstacles to be productive and contribute to the economy. In extreme cases, inequalities can threaten social unrest, which further undermines economic activity.

Global disparities have grown between many wealthy and low-income countries, in large part from “austerity” measures, including structural adjustment programs, imposed on many postcolonial countries by the International Monetary Fund (IMF) and World Bank. In order to receive loans and pay off their debt, many of these countries were required to take on austerity measures that transformed their economies to produce cash crops and export natural resources to higher-income countries, rather than supporting local industries and investing in human capital and providing social services.

Foreign aid for healthcare programs has led to significant health improvements, with countries receiving more health aid demonstrating a more rapid rise in life expectancy and larger declines in child mortality than countries that received less health aid. National security concerns continue to drive U.S. assistance policy, which aims to reinforce ally countries, provide stability in conflict regions, promote democracy, and contribute to counterterrorism and law enforcement efforts abroad. Other goals, such as contributing humanitarian relief during natural disasters, poverty reduction, and health promotion, also drive assistance.

**Sustainable Development Goals**

The prioritization and planning of global development and international aid has been guided by international goals. In 2015, world leaders agreed to 17 goals, the **Sustainability Development Goals (SDGs)**, to improve global well-being by 2030 (Fig. 3.7). The SDGs were built on the eight **Millennium Development Goals (MDGs)**, which were concrete, specific, and measurable targets set by the United Nations in 2000 to eradicate poverty, hunger, illiteracy, and disease by 2015. Significant, although uneven, progress had been made
toward meeting the MDGs, falling short in improving the lives of the poorest and most disadvantaged countries, and bypassing social groups because of gender, age, disability, or ethnicity.

Unlike the MDGs, in which health was prominently featured in 3 of the goals, the SDG-3 is the primary SDG that focuses on health-related subtargets, including the reduction of U5MR to 25 deaths per 1,000 live births and neonatal mortality rate to 12 deaths per 1,000 live births by 2030. The other 16 SDGs focus mainly on social and economic determinants and the environment. This reflects an important shift to broaden the global targets to include upstream determinants of health, including health systems and socioeconomic, gender-based, political, and environmental factors. As a social movement to support sustainable development, the SDGs were founded on the recognition that the world's environment, socioeconomic development, and human health are interconnected and dependent. Therefore the SDGs were formulated with core principles and values for economic development, environmental sustainability, and social inclusion for all.

The Global Strategy for Women's, Children's and Adolescent's Health 2016–2030 maps out the strategies to achieve the SDGs by centering on the goal of health for all women, children, and adolescents using evidence-based
approaches, backed by innovative and sustainable financing mechanisms. An important component of the Global Strategy is the inclusion of adolescents as central to the 2030 Agenda for Sustainable Development. In alignment with the SDGs, the Global Strategy focuses on 3 pillars of action: (1) ending preventable deaths among women, children, and adolescents; (2) ensuring their health and well-being by ending malnutrition and ensuring access to family planning, reducing exposure to pollution, and achieving universal health coverage; and (3) expanding enabling environments by efforts such as eradicating extreme poverty, ensuring good-quality education, eliminating violence against women and girls, enhancing research and technologic capabilities, and encouraging innovation.

In addition to being much broader in scope, the Global Strategy focuses on equity in that the strategy is meant to apply to all people, including the marginalized and difficult-to-reach populations, in all situations, including during crisis. Thus, for example, health insurance coverage would not be assessed based simply on the national average of coverage, but also by how well the increases in coverage benefit all population groups, regardless of income or educational level.

**Evidence-Based Interventions and Innovations to Address Child Health Inequities**

Estimates indicate that most of the 5.6 million annual deaths in children <5 yr old could be averted by increasing coverage of proven low-cost interventions (Table 3.1). Childhood deaths from diarrheal illness and pneumonia can be prevented by simple measures such as vaccinations and exclusive breastfeeding until 6 mo of age. Deaths related to undernutrition, which predisposes children to infectious diseases, may be prevented by proper infant and young child feeding practices, micronutrient supplementation, and community-based screening and management of malnutrition.

• Intermittent preventive treatment for malaria |
| **CHILDBIRTH** | |
| • Maternal intrapartum care and monitoring | • Newborn resuscitation (e.g., Healthy Babies Breathe)
• Premature: surfactant administration, continuous positive airway pressure (CPAP), treatment of jaundice
• Feeding support for small/preterm infants |
| • Skilled delivery |
| • Thermal care for all newborns | |
| • Clean cord and skin care | |
| • Early initiation and exclusive breastfeeding within 1st hr | |
| **PRENATAL PERIOD** | |
| • Appropriate postnatal visits | • Extra care for small and sick babies (kangaroo mother care, treatment of infection, support for feeding, management of respiratory complications)
• Antibiotics for newborns at risk and for treatment of bacterial infections (PROM, sepsis, meningitis, pneumonia) |
| **INFANCY AND CHILDHOOD** | |
| • Exclusive breastfeeding for 6 mo and continued breastfeeding up to at least 2 yr with appropriate complementary feeding from 6 mo | • Case management of severe acute malnutrition |
| • Monitoring and care for child growth and development |
| • Routine immunization childhood diseases | |
| • Micronutrient supplementation, including vitamin A from 6 mo | |
| • Prevention of childhood diseases |
| • Malaria (insecticide-treated bed nets) | • Management of childhood diseases
• Pneumonia |
• Diarrhea (rotavirus immunization) |
• Meningitis (meningococcal/Hib/pneumococcal vaccination) |
• Measles (vaccination) |
• Prevention of mother-to-child HIV transmission |
• Malaria (antimalarials) |
• Pneumonia (case management, antibiotics) |
• Diarrhea (ORS, zinc supplement, continued feeding) |
• Meningitis (case management, antibiotics) |
• Measles (vitamin A suppl) |
• Comprehensive care of children exposed to or infected with HIV (HAART) |

HAART, Highly active antiretroviral therapy; ORS, oral rehydration solution (salts).

Addressing the SDGs to improve health of mothers, children, and adolescents takes a life course approach. *Fig. 3.8* displays estimates of coverage for essential
interventions across the continuum of care, indicating the wide range of coverage rates within countries that will need to be addressed if SDGs are to be attained.

FIG. 3.8 Coverage of interventions across the continuum of care based on the most recent data since 2012 in Countdown countries. Bars show median national coverage of interventions; dots show country-specific data. (From Countdown to 2030 Collaboration: Tracking progress towards universal coverage for reproductive, maternal, newborn, and child health, *Lancet* 391:1538-1548, 2018. Fig 1.)

Vaccine-Preventable Diseases

In 2002 an estimated 1.5 million under-5 deaths were caused by vaccine-preventable diseases. Top contributors were pneumococcus and rotavirus, followed by *Haemophilus influenzae* B (Hib), measles, pertussis, and tetanus. The World Health Organization (WHO) *Expanded Program on Immunization* (EPI) has resulted in a dramatic reduction in deaths, illness, and disability from many of these diseases, as well as the near-elimination of poliomyelitis. Recommendations for routine immunizations have continued to grow with the development of new vaccines that have demonstrated significant lifesaving potential in industrialized countries (Table 3.2).

Adapted from WHO Routine Guidelines for Immunization.

http://www.who.int/immunization/policy/Immunization_routine_table2.pdf?ua=1

In 2015, 86% of the world's infants were vaccinated with 3 doses of
diphtheria-tetanus-pertussis (DTP). Although vaccines are very effective in improving child survival, rates of coverage are low in many countries. In 2016 a total of 19.5 million children did not receive all routine lifesaving vaccinations, and 90,000 deaths were reported from measles. Although coverage rates are still improving, and lifesaving vaccines are still not available in many countries, progress has been made to expand availability to new countries every year. The lowest number of wild poliovirus cases (37) was reported in 2016.

**Reaching Every Child, Everywhere**

Global vaccine organizations aim for universal coverage of immunizations but face challenges within countries to attain this goal. Other lifesaving interventions have met barriers to attain universal coverage. Oral rehydration therapy (ORT) has been the evidence-based intervention recommended to prevent dehydration from diarrheal disease since the 1970s, yet only 2 in 5 children <5 yr with diarrheal illness receive this treatment. Many factors determine whether a child receives a lifesaving intervention. Characteristics of the healthcare system, social attitudes and practices, and the political climate impact whether universal coverage can be reached for evidence-based essential interventions. Innovations to strengthen vaccine coverage to reach every child in every district of a country range from programs such as **Reaching Every Child through Quality Improvement** (REC-QI) using community mapping techniques, to integrating service delivery mechanisms and strengthening the health system with improved surveillance.

**Effective Delivery Strategies: Integrated Management of Childhood Illness**

Weak health systems impede the ability of countries to deliver cost-effective interventions and lifesaving health messages for children. Such systems are characterized by insufficient numbers of health workers, low-quality training and supervision, and poorly functioning supply chains. The provision of child health services may focus on a single level, such as the health facility, but effective and lasting improvements can only be achieved with the integration of delivery at all levels, such as adequate referrals and follow-up between community, clinic, and health facility. Other important lifesaving strategies include outreach services (e.g., mass immunization, vitamin A campaigns) and community-based health
The Integrated Management of Childhood Illnesses (IMCI) was launched in the mid-1990s by the United Nations Children's Fund (UNICEF) and WHO as an approach to reduce child mortality, illness, and disability and to promote improved growth and development in countries struggling with high child mortality rates. The IMCI was designed to increase coverage of evidence-based, high-impact interventions that address the top causes of child mortality by integrating health promotion, illness prevention, and disease treatment. The IMCI contains both preventive and curative elements, set forth through a series of clinical algorithms and guidelines for case management (see Fig. 3.10 for an
example) and implemented by health care workers in collaboration with families and communities. One key component of the IMCI strategy involves training frontline health care workers to use the algorithms to identify signs of common childhood illness and to decide when a child needs referral to a hospital. In early 2003, guidelines for newborn care were added to create the Integrated Management of Neonatal and Childhood Illnesses (IMNCI).
As facility-based services alone do not provide adequate access to timely treatment of childhood illnesses, in early 2000 the Integrated Community Case Management (i-CCM) was implemented to train community health workers to instruct parents on home management of ill children, including ORS and zinc for diarrhea, antimalarial medicine for febrile children who test positive for malaria, and antibiotics for children with signs of pneumonia. Community health workers (CHWs) are members of communities that have selected them to provide basic health care with support and training from the health system. CHWs carry out health promotional activities such as promotion of proper infant and young child feeding, hand-hygiene practices, and use of bed nets. The i-CCM strategy involved training CHWs to screen and manage diseases, including mild to moderate cases of undernutrition, diarrheal disease, and pneumonia. CHWs schedule follow-up visits for ill children managed in the community, and refer serious cases in a timely manner to healthcare facilities. Community-based interventions are effective in extending healthcare delivery, are low cost, improve healthcare-seeking behavior, and can reduce infant and child mortality and morbidity.

Over 100 countries have adopted IMNCI and implement some or all of its components, not only improving health workers’ skills but also strengthening health systems and improving family and community practices. After 20 yr of implementation, a review noted that IMNCI was associated with a 15% reduction in child mortality when activities were properly implemented in health facilities and communities. However, the implementation of IMNCI was found to be uneven between and within countries. In many countries the resources for CHW training and supervision, supply of medications, and referrals were limited or absent. IMNCI was only successful in countries with strong government leadership and a commitment to implement IMNCI in partnership with support groups such as UNICEF and WHO. In addition, the success of IMNCI required an adequate health system and a systematic approach to planning and implementation.

Social Protection Programs: Conditional and Unconditional Cash Transfers
Financial incentives are becoming widely used to improve healthcare coverage, alleviate poverty, and improve access to child health services. In industrialized countries, **cash transfers** is a common mechanism for ensuring that the poorest, most marginalized subgroups of the population, particularly with children, receive adequate support to meet their basic needs. Cash transfer programs are increasingly being used in low- and middle-income countries to support vulnerable populations.

Out-of-pocket expenses by households form the major share of total health expenditure in most low- and middle-income countries. Many social protection programs work to serve a dual purpose of reducing financial barriers and strengthening service delivery. Financial incentives may include cash transfers, microcredit, vouchers, and user fee removal and health insurance. Financial incentive programs may be unconditional, provided to eligible families without any requirements or expectations, based on the belief that families will use this type of financial support for their children's best interests. Other incentives are conditional on health promotion behavior targeting child health, such as providing cash or vouchers only to families who participate in preventive health behaviors, such as attending mother groups to learn about breastfeeding practices, visiting clinics for child vaccinations and growth monitoring, engaging in deworming, and ensuring their children receive vitamin A and iron supplementation. Some social protection programs are also directed toward education improvement by making cash transfers conditional on child school enrollment, attendance, and occasionally some measure of academic performance.

### Challenges in Global Health

#### Adolescent Health

The Global Strategy, which directs countries to attain their SDGs, has called on nations to focus efforts to support adolescent health given their potential role in breaking the *intergenerational cycle* of poverty. The challenge to attain these health goals will be to effectively advocate governments to invest in this age-group as a means to improve the national productivity and economy. Considerable gaps in data on adolescents pose one of the greatest challenges to promoting their health and their rights.

Strategies to address the unmet needs of adolescent health efforts must
highlight improving completion of secondary school education, particularly among females. The development of adolescents’ capacities and values through education can empower an entire generation to become economically independent, positive contributors to society and break the cycle of poverty.

Other threats to adolescent health include mental health, substance abuse, sexual and reproductive health, and noncommunicable diseases (NCDs), such as obesity, which vary depending on country type (Fig. 3.11). A common theme for these threats is that interventions to combat these issues must attempt to influence individual behavior and attitudes while promoting healthy lifestyles. It is estimated that 20% of the world's adolescents have a mental health or behavioral problem. Depression is the single largest contributor to the global burden of disease for individuals age 15-19, and suicide is 1 of the 3 leading causes of mortality among people age 15-35. Efforts to tackle these problems will require an interdisciplinary approach, with more research needed to identify and evaluate interventions and effectively influence adolescent behavior in low- and middle-income countries.

![FIG. 3.11](image-url)

Global Climate Change

Global climate change is currently the most urgent and alarming challenge to the environment. Contributing to environmental degradation, the loss of natural resources and change in climate undermine food and water sources. Climate change and increased frequency and severity of humanitarian crises adversely impact children health and nutrition, as well as threaten their education and development by disrupting school and home.

Conflict, Emergency Situations, and Migration

During times of crisis, children and adolescents are most vulnerable. Although the youngest are most likely to perish from disease or injuries, all children suffer as a result of food shortages, poor water and sanitation, interrupted education, and family separation or displacement. Approximately 214 million migrants live outside their countries of birth, which includes 33 million young children and adolescents under age 20 who have migrated either with their parents or unaccompanied. Many other children are directly or indirectly affected by migration, by parental separation, from deportation, or emigration.

Children and adolescents crossing borders may not be entitled to the same protection and rights as those who reside in a given country, leaving them at greater risk of discrimination and exploitation. A rights-based approach to migration is required to reinforce the steady buildup of national and international support. This approach must also address the root causes of migration (e.g., instability, inequality, discrimination, poverty) in the country of origin and should incorporate policies specifically targeted for young children and adolescents, girls and young women, and vulnerable populations, including those left behind when family members migrate.

Information and Communications Technology

Social network sites, mobile phones, programmers, and other stakeholders are implementing methods to appeal to youth in middle-income countries, harnessing this technology and their attention to increase awareness and build health skills. Parents and educators raise concern about the well-being and safety of children and adolescents who use these tools. The exposure to the immense amount of information on the internet places their privacy and psychological well-being at risk, since adults have not caught up to fully understand the

CHAPTER 4

Quality and Value in Healthcare for Children

Jeffrey M. Simmons, Samir S. Shah

The Need for Improvement in Quality and Value

Adults and children only receive recommended evidence-based care about half the time. The gap between knowledge and practice widens to a chasm in part because of variations in practice and disparities in care from doctor to doctor, institution to institution, geographic region to geographic region, and socioeconomic group to socioeconomic group. Furthermore, it is estimated that it takes about 17 yr for new knowledge to be adopted into clinical practice.

In addition to appropriate care that patients do not receive, U.S. healthcare systems also deliver much care that is unnecessary and waste many resources in doing so. This overuse and waste is one key driver of the disproportionate costs of care in the United States compared with other developed countries’ delivery systems (in 2016, the United States spent about twice as much per capita, adjusting for gross domestic product (GDP), on healthcare compared to the average of peer wealthy nations). It is estimated that more than one quarter of all U.S. healthcare spending is waste. Gaps in appropriate care, combined with overuse and high costs, have driven conversations about the need to improve the value of care, which would mean better quality at lower overall costs. Choosing Wisely, an initiative initially sponsored by the American Board of Internal Medicine and subsequently endorsed by the American Academy of Pediatrics (AAP), asked medical societies to identify practices typically overused that clinicians could then make collective efforts to address.

Quality improvement (QI) science has become a predominant method
utilized to close gaps and improve value. Initially focused on improving performance and reliability in care processes, more recently, in part inspired by the Institute for Healthcare Improvement's **Triple Aim** approach, QI is being used to improve value for *populations* of patients by focusing more on *outcomes* defined by patients’ needs. The **Quadruple Aim** approach adds the 4th dimension of healthcare worker experience or *joy in work* to focus delivery systems on the need to enhance the resiliency of the clinical workforce in order to sustain high-value care approaches.

### What Is Quality?

The Institute of Medicine (IOM) defines *quality of healthcare* as “the degree to which healthcare services for individuals and populations increases the likelihood of desired health outcomes and are consistent with current professional knowledge.” This definition incorporates 2 key concepts related to healthcare quality: the direct relationship between the provision of healthcare services and health outcomes, and the need for healthcare services to be based on current evidence.

To measure healthcare quality, the IOM has identified *Six Dimensions of Quality*: **effectiveness**, **efficiency**, **equity**, **timeliness**, **patient safety**, and **patient-centered care**. Quality of care needs to be **effective**, which means that healthcare services should result in benefits and outcomes. Healthcare services also need to be **efficient**, which incorporates the idea of avoiding waste and improving system cost efficiencies. Healthcare quality should improve **patient safety**, which incorporates the concept of patient safety as 1 of the key elements in the Six Dimensions of Quality. Healthcare quality must be **timely**, thus incorporating the need for appropriate access to care (see Chapter 5). Healthcare quality should be **equitable**, which highlights the importance of minimizing variations as a result of ethnicity, gender, geographic location, and socioeconomic status (SES). Healthcare quality should be **patient centered**, which underscores the importance of identifying and incorporating individual patient needs, preferences, and values in clinical decision-making. In pediatrics, the patient-centered dimension extends to family-centeredness, so that the needs, preferences, and values of parents and other child caregivers are considered in care decisions and system design.

The IOM framework emphasizes the concept that all Six Dimensions of Quality need to be met for the provision of *high-quality* healthcare. Collectively,
these concepts represent quality in the overall value proposition of quality per cost. From the standpoint of the practicing physician, these 6 dimensions can be categorized into clinical quality and operational quality. To provide high-quality care to children, both aspects of quality—clinical and operational—must be met. Historically, physicians have viewed quality to be limited in scope to clinical quality, with the goal of improving clinical outcomes, while considering improving efficiency and patient access to healthcare as the role of healthcare plans, hospitals, and insurers. Healthcare organizations, which are subject to regular accreditation requirements, viewed the practice of clinical care delivery as the responsibility of physicians and limited their efforts to improve quality largely to process improvement to enhance efficiencies.

The evolving healthcare system requires physicians, healthcare providers, hospitals, and healthcare organizations to partner together and with patients to define, measure, and improve the overall quality of care delivered. Concrete examples of the evolving U.S. perspective include the widespread adoption of Maintenance of Certification (MOC) requirements by medical-certifying bodies, which require providers to engage in activities that improve care in their practices, and the core quality measurement features and population health incentives of the Patient Protection and Affordable Care Act (ACA) of 2010. The ACA also established the Patient-Centered Outcomes Research Institute (PCORI) to develop a portfolio of effectiveness and implementation research that requires direct engagement of patients and families to partner in setting research priorities, formulating research questions, and designing studies that will directly impact the needs of patients to improve the value of the research.

Framework for Quality

Quality is broader in scope than QI. The approach to quality includes 4 building blocks. First, the standard for quality must be defined (i.e., developing evidence-based guidelines, best practices, or policies that guide the clinician for the specific clinical situation). These guidelines should change based on new evidence. In 2000–2001 the AAP had published guidelines for care of children with attention-deficit/hyperactivity disorder (ADHD). Subsequently, in 2011, these were updated to highlight a greater emphasis on behavioral interventions rather than pharmacologic options based on new evidence. Similarly, the AAP has emphasized that guidelines evolve to include greater consideration of value in care, an example being the update to the clinical practice guideline for urinary
tract infection in 2011, which called for a decrease in the use of screening radiologic tests and prophylactic antibiotics in certain populations of children due to a lack of cost-effectiveness. Second, gaps in quality need to be closed. One key gap is the difference between the recommended care and the actual care delivered to a patient. Third, quality needs to be measured. Quality measures can be developed as measures for accountability and measures for improvement. Accountability measures are developed with a high level of demonstrated rigor because these are used for measuring and comparing the quality of care at the state, regional, or health system (macro) level. Often, accountability measures are linked to pay-for-performance (P4P) incentive arrangements for enhanced reimbursement at the hospital and individual physician level. In contrast, improvement measures are metrics that can demonstrate the improvement accompanying a discrete QI project or program. These metrics need to be locally relevant, nimble, and typically have not had rigorous field testing. Fourth, the quality measurement approach should be used to advocate for providers and patients. For providers, meeting quality goals should be a key aspect of reimbursement if the system is designed to incentivize high-value care. At the population level, quality measurement strategies should advocate for preventive and early childhood healthcare, improving the value of care by decreasing costs across a patient's life span.

Lastly, many quality measurement systems have attempted to be more transparent with clinicians and patients about costs of care. Because more direct costs have been shifted to patients and families through widespread adoption of high-deductible insurance plans (i.e., families experience lower up-front insurance coverage costs but pay for certain acute healthcare expenses out-of-pocket until the preset deductible is met), better awareness of costs has become a more effective driver of improvement in value, in part by reducing overuse.

Developing Guidelines to Establish the Standard for Quality

Guidelines need to be developed based on accepted recommendations, such as the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system for rating the quality and strength of the evidence, which is crucial for guideline development. Guidelines must adopt a high level of transparency in the development process. This is particularly relevant in the
pediatric setting, where there may be limited research using methods such as randomized controlled trials (RCTs), which would have a high level of rating from an evidence standpoint. Because guidelines and policies related to quality need to be interpreted for specific settings, they should not be interpreted as “standards of care.”

**Improving Quality**

The applied science of QI currently in use in healthcare is also firmly grounded in the classic scientific method of observation, hypothesis, and planned experimentation. There are 4 key features of the applied science of quality improvement: appreciation of systems, understanding variation, knowledge theory, and psychology of change. In addition to this theoretical framework, statistical analytic techniques evolved to better evaluate variable systems over time. While each derives key features from this applied scientific foundation, multiple QI methodologies are currently in use in healthcare. At their most parsimonious level, each method can be described as a 3-step model: *Data → Information → Improvement*. Quality needs to be measured. Data obtained from measurement needs to be converted into meaningful information that can be analyzed, compared, and reported. Information must then be *actionable* to achieve improvements in clinical practice and health systems’ processes.

**Model for Improvement**

The Model for Improvement is structured around 3 key questions: (1) What are we trying to accomplish? (2) How will we know that a change is an improvement? and (3) What change can we make that will result in improvement? Clarifying the first question, the *goal*, is critical and is often a step skipped by clinicians, who typically already have change ideas in mind. The second question is about defining measures, with an emphasis on practicality and efficiency. The third question is about defining testable ideas for improvement, which are subsequently tested using a framework of rapid cycle improvement, also known as the **plan-do-study-act (PDSA) cycle** (Fig. 4.1A). The PDSA cycle is typically aimed at testing small, care process changes in iterative, rapid cycles. After discrete testing periods, results are analyzed, and the next cycle of change testing is planned and implemented (i.e., multiple PDSA cycles, often called a PDSA *ramp*, build on previous learning from PDSAs; Fig. 4.1B).
Valuable information can be obtained from PDSA cycles that are successful, and those that are not, to help plan the next iteration of the PDSA cycle. The PDSA cycle specifically requires that improvements be data driven. Many clinicians attempt to make changes for improvement in their practice based on clinical intuition rather than on interpretation of empirical data.

![Diagram of the PDSA cycle](Image)

The Model for Improvement has been successfully used in the Vermont Oxford Network (VON) to achieve improvements in care in the neonatal intensive care unit (NICU) setting. The VON is a global network of
collaborating NICUs involved in several studies that have favorably impacted the care of newborns. An example of a successful VON QI effort is a project aimed at reducing rates of chronic lung disease in extremely-low-birthweight infants. Clinical teams participating in this improvement effort used special reports from the VON database, reviewed the available evidence with content faculty experts, and then identified improvement goals. The teams received QI training through conference calls and emails for 1 yr. This effort resulted in a 37% increase in early surfactant administration for preterm infants.

One successful QI collaborative using the improvement model in the outpatient setting is related to improvement in remission rates and reduction in systemic corticosteroid use among children with inflammatory bowel disease (IBD, Crohn disease or ulcerative colitis). This work was supported by the ImproveCareNow Network (https://improvecarenow.org/), a learning health system. A learning health system is a collaborative endeavor organized around communities of patients, clinicians, and researchers working together to integrate research with QI (i.e., knowledge dissemination and implementation) to improve care delivery while advancing clinical research. The network model leverages the inherent motivation of participants to engage and contribute in a collaborative manner. Participants are supported by development of standard processes, such as common approaches to data transfer, measurement, and reporting, as well as emphasis on data transparency, and share knowledge, tools, and resources to accelerate learning and facilitate uptake of useful innovations.

For the IBD network, outpatient gastroenterology practices standardized treatment approaches to align with existing evidence though QI interventions adapted to local circumstances, and therapeutic decisions for individual patients remained at the discretion of physicians and their patients. This network also developed methods to more fully engage patients, particularly adolescents, and their caregivers through the use of social media, which helped drive improvement in some of the clinical behavior change aspects of the work.

**Six Sigma**

Six Sigma is related to the reduction in undesirable variation in processes. There are 2 types of variations in a process. Random variation refers to the variation that is inherent in a process simply because the process occurs within a system. Random variation in processes is expected in any system. In contrast, special cause variation refers to nonrandom variation that can impact a process and
implies something in the system has been perturbed. For example, when tracking infection rates in a nursery, a sudden increase in the infection rates may be secondary to poor handwashing techniques by a new healthcare provider in the system. This would represent a special cause variation; once this provider's practice is improved, the system perturbation is resolved, and the infection rates will likely go back to the baseline level. Alternatively, improvement ideas are intended to perturb the system positively such that outcomes improve, ideally without exacerbating the variation in the system (Fig. 4.2 ). Six Sigma attempts to provide a structured approach to unwanted variations in healthcare processes. Six Sigma approaches have been successfully used in healthcare to improve processes in both clinical and nonclinical settings.

Lean Methodology

Lean methodology focuses on reducing waste within a process in a system. Fig. 4.3A illustrates the steps in the process of a patient coming to the emergency department (ED). After the initial registration, the patient is seen by a nurse and then the physician. In a busy ED, a patient may need to wait for hours before registration is complete and the patient is placed in the examination room. This wait time is a waste from the perspective of the patient and the family. Incorporating the registration process after placing the patient in the physician
examination room can save time and minimize waste (Fig. 4.3B). Lean methods have been successfully used in several outpatient and inpatient settings with resulting improvements in efficiency. Lean principles have also been adopted as a core strategy for many children's hospitals and health systems with the goal of improving efficiencies and reducing waste. These efforts can improve aspects of quality while also typically reducing costs.

**FIG. 4.3** A and B, Lean methodology—waste reduction.

**Management Sciences**

Management sciences, also known as operations management, stems from operations research and refers to the use of mathematical principles to maximize efficiencies within systems. Management sciences principles have been...
successful in many European healthcare settings to optimize efficiencies in outpatient primary care office settings, inpatient acute care hospital settings, and surgical settings including operating rooms, as well as for effective planning of transport and hospital expansion policies. Management sciences principles are being explored for use in the U.S. healthcare system; one technique, discrete event simulation, was used at the Children's Hospital of Wisconsin to plan the expansion of the pediatric critical care services with the goal of improving quality and safety. The discrete event simulation model illustrated in Fig. 4.4 depicts the various steps of the process in a pediatric intensive care unit (PICU). Patients stratified across 3 levels of severity (low, medium, high) are admitted to the PICU, are initially seen by a nurse and physician, then stay in the PICU with ongoing care provided by physicians and nurses, and finally are discharged from the PICU. The discrete event simulation model is a computer model developed using real estimates of numbers of patients, number of physicians and nurses in a PICU, and patient outcomes. Discrete event simulation models are created using real historical data, which allows testing the what if scenarios, such as the impact on patient flow and throughput by increasing the number of beds and/or changing nurse and physician staffing.
**DES Model**
- Mathematically depicts a 24-bed PICU
- Depicts the patient experience from admission to discharge
- Factors the staffing of physicians and nurses in the PICU using historical experience
- DES Model starts with baseline and runs computer iterations to identify predicted outcomes with changing patient flow and staffing
- Results of DES Model provide insight into predicted outcomes of changing bed/staffing assumptions

**Illustration of DES Model**

1. **Emergency triage before PICU**
2. **Time waiting for PICU admission**
3. **Nurse evaluation at PICU admission**
4. **Physician evaluation at PICU admission**
5. **Nurse and physician ongoing care during PICU stay**
6. **Average length of stay: 5.2 days**
7. **PICU discharge by nurse**
8. **Time waiting for PICU discharge**
9. **Nurse transfer out of PICU**

**Conclusions**
- Simply adding new PICU beds will not improve patient flow in itself
- Critical ratio between MDs, RNs, and beds in PICU adjusted for patient severity is needed to maximize patient flow, safety, and outcomes
Another management sciences technique, **cognitive mapping**, measures the soft aspects of management sciences, as illustrated in Fig. 4.5. Cognitive mapping highlights the importance of perceptions and constructs of healthcare providers and the way these constructs are linked in a hierarchical manner. Goals and aspirations of individual healthcare providers are identified by structured interviews and are mapped to strategic issues and problems, and options. By using specialized computer software, complex relationships can be identified to better understand the relationships between different constructs in a system. A discrete event simulation model views patient throughput based on numbers of beds, physicians, and nurses, and accounts for differences in patient mix. It does not account for many other factors, such as individual unit characteristics related to culture. By interviewing healthcare providers, cognitive maps can be developed that can help to better inform decision-making.

**Tools for Organizing Quality Improvement Theory and Execution**

QI efforts need to be organized around a theory of how the desired changes in outcome will be achieved. Multiple tools are available to help organize a QI
team's thinking and execution. These tools typically help teams organize work into discrete projects or phases, and some of them also help teams develop change ideas.

**Key driver diagrams (KDDs)** are a tool to organize the theory of learning that underpins a QI project (Fig. 4.6), using the Model for Improvement. Important aspects of a KDD include a statement of the specific aim or improvement goal, a list of the key themes, or drivers, that are theorized to require improvement in order to achieve the aim, and lastly a list of the discrete change ideas or initiatives to be tested to determine whether or not they affect discrete drivers, and therefore the overall aim. Since most system outcomes are driven by multiple factors, a KDD allows a QI team to depict a theory that addresses multiple factors. Similarly, Lean and Six Sigma projects use a tool called an A3, that in addition to organizing the theory of a project, also prompts teams to assess the current state, and consider timelines and personnel for planned change (examples available at https://www.lean.org/common/display).

![Diagram of Key Driver Diagram](image)

**FIG. 4.6** Key driver diagram: theory of how to achieve an aim.

There are additional QI tools to help assess the current state of a system to better understand how to improve it. One, the **failure modes and effects analysis (FMEA)**, also helps teams develop change ideas (Fig. 4.7). Starting with a map of the processes in the current system, FMEA then asks teams to investigate and brainstorm the many ways discrete processes can go wrong—the **failure modes**. Once failure modes are identified, teams begin to develop
discrete interventions or countermeasures to address the failures (see Chapter 5).
A similar tool, the fishbone or cause-and-effect diagram, is organized around key components in a system (e.g., people, material, machines) and helps teams catalog how deficiencies in each component can affect the overall outcome of a system.

A final key tool to help teams prioritize action is a Pareto chart, which organizes system deficiencies in terms of their prevalence (Fig. 4.8). A Pareto chart typically displays the individual prevalence of discrete problems, determined by baseline analysis of data, as well as the cumulative prevalence, helping teams see which problems should be addressed first, to maximize impact on the overall outcome.
Measuring Quality

Robust quality indicators should have clinical and statistical relevance. *Clinical relevance* ensures that the indicators are meaningful to patient care from the standpoint of patients and clinicians. *Statistical relevance* ensures that the indicators have measurement properties to allow an acceptable level of accuracy and precision. These concepts are captured in the national recommendations that quality measures must meet the criteria of being valid, reliable, feasible, and usable (Table 4.1). *Validity* of quality measures refers to the measure being an estimate of the true concept of interest. *Reliability* refers to the measure being reproducible and providing the same result if retested. It is important that quality measures are *feasible* in practice, with an emphasis on how the data to support the measures are collected. Quality measures must be *usable*, which means that they should be clinically meaningful. The *Agency for Healthcare Research and Quality* and the *National Quality Forum* have provided specific criteria to be considered when developing quality measures.

Usability

Measure is useful in clinical practice.

Quality indicators can be used to measure the performance within 3 components of healthcare delivery: structure, process, and outcome. **Structure** refers to the organizational characteristics in healthcare delivery. Examples of organizational characteristics are the number of physicians and nurses in an acute care setting and the availability and use of systems such as electronic health records. **Process** measures estimate how services are provided; examples are the percentage of families of children with asthma who receive an asthma action plan as part of their office visit and percentage of hospitalized children who have documentation of pain assessments as part of their care. **Outcome** measures refer to the final health status of the child; examples are risk-adjusted survival in an intensive care unit setting, birthweight-adjusted survival in the NICU setting, and functional status of children with chronic conditions such as cystic fibrosis.

It is important to distinguish between measures for accountability and measures for improvement. Measures, particularly measures for accountability that may be linked to attribution and payment must be based on a rigorous process (Fig. 4.9). This can be resource intensive and time-consuming. In contrast, measures for improvement serve a different purpose—to track incremental improvements linked to specific QI efforts. These may not undergo rigorous testing, but they have limited applicability beyond the specific QI setting.
Quality data can be quantitative and qualitative. **Quantitative** data includes numerical data, which can be *continuous* (patient satisfaction scores represented as a percentage with higher numbers indicating better satisfaction) or *categorical* (patient satisfaction scores from a survey using a Likert scale indicating satisfactory, unsatisfactory, good, or superior care). Data can also be *qualitative* in nature, which includes nonnumerical data. Examples of qualitative data can include results from open-ended surveys related to the satisfaction of care in a clinic or hospital setting.

Data measuring quality of care can be obtained from a variety of sources, which include chart reviews, patient surveys, existing administrative data sources (billing data from hospitals), disease and specialty databases, and patient registries, which track individual patients over time. Sources of data vary in terms of reliability and accuracy, which will influence *rigor* and therefore appropriate-use cases for the data; many national databases invest significant resources in implementing processes to improve data reliability and accuracy.

It is important to distinguish between databases and data registries. **Databases** are data repositories that can be as simple as a Microsoft Excel spreadsheet or as complex as relational databases using sophisticated servers and information technology platforms. Databases can provide a rich source of aggregated data for
both quality measurement and research. Data registries allow tracking individual patients over time; this dynamic and longitudinal characteristic is important for population health management and QI.

Data quality can become a significant impediment when using data from secondary sources, which can adversely impact the overall quality evaluation. Once data on the quality indicator have been collected, quality measurement can occur at 3 levels: (1) measuring quality status at one point in time (e.g., percent of children seen in a primary care office setting who received the recommended 2-year immunizations); (2) tracking performance over time (e.g., change in immunization rates in the primary care office setting for children 2 yr of age); and (3) comparing performance across clinical settings after accounting for epidemiologic confounders (e.g., immunization rates for children <2 yr of age in a primary care office setting stratified by race and SES as compared to the rates of other practices in community and national rates).

Pediatric quality measures are being developed nationally. Table 4.2 lists some currently endorsed pediatric national quality indicators.

### Analyzing Quality Data

Three approaches have been used for analyzing and reporting data. The classic approach from a research paradigm has been applied to quality data for statistically comparing trends over time, and differences before and after an intervention. P-values are interpreted as being significant if ≤0.05, which suggests that the likelihood of seeing a difference as extreme as observed has a probability of ≤5% (type I error). Another approach from an improvement science paradigm uses techniques such as run charts and control charts to identify special cause variation. In the context of quality improvement, special cause variation in the desired direction is the intent, and these analytic techniques allow improvers to quickly recognize statistically significant changes in system performance over time. Lastly, quality data also have been reported on an individual patient level. This has gained popularity in the patient safety arena, where identifying individual patient events in the form of descriptive analysis (stories) may be more powerful in motivating a culture of change than statistical reporting of aggregate data in the form of rates of adverse patient safety events (see Chapter 5).

### Comparing and Reporting Quality

There is an increasing emphasis on quality reporting in the United States. Many states have mandatory policies for the reporting of quality data. This reporting may be tied to reimbursement using the policy of P4P, which implies that
reimbursements by insurers to hospitals and physicians will be partially based on the quality metrics. P4P can include both incentives and disincentives. Incentives relate to additional payments for meeting certain quality thresholds. Disincentives relate to withholding certain payments for not meeting those quality thresholds. An extension of the P4P concept relates to the implementation of the policy of nonreimbursable hospital-acquired conditions, formerly called never events by the Centers for Medicare and Medicaid Services. CMS has identified a list of hospital-acquired conditions, which are specific quality events that will result in no payment for care provided to patients, such as wrong-site surgery, catheter-associated bloodstream infection (CA-BSI), and decubitus ulcers. This approach has not yet been widely implemented for pediatric patients.

Quality reporting is also being used in a voluntary manner as a business growth strategy. Leading U.S. children's hospitals actively compete to have high ratings in national quality evaluations that are reported in publications such as Parents (formerly Child) magazine and US News & World Report. Many children's hospitals have also developed their own websites for voluntarily reporting their quality information for greater transparency. Although greater transparency may provide a competitive advantage to institutions, the underlying goal of transparency is to improve the quality of care being delivered, and for families to be able to make informed choices in selecting hospitals and physicians for their children.

Quality measures may also be used for purposes of certifying individual physicians as part of the Maintenance of Certification process. In the past, specialty and subspecialty certification in medicine, including pediatrics, was largely based on demonstrating a core fund of knowledge by being successful in an examination. No specific evidence of competency in actual practice needed to be demonstrated beyond successful completion of a training program. There continues to be significant variations in practice patterns even among physicians who are board certified, which highlights the concept that medical knowledge is important, but not sufficient for the delivery of high-quality care. Subsequently, the American Board of Medical Specialties, including its member board, the American Board of Pediatrics, implemented the MOC process in 2010. Within the MOC process, there is a specific requirement (Part IV) for the physician to demonstrate the assessment of quality of care and implementation of improvement strategies as part of recertification in pediatrics and pediatric subspecialties. Lifelong learning and the translation of learning into practice are
the basis for the MOC process and an essential competency for physicians’ professionalism. There are also discussions to adopt a similar requirement for Maintenance of Licensure for physicians by state medical regulatory boards.

The Accreditation Council for Graduate Medical Education requires residency programs to incorporate QI curriculum to ensure that systems-based practice and QI are part of the overall competencies within accredited graduate medical training programs. One form of continuing medical education, **performance improvement**, is used for ongoing physician education. These initiatives require physicians to measure the quality of care they deliver to their patients, to compare their performance to peers or known benchmarks, and to work toward improving their care by leveraging QI methods. This forms a feedback loop for continued learning and improvement in practice.

Prior to comparing quality measures data both within and across clinical settings, it is important to perform risk adjustment to the extent that is feasible. **Risk adjustment** is the statistical concept that utilizes measures of underlying severity or risk so that the outcomes can be compared in a meaningful manner. The importance of risk adjustment was highlighted in the PICU setting many years ago. The unadjusted mortality rate for large tertiary care centers was significantly higher than that for smaller hospital settings. By performing **severity of illness** risk adjustment, it was subsequently shown that the risks in tertiary care, large PICUs were higher because patients had higher levels of severity of illness. Although this concept is now intuitive for most clinicians, the use of severity of illness models in this study allowed a mathematical estimate of patient severity using physiologic and laboratory data, which allowed for the statistical adjustment of outcomes. This permits meaningful comparisons of the outcomes of large and small critical care units. Severity of illness models and the concepts of statistical risk adjustment are most developed in pediatric critical care. However, these concepts are relevant for all comparisons of outcomes in the hospital settings where sicker patients may be transferred to the larger institutions for care, and therefore would be expected to have poorer outcomes than other settings with less sick patients.

Risk adjustment can be performed at 3 levels. First, patients who are sicker can be excluded from the analysis, thereby allowing the comparisons to be within homogeneous groups. Although this approach is relatively simple to use, it is limited in that it would result in patient groups being excluded from the analysis. Second, risk stratification can be performed using measures of patient acuity; for example, in the **All-Patient Refined Diagnosis-Related Group**
system, patients can be grouped or stratified into different severity criteria based on acuity weights. This approach may provide more homogeneous strata within which comparisons can be performed. Third, severity of illness risk adjustment can use clinical data to predict the outcomes for patient groups, such as the **Pediatric Risk of Mortality (PRISM)** scoring system in the PICU setting. In the PRISM score and its subsequent iterations, physiologic and laboratory perimeters are weighted on a statistical logistic scale to predict mortality risk within that PICU admission. By comparing the observed and expected outcomes (i.e., mortality or survival), a quantitative estimate of the performance of that PICU can be established, which can then be used to compare outcomes with other PICUs (standardized mortality ratio).

Risk adjustment systems have been effectively incorporated into specialty databases. For example, the **Virtual Pediatric Intensive Care Unit System (VPS)** represents the pediatric critical care database system in the United States. Comprising >100 PICUs and pediatric cardiac ICUs across the United States, as well as international PICUs, the VPS currently has >300,000 patients within its database. The VPS database emphasizes data validity and reliability to ensure that the resulting data are accurate. Data validity has been established using standard data definitions with significant clinical input. Data reliability is established using interrater reliability to ensure that the manual data collection that involves several data collectors within pediatric institutions is consistent. The PRISM scoring system is programmed into the VPS software to allow the rapid estimation of the severity of illness of individual patients. This in turn allows risk adjustment of the various outcomes, which are compared within institutions over time and across institutions for purposes of QI.

**Implications of the U.S. Healthcare Reform for Quality**

Regarding quality of healthcare for children, healthcare reform had 3 key implications. First, expanded insurance coverage optimized access and include expanded coverage for young adults to age 26 yr. Second, various initiatives related to quality, safety, patient-centered outcomes research, and innovation were implemented and funded. For example, the **Agency for Healthcare Research and Quality (AHRQ)** funded a national effort to establish 7 centers of excellence through the **Pediatric Quality Measurement Program (PQMP)** to
improve existing pediatric quality measures and create new measures that can be used by states and in a variety of other settings to evaluate quality of care for children. Third, reform advocated a paradigm shift in the existing model of healthcare delivery from vertical integration toward a model of horizontal integration. This has led to the creation and rapid growth of integrated delivery systems and risk-sharing relationships of accountable care organizations (ACOs). Population health outcomes from these changes remain uncertain, although it appears healthcare cost inflation may have slowed somewhat.

Another area of increasing emphasis is population health. This is important because it expands the traditional role of physicians to improve quality of care for individual patients also to improve the quality of care for larger populations. Populations can be defined by geographic constraints or disease/patient condition. Efforts to link payment and reimbursement for care delivery by physicians and health systems are being increasingly tied to measurable improvements in population health. To achieve a meaningful improvement in population outcome, physician practices will need to embrace the emerging paradigm of practice transformation, whose many facets include the adoption of a medical home, the seamless connectivity across the primary care and subspecialty continuum, and a strong connection between the medical and social determinants of healthcare delivery. To implement successful practice transformation, hospitals are increasingly adopting a broader view to evolve into healthcare systems that serve children across the entire range of the care continuum, including preventive and primary care, acute hospital care, and partnerships with community organizations for enhancing the social support structure. In addition, new risk-sharing payment models are evolving, resulting in the growth of entities such as ACOs, which represent a financial risk-sharing model across primary and subspecialty care and hospitals.

Information Technology and Quality Improvement

Health information technology (HIT) is a critical component in the effort to improve quality. HIT includes electronic health records, personal health records, and health information exchange. The purpose of a well-functioning electronic health record is to allow collection and storage of patient data in an electronic form, to allow this information to be efficiently provided to clinicians and
healthcare providers, to have the ability to allow clinicians to enter patient care orders through the computerized physician order entry, and to have the infrastructure to provide clinical decision support that will improve physician decision-making at the individual patient level. The **personal health record** allows patients and families to be more actively engaged in managing their own health by monitoring their clinical progress and laboratory information, as well as to communicate with their physicians to make appointments, obtain medications, and have questions answered. Appropriate, timely, and seamless sharing of patient information across physician networks and healthcare organizations is critical to quality care and to achieve the full vision of a medical home for children. **Health information exchange** allows the sharing of healthcare information in an electronic format to facilitate the appropriate connections between providers and healthcare organizations within a community or region.

**Expanding Individual Quality Improvement Initiatives to Scale**

Despite the success of individual QI projects, the overall progress to achieve large-scale improvements to reach all children across the spectrum of geographic location and SES remains limited. This contributes to the health disparities that persist for children, with significant differences in access and quality of care. A potential factor that limits the full impact of QI is the lack of strategic alignment of improvement efforts with hospitals, health systems, and across states.

This challenge can be viewed from a system standpoint in being able to conduct and expand QI from a micro level (individual projects), to the meso level (regional), to the macro level (national and international). The learning from individual QI projects for addressing specific challenges can be expanded to the regional level by ensuring that there is optimal leadership, opportunity for education, and adoption of improvement science (Fig. 4.10). To further expand the learning to a national and international level, it is important to leverage implementation science to allow a strategic approach to the identification of the key factors that influence success. To leverage fully the synergies in order to impact the quality of care delivered to children, it is important for national and international healthcare organizations to collaborate effectively from a knowledge management and improvement standpoint (Table 4.3).

American Board of Internal Medicine Foundation. *Choosing Wisely Campaign*. http://www.choosingwisely.org/

e1041.
Guidelines for consumer-focused public reporting (PowerPoint file).

Children may be harmed by the healthcare that aims to make them better. Such harms include central line–associated bloodstream infections (CLA-BSIs) and medication overdoses. In 1991 the Harvard Medical Practice Study reviewed a large sample of adult medical records from New York State and found that adverse events occurred in an estimated 3.7% of hospitalizations. Most events gave rise to serious disability, and 13.6% led to death. The Institute of Medicine (IOM) estimated that as many as 98,000 Americans per year die in the hospital from medical errors.

Although fewer data are available for children, it is clear that children experience substantial healthcare-related harm. Nationally, hospitalized children experience approximately 1,700 CLA-BSIs and 84,000 adverse drug events each year. While the evidence is less robust, and not without controversy, substantial progress has been reported, particularly in healthcare-associated conditions (HACs). Less strong epidemiologic estimates are available for adverse events in the ambulatory environment, but these events are likely more common than reported.

The Solutions for Patient Safety (SPS) collaborative started with the 8 children's hospitals in Ohio and has expanded to include >130 hospitals across the United States and Canada (http://www.solutionsforpatientsafety.org ). The collaborative uses a learning network model to pursue the aim of eliminating serious harm across all children's hospitals. The American Academy of Pediatrics (AAP), Children's Hospital Association, and The Joint Commission (TJC) also have convened improvement collaboratives in pediatric safety. In addition, healthcare has recognized the high rates of healthcare worker injury and the critical role that the safety of healthcare providers plays in outcomes, burnout, and safe patient care.
Error vs Harm

Clinical leaders, improvers, and researchers often employ measures of error and harm to understand and improve safety, but the differences between these 2 measures can lead to confusion. **Errors** occur when a physician, nurse, or other member of the healthcare team does the wrong thing (*error of commission*) or fails to do the right thing (*error of omission*); errors of omission (e.g., not arriving at the right diagnosis) are considerably more difficult to measure. **Harm**, as defined by the Institute for Healthcare Improvement, is “unintended physical injury resulting from or contributed to by medical care (including the absence of indicated medical treatment), that requires additional monitoring, treatment, or hospitalization, or that results in death.” Most errors in healthcare do not lead to harm; harm may be both preventable and nonpreventable (Fig. 5.1). A physician may erroneously fail to add a decimal point in a medication order for an aminoglycoside antibiotic, ordering a dose of 25 mg/kg rather than the intended dose of 2.5 mg/kg of gentamicin. If this error is caught by the computerized order entry system or the pharmacist, this would be an error with no resultant harm. If this error was not reviewed and caught by a pharmacist and reached the patient, who suffered acute kidney injury, this would be preventable harm since evidence shows that pharmacist review can reduce the risk of these errors 10-fold. Alternatively, if a patient received a first lifetime dose of amoxicillin and had anaphylaxis requiring treatment and hospital admission, this harm would be considered nonpreventable since no valid predictive tests are available for antibiotic allergy. Furthermore, the concept of latent risk, independent of any actual error, is inherent in any system where patients can be harmed. Among errors that do not lead to harm, **near misses** that do not reach patients—or high-risk situations that do not lead to harm because of good fortune or mitigation—are important learning opportunities about safety threats.
Several classification systems exist to rate harm severity, including the NCC-MERP for medication-related harm and the severity scales for all-cause harm. **Serious safety events (SSEs)** are deviations from expected practice followed by death or severe harm. The SPS collaborative has SSE elimination as its primary goal. **Sentinel events** or **never events**, such as a wrong-site surgery, are also targets of external reporting as well as for elimination through quality improvement (QI) initiatives (see Chapter 4). Increasingly, health systems are using a composite serious harm index, which combines a variety of preventable HACs (e.g., CLA-BSIs) to examine system safety performance over time across various patient populations and sites of care.

### Safety Frameworks

Safety frameworks are conceptual models and tools to help clinicians, improvers, and researchers understand the myriad contributors to safe healthcare and safety events. Healthcare is delivered in a complex system with many care providers and technologies, such as electronic health records and continuous physiologic monitors. The Donabedian framework, which links structure, process, and outcome, can be a very useful tool. The **Systems Engineering Initiative for Patient Safety (SEIPS)** model, developed by human factors engineers and cognitive psychologists at the University of Wisconsin–Madison, provides more detailed tools to understand the work system and the complex interactions between people and task work and technology and the environment. The SEIPS 2.0 model more prominently includes the patient and family in co-
producing care outcomes. Other available safety frameworks include those from the Institute for Healthcare Improvement. The “Swiss cheese” model illustrates how an organization's defenses prevent failures from leading to harm, but only when the holes of the Swiss cheese slices, representing different components of the system, do not line up properly.

Traditionally, safety science and improvement have focused on identifying what went wrong (near misses, errors, and harm) and then tried to understand and improve the system of care that led these events. There is increasing focus on what goes right. This framework, called Safety-II to contrast with Safety-I and its focus on learning from what goes wrong, brings focus on the much greater number of things that go right and how people act every day to create safety in complex and unpredictable systems. Safety-II seeks to learn from people, the greatest source of system resilience, particularly in the midst of high levels of risk and stress, as often seen in healthcare.

**Identifying and Analyzing Harm, Errors, and Latent Threats**

Health systems use a toolbox of processes to discover, understand, and mitigate unsafe conditions.

**Incident Reporting Systems**

Many health systems and hospitals offer employees access to a system to report errors, harms, or near misses. Most frequently, these are anonymous so that healthcare workers feel safe to submit an event in which they may have been involved, or when the harm involved someone in a position of authority. Ideally, these systems would facilitate smooth and efficient entry of enough information for further review but avoid excessive burden of time or cognitive load on the reporter. Incident reporting systems likely work best in the presence of a strong safety culture and when employees have some confidence that the event will be reviewed and actions taken. From studies that use more proactive assessment of harm and error, it is clear that incident reports dramatically underreport safety events. With this being the chief limitation, other mechanisms must also be in place to learn about safety. Trigger tool systems have been evaluated in pediatrics with encouraging results. These systems use triggers, such as the
need for an antidote to an opioid overdose or the transfer of a patient to higher-level care, to facilitate targeted medical record review by trained nurses and physicians and elucidate any errors or system risks.

Simulation
Simulation is an excellent tool to better understand system and latent threats. High-fidelity simulation can allow clinicians to practice technical skills such as intubation in a safe environment; perhaps more importantly, simulation can help clinical teams improve non-technical skills such as using closed-loop communication and sharing a mental model (e.g., a team leader states, “I believe this patient has septic shock. We are rapidly infusing fluids and giving antibiotics. Blood pressure is normal for age. What other thoughts does the team have?”). It is often easier and more feasible to give feedback in a simulated scenario vs a real event.

Low-fidelity simulation on the hospital unit or in the clinic does not require costly simulated patients and may have advantages in identifying latent threats in the system. For example, a simulated scenario on a medical-surgical unit might identify that nurses do not know where to find a mask for continuous positive airway pressure (CPAP) to support an infant with respiratory failure. Identifying—and then mitigating—this latent threat in a simulated environment is preferable to doing so in an acutely deteriorating child.

Event Analysis
Several types of event analysis, including root cause analysis, apparent cause analysis, and common cause analysis, can help teams understand—and later mitigate—the causes of adverse events. Each model has its own strengths and weaknesses. Root cause analysis (RCA) is a useful, robust, and time-intensive process to ascertain the most fundamental, or root, causes of a safety event. TJC has required the use of RCA on sentinel events since 1997. Most health systems reserve this methodology primarily for sentinel events because RCAs can take months to complete and require convening a multidisciplinary team of experts. The safety event and its antecedents are reviewed in detail with a focus not on human behavior but instead on systems, hazards, and latent errors. The RCA team works to go beyond the event (e.g., enteral formula feeds connected to and administered through central line) to the proximal causes (e.g., “feeding tube and
intravenous tubing are visually identical and are easily attached”) and root cause (e.g., “organization lacks a system to assess human factors risks as new equipment is procured and put into practice”). When root causes are identified and tied to robust improvement action plans, safety can be substantially improved. In addition to the time-intensive nature of RCAs, hindsight bias is a risk and needs to be managed carefully by the team. Additional challenges with RCAs include the potential to overfit solutions —designing protocols or procedures that may have reduced the risk of the specific safety event reviewed but also introduce new problems and increase the probability of other safety threats—as well as difficulties in spreading solutions to different care areas that often have different needs, processes, and goals.

Apparent cause analysis, common cause analysis, and failure modes and effects analysis are complementary learning methods. Apparent cause analysis is performed by a smaller team and is feasible for events that occur often (e.g., the wrong medication is sent from pharmacy). Apparent cause analysis uses a multidisciplinary team to look for proximal causes. Importantly, in each analysis the team works to determine how likely it is that such an event will occur in the future and how widespread the proximate causes are in the microsystem. As with apparent cause analysis, common cause analysis seeks to aggregate learning across events. A similar common cause, such as poor handoff procedures, may lead to different safety events (e.g., a missed lab check and a delayed diagnosis); common cause analysis aids leaders in determining this. Failure mode and effects analysis (FMEA) is a powerful tool that clinicians use to describe a process and identify failure modes, or ways in which each step might fail. A more robust and quantitative form of FMEA rates potential failure modes in 3 categories: probability of event occurring, its severity, and its ability to be detected. The product of these, called the risk priority number, can help a team identify which failure modes may lead to the greatest harm and thus which to target first.

**Safety Culture**

A broad and supportive safety culture likely drives both patient and employee safety outcomes. An organization with a mature safety culture fosters a culture of learning and treats errors as opportunities to improve the system, rather than as the personal failures of individual clinicians. Just culture differentiates the mistakes and wrong decisions that a clinician makes commensurate with their
training and experience from willful violations and gross or repeated patterns of negligence. A safety culture prioritizes clear and consistent communication and teamwork. Several tools are available to measure safety culture, including the Safety Attitudes Questionnaire and the Agency for Healthcare Research and Quality (AHRQ) surveys on Patient Safety Culture. A strong safety culture supports transfer of responsibility within disciplines at handoffs and across disciplines (e.g., when a nurse is calling a physician with a new concern). Structured communication tools such as the Situation-Background-Assessment-Recommendation (SBAR) approach are valued in a safety culture, as are safety behaviors such as “repeat back or write back,” when a critical lab result is shared and repeated back by the receiving clinician. A safety culture also promotes teamwork and aims to ease authority gradients. Teamwork training can occur in simulation or in the clinical system. TeamSTEPPS (Strategies and Tools to Enhance Performance and Patient Safety) is a set of teamwork tools developed by AHRQ and the U.S. Department of Defense. It is an evidence-based training that facilitates learning in communication, leadership, situation monitoring, and mutual support.

Authority gradients are quite real in healthcare, and traditional medical culture may have done much to drive these. In a culture of safety, both junior and senior clinicians work together across disciplines to speak up when concerns are identified, to ask questions, and not to proceed if there is uncertainty about safe patient care. Unit/clinic and health system leaders have a critical role in supporting this culture, orienting new employees to its importance, and stepping in if authority gradients or disruptive behaviors contribute to safety events or unsafe conditions.

**Reliability Science and High-Reliability Organizations**

*Reliability* in healthcare is defined as the measurable capability of a process, procedure, or health service to perform its intended function in the required time under commonly occurring conditions. Most processes in healthcare organizations currently perform at Level 1 reliability, meaning a success rate of only 80–90%. To achieve Level 2 performance (≤5 failures/100 opportunities), processes must be intentionally designed with tools and concepts based on the principles of human factors engineering and reliability science. These
processes include creating intentional redundancy, such as independent verification on high-risk medication dosing, and making the default action the desired action based on evidence, such as a default to an influenza vaccination for high-risk patients with asthma. Performance at Level 3 (≤5 failures/1,000 opportunities), requires a well-designed system with low variation and cooperative relationships and a state of “mindfulness,” with attention to processes, structure, and their relationship to outcomes.

Healthcare can learn important safety lessons from disciplines such as human factors engineering and cognitive psychology. Industries that better leverage learnings from these disciplines—and robustly identify and mitigate threats and use simulation—including commercial aviation and nuclear power, termed high-reliability organizations. These organizations achieve exemplary safety records under dynamic and high-risk conditions through consistent application of 5 tenets: (1) a preoccupation with failure;—surprises and errors are thought of as learning opportunities, and learnings spread quickly through the organization; (2) reluctance to simplify interpretations—serious safety events receive an RCA; perspective of multiple stakeholders solicited on other safety events; (3) sensitivity to operations—proactive assessments and huddles target risks to patients and the organization; (4) a commitment to resilience—errors do not disable, and high-risk, uncommon scenarios are negotiated; and (5) deference to expertise—leaders defer to front-line experts when their knowledge is required.

### Serious Harm Events and Healthcare-Associated Conditions

Substantial improvement in patient safety has occurred through improvement teams targeting serious harm events. The serious harm event rate is a composite metric that groups preventable HACs into 1 number (usually a rate per at-risk patient-days), so that an organization or collaborative can track progress on a variety of conditions with 1 metric and chart. Table 5.1 lists frequently targeted HACs. Commonalities among successful improvement teams targeting these HACs include multidisciplinary team membership, clear outcome definitions and measurement, learning systems around each HAC, and attention to both process and outcome measures. Much of the successes with CLA-BSIs was associated with targeted improvements to reliably adhere to a line insertion bundle and a line maintenance bundle. Fig. 5.2 illustrates coincident
improvements in process measures and outcomes measure in a hypothetical CLA-BSI project. In this case, after improvement interventions targeted 2 process measures known to be important in CLA-BSI risk—the line insertion and the line maintenance bundles—the QI team saw improvement in both measures and coincident reduction in CLA-BSIs.

### Table 5.1

Common Healthcare-Associated Conditions (HACs) Targeted in Quality Improvement Efforts with Interventions

<table>
<thead>
<tr>
<th>HAC</th>
<th>DEFINITION</th>
<th>COST PER EVENT</th>
<th>POTENTIALLY EFFECTIVE INTERVENTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Central line–associated bloodstream infections</td>
<td>Laboratory-confirmed bloodstream infection with central line in place at time of or 48 hr before onset of event (details at <a href="https://www.cdc.gov/nhsn">https://www.cdc.gov/nhsn</a>)</td>
<td>$55,646</td>
<td>Line insurance bundle (e.g., handwashing, chlorhexidine scrub), maintenance bundle (catheter care, change dressing, discuss daily if catheter is needed)</td>
</tr>
<tr>
<td>Catheter-associated urinary tract infections</td>
<td>Urinary tract infection where an indwelling urinary catheter was in place &gt;2 days on day of event (details at <a href="https://www.cdc.gov/nhsn">https://www.cdc.gov/nhsn</a>)</td>
<td>$7,200</td>
<td>Protocols for reviewing and removing catheters daily, clear indications for inserting catheters, physician champions, audit and feedback of data</td>
</tr>
<tr>
<td>Adverse drug events</td>
<td>Harm associated with any dose of a drug (details at <a href="http://www.nccmerp.org/types-medication-errors">http://www.nccmerp.org/types-medication-errors</a>)</td>

</table>

IV, Intravenous line.
FIG. 5.2  Quality improvement interventions targeted process improvement in the A, line insertion bundle, where performance improved from 46% to 95%), and B, line maintenance bundle, where performance improved from 13% to 66%. Coincident with the improved bundle performance, the rate of
CLA-BSIs fell from 17.6 to 2.5 per 1,000 line-days.

A safety culture and experienced improvement teams are consistent drivers of success. A learning network model, as used in SPS, is effective in bringing project teams (e.g., groups with shared charters to reduce catheter-associated urinary tract infections) together from different hospitals to discuss lessons learned and common barriers faced and negotiated.

Safety Opportunities and Gaps

In addition to HACs, several other safety events are the targets of active study and improvement. Both the unrecognized clinical deterioration of hospitalized children and the poor handoffs across multiple stakeholders lead to substantial and preventable harm. Human factors interventions, such as timeouts, are also improving surgical safety.

Clinical Deterioration

The deterioration of hospitalized patients is rarely a sudden and unpredictable event; rather, it is preceded by abnormal vital signs and concerns from patients, families, and providers. Rapid response systems are designed to detect deterioration and then deploy teams with critical care expertise to provide treatment or escalate care to an intensive care unit (ICU). While there remains variation in how these teams are activated and how the rapid response teams are staffed (e.g., nurse vs physician led), all U.S. children's hospitals have some version of a rapid response system. The initiation of rapid response teams is associated with a significant reduction in codes outside the ICU and in-hospital mortality.

Pediatric early warning scores (PEWS) are used in most large children's hospitals to identify deteriorating patients by assigning scores based on the degree of abnormality in different body systems. Different versions of PEWS are often employed, but all include scores driven by age-based vital signs as well as nursing assessments in areas such as mental status and perfusion. Importantly, PEWS take these diverse exam elements and combine them into a single score, which when coupled with clear, expected actions (e.g., evaluation by physician at score of 5, evaluation by rapid response team at score of 7) may better detect deterioration and improve safety outcomes.
PEWS are one method of improving a clinician's *situation awareness*, the sense of what is going on around the clinician, the notion of what is important, and the anticipation of future consequences. Maintaining situation awareness can be challenging in dynamic, high-risk environments such as healthcare. Work at several children's hospitals to improve situation awareness has been associated with sustained and significant reductions in unrecognized clinical deterioration. This improvement work first designed systematic and proactive identification of high-risk *watcher* patients, those a nurse or physician felt were close to the edge of deterioration. High-risk patients are discussed at multidisciplinary bedside “huddles” and specific treatment plans and predictions outlined. Concerns are more fully addressed through the rapid response team as well as hospital-wide safety huddles and safety rounds. To gain a better sense of organization safety and performance threats, many hospitals in the SPS collaborative employ a daily safety or operations brief, where leaders from a variety of service lines (e.g., inpatient, pharmacy, perioperative care) can discuss unexpected events and rapidly develop solutions and follow-up plans to mitigate emerging threats that cross disciplines.

**Handoffs/I-PASS**

There is a growing evidence base on the consequences of poor handoffs and on complex interventions to improve handoffs and resultant safety outcomes. The best-studied handoff is resident-to-resident shift handoff in teaching hospitals. Use of the **I-PASS** mnemonic—i llness severity, p atient summary, a ction list, s ituation awareness and contingency planning, and s ynthesis by receiver—and the surrounding educational quality improvement curriculum was associated with a significant 23% reduction in medical errors and 30% reduction in adverse events in a 9-hospital study. Related work has described improved communication with work targeting ICU-to-floor, operating room–to-ICU, and inpatient medical team–to–primary care handoffs.

**Surgical Safety**

Initially, in response to the problem of wrong-patient or wrong-site surgeries, perioperative leaders have developed a set of safety strategies often termed the tenets of surgical safety, which are endorsed by the World Health Organization ([http://www.who.int/patientsafety/safesurgery](http://www.who.int/patientsafety/safesurgery)). The tenets are implemented as
several discrete checklists at key points, or “timeouts,” in the workflow around a procedure or surgery. Several studies have demonstrated reduced harm to patients, and surgical checklists are adopted widely throughout developed and developing world surgical and procedural environments. Typically, checklists are used at 3 key times during a procedure: before induction of anesthesia, before skin incision or insertion of a device into any body cavity or orifice, and before a patient leaves the procedural area or operating room. Key aspects of the impact of this approach include multidisciplinary active participation, visual display of the checklist or other key tools as references, and attention to hierarchies and team-based communication. An evolving area of surgical and procedural safety is the use of simulation and video-based procedure review to improve surgical technique and perioperative team function and identify latent threats.

**Ambulatory Safety**

Adverse drug events and medication dosing errors are the best-studied safety events in the outpatient environment. A study of children receiving chemotherapy used direct observation by a trained nurse at home and found approximately 70 errors per 100 patients, many of which were serious or significant. Families often make dosing errors in administering liquid medications, particularly when using kitchen spoons rather than dosing syringes. A health literacy–informed pictogram reduces the rates of these errors. Dosing errors and nonadherence also can occur in cancer care, epilepsy, and transplant settings. Additional ambulatory safety threats include delays in diagnosis or treatment caused by mishandling of lab or imaging results and failures in care coordination.

**Occupational Safety**

The provision of healthcare can be a dangerous profession, with injury rates that surpass those of coal miners. The magnitude of this challenge and efforts to improve workplace safety have gained considerable attention the last several years. Nurses and physicians still typically view a needlestick injury or back strain from lifting a patient as simply “part of the job.” A culture of safety should include employee safety, and health systems should have mechanisms for employees to report injuries, near misses, and threats. Focused improvement efforts might include the roll-out of safer needle systems, education on safe
processes, and easy access to lifts for larger children with limited mobility. Violence and patient interaction injuries, often from children with psychiatric disease or developmental disabilities, are a growing source of harm to clinicians.

Emerging Areas of Safety Research and Improvement

**Diagnostic error** is recognized as an increasingly common and impactful event. There are 2 systems of clinical decision-making. **System 1** is fast, instinctual, and largely unconscious. **System 2** is slow, effortful, and calculating. System 1 and its *heuristics* or *biases* allows for quick—almost automatic—decision-making, often by associating new information with existing patterns or beliefs (e.g., that red object on right side of road is a stop sign; I should stop). However, system 1 thinking can be dangerous in diagnostic thinking, particularly when new data are unconsciously made to fit the preconceived pattern, and are not seen as disconfirming. Many current efforts aim to better understand how well-described cognitive biases (e.g., premature closure, availability bias) play out in clinical care, and what system-based strategies can mitigate their effects (Tables 5.2 to 5.4). Diagnostic error is often an error of omission, making it difficult to measure or to produce valid epidemiologic estimates of its incidence. Despite this, many health systems are pursuing research and improvement to move clinicians from system 1 to system 2 thinking, such as being explicit on uncertainty (e.g., patients admitted from ED as “diagnosis unknown”) or using decision aids to prompt revisiting provisional diagnoses (Table 5.5).

### Table 5.2

**Cognitive Biases Related to Heuristic Failure**

<table>
<thead>
<tr>
<th>BIASES</th>
<th>DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchoring</td>
<td>Locking into a diagnosis based on initial presenting features, failing to adjust diagnostic impressions when new information becomes available.</td>
</tr>
<tr>
<td>Confirmation bias</td>
<td>Looking for and accepting only evidence that confirms a diagnostic impression, rejecting or not seeking contradictory evidence.</td>
</tr>
<tr>
<td>Diagnostic momentum</td>
<td>Perpetuating a diagnostic label over time, usually by multiple providers both within and across healthcare systems, despite the label being incomplete or inaccurate.</td>
</tr>
<tr>
<td>Expertise bias/yin-yang out</td>
<td>Believing that a patient who has already undergone an extensive evaluation will have nothing more to gain from further investigations, despite the possibility that the disease process or diagnostic techniques may have evolved so as to allow for appropriate diagnosis.</td>
</tr>
<tr>
<td>Overconfidence</td>
<td>Believing one knows more than one does, acting on incomplete information or hunches, and</td>
</tr>
</tbody>
</table>
bias | prioritizing opinion or authority, as opposed to evidence.
---|---
Premature closure | Accepting the first plausible diagnosis before obtaining confirmatory evidence or considering all available evidence. “When the diagnosis is made, thinking stops.”
Unpacking principle | Failing to explore primary evidence or data in its entirety and subsequently failing to uncover important facts or findings, such as accepting a biopsy report or imaging study report without reviewing the actual specimen or image; especially important in undiagnosed and rare diseases.

### Table 5.3

<table>
<thead>
<tr>
<th>BIASES</th>
<th>DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Affective bias</td>
<td>Allowing emotions to interfere with a diagnosis, either positively or negatively; dislikes of patient types (“frequent flyers”).</td>
</tr>
<tr>
<td>Appeal to authority</td>
<td>Deferring to authoritative recommendations from senior, supervising, or “expert” clinicians, independent of the evidentiary support for such recommendations.</td>
</tr>
<tr>
<td>Ascertainment bias</td>
<td>Maintaining preconceived expectations based on patient or disease stereotypes.</td>
</tr>
<tr>
<td>Attribution error</td>
<td>Placing undue importance on the perceived internal characteristics or motivations of others, whether they are the patient, the patient's family, or other members of the evaluation team.</td>
</tr>
<tr>
<td>Countertransference</td>
<td>Being influenced by positive or negative subjective feelings toward a specific patient.</td>
</tr>
<tr>
<td>Outcome bias</td>
<td>Minimizing or overemphasizing the significance of a finding or result, often based on subjective feelings about a patient, a desired outcome, or personal confidence in one's own clinical skills. The use of “slightly” to describe abnormal results.</td>
</tr>
<tr>
<td>Psych-out bias</td>
<td>Maintaining biases about people with presumed mental illness.</td>
</tr>
</tbody>
</table>

### Table 5.4

<table>
<thead>
<tr>
<th>BIASES</th>
<th>DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability bias</td>
<td>Basing decisions on the most recent patient with similar symptoms, preferentially recalling recent and more common diseases.</td>
</tr>
<tr>
<td>Base-rate neglect</td>
<td>Prioritizing specific information (e.g., a lab value) pertaining to a case while ignoring general base rate information about the prevalence of disease in populations (pre-test probability).</td>
</tr>
<tr>
<td>Framing effect</td>
<td>Being influenced by how or by whom a problem is described or by the context in which the evaluation takes place.</td>
</tr>
<tr>
<td>Frequency bias</td>
<td>Believing that common things happen commonly and usually are benign in general practice.</td>
</tr>
<tr>
<td>Hindsight bias</td>
<td>Reinforcing diagnostic errors once a diagnosis is discovered despite these errors. May lead to a clinician overestimating the efficacy of his or her clinical reasoning and may reinforce ineffective techniques.</td>
</tr>
<tr>
<td>Posterior probability error</td>
<td>Considering the likelihood of a particular diagnosis in light of a patient’s chronic illness. New headaches in a patient with a history of migraines may in fact be a tumor.</td>
</tr>
<tr>
<td>Representative bias</td>
<td>Basing decisions on an expected typical presentation. Not effective for atypical presentations.</td>
</tr>
<tr>
<td>Bias</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Overemphasis</td>
<td>Overemphasis on disease-diagnostic criteria or “classic” presentations. “Looks like a duck, quacks like a duck.”</td>
</tr>
<tr>
<td>Sutton’s slip</td>
<td>Ignoring alternate explanations for “obvious” diagnoses (Sutton’s law is that one should first consider the obvious).</td>
</tr>
<tr>
<td>Thinking in silo</td>
<td>Restricting diagnostic considerations to a particular specialty or organ system. Each discipline has a set of diseases within its comfort zone, which reduces diagnostic flexibility or team-based communication.</td>
</tr>
<tr>
<td>Zebra retreat</td>
<td>Lacking conviction to pursue rare disorders even when suggested by evidence.</td>
</tr>
</tbody>
</table>

**Table 5.5**

**Solutions to Avoid Diagnostic Errors**

1. Enhancing foundational knowledge in medical education
   - Teach symptoms and their differential pathophysiology, not just diseases.
   - Emphasize red flags and must-not-miss diagnoses.

2. Minimizing errors related to heuristic failure
   - Build understanding of system 1 and system 2 thought processes and the risks of heuristic failure.
   - Actively model and encourage counterfactual reasoning and hypothesis generation to enhance system 2 skills.

3. Mitigating errors of attribution
   - Increase awareness of biases toward specific patients by promoting self-reflection.
   - Use a team-based approach and diagnostic strategies that actively dispel biases.

4. Avoiding errors of context
   - Solicit input across a variety of specialties when appropriate.
   - Consciously acknowledge the risk of thinking in silo and actively seek explanations outside one's specialty.

5. Optimizing data gathering, analysis, and hypothesis generation
   - Develop differential diagnoses based on pathophysiology; consider alternatives and competing options.
   - Realize that diagnostic criteria for certain diseases do not account for atypical disease manifestations.
   - Rely on objective individual data, not just disease prevalence rates, when considering the pretest likelihood of a particular diagnosis.
Avoid diagnostic momentum and question-accumulated diagnostic labels, regardless of who applied the label.

6. Improving hypothesis testing
   • Know the limitations of laboratory tests (i.e., false positives and negatives).
   • Do not be so quick to “rule out” a diagnosis: consider the posttest likelihood of disease in terms of a probabilistic analysis that applies specifically to the patient.
   • Acknowledge that the initial “working” diagnosis may not always be the final diagnosis.
   • Rely on evidence-based data and avoid authority- or overconfidence-based errors.
   • Recognize that diagnosis is an iterative and interactive process that should not be bounded by premature closure or anchoring. Be open to both confirmatory and nonconfirmatory data.
   • Both know and accept what you do not know.

7. Critical solutions for complex and undiagnosed and rare disease patients
   • Maintain healthy skepticism, especially with patients who come prediagnosed.
   • Analyze historical diagnostic data methodically and thoroughly and unpack all data completely. Examine actual studies, such as tissue specimens and imaging investigations, and do not rely on written reports.
   • Question the working diagnosis when findings or the clinical course does not fit.
   • Realize that patients can have more than one disease process.
   • Incorporate all data and avoid minimizing the significance of abnormal results. Do not ignore contradictory clinical, laboratory, or imaging data.
   • Never say “never” or “it cannot be.”
   • Use a systematic team-based approach to enhance debiasing, broaden the collective knowledge base, and minimize context-related errors.
   • Be aware that patients with undiagnosed and rare diseases may have an atypical or rare manifestation of a recognizable common disease, or may have a rare disease.
   • Use extensive literature review and search strategies based on the
patient's phenotype and individual findings and hypotheses.

**Alarm fatigue**, when a healthcare provider is subject to so many interruptions that a potentially relevant alarm is not heard, is also an area of active research and improvement. In the hospital, many physiologic monitor alarms occur each day (up to 400 per patient in some environments), and nurses exposed to a high volume of alarms respond more slowly to them. Interventions currently being studied include removing monitors from patients unlikely to benefit from them and designing smart alarms that alert only when certain scenarios occur (e.g., bradycardia in context of hypoxia). Particularly in the case of bronchiolitis, the overuse of pulse oximetry monitors likely contributes to **overdiagnosis** — the identification of an existing abnormality but whose detection will have no net benefit for the patient. Overdiagnosis of hypoxemia in children with bronchiolitis may contribute to hospital admissions, prolong length of stay, and subject children to hospital-related harm.

**Alert fatigue** is related to alarm fatigue but refers to clinicians not processing an alert, such as a medication interaction from the electronic health record, when receiving a large burden of alerts often regarded as nonactionable.

The most important area of current and growing research may be how health care providers can partner with patients and families to improve the safety of care. Families often identify a wide number of errors and safety events that clinicians fail to report. More important than families simply reporting mistakes are early efforts to engage families more broadly and deeply to co-produce healthcare that is efficient, effective, and safe.

Lyren A, Brilli RJ, Zieker K, et al. Children's hospitals’ solutions for patient safety: collaborative impact on hospital-

Tundia NL, Heaton PC, Kelton CM. The national burden of E-code-identified adverse drug events among hospitalized

Pediatric ethics is the branch of bioethics that analyzes moral aspects of decisions made relating to the healthcare of children. In general terms, the autonomy-driven framework of adult medical ethics is replaced by a beneficent paternalism (or parentalism) in pediatrics. Pediatric ethics is distinctive because the pediatric clinician has an independent fiduciary obligation to act in a younger child's best interest that takes moral precedence over the wishes of the child's parent(s). For older children, the concept of assent suggests that the voice of the patient must be heard. These factors create the possibility of conflict among child, parent, and clinician. The approach to the ethical issues that arise in pediatric practice must include respect for parental responsibility and authority balanced with a child's developing capacity and autonomy. Heterogeneity of social, cultural, and religious views about the role of children adds complexity.

**Assent and Parental Permission**

The doctrine of informed consent has limited direct application to children and adolescents who lack decisional capacity. The capacity for informed decision-making in healthcare involves the ability to understand and communicate, to reason and deliberate, and to analyze conflicting elements of a decision using a set of personal values. The age at which a competent patient may legally exercise voluntary and informed consent for medical care varies from state to state and may be limited to specific conditions (sexually transmitted infections, family planning, drug or alcohol abuse).

In contrast to decisions about one's own care, a parent's right to direct a child's medical care is more limited. For this reason, the term parental consent is
misleading. The concept of parental permission (rather than consent) reflects a surrogate or proxy decision made by a parent on behalf of a child. It is constrained both by the child's best interest and the independent obligation of clinicians to act in the child's best interest, even if this places them in conflict with a parent. In any given instance, the decision of what is or is not in a child's best interest may be difficult, especially given the diverse views of acceptable child rearing and child welfare. Parents are (and should be) granted wide discretion in raising their children. In cases involving a substantial risk of harm, the moral focus should be on avoiding or preventing harm to the child, not on a parental right to decide. While the term best interests may be too high of a threshold requirement, a minimum standard of basic interests is ethically obligatory.

Respect for children must account for both a child's vulnerability and developing capacity. This respect encompasses both the protective role of parental permission and the developmental role of child assent (the child's affirmative agreement). Understanding the concept of assent is one of the major conceptual challenges in pediatric ethics. The dissent (or disagreement) of a child is the opposite of assent and is also morally relevant. Pediatric ethics requires clinicians and parents to override a child's dissent when a proposed intervention is essential to the child's welfare. Otherwise, assent should be solicited and dissent honored. In seeking younger children's assent, a clinician should help them understand their condition, tell them what they can expect, assess their understanding and whether they feel pressured to assent, and solicit their willingness to participate. All efforts must be made to delineate situations in which the test or procedure will be done regardless of the child's assent/dissent, and in such cases the charade of soliciting assent should be avoided. There is an important distinction between soliciting assent and respectfully informing a child that a test or procedure will take place regardless of the child's decision. Optimally, an educational process can transpire (if time allows) to gain the trust and assent of the child-patient. When this cannot occur, pediatric ethics requires that clinicians apologize to a child for acting to override dissent.

Older children or adolescents may have the cognitive and emotional capacity to participate fully in healthcare decisions. If so, the adolescent should be provided with the same information given to an adult patient. In such situations the patient may be able to provide informed consent ethically but not legally. The adolescent's parent(s) remain in a guiding and protective role. The process
of communication and negotiation will be more complex should disagreement arise between the parent and adolescent. Pediatricians can be effective intercessors when these situations arise, making use of communication skills in a respectful way that uses an ethical framework as recently described by Sisk et al.

**Treatment of Critically Ill Children**

Infants, children, and adolescents who become critically ill may recover fully, may die, or may survive with new or worsened limitations of function. Uncertainty about outcomes can make planning goals of care difficult, or if misunderstandings between patient, families, and medical staff occur, may drive conflict over treatment proposals. *Ethical issues* that arise during critical illness include balancing benefits, burdens, and harms of therapy in the face of uncertainty; maintaining a helpful degree of transparency and communication about medical standards of care at an institution; understanding and respecting religious and cultural differences that impact requests for or refusal of treatments; defining limits of therapy based on assessments of medical futility; recognizing the moral equivalence of not starting an ineffective treatment and stopping (although the 2 acts may seem very different to families and providers); and controversies such as withholding medically administered nutrition and hydration.

**Transitioning the Goals of Care**

Most acutely ill children who die in an intensive care unit do so after a decision has been made to forgo or withdraw *life-sustaining medical treatment (LSMT)*, and the same may apply in the chronically ill population. LSMT is justified when the anticipated benefit outweighs the burdens to the patient; the availability of technology does not in and of itself obligate its use. Decisions to use, limit, or withdraw LSMT should be made after careful consideration of all pertinent factors recognizable by both family and medical staff, including medical likelihood of particular outcomes, burdens on the patient and family, religious and cultural decision-making frameworks, and input by the patient when possible. Although fear of legal repercussions may sometimes drive treatment and medical advice, ultimately decisions should be based on what is thought to be best for the patient rather than based on fears of litigation.

The concept of *futility* has been used to support unilateral forgoing of LSMT
against the wishes of patients and families by holding that clinicians should not provide futile (or useless) interventions. If medical futility is defined narrowly as the impossibility of achieving a desired physiologic outcome, forgoing a particular intervention is ethically justified. However, this approach may not adequately engage professionals and families in understanding facts and values that might allow the same therapy to reach other goals, and may leave medical and family stakeholders in permanent conflict. Guidance from critical care groups recommend restricting use of the word futility to situations of strict physiologic futility, and instead use process guidelines to evaluate and manage situations of potentially inappropriate treatment. If agreement cannot be reached through clear and compassionate communication efforts, further input should be sought from an ethics consultant or committee.

**Communication** about life-threatening or life-altering illness is challenging and requires skills learned through both modeling and practice. These skills include choosing a setting conducive to what may become one or more long conversations; listening carefully to children's and families’ hopes, fears, understanding, and expectations; explaining medical information and uncertainties simply and clearly without complicated terms and concepts; conveying concern and openness to discussion; and being willing to share the burdens of decision-making with families by giving clear recommendations. Discussing difficult topics with children requires an understanding of child development and can be aided by professionals such as child psychologists or child life specialists. Such conversations and their outcomes have a major impact on the future care of the patient, on families, and on medical staff. For this reason, ongoing evaluation of goals and communication about them is needed with families and within complex medical teams as the course of the illness unfolds.

Experts recognize that good medical care involves providing for communication, symptom management, and a range of supportive services from the onset of acute illness. In this way, if an illness proves to be life-limiting despite aggressive therapies, the elements of palliative care are already in place. This concept has had difficulty gaining traction, especially in critical care settings, because of the mistaken conflation of broadly defined palliative measures with hospice care. **Palliative care** interventions focus on the relief of symptoms and conditions that may detract from quality of life regardless of the impact on a child's underlying disease process, and as such are important whether care is focused on cure or on transitioning to end-of-life care (see
Chapter 7). Some interventions regarded as life-sustaining, such as chemotherapy, may be ethically acceptable in the end-of-life setting if their use decreases pain and suffering rather than only prolonging dying.

**Withholding and Withdrawing Life-Sustaining Treatment**

Limitation of interventions or withdrawal of existing therapies are ethically acceptable if they are congruent with a plan of care focused on **comfort** and **improved quality** at the end of life rather than cure. The prevailing view in Western, traditional medical ethics is that there is no moral distinction between withholding or withdrawing interventions that are not medically indicated. Uncertainty in predicting a child's response to treatment may drive the initiation and continuation of interventions that are subsequently determined to be no longer supportive of shared goals of care. It is necessary to evaluate continually the results of these treatments and the evolution of the illness to recognize whether such interventions continue to be the best medical and moral choices. Maintaining the focus on the child rather than on the interests of parents or medical staff will help guide decision-making.

The decision about whether to attempt **cardiopulmonary resuscitation (CPR)** may become an issue to discuss with parents of children living with life-threatening or terminal conditions. All elements of end-of-life care approaches, including resuscitation status, should be supportive of agreed-on goals of care. It is imperative that decisions and plans are effectively communicated to all caregivers in order to avoid denying medically effective interventions and measures to ensure comfort. Orders about resuscitation status should clarify the plan regarding intubation and mechanical ventilation, the use of cardiac medications, chest compressions, and cardioversion. Because goals of care may change over time, a medical order regarding resuscitation is not irrevocable. Clinicians may assume that the absence of a **do-not-attempt-resuscitation (DNAR)** order obligates them to perform a prolonged resuscitation. This action may not be ethically supportable if resuscitative efforts will not achieve the desired physiologic end-point. In all cases, treatments should be tailored to the child's clinical condition, balancing benefits and burdens to the patient. Resuscitation should not be performed solely to mollify parental distress at the tragic time of the loss of their child.
Advance Directives

An advance directive is a mechanism that allows patients and/or appropriate surrogates to designate the desired medical interventions under applicable circumstances. Discussion and clarification of resuscitation status should be included in advance care planning, and for children attending school despite advanced illness, may need to be addressed in that setting. Decisions regarding resuscitation status in the out-of-hospital setting can be an important component of providing comprehensive care.

The 1991 federal Patient Self-Determination Act requires that healthcare institutions ask adult (>18 yr) patients whether they have completed an advance directive and, if not, inform them of their right to do so. Few states support creation of broad advance directives for minors because advance directives are traditionally created for persons with legal decision-making capacity. Some have moved in this direction, however, because it is recognized that minors may be capable of participating in decision-making, especially if they have experienced chronic disease. Most states have approved the implementation of prehospital or portable DNAR orders, through which adults may indicate their desire not to be resuscitated by emergency personnel. On a state-by-state basis, portable orders regarding resuscitation status may also apply to children. If DNAR orders exist for an infant or a child, it is important to communicate effectively about their intent among all potential caregivers, because nonmedical stakeholders such as teachers or sitters may not want to be in the position of interpreting or honoring them. Some institutions have established local policies and procedures by which an appropriately executed, outpatient DNAR order can be honored on a child's arrival in the emergency department. Key features may include a standardized document format, review by an attending physician, ongoing education, and involvement of a pediatric palliative medicine service.

In cases involving prenatal diagnosis of a lethal or significantly burdensome anomaly, parents may choose to carry their fetus/unborn child to term in order to cherish a short time with the infant after birth, but they do not feel that resuscitation or certain other aggressive measures would support their well-considered goals of care. In this setting, a birth plan explaining the reasons for each choice can be developed by the parents and medical staff before delivery and shared with involved medical staff. This approach gives staff a chance to find other caregivers if they are uncomfortable with the approach, without abandoning the care of the child. If, after evaluation at birth, the infant's condition is as had been expected, honoring the requested plan is ethically
supportable and should be done in a way that optimizes comfort of the infant and family.

Many states use **Physician Orders for Life-Sustaining Treatment** or **Medical Orders for Life-Sustaining Treatment** approaches to communicating a patient or surrogates wishes regarding advance care planning. Other tools, such as **Five Wishes**, have been adapted for use by adolescent patients to elicit values and desires. It is important for pediatricians to learn which pathways for communicating goals of care are available in their own states.

**Artificial Hydration and Nutrition**

Issues surrounding withholding or withdrawing artificial hydration and nutrition are controversial, and interpretations are affected by parental, religious, and medical beliefs. Any adult or child who is fully dependent on the care of others will die as a result of not receiving hydration and nutrition. Case law has supported the withholding of artificially administered nutrition and hydration in the setting of adult vegetative or permanently unconscious patients who can be shown to have previously expressed a wish not to be maintained in such a state. This requires a valid advance directive, or for a surrogate decision maker to speak on behalf of the patient's known wishes. Because infants and many children have not reached a developmental stage in which such discussions would have been possible, decisions about stopping artificially administered nutrition and hydration as a limitation of treatment are more problematic. These decisions should be based on what families and caregivers decide best support comfort. In the child who is imminently dying, unaware of hunger, does not tolerate enteral feedings, and in whom family and staff agree that IV nutrition and hydration only prolong the dying process, it may be ethically supportable to withhold or withdraw these treatments based on a benefit-burden analysis.

**The Doctrine of Double Effect**

Treatment decisions at the end of life may include limitations of certain LSMT or may involve the use of analgesic or sedative medications that some fear may shorten life, thereby causing death. The doctrine of double effect (DDE) holds that an action with both good and bad effects is morally justifiable if the good effect is the only one intended, and the bad effect is foreseen and accepted, but not desired. In pediatrics, DDE is most commonly applied in end-of-life cases, when upward titration of medication (opiates) necessary to relieve pain, anxiety,
or air hunger can be expected to result in a degree of respiratory depression. In such cases, meeting a provider's obligation to relieve suffering is the intended effect, and this obligation to the patient outweighs the acknowledged but unavoidable side effect. Choosing medications that adequately relieve symptoms with minimal adverse effects would be ethically preferable, but the obligation to provide comfort at the end of life outweighs the foreseeable occurrence of unavoidable side effects. Hastening death as a primary intention is not considered to be morally acceptable.

Providing pain medication guided by the DDE should not be confused with active euthanasia. The distinction is clear:

◆ **In active euthanasia**, causing death is chosen as a means of relieving the symptoms that cause suffering.
◆ **Under DDE**, adequate management of pain, anxiety, or air hunger is recognized as an obligation to dying patients, and is provided by careful titration of medications in response to symptoms. If death occurs sooner as a result, this is accepted.

In both cases the patient dies, and in both cases suffering ends, but immediate death is the intended consequence only in the case of euthanasia. Codes of ethics and legislation in many states support the obligation to provide pain and symptom relief at the end of life, even if this requires increasing doses of medication.

**Neonatal Ethics**

As neonatal care has evolved, the limits of viability of extremely premature infants are continuing to change. This introduces new elements of uncertainty to decision-making, often in emotionally fraught circumstances such as a precipitous premature delivery. In cases of uncertain prognosis, the American Academy of Pediatrics (AAP) supports parental desires as driving decision-making, while encouraging providers to recognize when treatments are inappropriate, and using a careful shared decision-making approach to
developing plans of care.

The federal **Child Abuse Prevention and Treatment Act** of 1984 (CAPTA), which became known as “Baby Doe Regulations,” required state child protective services agencies to develop and implement mechanisms to report to a specific government agency treatment that providers believed was withheld from infants on the basis of disability. Exceptions were (1) an infant is chronically and irreversibly comatose, (2) if providing a treatment would merely prolong dying, would not be effective in ameliorating or correcting all the infant's life-threatening conditions, or would be futile in terms of the infant's survival, and (3) if the treatment would be virtually futile and inhumane. This legislation pertains *only* to infants and is intended to prevent discrimination on the basis of disability alone. One consequence of the legislation was a shift from potential undertreatment to widespread overtreatment (LSMT that does not serve the interests of the child) of severely disabled newborns. As parental involvement in decisions-making is again taking a more central role, and as palliative care approaches in infants have become more available and skilled, balanced approaches to valuing lives of disabled infants should be considered.

Understanding institutional, regional, state, and national regulations related to care of infants is important in order to practice within regulatory frameworks while respecting family values and pursuing the interests of the patient.

Active euthanasia of severely suffering disabled newborns has been legalized in The Netherlands and Belgium, using protocols designed to minimize risk of abuse and maximize transparency. It is currently illegal in the United States, and although controversy surrounds the subject, the predominant view is that active euthanasia is not ethically acceptable in the care of infants and children, instead favoring palliative treatment and potential limitation of escalation.

---

**Declaring Death and Organ Donation**

Donation of solid organs necessary to support life can occur after a patient is declared dead based on either irreversible cessation of neurologic function of the brain and brainstem (death by neurologic criteria, or *brain death*) or a predetermined period of cardiac asystole called *circulatory death*. To avoid a potential conflict of interest by surgeons or others caring for a potential organ recipient, the request for organ donation should be separated from the clinical discussion of either brain death or withdrawal of LSMT. Although clinicians may be the first providers to enter discussion about death and organ donation
with family members during conversations about outcomes and options, detailed discussion of organ donation should be done by other individuals who are specifically trained for this purpose. This decoupling of clinical decision-making from a request for organ donation by trained individuals, perhaps by providing families with expert information without a perceived conflict of interest, has been associated with improved donation rates.

**Death by Neurologic Criteria**

Death by neurologic criteria (DBNC), commonly referred to as “brain death,” may be difficult for families to understand when the child appears to be breathing (although on a ventilator), pink, and warm to the touch, and when language such as “life support” is used at the bedside by staff. Studies also document clinician misunderstanding of the diagnosis of DBNC. For these reasons, strict criteria adhering to nationally accepted guidelines must be used to determine when irreversible cessation of brain and brainstem function has occurred and adequately document these findings (see Chapter 85).

The states of New York and New Jersey allow families to object on “religious grounds” to the declaration of DBNC. In this situation the clinical determination of DBNC sets the stage for a discussion of forgoing LSMT, rather than the death of the patient. A unilateral decision not to initiate new or escalate existing interventions is ethically supportable under these circumstances, given the documented death of the patient. Even though it would seem to follow that a similar unilateral decision to withdraw existing interventions would also be supportable, this act is not in accordance with the intent of the state laws. Institutional procedures for conflict resolution, including involvement of the courts if necessary, should be followed.

**Circulatory Death**

Protocols allowing for organ donation after determination of circulatory death (DDCD) rather than after DBNC have been developed. DDCD can occur under either controlled (after planned withdrawal of LSMT) or uncontrolled (after failed CPR) circumstances, but in both cases require rapid removal of organs in order for subsequent transplantation to be successful. An increasing number of programs are pursuing DDCD protocols after federal legislation began requiring accredited hospitals to address the issue in hopes of decreasing
organ shortages. Hospitals can make policy that either allows or disallows the process. In adults, consent for donation by either means can be obtained from patients or surrogates; for children, parents or guardians would make the decision to donate.

Ethical concerns about DDCD protocols focus on 2 principles that have served as the basis for organ donation: (1) the *dead donor* rule limiting the donation of vital organs to those who are irreversibly dead (either by circulatory or neurologic criteria, not both), and (2) the absence of conflict of interest between clinical care and organ procurement. With DDCD protocols, *irreversibility* has been declared at varying times after asystole occurs (usually 2-5 min), to avoid spontaneous return of circulation after forgoing CPR. To avoid a potential conflict of interest during the DDCD process, there is a requirement for strict decoupling of end-of-life care after discontinuation of LSMT and presence of the transplant team. Unlike in the setting of DBNC, a patient who is being considered for DDCD remains alive until after asystole has occurred. Careful evaluation by the transplantation team and organ procurement agency is performed before discontinuation of LSMT. Then, in most DDCD protocols, the medical caregivers from the ICU continue to care for the patient until after death by cardiac criteria has been declared, and only then is the surgical transplant team allowed into the room to procure organs.

It is *ethically imperative* to correctly diagnose the state of death, whether by neurologic criteria or prior to organ donation after cardiac death. Doing so avoids the danger of removing life-sustaining organs from a living person. Strict adherence to an ethically sound protocol is the best way to prevent both the perception and the potential reality of mistakes related to the pronunciation of death and organ procurement.

**Religious or Cultural Objections to Treatment**

Differences in religious beliefs or ethic-based cultural norms may lead to conflict between patients, families, and medical caregivers over the approach to medical care. Pediatricians need to remain sensitive to and maintain an attitude of respect for these differences, yet recognize that an independent obligation exists to provide effective medical treatment to the child. An adult with decision-making capacity is recognized as having the right to refuse treatment on religious or
cultural grounds, but children who have not yet developed this capacity are considered a vulnerable population who has a right to treatment. In situations that threaten the life of the child or that may result in substantial harm, legal intervention should be sought if reasonable efforts toward collaborative decision-making are ineffective. If a child's life is imminently threatened, medical intervention is ethically justified despite parental objections.

**Pediatric Ethics Committees and Ethics Consultation**

Most hospitals have *institutional ethics committees* to assist with policy development, education, and case consultation. When these committees serve institutions caring for children, they may be referred to as *pediatric ethics committees*. Because of the important differences in approach between adult and pediatric ethics, member expertise on this committee should include those with special insight into the unique ethical issues arising in the care of children. Such committees generally provide ethics consultation advice without mandating action or being determinative. For the vast majority of decisions involving the medical treatment of children (including forgoing LSMT), pediatric clinicians and parents are in agreement about the desirability of the proposed intervention. Because of the ethical importance of assent, the views of older children should also be given considerable weight.

Pediatric ethics committees typically perform at least 3 different functions: (1) the drafting and review of institutional policy on such issues as DNAR orders and forgoing LSMT; (2) the education of healthcare professionals, patients, and families about ethical issues in healthcare; and (3) case consultation and conflict resolution. Although the process of *case consultation* may vary, ideally the committee (or consultant) should adopt a collaborative approach that uncovers all the readily available and relevant facts, considers the values of those involved, and balances the relevant interests, while arriving at a recommendation based on a consistent ethical analysis. One helpful approach involves consideration of the 4 following elements: (1) medical indications, (2) patient preferences, (3) quality of life, and (4) contextual features. Another framework based on principles would suggest attention to respect for persons, beneficence/nonmaleficence, and justice.

Pediatric ethics committees often play a constructive role when parents and
medical staff cannot agree on the proper course of action. Over the past several decades, these committees have acquired considerable influence and are increasingly recognized by state courts as an important aid in decision-making. The membership, policies, and procedures of a pediatric ethics committee should conform to accepted professional standards.

**Newborn Screening**

The *Oxford Dictionary of Public Health* defines screening as “the identification of a previously unrecognized disease or disease precursor, using procedures or tests that can be conducted rapidly and economically on large numbers of people with the aim of sorting them into those who may have the condition(s)... and those who are free from evidence of the condition(s).” Several programs, such as newborn screening for inborn errors of metabolism (see Chapter 102; e.g., phenylketonuria and hypothyroidism), are rightly counted among the triumphs of contemporary pediatrics. The success of such programs sometimes obscures serious ethical issues that continue to arise in proposals to screen for other conditions for which the benefits, risks, and costs have not been clearly established. Advances in genetics and technology have led to exponential growth in the number of conditions for which screening programs might be considered, with insufficient opportunity to study each proposed testing program (see Chapter 95).

The introduction of screening efforts should be done in a carefully controlled manner that allows for the evaluation of the costs (financial, medical, and psychological) and benefits of screening, including the effectiveness of follow-up and treatment protocols. New programs should be considered experimental until the risks and benefits can be carefully evaluated. Screening tests that identify candidates for treatment must have demonstrated sensitivity, specificity, and high predictive value, lest individuals be falsely labeled and subject to possibly toxic treatments or to psychosocial risks. As newborn screening tests are being developed, parents should be given the opportunity to exercise informed parental permission or refusal. However, once a particular screening test has been clearly demonstrated to benefit the individual or public health, a formal, active parental permission process may not be ethically obligatory.

A persistent ethical issue is whether screening should be (1) voluntary (“opt in”), (2) routine, with the ability to “opt out” or refuse, or (3) mandatory. A voluntary approach entails an informed decision by parents before screening.
Concern is often expressed that seeking parental permission is ethically misguided for tests of clear benefit, such as phenylketonuria screening, because refusal would constitute neglect. **Routine** testing with an opt-out approach requires an explicit refusal of screening by parents who object to this intervention. The principal ethical justification for **mandatory** screening is the claim that society's obligation to promote child welfare through early detection and treatment of selected conditions supersedes any parental right to refuse this simple and low-risk medical intervention. Parental permission is clearly required when there is a research agenda (i.e., for incorporating experimental tests into established screening programs).

**Genetics, Genomics, and Precision Medicine**

**Genetics** refers to the study of particular genes, and **genomics** describes the entirety of an individual's genetic material. Genomics has been made possible by technologic advances that allowed the rapid and inexpensive sequencing now used in clinical care. The development of **precision medicine** is in large part predicated on genomic science and may have a major impact on the practice of pediatrics in the future. Efforts to undertake whole genome sequencing of newborns may yield actionable information to benefit the child, but also carry the risk of stigmatization, false positives, and unwanted information that could lead to anxiety and psychological distress.

Genetic testing of young children for late-onset disorders such as the **BRCA1** and **BRCA2** breast cancer risk genes has also been the subject of some ethical controversy. Knowledge of increased risk status may lead to lifestyle changes that can reduce morbidity and the risk of mortality, or may precipitate adverse emotional and psychological responses and discrimination. Because many adults choose not to be tested for late-onset disorders, one cannot assume that a child would want or will benefit from similar testing. Genetic testing of young children for late-onset disorders is generally inappropriate unless such testing will result in interventions that have been shown to reduce morbidity and mortality when initiated in childhood. Otherwise, such testing should be deferred until the child has the capacity to make an informed and voluntary choice.
Adolescent Healthcare

Adolescent Assent and Consent

Many adolescents are more like adults than children in their capacity to understand healthcare issues and to relate them to their life goals (see Chapter 132). Teenagers may lack legally defined competency, yet they may have developed the capacity meet the elements of informed consent for many aspects of medical care (see Chapter 137). There are also public health reasons for allowing adolescents to consent to their own healthcare with regard to reproductive decisions, such as contraception, abortion, and treatment of sexually transmitted infections. Strict requirements for parental permission may deter adolescents from seeking healthcare, with serious implications for their health and other community interests.

Counterbalancing these arguments are legitimate parental interests to maintain responsibility and authority for child rearing, including the opportunity to influence the sexual attitudes and practices of their children. Others claim that access to treatment such as contraception, abortion, or needle exchange programs implicitly endorses sexual activity or drug use during adolescence. Pediatricians should not impose their own moral beliefs in these disputes. Rather, they should provide unbiased evidence-based information and nonjudgmental support. One guiding principle should be encouragement of children and adolescents to begin taking responsibility, with guidance, for their own health. This requires some input from parents or guardians but also some privacy during decision-making as adolescents achieve developmentally anticipated separation from parental control.

Chronic Illness

The normal process of adolescent development involves gradually separating from parents, establishing self-confidence, asserting individuality, developing strong peer relationships, solidifying an ability to function independently outside the family, and taking on increasing autonomy in healthcare decisions. Most developmentally normal children older than age 14 yr understand the implications of well-explained medical options as well as the average adult, and their input into their own care should be respected. For children living with chronic illness, the ability to make medical decisions for themselves may either occur earlier than for those who have been previously healthy, or may occur later
if, because of illness, they have not been able to achieve normal developmental milestones or psychological maturity. The clinician's role involves assessment of the individual adolescent patient's ability to understand the medical situation, to support the patient's efforts to express wishes regarding medical treatment, to value and encourage parental support and involvement, and to foster cooperation and mutual understanding. This may be difficult in situations in which parents and adolescents disagree about life-sustaining treatments such as organ transplantation or chemotherapy, but many such conflicts may be resolved by exploring the reasons for the disagreement. Overriding an adolescent's wishes should be done very infrequently, and only after careful consideration of the potential consequences of unwanted interventions.

**Decisions in Terminally Ill Adolescents**

Most adolescents share end-of-life decision making with family members, although communication may be challenging because of a growing sense of independence. Open communication and flexibility about treatment preferences may help teens cope with fears and uncertainties. Development of an age-appropriate advance directive may support the patient's emerging autonomy by clarifying the adolescent's wishes, while fostering a collaborative process among the patient, family, and medical caregivers. From the time of diagnosis of a life-threatening condition through the end-of-life phase, children should be included in a developmentally tailored process of communication and shared decision-making that builds a foundation of mutual respect and trust. Some experts believe that most adolescents are not yet fully capable of making a decision to forgo life-sustaining treatment. Careful case-by-case evaluation is required to make this determination, and assistance from developmental psychologists and ethics consultants may be helpful.

**Research**

The central ethical challenge of pediatric research is the need to balance protection of children from research risk against the ethical imperative of conducting studies to better the lives of future children. *Research* is defined in the federal regulations as “a systematic investigation designed to develop or contribute to generalizable knowledge.” For any research to be performed, the risks should be minimized and reasonable with respect to any anticipated
benefits to the participants and the importance of the resulting knowledge. That some children derive a direct benefit from participation in research must also be considered, making it important to distinguish research with the prospect of direct benefit from nontherapeutic pediatric research. Because children are a vulnerable population, there are restrictions on the research risks to which a child may be exposed, in contrast to the risk level acceptable for research with consenting adults. These restrictions function by limiting the type of research that institutional review boards (IRBs) are permitted to approve and by specifying the conditions under which parents have the moral and legal authority to permit a child to participate in research.

Nontherapeutic research in children is the most ethically controversial because it holds no expected direct benefit for the individual. The prohibition against using a person (especially a child) solely as a means to an end has led some to argue that children should never be used in nontherapeutic research. The more widely held opinion is that children may be exposed to a limited degree of risk with IRB approval, parental permission, and assent if the child is capable. The federal regulations allow healthy children to participate in minimal-risk research regardless of the potential benefit to the child. More controversially, the regulations also state that children with a disorder or condition may be exposed to slightly more than minimal risk in nontherapeutic research if the child's experience is similar to everyday life with the condition and the anticipated knowledge is of vital importance for understanding the condition.

In pediatric research with the prospect of direct benefit, the risks must be justified by the anticipated benefit to the child, and the balance of anticipated benefit to the risk should be at least as favorable as that presented by available alternatives. The welfare of an individual child must always come before the scientific goals of the research study.

U.S. regulations for the protection of human research participants rest on 2 foundations: (1) independent review of the ethics and science of the research by an IRB prior to (2) voluntary and informed consent of the participant. Although it is not amenable to regulation, the integrity of the investigator is probably the most important element contributing to the protection of human research participants. The standard for informed consent in a research setting is higher than for clinical care because the risks and benefits are typically less clear, the investigator has a conflict of interest, and humans have historically been subjected to unauthorized risks when strict requirements for consent were not respected.
Adolescents who are competent may sometimes consent to be research participants. Younger children may participate in a process of assent, but this does not imply that a child's signature on an assent document is necessarily a legal or ethical requirement. Children should be given the opportunity to dissent, particularly for nontherapeutic research, when there cannot be a claim that participation is in the child's interest. In the United States, national regulations require that reasonable efforts be made at least to inform children who are capable of understanding that participation is not part of their care, and therefore they are free to refuse to participate. In the rare case that the research offers a direct benefit to the child that would not otherwise be available, the regulations do not require child assent but only parental permission.

In addition to the protection that informed consent or parental permission is intended to provide, virtually all research involving humans in the United States is reviewed by an IRB, as required by federal regulations for institutions receiving federal research funds and for drug research regulated by the U.S. Food and Drug Administration. For research that carries more than a minor increase over minimal risk without prospect of benefit to the child such that a local IRB cannot provide approval, there is a process for federal review of research that “presents a reasonable opportunity to further the understanding, prevention, or alleviation of a serious problem affecting the health or welfare of children.” Ultimately, the U.S. Secretary of Health and Human Services has the authority to approve such research.

Balancing Maternal and Fetal Interests

Some situations require balancing of maternal health and well-being with those of the fetus/unborn child to reach an ethically sound decision. For instance, innovative surgical treatment of a prenatally diagnosed anomaly may help the fetus/unborn child survive, but in the process place the mother at risk of injury or of loss of the pregnancy. Alternatively, a pregnant woman may object to cesarean delivery for various reasons despite advice that it may protect the fetus/unborn child during birth. Another important situation involves risk-taking behaviors during pregnancy that are known to injure the developing fetus/unborn child, such as drug or alcohol use. These issues raise conflicts over clinicians’ responsibility to the living, competent decision-maker—the pregnant mother—as opposed to the interests of the fetus/unborn child.

In certain cases, U.S. courts have decided that a woman can be required to
undergo cesarean birth against her will when the risk to her health is minimal and the benefit to the otherwise normal, near-term fetus/unborn child is clear, as in a case of placenta previa. Other factors, such as prematurity, have led to the opposite legal conclusion in otherwise similar situations, because the benefit of intervention was less clear. In general, a clinician should not oppose a pregnant woman's refusal of a recommended intervention unless (1) the risk to the pregnant woman is minimal, (2) the intervention is clearly effective, and (3) the harm to the fetus/unborn child without the intervention would be certain, substantial, and irrevocable. Attempts should be made to persuade the pregnant woman to comply with recommendations in the interest of the fetus/unborn child when these 3 conditions exist, using support strategies such as the influence of other trusted caregivers, clergy, and ethics consultation or committee involvement. If these approaches fail and there is time, a clinician may seek judicial intervention as a last resort in the attempt to prevent harm to the fetus/unborn child.

Obstetricians and pediatricians may consider reporting women under child abuse or neglect statutes if ingesting alcohol or illicit drugs during pregnancy is believed to place the fetus/unborn child at risk of injury. However, clinicians must consider the likelihood of benefit from reporting, the harm to the child as well as to the mother if criminal charges or custody changes are sought, and the possible effects of reporting on driving pregnant women away from prenatal or postnatal care. The U.S. Supreme Court has held that drug testing of pregnant women without consent was a violation of the Fourth Amendment, which provides protection from unreasonable searches.

Justice and Pediatric Ethics

The most serious ethical problem in U.S. healthcare may be inequality in access to healthcare. Children are particularly vulnerable to this disparity, and pediatricians have a moral obligation to advocate for children as a class. Because children do not vote and do not have financial resources at their disposal, they are subject to a greater risk of being uninsured or underinsured. This lack of adequate and affordable healthcare has serious consequences in terms of death, disability, and suffering. The per capita proportion of healthcare funding spent on adults greatly exceeds that spent on children, and Medicare is available to all adults who turn 65 yr old, whereas Medicaid is limited to those beneath a specific income level. Pediatricians should be familiar with policy issues around
the economics of childcare so that they will be better able to advocate for their own patients.

**Emerging Issues**

The ready availability of information on the internet and disease-specific social media support groups have encouraged parents to become more involved in advocating for specific approaches to the healthcare of their children, requiring physicians to remain aware of the quality of these information sources in order to counsel parents on treatment choices. Because the range of aggressive, innovative, or exceedingly expensive therapies has increased, without necessarily providing clear benefit to the patient, pediatricians must exercise care and judgment before agreeing to pursue these interventions. In addition, the growth of social media has presented expectations for clinicians to be quickly responsive, as well as challenges in maintaining privacy of medical information and professional boundaries. This will be an evolving issue, since the use of telemedicine is also gaining traction in certain sectors of healthcare, including the care of children and adolescents.

A growing number of parents are refusing to immunize their children because of fear of adverse reaction to vaccine. This raises the ethical problem of the *free rider*, in which a child may benefit from herd immunity because others have been immunized without contributing to this public good. Outbreaks of preventable infectious disease have been detected in communities where vaccine refusal is prevalent. Pediatricians should manage this issue with ethical sensitivity, educating parents about the safety profile of vaccines and encouraging appropriate immunization. More confrontational approaches are not generally effective or ethically warranted. Another emerging issue is children as stem cell or solid-organ donors. Here the risk/benefit balance should be carefully weighed, but in general, a permissive policy with regard to stem cell donation and a more restrictive approach to solid-organ donation are ethically justified.

Lastly, controversial medical and surgical interventions have raised awareness of situations in which families and children may not be in agreement with approaches that were recommended as “standard of care” in the past. Examples include delaying surgical treatment of sexual development disorders to determine the child’s gender identity and arresting puberty through hormonal treatment to allow transgender or questioning children or adolescents to make decisions about gender identity before developing enduring secondary sexual
characteristics. Attitudes about emerging technologies and treatments may be influenced by media coverage, special interest groups, and efforts by understandably desperate families to help their children. The clinician attempting to practice ethically must carefully consider all relevant facts in each case and try to focus families and caregivers on a reasonable best interest assessment for the child. The tension between finding optimal policy for groups of children and doing the right thing for an individual child raises formidable ethical challenges in this context. Ethics consultation may be helpful to frame the issues and design ethically supportable approaches to care.

Bibliography

Diekema DS. Parental refusals of medical treatment: the harm principle as threshold for state intervention. *Theor Med*

According to the World Health Organization (WHO), “Palliative care for children is the active total care of the child’s body, mind and spirit and also involves giving support to the family. Optimally, this care begins when a life-threatening illness or condition is diagnosed and continues regardless of whether or not a child receives treatment directed at the underlying illness.” Provision of palliative care applies to children with a wide variety of diagnoses, including cancer, cystic fibrosis, complex or severe cardiac disease, neurodegenerative disorders, severe malformations, and trauma with life-threatening sequelae (Table 7.1). Medical and technologic advances have resulted in children living longer, often with significant dependence on expensive technologies. These children have complex chronic conditions across the spectrum of congenital and acquired life-threatening disorders. Children with complex chronic conditions benefit from integration of palliative care strategies. These children, who often survive near-death crises followed by the renewed need for rehabilitative and life-prolonging treatments, are best served by a system that is flexible and responsive to changing needs and blended goals of care.

Conditions for Which There Is Intensive Long-Term Treatment Aimed at Prolonging Life and Maintaining Quality of Life, but Premature Death Is Still Possible

- Cystic fibrosis
- Severe immunodeficiency
- High-risk solid-organ transplant candidates and/or recipients (e.g., lung, multivisceral)
- Chronic or severe respiratory failure
- Muscular dystrophy
- Complex multiple congenital malformation syndromes
- Primary pulmonary hypertension
- Severe chromosomal disorders (aneuploidy, deletions, duplications)

Progressive Conditions for Which There Is No Curative Option and in Which Treatment Is Almost Exclusively Palliative After Diagnosis

- Progressive metabolic disorders (Tay-Sachs disease)
- Batten disease
- Severe forms of osteogenesis imperfecta

Conditions Involving Severe, Nonprogressive Disability, Causing Extreme Vulnerability to Health Complications

- Severe cerebral palsy with recurrent infection or difficult-to-control symptoms
- Severe neurologic sequelae of infectious disease
- Hypoxic or anoxic brain injury
- Brain malformations (e.g., holoprosencephaly, lissencephaly)

Adapted from The Together for Short Lives [formerly the Association for Children's Palliative Care (ACT)] Life-limiting/Life-threatening Condition Categories.
http://www.togetherforshortlives.org.uk/professionals/childrens_palliative_care_categories/
Although often mistakenly understood as equivalent to end-of-life care, the scope and potential benefits of palliative care are applicable throughout the illness trajectory. Palliative care emphasizes optimization of quality of life, communication, and symptom control, goals that may be congruent with maximal treatment aimed at sustaining or prolonging life.

The mandate of the pediatrician and other pediatric clinicians to attend to children's physical, mental, and emotional health and development includes the provision of palliative care for those who live with a significant possibility of death before adulthood (Fig. 7.1). Such comprehensive physical, psychological, social, and spiritual care requires an interdisciplinary approach.

In the United States the healthcare and reimbursement structure, combined with frequent use of medical technology (e.g., home ventilatory support) or continuous home nursing, historically precluded formal enrollment of children on the hospice benefit when they were otherwise eligible (i.e., had estimated prognosis of ≤6 mo). Section 2302 of the Patient Protection and Affordable Care Act (ACA), the Concurrent Care for Children Requirement (CCCR), eliminated the requirement that Medicaid patients <21 yr old forgo curative or
life-prolonging therapies to be eligible for hospice. Although Medicaid programs in every state are now required to provide concurrent curative/life-prolonging treatment and hospice services for hospice-eligible children, development of systems to make such concurrent care a reality has been slow. A limitation of the CCCR is that it does not expand access to hospice for children with life-threatening illness who do not meet hospice eligibility criteria (i.e., have a prognosis that cannot be estimated to be <6 mo) or those not receiving Medicaid. A number of state-based pediatric palliative care coalitions have formed in recent years to improve access to home-based pediatric hospice/palliative care services, using strategies such as Medicaid waivers or state plan amendments to increase coverage for hospice services. A growing number of home care agencies have also developed palliative care programs that serve as a bridge to hospice services for children not yet meeting hospice eligibility criteria. Some hospices have adopted an open hospice model with more flexible eligibility criteria. However, provision of hospice or palliative care for children is often also limited by the availability of clinicians who have training or experience in caring for seriously ill children.

Care Settings

Pediatric palliative care should be provided across settings, including hospital, outpatient, and home, as well as pediatric nursing facilities and sometimes inpatient hospice houses. Home care for the child with a life-threatening illness requires 24 hr/day access to experts in pediatric palliative care, a team approach, and an identified coordinator who serves as a link among hospitals, the community, and specialists and who may assist in preventing or arranging for hospital admissions, respite care, and increased home care support as needed. Adequate home care support and respite care, although sorely needed, is often not readily available because staffing or the high-tech skill required to care for these children is lacking. Furthermore, families may view using respite care as a personal failure, or they may worry that others cannot adequately care for their child's special needs or potential rapid escalation of symptoms.

At the end of life, children and families may need intensive support. About half of pediatric deaths occur in acute care hospitals, and end-of-life care may thus be provided in the home, hospital, pediatric nursing facility, or hospice house. Families need to feel safe and well cared for and given permission, if possible, to choose location of care. In tertiary care hospitals, most children die
in the neonatal and pediatric intensive care units (ICUs). In some instances, when death at home for a child in the ICU is preferred, transport and even extubation at home may be possible, if clinical and logistical circumstances permit it.

The philosophy of palliative care can be successfully integrated into any hospital setting, including the ICU, when the focus of care also includes the prevention or amelioration of suffering and improving comfort and quality of life. All interventions that affect the child and family need to be assessed in relationship to these goals. This proactive approach asks the question, “What can we offer that will improve the quality of this child's life and provide the most meaning and sense of control and choice for their family?” instead of “What therapies are we no longer going to offer this patient?” Staff may benefit from education, support, and guidance because pediatric palliative care, as with other types of intensive care, is an area of specialty. Regardless of the care setting, comprehensive palliative care requires an interdisciplinary approach that may include nurses, physicians, psychologists, psychiatrists, social workers, chaplains/clergy, child life specialists, and trained volunteers.

**Communication, Advance Care Planning, and Anticipatory Guidance**

Although accurate prognostication is a particular challenge in pediatrics, the medical team often recognizes a terminal prognosis before the prognosis is understood by parents or the child. This delay may impede informed decision-making about how the child lives at the end of life. Given the inherent prognostic uncertainty of a life-threatening diagnosis, discussions concerning resuscitation, symptom control, and end-of-life care planning should be initiated when the physician recognizes that a significant possibility of patient mortality exists. Having these conversations in the midst of a crisis is not ideal. Whenever possible, they should occur well in advance of the crisis or when the patient has recovered from a crisis but is at high risk for others.

Patients and families are most comfortable being cared for by physicians and other care providers with whom they have an established relationship. Even in the face of long-standing and highly connected relationships, clinicians often hold assumptions about parent prognostic awareness, as well as parent readiness and willingness to have such discussions. In an attempt to protect
families, clinicians may avoid conversations that they perceive as promoting distress or hopelessness. However, parents greatly value honesty, and in fact such conversations can promote parent hopefulness, as well as trust and connection with the care team. At times, therefore, a consultative palliative care team provides the family with an opportunity to engage in sensitive conversations that do not as readily occur with the primary team, at least initially.

The population of individuals who die before reaching adulthood includes a disproportionate number of nonverbal and preverbal children and adolescents who are developmentally unable to make autonomous care decisions. Although parents are usually the primary decision-makers, these youth should be as fully involved in discussions and decisions about their care as appropriate for their developmental status. Using communication experts, child life therapists, chaplains, social workers, psychologists, or psychiatrists to allow children to express themselves through art, play, music, talk, and writing will enhance the provider's knowledge of the child's understanding and hopes. Tools such as Five Wishes (for adults), Voicing My Choices (for adolescents), and My Wishes (for school-age children), have in practice been useful in helping to introduce advance care planning to children, adolescents, and their families (www.agingwithdignity.org/index.php).

The Parents

For parents, compassionate communication with medical providers who understand their child's illness, treatment options, and family beliefs and goals are the cornerstone of caring for children with life-threatening illness. During this time, one of the most significant relationships is that with the child's pediatrician, who often has an enduring relationship with the child and family, including healthy siblings. Parents need to know that their child's pediatrician will not abandon them as the goals of care evolve. A family's goals may change with the child's evolving clinical condition and other variable factors. A flexible approach rooted in ongoing communication and guidance that incorporates understanding of the family's values, goals, and religious, cultural, spiritual, and personal beliefs is of paramount importance.

Pediatricians should recognize the important role they have in continuing to care for the child and family, since the primary goal of treatment may simultaneously be prolongation of life and comfort, relief of suffering, and
promoting quality of life. Regular meetings between caregivers and the family are essential to reassess and manage symptoms, explore the impact of illness on immediate family members, and provide anticipatory guidance. At these meetings, important issues with lifelong implications for parents and their child may be discussed. Such discussions should be planned with care, ensuring that adequate time for in-depth conversation is allotted; a private, physical setting is arranged; devices are silenced; and that both parents and others who might be identified by the family as primary supports are present. Strategies for facilitating conversations related to goals of care and decision-making are detailed later.

Families may look to their pediatrician for assurance that all treatment options have been explored. Assisting a patient's family to arrange a second opinion may be helpful. Listening to families and children speak about the future even in the face of poor prognosis may help keep the focus on living even while the child may be dying. Hoping for a miracle can coexist for parents even as they are facing and accepting the more likely reality of death.

Parents also need to know about the availability of home care, respite services, web-based support (e.g., www.courageousparentsnetwork.org), educational materials, and support groups. Responding to parental requests or need for counseling referrals for themselves, other children, or family is essential. Also, attending to the concrete needs of families (e.g., financial, insurance, housing) can be paramount in freeing them of worries that might interfere or compete with their ability to be fully present in their child's care.

When closer to the patient's end of life, although broaching the topic may seem daunting, exploration of how parents envision their child's death, addressing their previous loss experiences (most often with death of an adult relative) and any misconceptions, is often a great relief to parents. Learning about cultural, spiritual, and family values regarding pain management, suffering, and the preferred place of end-of-life care is essential. Even mentioning funeral arrangements, possible autopsy, and organ/tissue donation can be helpful to give parents choices and know that these considerations can be discussed without fear. A major worry of many parents is how to involve and communicate with siblings, as well as the child, about the likelihood of impending death.

Ratings of “high satisfaction” with physician care have been directly correlated with receiving clear communication around end-of-life issues, delivered with sensitivity and caring; such communication included speaking
directly to the child when appropriate. Communication is complicated by an assumed need for mutual protection in which the child wants to protect his or her parents, and likewise the parents want to protect their child, from painful information or sadness. Honoring the uniqueness of the child, as well as understanding and respecting the family's communication style, values, spirituality, and culture, is critical in these highly sensitive conversations. Evidence shows that parents who have open conversations with their child about death and dying do not regret having done so.

In communications with the child and family, the physician should avoid giving specific estimates of survival length, even when the child or family explicitly asks for them. These predictions are invariably inaccurate because population-based statistics do not predict the course for individual patients. A more honest approach may be to explore ranges of time in general terms (weeks to months, months to years) while recognizing that children with serious illness are also susceptible to acute events that cause rapid deterioration. The physician can also ask parents what they might do differently if they knew how long their child would live, then assist them in thinking through the options relating to their specific concerns (e.g., suggest celebrating upcoming holidays or important events earlier to take advantage of times when the child may be feeling better). It is generally wise to suggest that relatives who wish to visit might do so earlier rather than later, given the unpredictable trajectory of many conditions.

For the child and family, the integration of “bad news” is a process, not an event, and when done sensitively, does not take away hope or alter the relationship between the family and physician. The physician should expect that some issues previously discussed may not be fully resolved for the child and parents (e.g., do-not-resuscitate [DNR] orders, artificial nutrition or hydration) and may need to be revisited over time. Parents of a child with chronic illness may reject the reality of an impending death because past predictions may not have been accurate. Whether they are parents of a child with a chronic illness or a child whose death is the result of accident or sudden catastrophic illness, they may experience great anxiety, guilt, or despair.

The Child

Truthful communication that takes into account the child's developmental stage and unique lived experience can help to address the fear and anxiety commonly experienced among children with life-threatening illness. Responding in a
developmentally appropriate fashion (Table 7.2) to a child's questions about death (e.g., “What's happening to me?” or “Am I dying?”) requires a careful exploration of what is already known by the child, what is really being asked (the question behind the question), and why the question is being asked at this particular time and in this setting. It may signal a need to be with someone who is comfortable listening to such unanswerable questions. Many children find nonverbal expression much easier than talking; art, play therapy, and storytelling may be more helpful than direct conversation.

### Table 7.2

**Developmental Questions, Thoughts, and Concepts of Dying, With Responsive Strategies**

<tr>
<td>“How will I die?” “Will it hurt?” “Is dying scary?”</td>
<td>Child begins to demonstrate organized, logical thought. Thinking becomes less esoteric. Child begins to problem-solve concretely, reason logically, and organize thoughts coherently. However, child has limited abstract reasoning.</td>
<td>Be honest and provide specific details if they are requested. Help and support the child's need for control. Permit and encourage the child’s participation in decision making. “We will work together to help you feel comfortable. It is very important that you let us know how you are feeling and what you need. We will always be with you, so you do not need to be afraid.”</td>
</tr>
</tbody>
</table>

**AGE 10-18 YR**

<table>
<thead>
<tr>
<th>Question</th>
<th>Description</th>
<th>Advice</th>
</tr>
</thead>
<tbody>
<tr>
<td>“I’m afraid if I die my mom will just break down.” “I’m too young to die. I want to get married and have children.” “Why is God letting this happen?”</td>
<td>Abstract thoughts and logic possible. Body image is important. Child needs peer relationships for support and for validation. Child expresses altruistic values, such as staying alive for family (parents, siblings) and donating organs/tissue. Disbelief that she is dying.</td>
<td>Understand death as irreversible, inevitable and universal. Child needs reassurance of continued care and love. Search for meaning and purpose of life. Reinforce child/adolescent's self-esteem, sense of worth, and self-respect. Allow need for privacy, independence, access to friends and peers. Tolerate expression of strong emotions and permit participation in decision-making. “I can't imagine how you must be feeling. Despite it all, you are doing an incredible job. I wonder how I can help?” “What's most important to you now?” “What are your hopes ... your worries?” “You have taught me so much; I will always remember you.”</td>
</tr>
</tbody>
</table>

A child's perception of death depends on his or her conceptual understanding of *universality* (that all things inevitably die), *irreversibility* (that dead people cannot come back to life), *nonfunctionality* (that being dead means that all biologic functions cease), and *causality* (that there are objective causes of death).

**Very young children** may struggle with the concepts of irreversibility and nonfunctionality. For young school-age children, who are beginning to understand the finality of death, worries may include *magical thinking* in which their thoughts, wishes, or bad behavior might be the underlying cause for their illness. Older children seek more factual information to gain some control over the situation.

**Children**'s fears of death are often centered on the concrete fear of being separated from parents and other loved ones and what will happen to their parents rather than themselves. This can be true for teens and young adults as well. This fear may be responded to in different ways: some families may give reassurance that loving relatives will be waiting, while others use religious concepts to refer to an eternal spiritual connection.

**Adolescents** may have a conceptual understanding of death similar to that of adults, but working with the adolescent with life-threatening illness presents unique concerns and issues. The developmental work of adolescence includes separating from their parents, developing strong peer relationships, and moving towards independent adulthood. For this population, the teenager's developmental need to separate is complicated by the increasing dependence both physically and emotionally on their parents.

In addition to developmental considerations, understanding related to the child's life experiences, the length of the child's illness, the understanding of the nature and prognosis of the illness, the child's role in the family (peacemaker, clown, troublemaker, the good child) should be considered in communication with children.

The question of whether and when to involve adolescents in decision-making arises particularly often. There is no one answer to this question. Instead, numerous considerations should be taken into account, including the adolescent's chronological age, developmental stage, adolescent preference with regard to such participation, and the family's preferred approach to communication and decision-making.

Parents have an instinctive and strong desire to protect their children from harm. When facing the death of their child, many parents attempt to keep the reality of impending death hidden from their child, hoping the child can be
protected from the harsh reality. Although it is important to respect parental wishes, it is also true that most children already have a sense of what is happening to their bodies, even when it has been purposely left unspoken. Children may blame themselves for their illness and the resulting hardships for their loved ones. Perpetuating the myth that “everything is going to be all right” takes away the chance to explore fears and provide reassurance. Assisting parents to understand that the key to honest communication is not telling a child he or she is dying but opening the door to conversation and validating what the child already knows. Honest communication also allows opportunities for memory and legacy making and saying goodbye.

School is the work of childhood and adolescence and is important in optimizing quality of life for a child seeking normalcy in the face of illness. Finding ways to help children and their families to maintain these connections through modification of the school day, and exploring options to promote educational and social connections into the home or into the hospital room, can be meaningful in the event that a child is not well enough to attend school. Video conferencing now can be readily arranged from almost any setting.

The Siblings

Brothers and sisters are at special risk both during their sibling’s illness and after the death. Because of the extraordinary demands placed on parents to meet the needs of their ill child, healthy siblings may feel that their own needs are not being acknowledged or fulfilled. These feelings of neglect may then trigger guilt about their own good health and resentment toward their parents and ill sibling. Younger siblings may react to the stress by becoming seemingly oblivious to the turmoil around them. Some younger siblings may feel guilty for wishing the affected child would die so they could get their parents back (magical thinking). Parents need to know that these are normal responses, and siblings should be encouraged to maintain the typical routines of daily living. Siblings who are most involved with their sick brothers or sisters before death usually adjust better both at the time of and after the death. Acknowledging and validating sibling feelings, being honest and open, and appropriately involving them in the life of their sick sibling provide a good foundation for the grief process. It is often helpful to identify a person in the family (e.g., caring aunt) or school (e.g., counselor) to offer confidential and supportive opportunities for the sibling to reflect on their family experience, particularly as parents may be too
overwhelmed to provide this at crucial times.

The Staff

Inadequate support for the staff providing palliative care can result in depression, emotional withdrawal, and other symptoms. Offering educational opportunities and emotional support for staff at various stages of caring for a child with life-threatening illness can be helpful in bettering patient/family care and preventing staff from experiencing compassion fatigue, burnout, and long-term repercussions, including leaving the field.

Goals of Care and Decision-Making

In the course of a child's life-limiting illness, a series of important decisions may arise in relation to location of care, medications with risks and benefits, not starting or discontinuing life-prolonging treatments, experimental treatments in research protocols, and use of integrative therapies (see Chapter 78). Such family decisions are greatly facilitated by opportunities for in-depth and guided discussions around goals of care for the child. This is often accomplished by eliciting parent (and child) understanding of the child's condition and asking open-ended questions that explore the parent's and child's hopes, worries, and family values. Goals-of-care conversations include what is most important for them as a family, considerations of their child's clinical condition, and their values and beliefs, including cultural, religious, and spiritual considerations. Table 7.3 presents specific questions that can effectively guide these discussions. The conversation should also include a review of previous discussions, active listening to concerns and issues as they are raised, opportunities to repeat back elements of the discussion to ensure clarity, and provision of honest, factual answers even in areas of uncertainty.

Table 7.3

Five Basic Questions to Guide “Goals of Care” Conversation

<table>
<thead>
<tr>
<th>PHRASING FOR ADULT OR OLDER ADOLESCENT</th>
<th>PHRASING FOR CHILD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tell us about your child as a person.</td>
<td>Tell me about yourself before you got sick.</td>
</tr>
<tr>
<td>What does your child enjoy?</td>
<td></td>
</tr>
<tr>
<td>What is your understanding of your child's illness/condition?</td>
<td>Why are you in the hospital?</td>
</tr>
<tr>
<td></td>
<td>What do you understand about your illness?</td>
</tr>
</tbody>
</table>
In light of your understanding, what is most important to you regarding your child's care? | What do you want others to know or do for you when taking care of you?
---|---
What are you hoping for? What are your worries? | I wonder if there is anything that is worrying you or that is keeping you up at night. Is there anything you wish you could talk about?
What gives you strength in the face of your child's illness/condition? | What helps you get through the day? What helps you feel good?

Decision-making should be focused on the goals of care, as opposed to limitations of care; “This is what we can offer,” instead of, “There is nothing more we can do.” Rather than meeting specifically to discuss withdrawing support or a do-not-resuscitate (DNR) order, a more general discussion centered on the goals of care will naturally lead to considering which interventions are in the child's best interests and can present an opportunity for the clinicians to make recommendations based on these goals. By offering medical recommendations based on family goals and the clinical reality, the team can decrease the burden of responsibility for decision-making that parents carry.

Resuscitation Status

Many parents do not understand the legal mandate requiring attempted resuscitation for cardiorespiratory arrest unless a written DNR order is in place. In broaching this topic, rather than asking parents if they want to forgo cardiopulmonary resuscitation (CPR) for their child (and placing the full burden of decision-making on them), it is preferable to discuss whether or not resuscitative interventions are likely to benefit the child. It is important to make recommendations based on overall goals of care and medical knowledge of potential benefit and/or harm of these interventions. Once the goals of therapy are agreed on, the physician is required to write a formal order. Out-of-hospital DNR verification forms are available in many states, which if completed on behalf of the child, affirm that rather than initiating resuscitative efforts, emergency response teams are obligated to provide appropriate symptom management with comfort and relief of suffering with appropriate interventions when called to the scene.

Almost half of all states have implemented the physician orders for life treatment (POLST) system. A POLST order is completed for children with life-threatening illness, translating the expressed parent's and/or child's wishes for interventions to do or not do into actionable orders (www.polst.org). It is usually helpful to frame discussions about POLST as ways for parents to maintain some control, by communicating their goals and care preferences, so
that they may be honored, irrespective of the setting. It may also be beneficial to write a letter that delineates decisions regarding resuscitation interventions and supportive care measures to be undertaken for the child, particularly if POLST are not available. The letter should be as detailed as possible, including recommendations for comfort medications and contact information for caregivers best known to the patient. Such a letter, given to the parents, with copies to involved caregivers and institutions, can be a useful communication aid, especially in times of crisis. In any case, if a child may die in the home setting, and the parents opt to use on out-of-hospital DNR verification form or POLST, plans to pronounce the child and provide support for the family must be in place. If the child has been referred to hospice, the hospice usually fulfills those responsibilities.

Conflicts in decision-making can occur within families, within healthcare teams, between the child and family, and between the family and professional caregivers (see Chapter 6). For children who are developmentally unable to provide guidance in decision-making (neonates, very young children, or children with cognitive impairment), parents and healthcare professionals may come to different conclusions as to what is in the child's best interests. Decision-making around the care of adolescents presents specific challenges, given the shifting boundary that separates childhood from adulthood. In some families and cultures, truth-telling and autonomy are secondary to maintaining the integrity of the family (see Chapter 11). Although frequently encountered, differences in opinion are often manageable for all involved when lines of communication are kept open, team and family meetings are held, and the goals of care are clear.

Symptom Management

Intensive symptom management is another cornerstone of pediatric palliative care. Alleviation of symptoms reduces suffering of the child and family and allows them to focus on other concerns and participate in meaningful experiences. Despite increasing attention to symptoms, and pharmacologic and technical advances in medicine, children often suffer from multiple symptoms. Table 7.4 provides key elements and general approaches to managing symptoms.

| Key Elements of Effective Symptom Management |
Setting the Stage

- Establish and periodically revisit goals of care and ensure that goals are communicated to entire care team.
- Plan for symptoms (including unanticipated ones) before they occur.

Assessment

- Assess the child for symptoms regularly, using consistent and developmentally appropriate assessment tools.
  - Utilize self-report, if the child is able to reliably report symptoms.
- Evaluate all aspects of the symptom, including quality, frequency, duration, and intensity.
- Consider the holistic nature of symptoms.
- Explore the meaning that symptoms may have for families in their social, cultural, and religious context.
- Assess distress caused by the symptom.
- Evaluate the degree of functional impairment from the symptom.

Treatment

- Understand the pathophysiology of the symptom, and establish a complete differential diagnosis.
- Treat the underlying cause if possible, weighing benefits and risks, in the context of goals of care.
- Choose the least invasive route for medications—by mouth whenever possible.
- Prescribe regular medications for constant symptoms, and consider prn doses for breakthrough or uncontrolled symptoms.
- Consider all approaches (i.e., pharmacologic/nonpharmacologic and local/systemic).
- Partner with families to identify and address any barriers to optimal control of symptoms.
- Address spiritual, emotional, and existential suffering in addition to physical
suffering since these are often interrelated.

**Ongoing Care**

- Reassess the symptom and response to interventions regularly.
- For refractory symptoms, revisit the differential diagnosis and review potentially contributing factors.
- Effective interventions relieve the symptom and reduce distress and functional impairment.

**Pain** is a complex sensation triggered by actual or potential tissue damage and influenced by cognitive, behavioral, emotional, social, and cultural factors. Effective pain relief is essential to prevent *central sensitization*, a central hyperexcitation response that may lead to hypersensitivity and escalating pain, and to diminish a stress response that may have a variety of physiologic effects. Assessment tools include self-report tools for children who are able to communicate their pain verbally, as well as tools based on behavioral cues for children who are unable to do so because of their medical condition or a neurodevelopmental disorder. Tables 7.5 to 7.7 address management of pain (see also Chapter 76).

**Table 7.5**

**Guidelines for Pain Management**

- Use nonopioid analgesics as monotherapy for mild pain, and together with opioids for more severe pain.
  
  Nonopioid analgesics include acetaminophen, nonsteroidal antiinflammatory drugs (NSAIDs), salicylates, and selective cyclooxygenase (COX-2) inhibitors.

- For moderate or severe pain, start with a short-acting opioid at regular intervals.

  When dose requirements have stabilized, consider converting opioid to a long-acting formulation with doses available for breakthrough or uncontrolled pain, as needed.

  - For uncontrolled pain, increase opioid dose by 30–50%; for severe pain, increase by 50–100%.
• Avoid codeine and opioids with mixed-agonist activity (e.g., butorphanol, pentazocine).

• Administer medications by the simplest, most effective, and least distressing route.

• Dispel the myth that strong medications should be saved for extreme situations or the very end of life.
  Opioids do not have a “ceiling effect,” and escalating symptoms can usually be treated with an increase in dose. If further titration does not provide adequate analgesia, the opioid may be rotated to another (see below).

• Clarify for families the differences among tolerance, physical dependence, and addiction.

• Anticipate and treat/prevent common analgesic side effects (gastritis with NSAIDs; constipation, pruritus, nausea, and sedation with opioids).
  Always initiate a bowel regimen to prevent constipation when starting opioids.
  Consider a stimulant for opioid-induced somnolence.
  Pruritus rarely indicates a true allergy. If not responsive to an antihistamine, consider low-dose naloxone or switching opioids.
  Consider switching to a different opioid for intolerable side effects or neurotoxicity (e.g., myoclonus).
  Use an equianalgesic conversion table when switching opioids, and account for incomplete cross-tolerance with dose reduction.

• Consider the use of adjuvant drugs for specific pain syndromes, and for their opioid-sparing effect:
  Antidepressants (e.g., amitriptyline, nortriptyline) and anticonvulsants (e.g., gabapentin, carbamazepine, topiramate) for neuropathic pain
  Steroids or NSAIDs for bone pain
  Sedatives and hypnotics for anxiety and muscle spasm
  To enhance analgesia from opioids, consider clonidine or ketamine.
    • Use topical local anesthetics (lidocaine, prilocaine, bupivacaine) when possible
    • Consider anesthetic blocks for regional pain.
    • Consider palliative radiation therapy.
    • Consider psychological approaches (e.g., cognitive or...
behavioral therapy) and integrative therapies (e.g., acupuncture, massage).

| Olanzapine        | 4-6 yr: 1.25 mg PO daily  
                      6-12 yr: 2.5 mg PO daily  
                      ≥12 yr: 5 mg daily | Little evidence to guide antiemetic dosing. Ranges largely derived from olanzapine dosing for other purposes. Avoid concomitant use with metoclopramide. |

### Anxiety

| Lorazepam | See previous listing. | See previous listing. |

### Agitation

| Haloperidol 0.01 mg/kg PO tid prn for acute onset: 0.025-0.050 mg/kg PO, may repeat 0.025 mg/kg in 1 hr prn | May cause extrapyramidal reactions, which can be reversed with diphenhydramine or Cogentin. Safety not established in children <3 yr. |

### Sleep disturbance/insomnia

| Lorazepam | See previous listing. | See previous listing. |

### Trazodone

| Children 6-18 yr: 0.75-1 mg/kg/dose, given bid-tid if needed  
                      If >18 yr, start at 25-50 mg/dose, given bid-tid if needed | Potentially arrhythmogenic |

### Fatigue

| Methylphenidate 0.3 mg/kg/dose titrated as needed, up to 60 mg/day | Rapid antidepressant effect; also improves cognition. Administer before meals to avoid appetite suppression. Use with caution in children at risk for cardiac arrhythmia. Available as liquid and chewable tablet. |

### Pruritus

| Diphenhydramine 0.5-1 mg/kg q6h IV/PO (100 mg max per day) | May reverse phenothiazine-induced dystonic reactions. Topical formulation on large areas of the skin or open area may cause toxic reactions. May cause paradoxical reaction in young children. |
| Hydroxyzine 0.5-1 mg/kg q6h IV/PO (600 mg max per day) |

### Constipation

| Docusate 40-150 mg/day PO in 1-4 divided doses | Stool softener available as liquid or capsule |
| Miralax  
<5 yr: ½ scoop (8.5 g) in 4 oz water daily  
>5 yr: 1 scoop (17 g) in 8 oz water daily | Tasteless powder may be mixed in beverage of choice. Now available over the counter. |
<p>| Lactulose 5-10 mL PO up to q2h until bowel movement | Bowel stimulant; dosing q2h may cause cramping. |
| Senna 2.5 mL PO daily (for children &gt;27 kg) | Bowel stimulant; available as granules |</p>

* Infants <6 mo should receive 25–30% of the usual opioid starting dose.
† Although the usual opioid starting dose is presented, dose may be titrated as needed. There is no ceiling/maximum dose for opioids.
‡ Breakthrough dose is 10% of 24 hr dose. See Chapter 76 for information regarding titration of opioids.
§ Side effects from opioids include constipation, respiratory depression, pruritus, nausea, urinary retention, physical dependence.

**Note:** Some medications or dosing may not apply to infants (≤12 mo). Verify suitability and dosing of all medications before administering to neonates.

IV, Intravenous(ly); PO, by mouth; PR, rectally; prn, as needed; gtt, drops; SC, subcutaneously; bid, twice daily; tid, 3 times daily; q4h, every 4 hours; q30min, every 30 minutes; CNS, central nervous system; ECG, electrocardiogram; ICP, intracranial pressure.

### Table 7.7
Nonpharmacologic Approach to Symptoms Commonly Experienced by Children With Life-Threatening Illness

<table>
<thead>
<tr>
<th>SYMPTOM</th>
<th>APPROACH TO MANAGEMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pain</td>
<td>Prevent pain when possible by limiting unnecessary painful procedures, providing sedation, and giving preemptive analgesia before a procedure (e.g., including sucrose for procedures in neonates). Address coincident depression, anxiety, sense of fear or lack of control. Consider guided imagery, relaxation, hypnosis, art/pet/play therapy, acupuncture/acupressure, biofeedback, massage, heat/cold, yoga, transcutaneous electric nerve stimulation, distraction.</td>
</tr>
<tr>
<td>Dyspnea or air hunger</td>
<td>Suction oral secretions if present; positioning, comfortable loose clothing, fan to provide cool, blowing air. Limit volume of intravenous fluids; consider diuretics if fluid overload/pulmonary edema</td>
</tr>
<tr>
<td>Symptom</td>
<td>Strategies/Recommendations</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Fatigue</td>
<td>Sleep hygiene (establish a routine, promote habits for restorative sleep). Regular, gentle exercise; prioritize or modify activities. Address potentially contributing factors (e.g., anemia, depression, side effects of medications). Aromatherapy*: peppermint, rosemary, basil.</td>
</tr>
<tr>
<td>Nausea/vomiting</td>
<td>Consider dietary modifications (bland, soft, adjust timing/volume of foods or feeds). Aromatherapy*: ginger, peppermint, lavender, acupuncture/acupressure.</td>
</tr>
<tr>
<td>Constipation</td>
<td>Increase fiber in diet, encourage fluids, ambulation (if possible).</td>
</tr>
<tr>
<td>Oral lesions/dysphagia</td>
<td>Oral hygiene and appropriate liquid, solid and oral medication formulation (texture, taste, fluidity). Treat infections, complications (mucositis, pharyngitis, dental abscess, esophagitis). Oropharyngeal motility study and speech (feeding team) consultation.</td>
</tr>
<tr>
<td>Anorexia/cachexia</td>
<td>Manage treatable lesions causing oral pain, dysphagia, or anorexia. Support caloric intake during phase of illness when anorexia is reversible. Acknowledge that anorexia/cachexia is intrinsic to the dying process and may not be reversible. Prevent/treat coexisting constipation.</td>
</tr>
<tr>
<td>Diarrhea</td>
<td>Evaluate/treat if obstruction. Assess and treat infection. Dietary modification.</td>
</tr>
<tr>
<td>Depression</td>
<td>Psychotherapy, behavioral techniques, setting attainable daily goals. Aromatherapy*: bergamot, lavender.</td>
</tr>
<tr>
<td>Anxiety</td>
<td>Psychotherapy (individual and family), behavioral techniques. Aromatherapy*: clary sage, angelica, mandarin, lavender.</td>
</tr>
<tr>
<td>Agitation/terminal restlessness</td>
<td>Evaluate for organic or drug causes. Educate family. Orient and reassure child; provide calm, nonstimulating environment, use familiar music, verse, voice, touch. Aromatherapy*: frankincense, ylang ylang.</td>
</tr>
</tbody>
</table>

* Best if aromatherapy is administered by a practitioner trained in aromatherapy use and safety and if child has choice of essential oil aroma that stimulates positive response.

Many children with life-threatening illness experience pain that requires opioids for adequate relief at some point in their illness trajectory. The WHO pain guidelines recommend the first step for mild pain and the second step for moderate to severe pain. Although it was previously recommended, prescribing codeine should generally be avoided because of its side effect profile and lack of superiority over nonopioid analgesics. Furthermore, relatively common genetic polymorphisms in the *CYP2D6* gene lead to wide variation in codeine metabolism. Specifically, 10–40% of individuals carry polymorphisms causing them to be poor metabolizers who cannot convert codeine to its active form,
morphine, and therefore are at risk for inadequate pain control. Others are ultrametabolizers who may even experience respiratory depression from rapid generation of morphine from codeine. It is therefore preferable to use a known amount of the active agent, morphine.

It is important to explore with families, as well as members of the care team, misconceptions that they may have regarding respiratory suppression, addiction, dependence, the symbolic meaning of starting an opioid such as methadone or morphine and/or a morphine drip, and the potential for opioids to hasten death. There is no association between administration or escalation of opioids and length of survival. Evidence supports longer survival in individuals with symptoms that are well controlled.

Children also often experience a multitude of nonpain symptoms. A combination of both pharmacologic (Table 7.6) and nonpharmacologic (Table 7.7) interventions is often optimal. Fatigue is one of the most common symptoms in children with advanced illness. Children may experience fatigue as a physical symptom (e.g., weakness or somnolence), a decline in cognition (e.g., diminished attention or concentration), and impaired emotional function (e.g., depressed mood or decreased motivation). Because of its multidimensional and incapacitating nature, fatigue can prevent children from participating in meaningful or pleasurable activities, thereby impairing quality of life. Fatigue is usually multifactorial in etiology. A careful history may reveal contributing physical factors (uncontrolled symptoms, medication side effects), psychological factors (anxiety, depression), spiritual distress, or sleep disturbance. Interventions to reduce fatigue include treatment of contributing factors, exercise, pharmacologic agents, and behavior modification strategies. Challenges to effectively addressing fatigue include the common belief that fatigue is inevitable, lack of communication between families and care teams about it, and limited awareness of potential interventions for fatigue.

Dyspnea (the subjective sensation of shortness of breath) results from a mismatch between afferent sensory input to the brain and the outgoing motor signal from the brain. It may stem from respiratory causes (e.g., airway secretions, obstruction, infection) or other factors (e.g., cardiac) and may also be influenced by psychological factors (e.g., anxiety). Respiratory parameters such as respiratory rate and oxygen saturation correlate unreliably with the degree of dyspnea. Therefore, giving oxygen to a cyanotic or hypoxic child who is otherwise quiet and relaxed may relieve staff discomfort while having no impact on patient distress and may also add burden if the child cannot tolerate the mask
or cannula. Dyspnea can be relieved with the use of regularly scheduled plus as-needed doses of opioids. Opioids work directly on the brainstem to reduce the sensation of respiratory distress, as opposed to relieving dyspnea by sedation. The dose of opioid needed to reduce dyspnea is as little as 25% of the amount that would be given for analgesia. Nonpharmacologic interventions, including guided imagery or hypnosis to reduce anxiety, or cool, flowing air, aimed toward the face, are also frequently helpful in alleviating dyspnea. While oxygen may relieve hypoxemia-related headaches, it is no more effective than blowing room air in reducing the distressing sensation of shortness of breath.

As death approaches, a buildup of secretions may result in noisy respiration sometimes referred to as a “death rattle.” Patients at this stage are usually unconscious, and noisy respirations are often more distressing for others than for the child. It is often helpful to discuss this anticipated phenomenon with families in advance, and if it occurs, to point out the child's lack of distress from it. If treatment is needed, an anticholinergic medication, such as glycopyrrolate, may reduce secretions.

Neurologic symptoms include seizures that are often part of the antecedent illness but may increase in frequency and severity toward the end of life. A plan for managing seizures should be made in advance, and anticonvulsants should be readily available in the event of seizure. Parents can be taught to use rectal diazepam at home. Increased neuroirritability accompanies some neurodegenerative disorders; it may be particularly disruptive because of the resultant break in normal sleep–wake patterns and the difficulty in finding respite facilities for children who have prolonged crying. Such neuroirritability may respond to gabapentin. Judicious use of sedatives, benzodiazepines, clonidine, nortriptyline, or methadone may also reduce irritability without inducing excessive sedation; such treatment can dramatically improve the quality of life for both child and caregivers. Increased intracranial pressure and spinal cord compression are most often encountered in children with brain tumors or metastatic and solid tumors. Depending on the clinical situation and the goals of care, radiation therapy, surgical interventions, and steroids are potential therapeutic options.

Delirium is an underrecognized brain disorder characterized by waxing-and-waning attention, confusion, and disorientation. Agitation may occur, as well as features of hypomania. Although delirium as a whole is often not diagnosed, the hypomanic form is particularly underrecognized. Delirium has a range of causes, including medications such as anticholinergics and benzodiazepines.
Environmental strategies to calm and orient the child while addressing potentially contributing factors are helpful. In some patients, antipsychotic/neuroleptic medications are indicated (see Chapter 33 and 47).

**Feeding and hydration** issues can raise ethical questions that evoke intense emotions in families and medical caregivers alike. Options that may be considered to artificially support nutrition and hydration in a child who can no longer feed by mouth include nasogastric and gastrostomy feedings or intravenous nutrition or hydration (see Chapter 55). These complex decisions require evaluating the risks and benefits of artificial feedings and taking into consideration the child's functional level and prognosis. At times, it may be appropriate to initiate a trial of tube feedings, with the understanding that they may be discontinued at a later stage of the illness. A commonly held but unsubstantiated belief is that artificial nutrition and hydration are comfort measures, without which a child may suffer from starvation or thirst. This may result in well-meaning but disruptive and invasive attempts to administer nutrition or fluids to a dying child. In dying adults, the sensation of thirst may be alleviated by careful efforts to keep the mouth moist and clean. There may also be deleterious side effects to artificial hydration in the form of increased secretions, need for frequent urination, edema, and exacerbation of dyspnea. For these reasons, it is important to educate families about anticipated decreases in appetite/thirst and therefore little need for nutrition and hydration as the child approaches death. In addition, exploring the meaning that provision of nutrition and hydration may hold for families, as well as helping families anticipate the changes in their child's appearance and exploring alternative ways that they may love and nurture their child, may ease distress around this issue.

**Nausea and vomiting** may be caused by medications or toxins, irritation to or obstruction of the gastrointestinal tract, motion, and emotions. Drugs such as metoclopramide, 5-hydroxytryptamine antagonists, corticosteroids, olanzapine, and aprepitant may be used and should be chosen depending on the underlying pathophysiology and neurotransmitters involved. Vomiting may accompany nausea but may also occur without nausea, as with increased intracranial pressure. **Constipation** is commonly encountered in children with neurologic impairment or children receiving medications that impair gastrointestinal motility (most notably opioids). Stool frequency and quantity should be evaluated in the context of the child's diet and usual bowel pattern. Children taking regular opioids should routinely be placed on stool softeners (docusate) in addition to a laxative agent (e.g., senna). For some patients, parenteral
methylnaltrexone is also helpful in relieving opioid-induced constipation. Diarrhea may be particularly difficult for the child and family and may be treated with loperamide (an opioid that does not cross the blood-brain barrier), and in some cases, colestyramine or octreotide may be indicated. Paradoxical diarrhea, a result of overflow resulting from constipation, should also be included in the differential diagnosis.

Hematologic issues include consideration of anemia and thrombocytopenia or bleeding. If the child has symptomatic anemia (weakness, dizziness, shortness of breath, tachycardia), red blood cell transfusions may be considered. Platelet transfusions may be an option if the child has symptoms of bleeding. Life-ending hemorrhage is disturbing for all concerned, and a plan involving the use of fast-acting sedatives should be prepared in advance if such an event is a possibility.

Skin care issues include primary prevention of problems by ongoing and timely assessment (including observation of indwelling lines and tubes) and frequent turning and repositioning and alleviating pressure wherever possible (e.g., elevating heels off the bed with pillows). Pruritus may be secondary to systemic disorders or drug therapy. Treatment includes avoiding excessive use of drying soaps, using moisturizers, trimming fingernails, and wearing loose-fitting clothing, in addition to administering topical or systemic corticosteroids. Oral antihistamines and other specific therapies may also be indicated (e.g., cholestyramine in biliary disease). Opioids can cause histamine release from mast cells, but this does not account for most of the pruritus caused by opioids. A trial of diphenhydramine may provide relief; alternatively, rotating opioids or instituting a low dose of opioid antagonist may be needed for refractory pruritus.

Children with life-threatening illness may experience psychological symptoms such as anxiety and depression. Such symptoms are frequently multifactorial and sometimes interrelated with uncontrolled symptoms such as pain and fatigue. Diagnosing depression in the context of serious illness may pose challenges because neurovegetative symptoms may not be reliable indicators. Instead, expressions of hopelessness, helplessness, worthlessness, and guilt may be more useful. Pharmacologic agents such as antidepressants may be helpful, although their effect is often preceded by a significant lag phase. Because of its immediate and positive effect on mood, methylphenidate may be an effective antidepressant for children at end of life, when there may not be time for a traditional antidepressant to take effect. Interventions and opportunities for children to explore worries, hopes, and concerns in an open, supportive, and
nonjudgmental setting are equally if not more important approaches to psychological distress. Skilled members from a variety of disciplines, including psychology, social work, chaplaincy, child life, and expressive therapy, may help children and their families in this regard. Such opportunities may create positive moments in which meaning, connection, and new definitions of hope are found.

Discussions with adolescent patients, or with the parents of any ill child, about possible therapies or interventions should include integrative therapies such as massage therapy, Reiki, acupuncture, clinical aromatherapy, prayer, and nutritional supplements. Many families use integrative therapy but do not bring it up with their physician unless explicitly asked (see Chapter 78). Although largely unproven, some of these therapies are inexpensive and provide relief to individual patients. Other therapies may be expensive, painful, intrusive, and even toxic. By initiating conversation and inviting discussion in a nonjudgmental way, the clinician can offer advice on the safety of different therapies and may help avoid expensive, dangerous, or burdensome interventions. Medical marijuana (cannabis) for pediatric use has been legalized by some states, and pediatricians are increasingly asked about it. In such cases, it is most helpful to use this opportunity to engage in a broader conversation about symptoms and symptom management, even in states where use of cannabis for pediatric medicinal purposes is legal.

**Intensive Symptom Management**

At the end of life, when intensive efforts to relieve the symptom have been exhausted, or when efforts to address suffering are incapable of providing relief with acceptable toxicity/morbidity or in an acceptable time frame, palliative sedation may be considered. Palliative sedation may relieve suffering from refractory symptoms by reducing a child's level of consciousness. It is most often used for intractable pain, dyspnea, or agitation, but is not limited to these distressing indications. Palliative sedation provides opportunities for parents, staff, and primary clinicians to discuss the indications and goals for sedation, as well as questions or concerns about this therapy, both before and after initiation of sedation.

The doctrine of double effect (DDE) is often invoked to justify escalation of symptom-relieving medications or palliative sedation for uncontrolled symptoms at the end of life. Use of DDE emphasizes the risk of hastening death posed by escalating opioids or sedation, which is theoretical and unproven (see Chapter 6
). There is mounting evidence that patients with well-controlled symptoms live longer.

**Approaching End of Life**

As death seems imminent, the major task of the physician and team are to help the child have as many good days as possible and not suffer. If not already in place, a referral for hospice care (usually provided in the home, not a hospice house for children) may provide the most comprehensive care for the child and family. Gently preparing the family for what to expect and offering choices, when possible, will allow them a sense of control in the midst of tragic circumstances. Before death, it can be very helpful to discuss the following:

- Support of siblings or other family members
- Resuscitation status
- Limiting technology when no longer beneficial to the child
- Cultural, spiritual, or religious needs
- Location of death
  - Who will pronounce if death occurs at home
- Funeral arrangements
  - Offering siblings choice and appropriate support to attend
- Autopsy and/or tissue/organ donation
  - Legacy building, benefits others, informs science and family

Offered the opportunity, families will often tolerate thinking and speaking about their hopes and fears regarding their child's end of life, and some even express relief when the door to such conversation in opened by the care team. It may help to let the family know these conversations are not about *whether* the child will die but *how* the child may die.
Families gain tremendous support from having a physician and team who will continue to stay involved in the child's care. If the child is at home or hospitalized, regular phone calls or visits, assisting with symptom management, and offering emotional support is invaluable for families.

In an intensive care setting, where technology can be overwhelming and put distance between the child and parent, the physician can offer discontinuation of that which is not benefiting the child or adding to quality of life. Less invasive ways to control symptoms, such as subcutaneous infusions or topical applications, may be helpful. Parents may be afraid to ask about holding or sleeping next to their child. They may need reassurance and assistance in holding, touching, and speaking with their child, despite tubes and technology, even if the child appears unresponsive.

It is believed that hearing and the ability to sense touch are often present until death; all family members should be encouraged to continue interacting with their loved one through the dying process. Parents may be afraid to leave the bedside so that their child will not die alone. Offering parents other supports such as chaplaincy/clergy, social work, and extended family members may be helpful. In most instances the moment of death cannot be predicted. Some propose that children wait to die until their parents are ready, an important event has passed, or they are given permission. Caregivers need not dispute this, nor the hope for a miracle often held by families until the child takes the last breath.

For the family, the moment of death is an event that is recalled in detail for years to come, and thus enhancing opportunity for dignity and limited suffering is essential. Research suggests that improved symptom control and easing of difficult moments at the time of death may lessen the long-term distress of bereaved parents. Clinical experience has shown that families often find solace in clinician presence, whether at home or in the hospital. After death, families should be given the option of remaining with their child for as long as they would like and should be prepared for changes in the child's body. During this time, physicians and other professionals may ask permission to say goodbye. The family may be invited to bathe and dress the body as a final act of caring for the child.

The physician's decision to attend the funeral is a personal one. Participation may serve the dual purpose of showing respect and helping the clinician cope with a personal sense of loss. If unable to attend services, families report highly valuing the importance of receiving a call, card, or note from the physician. To know that their child made a difference and will not be forgotten is often very
important to families in their bereavement.

**The Pediatrician**

Although optimal palliative care for children entails caregivers from a variety of disciplines, pediatricians are well positioned to support children and their families, particularly if they have a long-standing relationship with multiple family members. A pediatrician who has cared for a family over time may already know and care for other family members, understand preexisting stressors for the family, and may be familiar with coping strategies used by family members. Pediatricians are familiar with the process of eliciting concerns and providing anticipatory guidance for parents, as well as developmentally appropriate explanations for children.

**Bibliography**

Adoption is a social, emotional, and legal process that provides a new family for a child when the birth family is unable or unwilling to parent. In the United States, about 1 million children <18 yr of age are adopted; 2–4% of all American families have adopted. Annually across the globe, approximately 250,000 children are adopted, with 30,000 of these between nations. In the United States, approximately 120,000 children are adopted every year. Of these, 49% are from private agencies, American Indian Tribes, stepparent, or other forms of kinship care. The remaining 51% of adoptions include public and international adoptions. Public adoptions account for the majority of these. Because of changing policies toward adoption and social change in several of the sending countries, the number of international adoptions has decreased dramatically over the last 10 yr. Public agencies support approximately 50% of total annual adoptions in the United States, private agencies facilitate 25% of adoptions, and independent practitioners (e.g., lawyers) handle 15% of adoptions. Compared to 19% of the general population, approximately 39% of adopted children have special healthcare needs.

**Domestic Adoption**

The *Adoption and Safe Families Act* (P.L. 105-89) requires children in foster care to be placed with adoptive families if they cannot be safely returned to their families within a reasonable time. In fiscal year (FY) 2014, there were an estimated 415,129 children in foster care, and 107,918 were waiting for adoption. Of the 238,230 children who exited foster care, 51% were reunited with parent(s) or primary caretakers(s), and 21% were adopted (see Chapter 9).

Many children awaiting adoption are less likely to be adopted because they
are of school age, part of a sibling group, members of historically oppressed racial/ethnic groups, or because they have considerable physical, emotional, or developmental needs. A number of policy efforts are aimed at increasing adoption opportunities for these children, including federal adoption subsidies, tax credits, recruitment efforts to identify ethnically diverse adults willing to adopt, increased preplacement services, and expanding adoption opportunities to single adults, older couples, and gay/lesbian partners.

Although same-sex couple adoption is legal in more than a dozen countries worldwide, it is actively debated in the United States. Although legislation regarding same-sex couple adoption varies by state, increasing numbers of gay and lesbian partners have been able to adopt. Current estimates suggest that almost 2 million children, including 5% of all adopted children, are raised by gay and lesbian parents. Adopted children include those adopted domestically, those from foster care, and internationally adopted children. There is increasing evidence that children raised by same-sex couples are as physically or psychologically healthy, capable, and successful as those raised by opposite-sex couples. Pediatricians can advocate for adopted children by supporting gay and lesbian parents.

Open adoption, usually through an agency or privately, occurs when the birth mother arranges to continue to be involved, although in a limited manner, with the legally adopted family. This may occur through surrogacy or more often in an unplanned pregnancy.

**Intercountry Adoption**

Along with foster care adoptions, international adoptions are a way of providing stable, long-term care to vulnerable children throughout the world. There is concern that in some countries of origin, the rapid growth of international adoption has outpaced regulation and oversight to protect vulnerable children and families. Opportunities for financial gain have led to abuses, including the sale and abduction of children, bribery, and financial coercion of families, but the extent and scope of the potential concern is difficult to ascertain. Increasing global efforts, such as the **Hague Convention on Protection of Children and Co-operation in Respect of Intercountry Adoption**, have promoted political cooperation between nations and established international law to reduce potential for child abduction and child trafficking and to ensure that the best interests of the child are paramount in decision making.
Participating nations, including the United States, are working to address the myriad of sociopolitical conditions that create the need for out-of-family care, and are working to support children within their nation's borders. International adoption is increasingly considered a measure of last resort if the child cannot be cared for within his or her birth family (including extended relatives), the immediate community, or the larger national culture. As a result, children adopted internationally into the United States are more likely to enter their families at older ages or with complex medical, developmental, or social-emotional needs.

Although the vast majority of children adopted internationally enter the United States for purposes of adoption, a small but growing number of children exit the United States for adoption into other countries. For example, in FY 2014, 96 children exited the United States for adoption by families in other countries (e.g., Canada, Netherlands, Ireland, United Kingdom). Little is known about the circumstances surrounding these adoptions and the eventual outcomes of the children who are adopted internationally from the United States.

In 2015, U.S. families adopted 5,647 children from other countries (compared with a peak of 22,884 in 2004). Children from China, Ethiopia, South Korea, Ukraine, Bulgaria, and the Congo represented 65% of children adopted internationally into the United States in 2015; 42% were from China alone. Although individual experiences vary, most children placed for international adoption have some history of poverty and social hardship in their home countries, and most are adopted from orphanages or institutional settings. Many young infants are placed into orphanage care shortly after birth. Some older children have experienced family disruption resulting from parental illness, war, or natural disasters. Still others enter orphanage care after determination of significant abuse or neglect within their biological families. The effects of institutionalization and other life stresses may impact all areas of growth and development. As a result, many children require specialized support and understanding to overcome the impact of stress and early adversity and to reach their full potential.

**Role of Pediatricians**

**Preadoption Medical Record Reviews**

Preadoption medical record reviews are important for both domestic and
international adoptions. Adoption agencies are making increased efforts to obtain biological family health information and genetic histories to share with adoptive families prior to adoption. Such information is often becomes increasingly relevant as the child ages. Pediatricians can help prospective adoptive parents understand the health and developmental history of a child and available background information from birth families in order to assess actual and potential medical risk factors to support adult decision-making about the family's ability to parent the waiting child.

Under the Hague Convention, U.S. agencies that arrange international adoptions must make efforts to obtain accurate and complete health histories on children awaiting adoption. The nature and quality of medical and genetic information, when available, vary greatly. Poor translation and use of medical terminology and medications that are unfamiliar to U.S.-trained physicians are common. Results of specific diagnostic studies and laboratory tests performed outside the United States should not be relied on and should be repeated once the child arrives in the United States. Paradoxically, review of the child's medical records may raise more questions than provide answers. Each medical diagnosis should be considered carefully before being rejected or accepted. Country-specific growth curves should be avoided because they may be inaccurate or may reflect a general level of poor health and nutrition in the country of origin. Instead, serial growth data should be plotted on U.S. standard growth curves; this may reveal a pattern of poor growth because of malnutrition or other chronic illness. Photographs or video files may provide the only objective information from which medical status can be determined. Full-face photographs may reveal dysmorphic features consistent with fetal alcohol syndrome (see Chapter 126.3) or findings suggestive of other congenital disorders.

Frank interpretations of available information should be shared with the prospective adoptive parents. The role of the healthcare provider is not to comment on the advisability of an adoption, but to inform the prospective parents of any significant health needs identified now or anticipated in the future.

**Postadoption Medical Care**

**Arrival Visit–International Adoption**

All internationally adopted children should have a thorough medical evaluation shortly after arriving in the United States. Many children may have acute or
chronic medical problems that are not always immediately evident, including malnutrition, growth deficiencies; stool pathogens, anemia, elevated blood lead, dental decay, strabismus, birth defects, developmental delay, feeding and sensory difficulty, and social-emotional concerns. All children who are adopted from other countries undergo comprehensive screening for infectious diseases and disorders of growth, development, vision, and hearing (Tables 8.1 and 8.2). Regardless of test results before arrival, all children should be screened for tuberculosis with either a tuberculin skin test (TST) or interferon-γ release assays (IGRA). If the child's purified protein derivative (PPD) skin test is negative, it should be repeated in 4-6 mo; children may have false-negative tests because of poor nutrition. Additional tests (e.g., malaria) should be ordered depending on the prevalence of disease in the child's country of origin (see Chapter 10). Immunization records should be carefully reviewed. Internationally adopted children frequently have incomplete records or have been vaccinated using alternative schedules. Pediatricians may choose to check titers to determine which vaccines need to be given, or they can choose to reimmunize the child. The unique medical and developmental needs of internationally adopted children have led to the creation of specialty clinics throughout the United States, which may be a valuable resource for adoptive families at all stages in the adoption process and throughout the adopted child's life.

Other Screening Tests to Consider Based on Clinical Findings and Age of Child
Stool cultures for bacterial pathogens
Glucose-6-phosphate dehydrogenase deficiency screening
Sickle cell test
Urine pregnancy test

**INFECTIONOUS DISEASE SCREENING (see Table 8.2)**

### Table 8.2

**Screening Tests for Infectious Diseases in International Adoptees**

#### Recommended Tests

- **Hepatitis A** total Ig (with reflex testing for IgM if total Ig is positive)
- **Hepatitis B** virus serologic testing
  - Hepatitis B surface antigen (HBsAg)
  - Antibody to hepatitis B surface antigen (anti-HBs)
  - Antibody to hepatitis B core antigen (anti-HBc)
- **Hepatitis C** virus serologic testing
- **Syphilis** serologic testing
  - Nontreponemal test (RPR, VDRL, or ART)
  - Treponemal test (MHA-TP or FTA-ABS)
- **HIV-1 and HIV-2** testing (ELISA if >18 mo, PCR if <18 mo)*
- Complete blood cell count with red blood cell indices and differential (if eosinophilia, see Chapter 10)
- Stool examination for ova and parasites (optimal: 3 specimens) with specific requests for *Giardia lamblia* and *Cryptosporidium* spp. testing
- Tuberculin skin test (with CXR if >5 mm induration) or interferon-γ release assay

#### Optional Tests (for Special Populations or Circumstances)

- GC/Chlamydia
- *Strongyloides* spp.
- *Schistosoma* spp.
- *Trypanosoma cruzi*
Growth Delays
Physical growth delays are common in internationally adopted children and may represent the combined result of many factors, such as unknown/untreated medical conditions, malnutrition, and psychological deprivation. It is more important to monitor growth over time, including preplacement measurements, since trend data may provide a more objective assessment of the child's nutritional and medical status. Children who present with low height-for-age (growth stunting) may have a history of inadequate nutrition as well as chronic adversity. Although most children experience a significant catch-up in physical growth following adoption, many remain shorter than their U.S. peers.

Developmental Delays
Many children adopted internationally exhibit delays in at least 1 area of development, but most exhibit significant gains within the 1st 12 mo after adoption. Children adopted at older ages are likely to have more variable outcomes. In the immediate post-adoption period, it may be impossible to determine with any certainty whether developmental delays will be transient or long-lasting. Careful monitoring of development within the first years of adoption can identify a developmental trend over time that may be more predictive of long-term functioning than assessment at any specific point in time. When in doubt, it is better to refer early for developmental intervention, rather than wait to see if the children will catch up.

Language Development
For both domestic and international adoptees, genetic or biologic risk factors for poor language development may be identified preadoptively, but it is unlikely that international adoptees will have had these delays identified before adoption. These children typically have not had an assessment in their native language and have had little exposure to English. It may not be possible to fully assess their language abilities until they have had a chance to learn English. Regardless of the age at adoption, most internationally adopted children will reach age-expected language skills over time.

If a child has language delays, referral to early intervention or the school district should be made. Clinicians may need to work with these groups to help them understand the unique circumstances surrounding an adopted child's language development. For example, English language acquisition in internationally adopted children depends on the age of adoption and native language skills. Placing the recently adopted, school-age child in an English as a Second Language class may not be sufficient if the child's language development in the primary language has been atypical.

Eating Concerns

Initial concerns about eating, sleep regulation, and repetitive (e.g., self-stimulating or self-soothing) behaviors are common, especially among children adopted following a high degree of neglect or developmental trauma. Feeding behaviors of international adoptees may be linked to orphanage feeding practices, or limited exposure to textured or solid foods during later infancy/toddlerhood. Children who have experienced chronic lack of food may not have developed an awareness of satiation cues, leading to hoarding or frequent vomiting. Feeding concerns often subside gradually with introduction of age-appropriate foods and parental support for positive feeding practices. Many children who were adopted after significant malnutrition may eat an excessive amount of food. Unless the child is eating to the point of vomiting (which would indicate little awareness of satiation cues), it is generally best to allow them to eat until satiation. Typically, within several months, the child will regulate food intake appropriately. Occasionally, additional support from a speech pathologist or feeding specialist is warranted to address possible sensory, physical, or psychological issues around proper feeding.

Sleep Concerns
Sleep is often disrupted as the child reacts to changes in routines and environments. Efforts to create continuity between the preadoption and postadoption environment can be helpful. Within the 1st 3-6 mo, as the child's emotional self-regulation improves, many sleep concerns subside. Similarly, stereotypical behaviors, such as rocking or head banging, often diminish within the 1st few mo after adoption.

Social and Emotional Development

Dyadic interactions between child and caretaker are a critical component to later regulatory functioning and social-emotional development. The amount and quality of individualized caretaking that children have received before their adoption, whether international, domestic, or through the foster care system, is usually unknown. In many cases, entry into a secure, stable home setting with consistent childcare routines is sufficient to support the child's emerging social-emotional development. Pediatricians can help parents remember that adoption is part of a child's history. Throughout one's childhood, prior experiences or biologic disposition may result in behavior that is confusing to the adoptive parents. The child's reactions may be subtle or difficult to interpret, interfering with the parents’ ability to respond in a sensitive manner. In these circumstances, additional support may be helpful to foster the emerging relationships and behavioral regulation in the newly formed family.

Racial Identity Development

Transracial adoption (where the racial background of the child differs from that of the parent/parents) accounts for a significant percentage of adoptions each year in the United States. In most of these adoptive placements, children of color have been adopted by white parents. Racial identity development, including ways to understand and respond to discrimination, is increasingly recognized as important in the overall development of children. Surveys of adults adopted transracially indicate that racial identity is of central importance at many ages and tends to increase in significance during young adulthood. Integrating race/ethnicity into identity can be a complex process for all children, but it may be especially complicated when they are raised in a family where racial differences are noted. Adults raised within interracial families have noted the value of attending racially diverse schools and of having adult role models (e.g., teachers, doctors, coaches) who share their racial background. Parents who adopt
transracially are often encouraged to support interactions within diverse communities and to discuss race (and associated discrimination) often within the family. Black children raised by white families in white communities may have been sheltered from overt racism but need to be taught that many others (including law enforcement officers) will regard them as black with all the intense biases associated with race (see Chapter 2.1).

**Toxic Stress**
The cumulative amount of early adversity (e.g., numerous years within international orphanage care, extensive abuse/neglect prior to removal from biological family, or multiple foster care placements) experienced by a child before adoption, referred to as toxic stress, can impact both immediate placement stability and long-term functioning (see Chapter 2). The degree of presumed toxic stress may be helpful in interpreting a child's behavior and supporting family functioning.*

**Family Support**
The unique aspects to adoptive family formation can create familial stress and impact child and family functioning. Some adoptive families may have to address infertility, creation of a multiracial family, disclosure of adoptive status, concerns and questions the child may have about their biologic origins, and ongoing scrutiny by adoption agencies. With gay/lesbian parents, there are often additional psychosocial stressors, including continued barriers to legal recognition of both parents in a gay/lesbian partnership that can negatively impact family functioning. Although most families acclimate well to adoption-related stressors, some parents experience postadoption depression and may benefit from additional support to ease the family's transition.

**Adoption Narrative**
Families are encouraged to speak openly and repeatedly about adoption with their child, beginning in the toddler years and continuing through adolescence. Creating a *Lifebook* for the adopted child provides a way to support family communication about the child's history and significant relationships (including birth family members) and to document the child's important life transitions (e.g., through foster care or immigration to the United States). It is common, and normal, for children to have questions about adoption and their biological family
throughout their development. An increase in cognitive understanding between ages 7 and 10 yr can sometimes increase adoption-related questions and distress. Youth who have questions about biological family members are increasingly able to access information via social media and web-based searching, raising the importance of ongoing open communication about adoption. Pediatricians may need to respond to increased concerns/questions when the adoptee's health and genetic history is incomplete or unknown. At any time, concerns about development, behavior, and social-emotional functioning may or may not be related to the child's adoption history.

The vast majority of adopted children and families adjust well and lead healthy, productive lives. Adoptions infrequently disrupt; disruption rates are higher among children adopted from foster care, which research associates with their age at adoption and a history of multiple placements before adoption. With increased understanding of the needs of families who adopt children from foster care, agencies are placing greater emphasis on the preparation of adoptive parents and ensuring the availability of a full range of postadoption services, including physical health, mental health, and developmental services for their adopted children.

The placement of children in out-of-home care has served the needs of children in many societies worldwide throughout history. The institution of foster care was developed in the United States as a temporary resource for children during times of family crisis and is rooted in the principle that children fare best when raised in family settings. The mission of foster care is to provide for the safety, permanency, and well-being of children while assisting their families with services to promote reunification.

**Epidemiology**

The number of children in foster care worldwide is unknown, although it has been estimated that 8 million may be in foster and residential care. On September 11, 2015, approximately 427,910 children in the United States resided in foster care, representing a slight increase since the nadir of 397,301 reached in 2012. Early in the millennium, foster care numbers decreased despite an increase in maltreatment reports, as child welfare offered families more preventive services and alternative placement with relatives or nonrelative caregivers (kinship care) as an alternative to court-ordered removal. The more recent increase in numbers appears to be related to the opioid epidemic. Over the last 15 years, reunification rates have stabilized while adoption of children from foster care has increased. Nationally, approximately 45% of children live with a nonrelative foster parent, 30% of children are in placement with a relative who is a certified foster parent, and just under 15% are in congregate (group) care.

Approximately 33% of children in foster care in the United States are younger than 5 yr, and 34% are older than 12 yr. Most children are white (41%); 24% are black, 21% are Hispanic of any race, and 7% are identified as ≥2 races. As foster
care numbers declined by 25% beginning in 1999, the reduction in African American children was even greater as child welfare made efforts to reduce the disparities in investigation and removal. The average length of stay in foster care continues to decline (median in 2015, 20.4 mo), with a significant drop in the number who spend ≥2 yr from 31% in 2011 to 26% in 2015. Only approximately half of children achieve reunification, while 22% (53,000) are adopted and 6% reside with relatives. Among remaining children, 9% (20,800) emancipate between ages 18 and 21 yr, 9% enter into long-term state guardianship, <1% run away, and 2% transfer to other institutions. There were 336 deaths reported in foster care in fiscal year 2015.

Only 4% of children reside in a preadoptive home, although they represent 12% of children awaiting adoption; 52% of children awaiting adoption reside with a foster parent who is a relative. The average number of placements a child experiences in foster care is not included in Adoption and Foster Care Analysis and Reporting System (AFCARS), but important predictors of an increased number of different placements include severe behavioral and developmental problems, larger sibling group size, and longer time spent in foster care. Within 12 mo, almost all emancipated youth have at least 1 homeless night. Within a decade, less than half have achieved a high school degree, most are living in poverty, and many have psychiatric disorders, including posttraumatic stress disorder and depression.

**Legislation in the United States**

In the United States the Adoption and Safe Families Act (P.L. 105-89) requires that a permanency plan be made for each child no later than 12 mo after entry into foster care, and that a petition to terminate parental rights typically be filed when a child has been in foster care for at least 15 of the previous 22 mo. The Fostering Connections and Promoting Adoptions Act of 2009 (P.L. 110-351) focused on incentives for guardianship and adoption, supports for the young adults at the age of emancipation, and rights of Native American children to care within their tribe. This act also contained a clause requiring states to develop and coordinate healthcare systems for children in foster care in collaboration with Medicaid and pediatricians. In 2018 the Family First Prevention Services Act was signed into law. This legislation emphasizes providing evidence-based mental health and substance abuse services for families whose children are at imminent risk of entering foster care.
Early Childhood Trauma Leads to Poor Health Outcomes

Children in foster care have high rates of early childhood trauma and adversity. More than 60% are placed for neglect, 13% for physical abuse, and 5% are abandoned. Parental substance abuse is a factor in 32% of removals, and parent alcohol abuse in 6%. Violence in the home is common, with >80% having experienced domestic and/or community violence, but domestic violence is not included in the AFCARS reporting system as a reason for removal. Parental mental illness is also not reported as a reason for removal in AFCARS, but the literature indicates that birth parents have high rates of mental illness, criminal justice system involvement, substance abuse, unemployment, and cognitive impairment. Many children, particularly infants entering care, have had prenatal substance exposure, multiple caregivers of varying quality, and are from families with long involvement with child protective services.

Removal from the family of origin may compound prior trauma experiences, although some children experience relief at removal from a chaotic, abusive, or dangerous home. Most children miss their family, worry about their parents and siblings, and long for reunification. Separation, loss and grief, unpredictable contact with birth parents, placement changes, the process of terminating parental rights, and the sheer uncertainty of foster care may further erode a child’s well-being.

Childhood trauma is correlated with poor developmental, behavioral, and health outcomes. Early trauma and chronic stress adversely affect the neurobiology of the developing brain, especially those areas involved in attention, emotional regulation, memory, executive function, and cognition. As a result, shortened attention span, hyperactivity, poorer cognitive function, aggression, and memory issues are problems encountered frequently among children in foster care. However, evidence shows that specific interventions, such as specially trained foster parents for children or youth and mentoring for adolescents in foster care, can improve outcomes, although replication and dissemination of these evidence-based interventions are limited.

Health Issues

Experiencing multiple childhood adversities and receiving fragmented and
inadequate health services before placement into foster care mean that children enter foster care with a high prevalence of chronic medical, mental health, developmental, dental, and educational problems (Table 9.1). Thus they are defined as children with special health care needs (CSHCN). The greatest single healthcare need of this population is for high-quality, evidence-based trauma-informed mental health services to address the impacts of prior and ongoing trauma, loss, and unpredictability. In addition, children in foster care have higher rates of asthma, growth failure, obesity, vertically transmitted infections, and neurologic conditions than the general pediatric population. Adolescents need access to reproductive health and substance abuse services. Up to 60% of children <5 yr old have a developmental delay in at least 1 domain and >40% of school-age children qualify for special education services. Unfortunately, educational difficulties persist despite improvements in school attendance and performance after placement in foster care. Each placement change that is accompanied by a change in school sets children back academically by about 4 mo. Federal legislation requires child welfare to maintain children in their school of origin when possible, even if child welfare has to provide transportation to ensure this.

**Table 9.1**

### Health Issues of Children in Foster Care

#### Chronic Medical Problems

- Affect 40–60% of children.
- Asthma, dermatologic, neurologic, obesity, growth failure, hearing, and vision problems are most common.

#### Abuse and Neglect

> 70% of children have a history of abuse and neglect at entry into foster care.
- Monitor at all health visits for abuse or neglect or poor care in the home.

#### Complex Chronic Medical Problems
Involves up to 10% of children in foster care. Children may be dependent on medical technologies or may have multiple disabilities.

**Mental Health Concerns**

Affects 80% of children >4 yr of age. Result of childhood trauma and adversity. Most common diagnoses are adjustment disorder, posttraumatic stress disorder, attention-deficit/hyperactivity disorder, oppositional defiant disorder, and conduct disorder. Externalizing problems are more likely to result in therapy. Minority children and those in kinship care have less access to mental health services.

**Developmental Problems**

60% of children <5 yr of age have at least 1 documented delay. Typically affect communication, cognition, problem-solving, and personal-social domains, including emotional self-regulation.

**Dental Problems**

20–35% of children have significant dental disease.

**Adolescent Health Issues**

High rates of sexually transmitted infections, high-risk behaviors, and substance abuse.

**Educational Problems**

Half of special education placements relate to behavioral or emotional issues, not cognitive. Only 32% of adolescents eventually graduate from high school; 32%
obtain a general equivalency diploma; 1–2% complete any amount of college.

**Family Relationship Problems**

100% of children have family relationship problems.

Although children in foster care are CSHCN, they often lack access to the services they need. Most public and private child welfare agencies do not have formal arrangements for accessing the needed array of health services and rely on local physicians and health clinics funded by Medicaid. Health histories are often sparse at admission because many have lacked regular care, or their biological parents may not be available or forthcoming. Once children enter foster care, there is often a diffusion of responsibility across caregivers and child welfare. Foster parents usually receive little information about a child's healthcare needs, but they are typically expected to decide when and where children receive healthcare services. Child welfare caseworkers are responsible for ensuring that a child's health needs are addressed but coordination across multiple healthcare providers may be daunting. Uncertainty about who is legally responsible for making healthcare treatment decisions and who may have access to health information may delay or result in the denial of healthcare services.

**Healthcare for Children and Adolescents in Foster Care**

The American Academy of Pediatrics (AAP) has published detailed healthcare standards for children in foster care, available on the *Healthy Foster Care America* website. The AAP recommends that children receive healthcare services in a medical home setting, where comprehensive healthcare is continuous over time (Table 9.2). Compassionate, culturally competent healthcare that is **trauma informed** means that health staff should understand, recognize, and respond to symptoms and risk factors of traumatic stress and provide an environment that offers physical, emotional, and psychological safety for children and caregivers. In foster care, attention must be paid to the effects of past trauma and the impact of ongoing uncertainty and loss on a child's health.
and well-being, as well as that of their birth and foster/kinship families.

Table 9.2

Trauma-Informed Pediatric Medical Home for Children in Foster Care

<table>
<thead>
<tr>
<th>CHARACTERISTIC</th>
<th>APPLICATION IN FOSTER CARE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comprehensive healthcare</td>
<td>Perform comprehensive admission assessment within 30 days of entry. Ensure access to mental health, developmental, and dental evaluation and services. Screen and refer as needed for abuse and neglect.</td>
</tr>
<tr>
<td>Coordination of care</td>
<td>Make timely referrals and follow up subspecialist visits. Communicate with caseworkers, foster parents, and legal professionals. Maintain a comprehensive medical record despite changes in placement.</td>
</tr>
<tr>
<td>Compassionate care</td>
<td>Understand and educate children, families, and other healthcare professionals on the impact of early childhood adversities, trauma, and ongoing uncertainties of foster care on the developing child. Promote positive purposeful parenting strategies and minimizing conflict among caregivers.</td>
</tr>
<tr>
<td>Child-centered and family-focused care</td>
<td>Prioritize the needs of children first and foremost. Partner with families to increase understanding of a child's needs. Focus on the strengths of children and caregivers. Understand the conflicts for the child of belonging in multiple families.</td>
</tr>
<tr>
<td>Continuity of care</td>
<td>Invite children to remain patients throughout their stay in foster care, and beyond when feasible.</td>
</tr>
<tr>
<td>Cultural competence</td>
<td>Extend this concept to include the microculture of foster care and the multiple transitions that can further erode a child's well-being. Understand the roles of caseworkers, foster parents, law guardians, etc. Understand the importance of quality visitation for family reunification.</td>
</tr>
<tr>
<td>Accessibility</td>
<td>Create a welcoming environment for children and all their families (birth, foster, kin, preadoptive).</td>
</tr>
</tbody>
</table>

The trauma-informed office is one in which symptoms such as dysregulation of sleep, behavioral problems, developmental delays, poor school function, and somatic complaints are recognized as potential effects of childhood trauma. Understanding the child's psychosocial context and history, as well as that of the caregiver, and exploring their strengths, assets, and challenges are the foundation of a trauma-informed approach. The office should have print resources for education of families and child welfare professionals and a list of helpful local community resources. Referral to trauma-informed pediatric mental health services, when available, should be considered in collaboration with caregivers, child welfare, and educators. **Continuity of care** is very important for the child in foster care and includes ongoing monitoring and management of progress and care. The AAP has several resources for caring for traumatized children. *

Several recommendations are specific to the care of children and youth in foster care. Children should be seen early and often when they first enter a new placement to identify all their health issues, and to support the child and
caregivers through a major transition that involves considerable loss and adjustment, including the development of an attachment relationship with a new caregiver, for the child and many challenges for the foster/kinship parent.

The AAP recommends that every child in foster care have comprehensive medical, dental, developmental, and mental health assessments within 30 days of entering foster care. Almost every child in foster care deserves a full mental health evaluation to assess for the impact of trauma and loss on emotional well-being. *Psychotropic medication* should only be considered, if at all, after a thorough high-quality trauma-informed mental health evaluation by a pediatric-trained mental health professional. The pediatrician should remember that inattention, impulsivity, and hyperactivity may reflect the impact of past trauma on the developing brain rather than attention-deficit/hyperactivity disorder (see Chapter 49). Childhood trauma may impair cognition and memory (see Chapter 16), so that children <6 yr of age benefit from a comprehensive developmental assessment, whereas older children often benefit from a comprehensive educational assessment. The caseworker should provide consents for healthcare and any available health history and encourage the appropriate involvement of the birth parent. The primary care provider can help caseworkers and caregivers by obtaining and interpreting the results of these assessments. Pediatricians, caregivers, and caseworkers should share health information.

**Foster/kinship parents** are the major therapeutic intervention of the foster care system, and pediatricians are in a unique position to provide them with appropriate education and support. Important topics include positive parenting strategies, supporting children through transitions, providing a consistent and nurturing environment, and helping children heal from past trauma and adversity (Table 9.3). All caregivers may need extensive education about behavioral and emotional problems within the context of the child's trauma history to remove blame and promote healing. Minimizing conflict among caregivers is extremely important because children ideally have affection and loyalty for all their caregivers. Pediatricians can promote resilience by focusing on both caregiver and child strengths. For teens and young adults in foster care, the pediatrician can provide anticipatory guidance around education, identifying formation in the face of past trauma, independent decision-making, health promotion including reproductive health, healthy relationships, and developing the skills and competencies needed for a successful future life. The pediatrician can advocate for placement stability in a nurturing and responsive foster family where caregivers possess the appropriate skills to help children and youth heal.
<table>
<thead>
<tr>
<th>SITUATION</th>
<th>ANTICIPATORY GUIDANCE FOR FOSTER PARENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preparing for visits</td>
<td>Educate foster/kinship parents about impact of visitation on children and ways to improve the experience for children. Send familiar object with child to visit. Have child draw picture to give birth parent. Reassure child that foster parent will be there when child returns from visits. Advise all caregivers to minimize conflict with and negativity toward each other. Ideally, visits are coached by trained professionals.</td>
</tr>
<tr>
<td>Returning from visits and other transitions</td>
<td>Greet child warmly and help with unpacking. Establish reentry rituals, such as quiet play, reading together, active play, having a healthy snack.</td>
</tr>
<tr>
<td>Relationship with birth parent(s)</td>
<td>Encourage caseworker to have birth parents keep child's rituals and routines consistent with those in foster/kinship home (vice versa when appropriate). Focus on birth parent's positive qualities; maintain a neutral or positive affect.</td>
</tr>
<tr>
<td>Building on child's strengths</td>
<td>Encourage participation in child-directed play. Time-in with child. Encourage participation in normalizing activities (e.g., hobbies, sports) “Catch the child being good.” Give specific praise. Practice attentive listening. Provide child with words for emotions. Ignore negative behavior or redirect unless there is a safety issue.</td>
</tr>
<tr>
<td>Preparing for court dates</td>
<td>Foster/kinship parent, caseworker or law guardian should explain purpose of court hearings to child in simple terms.</td>
</tr>
<tr>
<td>School</td>
<td>If changing schools, visit school together a few times, and meet teacher. Check in regularly (weekly or monthly depending on need) with child's teacher.</td>
</tr>
<tr>
<td>Adolescent</td>
<td>Decide what issues demand firm limits and guidelines (e.g., curfews, no smoking, party at a friend's house), what issues are not important and can be left up to teen (e.g., hair length and color), and what issues are ideal for negotiation (e.g., transportation to school function, style of dress). Encourage responsible decision-making by recognizing and complimenting it. Encourage after-school activities. Teach driving when age and developmentally appropriate. Encourage teen to seek employment and teach job skills. Help teen to identify mentors and focus on the future.</td>
</tr>

More than 210,000 foreign-born children (≤16 yr old) enter the United States each year as asylees (asylum seekers), refugees, and immigrants, including international adoptees (see Chapter 8). This number does not include undocumented children living and working in the United States, the U.S.-born children of foreign-born parents, or the approximately 2.7 million nonimmigrant visitors ≤16 yr old who legally enter the United States annually with temporary visas. With the exception of internationally adopted children, pediatric guidelines for screening these newly arrived children are sparse. The diverse countries of origin and patterns of infectious disease, the possibility of previous high-risk living circumstances (e.g., refugee camps, orphanages, foster care, rural/urban poor), the limited availability of reliable healthcare in many economically developing countries, the generally unknown past medical histories, and interactions with parents who may have limited English proficiency and/or varied educational and economic experiences, make the medical evaluation of immigrant children a challenging but important task.

Before admission into the United States, all immigrant children are required to have a medical examination performed by a physician designated by the U.S. Department of State in their country of origin. This examination is limited to completing legal requirements for screening for certain communicable diseases and examination for serious physical or mental problems that would prevent issuing a permanent residency visa. This evaluation is not a comprehensive assessment of the child’s health, and except in limited circumstances, laboratory or radiographic screening for infectious diseases is not required for children <15 yr old. After entry into the United States, health screenings of refugees, but not other immigrants, are recommended to be done by the resettlement state.
is limited tracking of refugees as they move to different cities or states. Thus, many foreign-born children have had minimal pre- or postarrival screening for infectious diseases or other health issues.

**Immunization** requirements and records also vary depending on entry status. Internationally adopted children who are younger than 10 yr are exempt from Immigration and Nationality Act regulations pertaining to immunization of immigrants before arrival in the United States. Adoptive parents are required to sign a waiver indicating their intention to comply with U.S.-recommended immunizations, whereas older immigrants need only show evidence of up-to-date, not necessarily complete, immunizations before application for permanent resident (green card) status after arrival in the United States.

**Infectious diseases** are among the most common medical diagnoses identified in immigrant children after arrival in the United States. Children may be asymptomatic; therefore, diagnoses must be made by screening tests in addition to history and physical examination. Because of inconsistent perinatal screening for hepatitis B and hepatitis C viruses, syphilis, and HIV, and the high prevalence of certain intestinal parasites and tuberculosis, all foreign-born children should be screened for these infections on arrival in the United States. Table 10.1 lists suggested screening tests for infectious diseases. Table 10.2 lists incubation periods of common internationally acquired diseases. In addition to these infections, other medical and developmental issues, including hearing, vision, dental, and mental health assessments; evaluation of growth and development; nutritional assessment; lead exposure risk; complete blood cell count with red blood cell indices; microscopic urinalysis; newborn screening (this could also be done in non-neonates) and/or measurement of thyroid-stimulating hormone concentration; and examination for congenital anomalies (including fetal alcohol syndrome) should be considered as part of the initial evaluation of any immigrant child.*

**Table 10.1**

**Screening Tests for Infectious Diseases in International Adoptees and Foreign-Born (Immigrant) Children**

**Recommended Tests**

- Hepatitis B virus serologic testing*
• Hepatitis B surface antigen (HBsAg)
• Antibody to hepatitis B surface antigen (anti-HBs)
Hepatitis C virus serologic testing* †
Hepatitis A virus serologic testing †
Varicella virus serologic testing †
Syphilis serologic testing
  • Nontreponemal test (RPR, VDRL, or ART)
  • Treponemal test (MHA-TP or FTA-ABS)
Human immunodeficiency viruses 1 and 2 testing (ELISA if >18 mo, PCR if <18 mo)*
Complete blood cell count with red blood cell indices and differential (if eosinophilia, see text)
Strongyloides serology
Stool examination for O&P (2-3 specimens) †
Stool examination for Giardia lamblia and Cryptosporidium antigen (1 specimen) †
Tuberculin skin test (with CXR if >5 mm induration) or interferon-γ release assay* †

Optional Tests (for Special Populations or Circumstances)

GC/Chlamydia
Chagas disease serology (endemic areas)
Malaria, thick and thin smears (endemic areas)
Filaria testing (endemic areas)
Urine for O&P for schistosomiasis, if hematuria present
Stool testing for enteric bacteria and viruses in children with diarrhea

ART, Automated reagin test; CXR, chest radiograph; ELISA, enzyme-linked immunosorbent assay; FTA-ABS, fluorescent treponemal antibody absorption; GC, gonococcus; MHA-TP, microhemagglutination test for Treponema pallidum; O&P, ova and parasites; PCR, polymerase chain reaction; RPR, rapid plasma reagin; VDRL, Venereal Disease Research Laboratories.
* Repeat 3-6 mo after arrival.
† See text.

* Diseases that commonly have variable incubation periods are shown more than once. However, most diseases may rarely have an atypical incubation period, and this is not shown here.

HIV, Human immunodeficiency virus.

Children should be examined within 1 mo of arrival in the United States, or earlier if there are immediate health concerns, but foreign-born parents may not access the healthcare system with their children unless prompted by illness, school vaccination, or other legal requirements. *It is important to assess the completeness of previous medical screenings at any first visit with a foreign-born*
Clinicians should be aware of potential diseases in high-risk immigrant children and their clinical manifestations. Some diseases, such as central nervous system cysticercosis, may have incubation periods as long as several years, and thus may not be detected during initial screening. On the basis of findings at the initial evaluation, consideration should be given to a repeat evaluation 6 mo after arrival. In most cases, the longer the interval from arrival to development of a clinical syndrome, the less likely the syndrome can be attributed to a pathogen acquired in the country of origin.

Commonly Encountered Infections

**Hepatitis B**

See also Chapter 385.

The prevalence of hepatitis B surface antigen (HBsAg) in refugee children ranges from 4–14%, depending on the country of origin, age, and year studied. Prevalence of markers of past hepatitis B virus (HBV) infection is higher. HBV infection is most prevalent in immigrants from Asia, Africa, and some countries in Central and Eastern Europe, as well as the former Soviet Union (e.g., Bulgaria, Romania, Russia, Ukraine), but also occurs in immigrants born in other countries. All immigrant children, even if previously vaccinated, coming from high-risk countries (HBsAg seropositivity >2%) should undergo serologic testing for HBV infection, including both HBsAg and antibody to HBsAg (anti-HBs), to identify current or chronic infection, past resolved infection, or evidence of previous immunization. Because HBV has a long incubation period (6 wk–6 mo), the child may have become infected at or near the time of migration, and initial testing might be falsely negative. Therefore, strong consideration should be given to a repeated evaluation 6 mo after arrival for all children, especially those from highly endemic countries. Chronic HBV infection is indicated by persistence of HBsAg for >6 mo. Children with HBsAg-positive test results should be evaluated to identify the presence of chronic HBV infection, which occurs in >90% of infants infected at birth or in the 1st yr of life and in 30% of children exposed at ages 1-5 yr. Once identified as being infected, additional testing should be done to assess for biochemical evidence of severe or chronic liver disease or liver cancer.
Hepatitis A
See Chapter 385.

Hepatitis C
See also Chapter 385.

The decision to screen children should depend on history (e.g., receipt of blood products; traditional percutaneous procedures such as tattooing, body piercing, circumcisions, or other exposures to reused, unsterile medical devices) and the prevalence of hepatitis C virus (HCV) infection in the child's country of origin. Children from Eastern Mediterranean and Western Pacific countries, Africa, China, and Southeast Asia should be considered for HCV infection screening. All children coming from Egypt, which has the highest known HCV seroprevalence (12% nationally and 40% in some villages), should be tested for hepatitis C.

Intestinal Pathogens
Fecal examinations for ova and parasites (O&P) by an experienced laboratory will identify a pathogen in 8–86% of immigrants and refugees. The prevalence of intestinal parasites varies by country of origin, time period when studied, previous living conditions (including water quality, sanitation, and access to footwear) and age, with toddler/young school-age children being most affected. If documented predeparture treatment was given, an eosinophil count should be performed. An absolute eosinophil count of >400 cells/µL, if persistently elevated for 3–6 mo after arrival, should prompt further investigation for tissue-invasive parasites such as Strongyloides (see Chapter 321) and Schistosoma (Chapter 326) species (if no predeparture praziquantel given). If no documented predeparture treatment was given, 2 stool O&P specimens obtained from separate morning stools should be examined by the concentration method, and an eosinophil count performed. If the child is symptomatic, including evidence of poor physical growth, but no eosinophilia is present, a single stool specimen should also be sent for Giardia lamblia (see Chapter 308.1) and Cryptosporidium parvum (Chapter 309) antigen detection. All potentially pathogenic parasites found should be treated appropriately. All nonpregnant refugees >2 yr of age coming from sub-Saharan Africa and Southeast Asia should be presumptively treated with predeparture albendazole.
**Tuberculosis**

See also Chapter 242.

Tuberculosis (TB) commonly is encountered in immigrants from all countries because *Mycobacterium tuberculosis* infects approximately 30% of the world's population. Latent TB infection rates can be up to 60% in some refugee children from North Africa and the Middle East. Prior to 2007, chest radiographs or tuberculin skin tests were generally not administered in children <15 yr of age, and reports indicate that 1–2% of these unscreened children may enter the United States with undiagnosed active TB disease.

Since 2007, TB *Technical Instructions for Medical Evaluation of Aliens* have required that children ages 2-14 yr undergo a TB skin test or interferon-γ release assay if they are medically screened in countries where the TB rate is ≥20 cases per 100,000 population. If the testing is positive, a chest radiograph is required. If the chest film suggests TB, cultures and 3 sputum smears are required, all before arrival in the United States. Check with the Centers for Disease Control and Prevention, Division of Global Migration and Quarantine, for the latest information (www.cdc.gov/ncidod/dq/technica.htm).

**Congenital Syphilis**

See Chapter 245.

**HIV Infection**

See Chapter 302.

**Immunizations**

See Chapter 197.

Immigrant children and adolescents should receive immunizations according to the recommended schedules in the United States for healthy children and adolescents. Some immigrants will have written documentation of immunizations received in their birth or home country. Although immunizations such as bacille Calmette-Guérin, diphtheria and tetanus toxoids and pertussis (DTP), poliovirus, measles, and HBV vaccines often are documented, other immunizations, such as *Haemophilus influenzae* type b, mumps, and rubella
vaccines, are given less frequently, and *Streptococcus pneumoniae*, human papillomavirus, meningococcal, and varicella vaccines are given rarely. When doubt exists, an equally acceptable alternative is to reimmunize the child. Because the rate of more serious local reactions after diphtheria, tetanus toxoid, and acellular pertussis vaccine increases with the number of doses administered, serologic testing for antibody to tetanus and diphtheria toxins before reimmunizing, or if a serious reaction occurs, can decrease risk.

In children older than 6 mo with or without written documentation of immunization, testing for antibodies to diphtheria and tetanus toxoid and poliovirus may be considered to determine whether the child has protective antibody concentrations. If the child has protective concentrations, the immunization series should be completed as appropriate for that child's age. In children older than 12 mo, measles, mumps, rubella, and varicella antibody concentrations may be measured to determine whether the child is immune; these antibody tests should not be performed in children younger than 12 mo because of the potential presence of maternal antibody.

* For the most up-to-date guidelines, see: [https://www.cdc.gov/immigrantrefugeehealth/guidelines/domestic/domestic-guidelines.html](https://www.cdc.gov/immigrantrefugeehealth/guidelines/domestic/domestic-guidelines.html).
Pediatricians live and work in a multicultural world. Among the world's 7 billion people residing in over 200 countries, more than 6,000 languages are spoken. As the global population becomes more mobile, population diversity increases in all countries. In the United States, sources of ethnic and cultural diversity come from indigenous cultural groups such as Native Americans and Alaskan and Hawaiian natives, groups from U.S. territories such as Puerto Rico, recent immigrant groups, those whose heritage originates from the African diaspora, as well as others whose families and communities migrated to the United States from Europe and Asia generations ago but who have retained cultural identification. U.S. census estimates suggest that in 2016, almost 40% of the U.S. population self-identified as belonging to a racial/ethnic group other than non-Hispanic white. Recent immigrants comprise 13.5% of the U.S. population, but if U.S.-born children of these immigrants are included, 27% of the population are either new immigrants or first-generation Americans. Immigrants from China and India account for the largest groups coming to the United States, followed by those from Mexico. This national and international diversity allows for a heterogeneity of experience that enriches the lives of everyone. Much of this diversity is based on varied cultural orientation.

What Is Culture?

The concept of culture does not refer exclusively to racial and ethnic categorizations. A common definition of cultural group is a collective that shares common heritage, worldviews, beliefs, values, attitudes, behaviors, practices, and identity. Cultural groups can be based on identities such as gender orientation (gay/lesbian, bisexual, transgender), age (teen culture), being
deaf or hearing impaired (deaf culture), and having neurodevelopmental differences (neurodiversity; neurotypical and neuroatypical). All these groups to a certain extent share common worldviews, attitudes, beliefs, values, practices, and identities.

Medical professionals can also be considered as belonging to a specific cultural group. Those who identify with the culture of medicine share common theories of well-being and disease, acceptance of the biomedical and biopsychosocial models of health, and common practices and rituals. As with other cultural groups, physicians and other healthcare professionals have a distinct language and share a common history, the same preparatory courses that must be mastered for entrance into training for the profession (a rite of passage). Medical professionals subscribe to common norms in medical practice. Young physicians learn a new way to describe health and illness that requires a new common vocabulary and an accepted structure for communicating a patient's history. These common beliefs, orientations, and practices are often not shared by those outside medicine. Therefore, any clinical interaction between a healthcare provider and a patient can be a potential cross-cultural interaction — between the culture of medicine and the culture of the patient—regardless of the race or ethnicity of the participants. A culturally informed and sensitized approach to clinical communication is a fundamental skill required of all medical professionals, regardless of the demographic makeup of one's patient population.

**Culture and Identity**

We are all members of multiple cultural groups. Our identification or affiliation with different groups is not fixed or unchangeable. With whom we self-identify may depend on specific situations and contexts and may change over time. A gay Latino physician may feel, at different times and in different situations, greatest affinity as a member of Latino culture, a member of the culture of medicine, a minority in the United States, or a gay man. An immigrant from India may initially feel great connection with her Indian culture and heritage, which may wane during periods of assimilation into American cultural life, then increase again in later life. Culturally informed clinicians should never assume that they know or understand the cultural identity of a person based solely on perception of ethnic, racial, or other group affiliation.
Intracultural Variability

There can be significantly different beliefs, values, and behaviors among members of the same cultural group. Often, there is as much variability within cultures as there is between cultures. The sources of this variability include differences in personal psychology and philosophy, family beliefs and practices, social context, and other demographic differences, as well as acculturation, defined as the changes in beliefs and practices resulting from continuous interactions with another culture. The literature on acculturation and health outcomes shows varied effects of cultural change on health and well-being. These differences are in part caused by overly simplistic ways of measuring acculturation in public health and health services research. The use of proxies, such as generational status (recent immigration, first generation) and socioeconomic status, as measures of acculturation does not allow for an understanding of the complex behavioral changes that occur during shifts in cultural orientation. Often, acculturation is seen as a linear process where individuals move from unacculturated to acculturated or assimilated into the host culture. This simplistic view does not take into account the reality that acculturation is bidimensional: the degree to which an individual continues to identify with her original cultural identity, and the degree to which the host cultural orientation is adopted. These are separate and independent processes. One can become bicultural (adopting the host culture while retaining aspects of the original culture), assimilated (host culture is adopted, but original culture is not retained), separated (original cultural orientation is retained, but host culture is not greatly adopted), or marginalized (does not adopt host culture and does not retain original culture). These variations in the acculturation process are determined not only by the individual going through the cultural change process but also by the degree of acceptance of diversity in the host culture. In theory, individuals who best adapt to the multicultural society are those who are bicultural, since they retain the strengths and assets of their heritage culture while being able to positively adjust to host cultural norms. Likewise, members of the majority culture who are able to take a bicultural perspective will have relative advantage in the multicultural society. This type of perspective is a foundation of cultural awareness and culturally informed practice.

Culturally Informed Care
Physicians and patients bring to their interactions diverse orientations from multiple cultural systems. These different belief systems and practices could have significant implications for the delivery of healthcare (Table 11.1). Consequently, physician cultural awareness, sensitivity, and humility is critical to successful patient–provider interaction.

**Table 11.1**

</tr>
</tbody>
</table>

The culturally informed physician (1) attempts to understand and respect the beliefs, values, attitudes, and lifestyles of patients; (2) understands that health and illness are influenced by ethnic and cultural orientation, religious and spiritual beliefs, and linguistic considerations; (3) has insight into own cultural biases and does not see cultural issues as something that only affects the patient; (4) is sensitive to how differences in power and privilege may affect the quality of the clinical encounter; (5) recognizes that in addition to the physiologic aspects of disease, the culturally and psychologically constructed meaning of illness and health is a central clinical issue; and (6) is sensitive to intragroup variations in beliefs and practices and avoids stereotyping based on any group affiliation. These core components of culturally-informed care are important for interactions with all patients, regardless of race or ethnicity. Culturally sensitive clinical care is essentially generally sensitive clinical care.

Becoming culturally informed is a developmental process. Figure 11.1 displays a framework that includes a continuum of perceptions and orientations to cultural awareness. Individuals in the denial stage perceive their own cultural orientation as the true one, with other cultures either undifferentiated or unnoticed. In the defensive stage, other cultures are acknowledged but regarded as inferior to one's own culture. The minimization stage is characterized by beliefs that fundamental similarities among people outweigh any differences, and downplays the role of culture as a source of human variation. The idea that one should be “color blind”
is an example of a common belief of individuals in the minimization stage.

As one moves to the *acceptance* stage, cultural differences are acknowledged. Further expansion and understanding lead to *adaptation*, where one not only acknowledges differences but can shift frames of reference and have a level of comfort outside one's own cultural frame. This eventually leads to further comfort with different worldviews seen at the *integration* stage, where individuals respect cultural differences and can comfortably interact across cultures, even incorporating aspects of different cultural orientations into their own.

**Understanding Culture in the Context of Healthcare**

Cultural orientation is just one of many different perspectives that individuals draw on as they make health and healthcare decisions. Individual psychology, past experiences, religious and spiritual views, social position, socioeconomic status, and family norms all can contribute to a person’s health beliefs and practices. These beliefs and practices can also change over time and may be expressed differently in different situations and circumstances. Because of the significant variability in health beliefs and behaviors seen among members of the same cultural group, an approach to cultural competency that emphasizes a knowledge set of specific cultural health practices in different cultural groups could lead to false assumptions and stereotyping. Knowledge is important, but it
only goes so far. Instead, an approach that focuses on the healthcare provider acquiring skills and attitudes relating to open and effective communication styles is a preferable approach to culturally effective and informed care. Such an approach does not rely on rote knowledge of facts that may change depending on time, place, and individuals. Instead, it provides a skills toolbox that can be used in all circumstances. The following skills can lead to a culturally informed approach to care:

1. *Don't assume.* Presupposing that a particular patient may have certain beliefs, or may act in a particular way based on their cultural group affiliation, could lead to incorrect assumptions. Sources of intracultural diversity are varied.

2. *Practice humility.* Cultural humility has been described by Hook et al. (2013) as “the ability to maintain an interpersonal stance that is other-oriented (or open to the other) in relation to aspects of cultural identity.” Cultural humility goes beyond cultural competency in that it requires the clinician to self-reflect and acknowledge that one’s own cultural orientation enters into any transaction with a patient (see Chapter 2.1).

**Cultural humility** aims to fix power imbalances between the dominant (hospital-medical) culture and the patient. It recognizes the value of the patient's culture and incorporates the patient's life experiences and understanding outside the scope of the provider; it creates a collaboration and a partnership.

**Cultural competency** is an approach that typically focuses on the patient's culture, whereas cultural humility acknowledges that both physicians and patients have cultural orientations, and that a successful relationship requires give and take among those differing perspectives. It also includes an understanding that differences in social power, which are inherent in the physician–patient relationship, need to be understood and addressed so that open communication can occur.

3. *Understand privilege.* Members of the majority culture have certain privileges and benefits that are often unrecognized and unacknowledged. For example, they can have high expectations that they will be positively represented in media such as movies and television. Compared with minority groups, those in the majority culture have less
chance of being followed by security guards at stores, or having their bags checked. They have a greater chance of having a positive reception in a new neighborhood, or of finding food in the supermarket that is consistent with one's heritage. These privileges typically go unnoticed by members of the majority culture, but their absence is painfully recognized by members of nonmajority cultural groups. The culturally informed physician should try to be mindful of these privileges, and how they may influence the interaction between physicians and patients.

4. **Be inquisitive.** Because of the significant amount of intracultural diversity of beliefs and practices, the only way to know a particular patient's approach to issues concerning health and illness is through direct and effective communication. Asking about the patient's/family's perspective in an inquisitive and respectful manner will usually be met with open and honest responses, as long as the patient does not feel looked down on and the questions are asked in genuine interest.

Obtaining a **health beliefs history** is an effective way of understanding clinical issues from the patient's and family's perspective (Table 11.2). The health beliefs history gathers information on the patient's views on the identification of health problems, causes, susceptibility, signs and symptoms, concerns, treatment, and expectations. Responses gathered from the health beliefs history can be helpful in guiding care plans and health education interventions.

5. Be flexible. As members of the culture of medicine, clinicians have been educated and acculturated to the biomedical model as the optimal approach to health and illness. Patients and families may have health beliefs and practices that do not fully fit the biomedical model. Traditional beliefs and practices may be used in tandem with biomedical approaches. An individual's approach to health rarely is exclusively biomedical or traditional, and often a combination of multiple approaches. The health beliefs history provides clinicians with information regarding the nonbiomedical beliefs and practices that may be held by the patient. Culturally informed physicians should be flexible and find ways of integrating nonharmful traditional beliefs and practices into the medical care plan to make that plan fit the patient's needs and worldview. This will likely result in better adherence to treatment and prevention.

Obtaining a health beliefs history for a child with asthma, for example, may reveal that the family uses an alternative remedy when the symptoms first occur. If the symptoms do not resolve after giving the remedy, the family administers standard medical care. In this case, if the alternative remedy is safe and has no significant likelihood of causing adverse effects, the culturally informed physician might say, “I'm not sure if the remedy you're using is helpful or not, but I can say that if used as directed, it's not likely to be harmful. So if you think it may work, feel free to try it. But instead of waiting to give the prescription medicine until after you see if the remedy works, why don't you give it at the same time you give the remedy? Maybe they’ll work well together.” This approach shows respect for the family-held beliefs and practices while increasing timely adherence to the biomedical therapy.

At times, an alternative therapy the patient is using may be contraindicated or may have adverse effects. In this case it is advisable to recommend against the therapy, but whenever possible, one should attempt to replace the therapy with another, safer, culturally acceptable treatment. If a parent is giving a child tea containing harmful ingredients to treat a cold, the culturally informed physician could recommend stopping the practice and explain the concerns, but then recommend replacing the harmful tea with something safer that fits the family's cultural belief system, such as a weak herbal tea with no harmful ingredients. This requires an awareness and background knowledge of the cultural belief system, but this approach increases the chances that the family will follow
through on the recommendation and feel that their beliefs are respected.

**Awareness-Assessment-Negotiation Model**

Providing care in the multicultural context can be challenging, but it offers opportunities for creativity and can result in improved long-term physician–patient relationships, which will ultimately improve the quality and outcomes of healthcare. Culturally informed care combines knowledge with effective communication skills, an open attitude, and the qualities of flexibility and humility.

The culturally informed physician should first become aware of common health beliefs and practices of patients in the practice. Reading literature on the particular groups could increase awareness, but with the caution that such information may be outdated (cultural beliefs and practices change over time) and not specific to the local context. The best approach to becoming aware of specific health beliefs and practices is to ask—enter into conversations with patients, families, and community members. One might say, “I've heard that there are ways of treating this illness [or staying healthy] that people believe work, but doctors don't know about. Sometimes they're recommended by grandparents or others in your community. They may be effective. Have you heard of any of these?” This approach shows genuine interest and openness, is not based on presumptions, and does not ask about behaviors or practices, only if the patient has *heard* of these practices. If the question elicits a positive response, the conversation can then continue, including asking whether the patient has personally tried any of the therapies, under what circumstances, and if they thought it was helpful. This approach shows respect for the patient as an individual and avoids stereotyping all members of a particular group as having a uniform set of cultural beliefs and practices.

The information obtained should be seen only as common ways that members of a community *may* interpret health-related issues. Assuming that all members subscribe to similar beliefs and practices would be incorrect and potentially damaging by promoting stereotypes. Since the unit of measurement in clinical care is the individual patient and family, clinicians must assess to what extent a specific patient may act on these general beliefs and under what circumstances. The health beliefs history can help the physician become aware of the specific beliefs and practices that a patient holds, and allow one to tailor the care to the individual patient.
Once the patient's explanatory model is elicited and understood, the clinician should be able to assess the congruity of this model and the biomedical model, finding similarities. Then the process of negotiating can occur. Integrating patient-held approaches to health with evidence-based biomedical standards of care will help place care within the lifestyle and worldview of patients, leading to increased adherence to medical care plans, better physician–patient communication, enhanced long-term therapeutic relationship, and improved patient (and physician) satisfaction.

11.1

Culture-Specific Beliefs

Robert M. Kliegman

Cultural group-specific practices that affect health-seeking behaviors are noted in Tables 11.3 and 11.4.

Table 11.3

Cultural Values* Relevant to Health and Health-Seeking Behavior

<td>--------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Muslim</td>
<td>Fasting during the holy month of Ramadan: fasting from sunrise to sundown, beginning during the teen years. Women are exempted during pregnancy, lactation, and menstruation, and there are exemptions for illness, but an exemption may be associated with a sense of personal failure.</td>
<td>Inappropriate therapy; will not take medicines during daytime misinterpreted as noncompliance; misdiagnosed</td>
</tr>
<tr>
<td></td>
<td>Modesty: Women's body, including hair, body, arms, and legs, not to be seen by men other than in immediate family. Female chaperone and/or husband must be present during exam, and only that part of the body being examined should be uncovered.</td>
<td>Deep personal outrage, seeking alternative care</td>
</tr>
<tr>
<td></td>
<td>Touch: Forbidden to touch members of the opposite sex other than close family. Even a handshake may be inappropriate.</td>
<td>Patient discomfort, seeking care elsewhere</td>
</tr>
<tr>
<td></td>
<td>After death, body belongs to God. Postmortem examination will not be permitted unless required by law; family may wish to perform after-death care.</td>
<td>Unnecessary intensification of grief and loss</td>
</tr>
<tr>
<td></td>
<td>Cleanliness essential before prayer. Individual must perform ritual ablutions before prayer, especially elimination of urine and stool. Nurse may need to assist in cleaning if patient is incapable.</td>
<td>Affront to religious beliefs</td>
</tr>
<tr>
<td></td>
<td>God's will: God causes all to happen for a reason, and only God can bring about healing.</td>
<td>Allopathic medicine will be rejected if it conflicts with religious beliefs, family may not seek healthcare.</td>
</tr>
<tr>
<td></td>
<td>Patriarchal, extended family. Older male typically is head of household, and family may defer to him for decision-making.</td>
<td>Child's mother or even both parents may not be able to make decisions about child's care; emergency decisions may require additional time.</td>
</tr>
<tr>
<td></td>
<td>Halal (permitted) vs haram (forbidden) foods and medications. Foods and medicine containing alcohol (some cough and cold syrups) or pork (some gelatin-coated pills) are not permitted.</td>
<td>Refusal of medication, religious effrontery</td>
</tr>
<tr>
<td>Native American</td>
<td>Nature provides the spiritual, emotional, physical, social, and biologic means for human life; by caring for the earth, Native Americans will be provided for. Harmonious living is important.</td>
<td>Spiritual living is required of Native Americans; if treatments do not reflect this view, they are likely not to be followed.</td>
</tr>
<tr>
<td></td>
<td>Passive forbearance: Right of the individual to choose his or her path. Another family member cannot intervene.</td>
<td>Mother's failure to intervene in a child's behavior and/or use of noncoercive disciplinary techniques may be mistaken for neglect.</td>
</tr>
<tr>
<td></td>
<td>Natural unfolding of the individual. Parents further the development of their children by limiting direct interventions and viewing their natural unfolding.</td>
<td>Many pediatric preventive practices will run counter to this philosophy.</td>
</tr>
<tr>
<td></td>
<td>Talking circle format to decision-making. Interactive learning format including diverse tribal members.</td>
<td>Lecturing, excluding the views of elders, is likely to result in advice that will be disregarded.</td>
</tr>
<tr>
<td>African-American</td>
<td>Great heterogeneity in beliefs and culture among African-Americans.</td>
<td>Risk of stereotyping and/or making assumptions that do not apply to a specific patient or family.</td>
</tr>
<tr>
<td></td>
<td>Extended family and variations in family size and childcare arrangements are common; matriarchal decision-making regarding healthcare.</td>
<td>Advice/instructions given only to the parent and not to others involved in health decision-making may not be effective.</td>
</tr>
</tbody>
</table>
Parenting style often involves stricter adherence to rules than seen in some other cultures. Advice regarding discipline may be disregarded if it is inconsistent with perceived norms; other parenting styles may not be effective.

History-based widespread mistrust of medical profession and strong orientation toward culturally specific alternative/complementary medicine. In patient noncompliance, physicians will be consulted as a last resort.

Greater orientation toward others; the role of an individual is emphasized as it relates to others within a social network. Compliance may be difficult if the needs of 1 individual are stressed above the needs of the group.

Spirituality/religiosity important; church attendance central in most African American families. Loss of opportunity to work with the church as an ally in healthcare.

<table>
<thead>
<tr>
<th>East and Southeast Asian</th>
<th>Long history of Eastern medicines (e.g., Chinese medicine) as well as more localized medical traditions.</th>
<th>May engage with multiple health systems (Western biomedical and traditional) for treatment of symptoms and diseases.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Extended families and care networks. Grandparents may provide day-to-day care for children while parents work outside of the home.</td>
<td>Parents may not be the only individuals a physician needs to communicate with in regard to symptoms, follow-through on treatments, and preventive behaviors.</td>
</tr>
<tr>
<td></td>
<td>Sexually conservative. Strong taboos for premarital sexual relationships, especially for women.</td>
<td>Adolescents may be reluctant to talk about issues of sexuality, pregnancy, and birth control with physicians. Recent immigrants or native populations may have less knowledge regarding pregnancy prevention, sexually transmitted infections, and HIV.</td>
</tr>
<tr>
<td></td>
<td>Infant/child feeding practices may overemphasize infant’s or child’s need to eat a certain amount of food to stay “healthy.”</td>
<td>Guidelines for child nutrition and feeding practices may not be followed out of concern for child’s well-being.</td>
</tr>
<tr>
<td></td>
<td><em>Saving face.</em> This is a complex value whereby an individual may lose prestige or respect of a 3rd party when a 2nd individual makes negative or contradictory statements.</td>
<td>Avoid statements that are potentially value laden or imply a criticism of an individual. Use statements such as, “We have now found that it is better to …,” rather than criticizing a practice.</td>
</tr>
</tbody>
</table>

* Adherence to these or other beliefs will vary among members of a cultural group based on nation of origin, specific religious sect, degree of acculturation, age of patient, etc.

**Bibliography**

Hook JN, Davis DE, Owen J, et al. Cultural humility:

Routine, scheduled care of well infants, children, and adolescents is an essential prevention effort for children and youth worldwide. Children's constantly changing development lends added value to regular and periodic encounters between children and their families and practitioners of pediatric healthcare. Health supervision visits from birth to age 21 yr are the platform for a young person's healthcare. The provision of well care in the medical home fosters strong relationships between the clinic or practice and the child and family, enabling the provision of appropriate surveillance, screening, and sick care.

To ensure the optimal health of the developing child, pediatric care in the United States and other countries evolved into regularly-scheduled visits to ensure adequate nutrition, to detect and immunize against infectious diseases, and to observe the child's development. Assessment of these key arenas remains essential to the well-child health supervision visit. However, contemporary analysis of changes in the population's health, coupled with the recognition that early life experiences and social factors impact health along the entire life course, have led to the addition of other components to the content of today's well-child encounter.

Stressful circumstances impair development, and adverse childhood experiences (ACEs) early in life increase the risk of disease (see Chapter 2). Adults who experienced abuse, violence, or other stressors as children have an increased risk for depression, heart disease, and other morbidities. Biology
informs us that **stress** leads to increased heart rate and blood pressure and increased levels of inflammatory cytokines, cortisol, and other stress hormones, all of which impair brain activity, immune status, and cardiovascular function. There are both a causal model and evidence that ACEs, including those that could have been prevented, negatively impact the life course.

**Preventive care** for children and youth is a component of contemporary U.S. health reform activities and offers great opportunity for health cost savings. A healthy economy requires educated and healthy workers. For children to have a successful, meaningful, and useful educational experience, they must have physical, cognitive, and emotional health. Educational success, in particular, is tied to early childhood developmental competence. Thus, well-child care plays a vital role in promoting adult health, a concept endorsed by business leaders as essential to building the human infrastructure of the U.S. economy and society.

Although well-child care focuses on the health and well-being of the child, the reality is that children live in families. The context of the child within the family unit is also key to this primary goal and therefore also may necessitate the addressing of needs in the family, including the parents or other adults. Addressing of needs may be as straightforward as supportive listening, validation, and referral to an appropriate resource, whether in the community or the adult’s own medical home. The importance of dual-generation approaches that benefit both the parent and the child is immense.

**Periodicity Schedule and Guidelines**

The frequency and content for well-child care activities are derived from evidence-based practice and research. In addition, federal agencies and professional organizations, such as the American Academy of Pediatrics (AAP), have developed evidence-informed, expert consensus guidelines for care. The *Recommendations for Preventive Pediatric Health Care* or **Periodicity Schedule** is a compilation of recommendations listed by age-based visits (Fig. 12.1). It is intended to guide practitioners of pediatric primary care to perform certain services and intentionally make observations at age-specific visits; it designates the standard for preventive services for U.S. children and youth and is referred to as such in some legislation. It is updated regularly and is available online.
Comprehensive guides for care of well infants, children, and adolescents have been developed based on the Periodicity Schedule to expand and further recommend how practitioners might accomplish the tasks outlined. The current guideline standard is The Bright Futures Guidelines for Health Supervision of Infants, Children, and Adolescents, 4th edition (https://brightfutures.aap.org/Pages/default.aspx). These guidelines were developed by AAP under the leadership of the Maternal Child Health Bureau of the U.S. Department of Health and Human Services, in collaboration with the National Association of Pediatric Nurse Practitioners, American Academy of Family Physicians, American Medical Association, American Academy of Pediatric Dentistry, Family Voices, and others.

**Tasks of Well-Child Care**

The well-child encounter aims to promote the physical and emotional well-being of children and youth. Child health professionals, including pediatricians, family medicine physicians, nurse practitioners, and physician assistants, take
advantage of the opportunity well-child visits provide to elicit parental questions and concerns, gather relevant family and individual health information, perform a physical examination, and initiate screening tests. The tasks of each well-child visit include the following:

1. Disease detection
2. Disease prevention
3. Health promotion
4. Anticipatory guidance

To achieve these outcomes, healthcare professionals employ techniques to screen for disease—or for the risk of disease—and provide advice about healthy behaviors. These activities lead to the formulation of appropriate anticipatory guidance and health advice.

Clinical detection of disease in the well-child encounter is accomplished by a careful physical examination and both surveillance and screening. In well-child care, surveillance occurs in every health encounter and is enhanced by repeated visits and observations with advancing developmental stages. It relies on the experience of a skilled clinician performing intentional observation over time. Screening is a more formal process using some form of validated assessment tool and has known sensitivity and specificity. For example, anemia surveillance is accomplished through taking a dietary history and seeking signs of anemia in the physical examination. Anemia screening is done by hematocrit or hemoglobin tests. Developmental surveillance relies on the observations of parents and the assessment of clinicians in pediatric healthcare who are experienced in child development. Developmental screening uses a structured developmental screening tool by personnel trained in its use or in the scoring and interpretation of parent report questionnaires.

The 2nd essential action of the well-child encounter, disease prevention, may include both primary prevention activities applied to a whole population and secondary prevention activities aimed at patients with specific factors of risk. For example, counseling about reducing fat intake is appropriate for all children and families. However, counseling is intensified for overweight and obese youth or in the presence of a family history of hyperlipidemia and its sequelae. The child and adolescent healthcare professional needs to individualize disease prevention strategies to the specific patient, family, and community.

Health promotion and anticipatory guidance activities distinguish the well-
child health supervision visit from all other encounters with the healthcare system. Disease detection and disease prevention activities are germane to all interactions of children with physicians and other healthcare clinicians, but health promotion and anticipatory guidance shift the focus to wellness and to the strengths of the family (e.g., what is being done well and how this might be improved). This approach is an opportunity to help the family address relationship issues, broach important safety topics, access needed services, and engage with extended family, school, neighborhood, and community and spiritual organizations.

It is not possible to cover all the topics suggested by comprehensive guidelines such as Bright Futures in the average 18 min well-child visit. Child health professionals must prioritize the most important topics to cover. Consideration should be given to a discussion of the following:

◆ First and foremost, the agenda the parent or child brings to the health supervision visit.
◆ The topics where evidence suggests counseling is effective in behavioral change.
◆ The topics where there is a clear rationale for the issue's critical importance to health, such as sleep environment to prevent sudden unexpected infant death (SUID) or attention to diet and physical activity.
◆ A summary of the child's progress in emotional, cognitive, and social development, physical growth, and strengths.
◆ Issues that address the questions, concerns, or specific health problems relevant to the individual family.
◆ Community-specific problems that could significantly impact the child's health (e.g.,
neighborhood violence from which children need protection, absence of bike paths that would promote activity).

This approach must be directed at all children, including children and youth with special health care needs. CSHCN are no different from other children in their need for guidance about healthy nutrition, physical activity, progress in school, connection with friends, a healthy sense of self-efficacy, and avoidance of risk-taking behaviors. The existence of frequent visits to the medical home or specialists to address the special health needs sometimes masks the lack of general health supervision care. The coordination of specialty consultation, medication monitoring, and functional assessment, which should occur in their periodic visits, needs to be balanced with a discussion of the child's unique ways of accomplishing the emotional, social, and developmental tasks of childhood and adolescence. Comprehensive, integrated care planning for CSHCN should support partnerships between medical homes and families and youth through goal setting and negotiating next steps. In this process, chronic condition management and health surveillance (including adolescent engagement and planning for transition to adult care) occur within an effective patient care relationship, partnering to improve health outcomes and efficiencies of care provision.

**Infancy and Early Childhood**

Nutrition, physical activity, sleep, safety, and emotional, social, and physical growth, along with parental well-being, are critical for all children. For each well-child visit, there are topics specific to individual children based on their age, family situation, chronic health condition, or a parental concern, such as sleep environment to prevent SUID, activities to lose weight, and fences around swimming pools. Attention should also be focused on the family milieu and other social determinants of health, including screening for parental depression (especially maternal postpartum depression) and other mental illness, family violence, substance abuse, nutritional inadequacy, and lack of housing. It is equally important to identify, acknowledge, and empower family strengths. These issues are essential to the care of young children.
Answering parents’ questions while creating an environment where parents feel comfortable asking is the most important priority of the well-child visit. Promoting family-centered care and partnership with parents increases the ability to elicit parental concerns, especially about their child's development, learning, and behavior. Evidence-based approaches such as early literacy assessment and promotion (e.g., Reach Out and Read) provide a structure for enquiry, surveillance, and parent coaching efficiently within the health supervision visit.

It is important to identify children with developmental disorders as early as possible. Developmental surveillance at every visit combined with a structured developmental screening, neuromuscular screening, and autism screening at certain visits is a way to improve diagnosis, especially for some of the subtler delays or autism spectrum disorders for which early intervention is believed to be associated with reduced morbidity.

Middle Childhood and Adolescence

As the child enters school-age years, additional considerations emerge. Attention to their developing autonomy requires fostering a clinician–patient relationship separate from the clinician–child-family relationship, with increasing needs for privacy and confidentiality as the child ages. The 6 health behaviors that most significantly impact adolescent and adult morbidity and mortality are inadequate physical activity, poor nutrition, sexuality-related behaviors, substance use and abuse (including tobacco and vaporized nicotine), unintentional injury–related behaviors, and intentional injury–related behaviors. Emotional well-being and early diagnosis and treatment of mental health problems are equally important, with attention to the developmental tasks of adolescence: competence at school and other activities, connection to friends and family, autonomy, empathy, and a sense of self-worth.

Office Intervention for Behavioral and Mental Health Issues

One fifth of primary care encounters with children are for a behavioral or mental health problem or sickness visits complicated by a mental health issue. Pediatricians and other primary care clinicians seeing children must have
reasonable comfort and knowledge for diagnosis, treatment, and referral criteria for attention-deficit/hyperactivity disorder (see Chapter 49), depression and other mood disorders (Chapter 39), anxiety (Chapter 38), and conduct disorder (Chapter 42), as well as an understanding of the pharmacology of the frequently prescribed psychotropic medications. Familiarity with available local mental health services and clinicians and knowledge of the types of services indicated are important for effective consultation or referral. With new understanding of the impact of lifestyle on mood disorders and anxiety, encouragement of behavioral change to implement regular exercise, a healthy diet, avoidance of substances, and judicious use of media has become an important responsibility of the primary care clinician. Motivational interviewing provides a structured approach that has been designed to help patients and parents identify the discrepancy between their desire for health and the outcomes of their current behavioral choices. It also allows the clinician to use proven strategies that lead to a patient-initiated plan for change.

**Strength-Based Approaches and Framework**

Questions about school or extracurricular accomplishments or competent personal characteristics should be integrated into the content of the well-child visit. Such inquiries set a positive context for the visit, deepen the partnership with the family, acknowledge the child's healthy development, and facilitate discussing social-emotional development with children and their parents. There is a strong relationship between appropriate social-emotional development (e.g., children's strong connection to their family, social friends, and mentors; competence; empathy; appropriate autonomy) and decreased participation in all the risk behaviors of adolescence (related to drugs, sex, and violence). An organized approach to the identification and encouragement of a child's strengths during health supervision visits provides both the child and the parent with an understanding of how to promote healthy achievement of the developmental tasks of childhood and adolescence. It also provides an opportunity to assess and comment on the relational health in the family. CSHCN often have a different timetable, but they have an equal need to be encouraged to develop strong family and peer connections, competence in a variety of arenas, ways to do things for others, and appropriate independent decision-making.

**Office System Change for Quality Improvement**
To facilitate the effective delivery of preventive services for children and youth, screening schedules and parent handouts, flow sheets, registries, and parent and youth previsit questionnaires are available in *The Bright Futures Guidelines Toolkit*; online previsit tools are under construction. These efforts are part of a larger national effort that is built on a coordinated team approach in the office setting and the use of continuous measurement for improvement.

**Evidence**

Available evidence should be utilized in developing health-promotion and disease-detection recommendations. Revisions to the AAP Periodicity Schedule undergo rigorous evidence assessment; however, many highly valued well-child care activities have not been evaluated for efficacy. Lack of evidence is most often related to absence of systematic study and does not necessarily mean lack of benefit. Thus the clinical encounter with the well child is also guideline and recommendation driven and requires the integration of clinician goals, family needs, and community realities in seeking better health for the child. The evidence and rationale for recommendations in the Periodicity Schedule (see Fig. 12.1) and *Bright Futures Guidelines* regarding well-child care activities are a balance of evidence from research, clinical practice guidelines, professional recommendations, expert opinion, experience, and knowledge of the needs of the patient population in the context of community assets and challenges. Clinical or counseling decisions and recommendations may also be based on local legislation (e.g., seat belts), on commonsense measures not likely to be studied experimentally (e.g., lowering water heater temperatures, use of car seats), or on the basis of relational evidence (e.g., television watching associated with violent behavior in young children). Most important, sound clinical and counseling decisions are responsive to family needs and desires and support patient-centered decision-making.

**Caring for the Child and Youth in the Context of the Family and Community**

A successful primary care practice for children incorporates families, is family centered, and embraces the concept of the medical home. A medical home is defined as primary care that is accessible, continuous, comprehensive, family
centered, coordinated, compassionate, and culturally effective. In a medical home, a clinician works in partnership with the family and patient to ensure that all medical and nonmedical needs of the child are met. Through this partnership, the child healthcare professional helps the family/patient access and coordinate specialty care, educational services, out-of-home care, family support, and other public and private community services that are important to the overall health of the child and family.

Ideally, health promotion activities occur not only in the medical home, but also through community members and other health and education professionals. To be most effective, communication and coordination around providing accurate, consistent information is key, with a clear understanding of the important role that the community plays in supporting healthy behaviors among families. Communities where children and families feel safe and valued and have access to positive activities and relationships provide the important base that the healthcare professional can build on and refer to for needed services that support health but are outside the realm of the healthcare system or primary care medical home. It is important for the medical home and community agencies to identify mutual resources, communicate well with families and each other, and partner in designing service delivery systems. This interaction is the practice of community pediatrics, whose unique feature is its concern for all the population: those who remain well but need preventive services, those who have symptoms but do not receive effective care, and those who do seek medical care in a physician's office or hospital.

**Bibliography**

American Academy of Pediatrics, Council on Children with

In all high-income countries of the world, and increasingly in many low- and middle-income countries, injuries are the most common cause of death during childhood and adolescence beyond the 1st few mo of life (Table 13.1 and Fig. 13.1). Injuries represent one of the most important causes of preventable pediatric morbidity and mortality in the United States. Identification of risk factors for injuries has led to the development of successful programs for prevention and control. Strategies for injury prevention and control should be pursued by the pediatrician in the office, emergency department (ED), hospital, and community setting and should be done in a multidisciplinary, multifaceted way.

*All-cause data* from CDC, National Center for Health Statistics: Compressed Mortality File 1999–2015, Series 20, No 2U, 2016, as compiled from data provided by the 57 vital statistics jurisdictions through the Vital Statistics Cooperative Program, CDC WONDER online database, October 2018.

Injuries have identifiable risk and protective factors that can be used to define prevention strategies. The term *accidents* implies a chance event occurring without pattern or predictability. In fact, most injuries occur under fairly predictable circumstances to high-risk children and families. *Most injuries are preventable.*

Reduction of morbidity and mortality from injuries can be accomplished not only through primary prevention (averting the event or injury), but also through secondary and tertiary prevention. The latter 2 approaches include appropriate
emergency medical services (EMS) for injured children; regionalized trauma care for the child with multiple injuries, severe burns, or traumatic brain injury; and specialized pediatric rehabilitation services that attempt to return children to their previous level of functioning.

Injury control also encompasses intentional injuries (assaults and self-inflicted injuries). These injuries are important in adolescents and young adults, and in some populations, these rank 1st or 2nd as causes of death in these age-groups. Many of the same principles of injury control can be applied to these problems; for example, limiting access to firearms may reduce both unintentional shootings, homicides, and suicides.

**Scope of the Problem**

**Mortality**

In the United States, injuries cause 42% of deaths among 1-4 yr old children and 3.5 times more deaths than the next leading cause, congenital anomalies. For the rest of childhood and adolescence up to age 19 yr, 64% of deaths are a result of injuries, more than all other causes combined. In 2016, injuries caused 13,952 deaths (16.78 deaths per 100,000 population) among individuals ≤19 yr old in the United States, resulting in more years of potential life lost than any other cause. Unintentional injuries remained the leading cause of death among those <24 yr old in 2016 (see Table 13.1 and Fig. 13.1).

Motor vehicle injuries lead the list of injury deaths among school-age children and adolescents and are the 2nd leading cause of injury death for those age 1-4 yr. In children and adults, motor vehicle occupant injuries account for the majority of these deaths. During adolescence, occupant injuries are the leading cause of injury death, accounting for >50% of unintentional trauma mortality in this age-group.

Drowning ranks 2nd overall as a cause of unintentional injury deaths among those age 1-19 yr, with peaks in the preschool and later teenage years (see Chapter 91). In some areas of the United States, drowning is the leading cause of death from trauma for preschool-age children. The causes of drowning deaths vary with age and geographic area. In young children, bathtub and swimming pool drowning predominates, whereas in older children and adolescents, drowning occurs predominantly in natural bodies of water while the victim is swimming or boating.
**Fire- and burn-related deaths** account for 3% of all unintentional trauma deaths, with the highest rates among those <5 yr of age (see Chapter 92). Most deaths are a result of house fires and are caused by smoke inhalation or asphyxiation rather than severe burns. Children and elderly persons are at greatest risk for these deaths because of difficulty in escaping from burning buildings.

**Suffocation** accounts for approximately 87% of all unintentional deaths in children <1 yr old. Some cases result from choking on food items, such as hot dogs, candy, grapes, and nuts. Nonfood items that can cause choking include undersize infant pacifiers, small balls, and latex balloons. An increasing number of infant suffocation deaths represent sleep-related mortality in the presence of unsafe bedding, crib bumpers, or cosleeping with an impaired adult. In previous years these might have been classified as sudden infant death syndrome (see Chapter 402).

**Homicide** is the 3rd leading cause of injury death in children 1-4 yr old and the 3rd leading cause of injury death in adolescents (15-19 yr old) (Fig. 13.2). Homicide in the pediatric age-group falls into 2 patterns: infant (child) and adolescent. Child homicide involves children <5 yr old and represents child abuse (see Chapter 16). The perpetrator is usually a caretaker; death is generally the result of blunt trauma to the head and/or abdomen. The adolescent pattern of homicide involves peers and acquaintances and is caused by firearms in 88% of cases. The majority of these deaths involve handguns. Children between these 2 age-groups experience homicides of both types.
FIG. 13.2 Chart showing 3rd leading cause of death (homicide) among persons age 10-24 yr compared with 4th through 10th leading causes of death in the same age-group in the United States in 2013. *Does not include the 2 leading causes of death among persons age 10-24 yr in 2013: unintentional injuries (12,394 deaths) and suicide (5,264); † congenital anomalies; § cerebrovascular diseases. (From David-Ferdon C,
Suicide is rare in children <10 yr old; only 1% of all suicides occur in children <15 yr. The suicide rate increases greatly after age 10 yr, with the result that suicide is now the 2nd leading cause of death for 15-19 yr olds. Native American teenagers are at the highest risk, followed by white males; black females have the lowest rate of suicide in this age-group. Approximately 40% of teenage suicides involve firearms (see Chapter 40).

There has been a sharp and substantial increase in unintentional poisoning deaths among teens and young adults. In 2016, unintentional poisonings were the 2nd leading cause of injury deaths among 15-24 yr olds. Many of these were from prescription analgesic and opioid medications such as fentanyl.

Nonfatal Injuries

Most childhood injuries do not result in death. Approximately 12% of children and adolescents receive medical care for an injury each year in hospital EDs, and at least as many are treated in physicians’ offices. Of these, 2% require inpatient care, and 55% have at least short-term temporary disability as a result of their injuries.

The distribution of nonfatal injuries is very different from that of fatal trauma (Fig. 13.3). Falls are the leading cause of both ED visits and hospitalizations. Bicycle-related trauma is the most common type of sports and recreational injury, accounting for approximately 300,000 ED visits annually. Nonfatal injuries, such as anoxic encephalopathy from near-drowning, scarring and disfigurement from burns, and persistent neurologic deficits from head injury, may be associated with severe morbidity, leading to substantial changes in the quality of life for victims and their families. In 2010, nonfatal injuries to U.S. children <19 yr old resulted in >$32 billion in direct medical and lifetime work loss costs.
Global Child Injuries

Child injuries are a global public health issue, and prevention efforts are necessary in low-, middle-, and high-income countries. Between 1990 and 2010 there was a 53% decrease in mortality of people of all ages from communicable, maternal, neonatal, and nutritional disorders, while injury mortality decreased by only 16% (Fig. 13.4).
Worldwide, almost 1 million children and adolescents die from injuries and violence each year, and >90% of these deaths are in low- and middle-income countries. As child mortality undergoes an epidemiologic transition because of better control of infectious diseases and malnutrition, injuries have and will increasingly become the leading cause of death for children in the developing world, as it now is in all industrialized countries. Drowning is the 5th most common cause of death for 5-9 yr old children globally, and in some countries, such as Bangladesh, it is the leading cause of death among children beyond the 1st yr of life, with a rate 22 times greater than that in the Americas. An estimated 1 billion people do not currently have immediate access to roads; as industrialization and motorization spreads, the incidence of motor vehicle crashes, injuries, and fatalities will climb. The rate of child injury death in low- and middle-income countries is 3-fold higher than that in high-income countries and reflects both a higher incidence of many types of injuries and a much higher case fatality rate in those injured because of a lack of access to emergency and surgical care. As in high-income countries, prevention of child injuries and consequent morbidity and mortality is feasible with multifaceted approaches, many of which are low cost and of proven effectiveness.

**Principles of Injury Control**

Injury prevention once centered on attempts to pinpoint the innate characteristics of a child that result in greater frequency of injury. Most discount the theory of the “accident-prone child.” Although longitudinal studies have demonstrated an association between attention-deficit/hyperactivity disorder (ADHD) and increased rates of injury, the sensitivity and specificity of these traits as a test to identify individuals at high risk for injury are extremely low. The concept of *accident proneness* is counterproductive in that it shifts attention away from potentially more modifiable factors, such as product design or the environment. It is more appropriate to examine the physical and social environment of children with frequent rates of injury than to try to identify particular personality traits or temperaments, which are difficult to modify. Children at high risk for injury are likely to be relatively poorly supervised, to have disorganized or
stressed families, and to live in hazardous environments.

Efforts to control injuries include education or persuasion, changes in product design, and modification of the social and physical environment. Efforts to persuade individuals, particularly parents, to change their behaviors have constituted the greater part of injury control efforts. Speaking with parents specifically about using child car-seat restraints and bicycle helmets, installing smoke detectors, and checking the tap water temperature is likely to be more successful than offering well-meaning but too-general advice about supervising the child closely, being careful, and childproofing the home. This information should be geared to the developmental stage of the child and presented in moderate doses in the form of anticipatory guidance at well-child visits. Table 13.2 lists important topics to discuss at each developmental stage. It is important to acknowledge that there are many barriers to prevention adherence beyond simple knowledge acquisition; pediatricians should be familiar with low-cost sources for safety equipment such as bicycle helmets, smoke detectors, trigger locks, and car seats in their community.

Table 13.2
Injury Prevention Topics for Anticipatory Guidance by the Pediatrician

Newborn

- Car seats
- Tap water temperature
- Smoke detectors
- Sleep safe environments

Infant

- Car seats
- Tap water temperature
- Bath safety
- Choking prevention

Toddler and Preschooler
Car seats and booster seats
Water safety
Poison prevention
Fall prevention

**Primary School Child**

Pedestrian skills training
Water skills training
Booster seats and seat belts
Bicycle helmets
Safe storage of firearms in the home

**Middle School Child**

Seatbelts
Safe storage of firearms in the home
Water skills training
Sports safety and concussion prevention

**High School and Older Adolescent**

Seatbelts
Alcohol and drug use, especially while driving and swimming
Mobile phone use while driving
Safe storage of firearms
Sports safety and concussion prevention
Occupational injuries

The most successful injury prevention strategies generally are those involving **changes in product design**. These passive interventions protect all individuals in the population, regardless of cooperation or level of skill, and are likely to be more successful than active measures that require repeated behavior change by the parent or child. The most important and effective product changes have been in motor vehicles, in which protection of the passenger compartment and use of
airbags have had large effects on injury risk. Turning down the water heater temperature, installing smoke detectors, and using child-resistant caps on medicines and household products are other examples of effective product modifications. Many interventions require both active and passive measures. Smoke detectors provide passive protection when fully functional, but behavior change is required to ensure periodic battery changes and proper testing.

**Modification of the environment** often requires greater changes than individual product modification but may be very effective in reducing injuries. Safe roadway design, decreased traffic volume and speed limits in neighborhoods, and elimination or safe storage of guns in households are examples of such interventions. Included in this concept are changes in the social environment through legislation, such as laws mandating child seat restraint and seatbelt use, bicycle helmet use, and graduated driver's licensing laws.

Prevention campaigns combining 2 or more of these approaches have been particularly effective in reducing injuries. The classic example is the combination of legislation/regulation and education to increase child seat restraint and seatbelt use; other examples are programs to promote bike helmet use among school-aged children and improvements in occupant protection in motor vehicles.

## Risk Factors for Childhood Injuries

Major factors associated with an increased risk of injuries to children include age, sex, race and ethnicity, socioeconomic status, rural-urban location, and the environment.

### Age

Toddlers are at the greatest risk for burns, drowning, and falling. Poisonings become another risk as these children acquire mobility and exploratory behavior. Young school-age children are at greatest risk for pedestrian injuries, bicycle-related injuries (the most serious of which usually involve motor vehicles), motor vehicle occupant injuries, burns, and drowning. During the teenage years, there is a greatly increased risk from motor vehicle occupant trauma, a continued risk from drowning and burns, and the new risk of intentional trauma. Sports- and recreation-related injuries, including concussion, become more common,
and more serious, as children age. Work-related injuries associated with child labor, especially for 14-16 yr olds, are an additional risk.

Injuries occurring at a particular age represent a period of vulnerability during which a child or an adolescent encounters a new task or hazard that they may not have the developmental skills to handle successfully. Toddlers do not have the judgment to know that medications can be poisonous or that some houseplants are not to be eaten; they do not understand the hazard presented by a swimming pool or an open second-story window. For young children, parents may inadvertently set up this mismatch between the skills of the child and the demands of the task. Many parents expect young school-age children to walk home from school, the playground, or the local convenience store, tasks for which most children are not developmentally ready. Likewise, the lack of skills and experience to handle many tasks during the teenage years contributes to an increased risk of injuries, particularly motor vehicle injuries. The high rate of motor vehicle crashes among 15-17 yr olds is caused in part by inexperience but also appears to reflect their level of cognitive development and emotional maturity. Alcohol, other drugs, and mobile phone use substantially add to these limitations.

Age also influences the severity of injury and the risk of long-term disability. Young school-age children have an incompletely developed pelvis. In a motor vehicle crash the seatbelt does not anchor onto the pelvis, but rides up onto the abdomen, resulting in the risk of serious abdominal injury. Proper restraint for 4-8 yr old children requires the use of booster seats. Children <2 yr old have much poorer outcomes from traumatic brain injuries than older children and adolescents, partly related to the severity of abusive head trauma.

**Gender**

Beginning at 1-2 yr of age and continuing throughout the life span, males have higher rates of fatal injury than females. During childhood, this does not appear to be primarily a result of developmental differences between the sexes, differences in coordination, or differences in muscle strength. Variation in exposure to risk may account for the male predominance in some types of injuries. Although males in all age-groups have higher rates of bicycle-related injuries, adjusting for exposure reduces this excess rate. Sex differences in rates of pedestrian injuries do not appear to be caused by differences in the amount of walking, but rather reflect differences in behavior between young females and
males; whether these are genetic or the result of gender socialization is uncertain. Greater risk-taking behavior, combined with greater frequency of alcohol use, may lead to the disproportionately high rate of motor vehicle crashes among teenage males. The rate of violence-related injuries is higher among males because of their risk-taking behavior.

**Race and Ethnicity**

In the United States, Native Americans have the highest death rate from unintentional injuries, reflecting both the increased incidence and the poorer access to trauma care because of their rural location. African American children and adolescents have higher rates of fatal injuries than whites, whereas Asians have lower rates; rates for Hispanic children and adolescents are intermediate between those for blacks and those for whites. These discrepancies are even more pronounced for some injuries. The homicide rate for African Americans age 15-19 yr was 32.74 per 100,000 population in 2016, compared with 5.59/100,000 for American Indians and Alaskan Natives and 3.91/100,000 for whites and 2.18/100,000 for Asians. The suicide rate for Native American youth was 1.5 times the rate for whites and 2.7 times rates for blacks. The rate of firearm homicide deaths for African American youth ages 15-19 is 10-fold higher than that for whites and 17 times that of Asian American youth.

These disparities appear to be primarily related to poverty, the educational status of parents, and the presence of hazardous environments. Homicide rates among blacks are nearly equivalent to those among whites, when adjusted for socioeconomic status. *It is important to acknowledge racial disparities in injury rates and the importance of racism at all levels in society, but inappropriate to ascribe the etiology of these differences solely to the effect of race or ethnicity.*

**Socioeconomic Status**

**Poverty** is one of the most important risk factors for childhood injury. Mortality from fires, motor vehicle crashes, and drowning is 2-4 times higher in poor children. Death rates among both blacks and whites have an inverse relationship to income level: the higher the income level, the lower the death rate. Native Americans have especially high mortality rates. Other factors are single-parent families, teenage mothers, multiple care providers, family stress, and multiple siblings; these are primarily a function of poverty rather than independent risk
factors.

**Rural-Urban Location**

Injury rates are generally higher in rural than in urban areas. Homicide rates are higher in urban areas, as is violent crime in general. However, suicide among adolescents is higher in rural than urban areas. Case fatality from injury is generally twice as high in rural areas than in urban areas, reflecting both the increased severity of some injuries (e.g., motor vehicle crashes occurring at higher speeds) and poorer access to EMS and definitive trauma care in rural areas. Some injuries are unique to rural areas, such as agricultural injuries to children and adolescents.

**Environment**

Poverty increases the risk of injury to children, at least in part through its effect on the environment. Children who are poor are at increased risk for injury because they are exposed to more hazards in their living environments. They may live in poor housing, which is more likely to be dilapidated and less likely to be protected by smoke detectors. The roads in their neighborhoods are more likely to be major thoroughfares. Their neighborhoods are more likely to experience higher levels of violence, and they are more likely to be victims of assault than children and adolescents living in the suburbs. The focus on the environment is also important because it directs attention away from relatively immutable factors, such as family dynamics, poverty, and race, and directs efforts toward factors that can be changed through interventions.

**Mechanisms of Injury**

**Motor Vehicle Injuries**

Motor vehicle injuries are the leading cause of serious and fatal injuries for children and adolescents. Large and sustained reductions in motor vehicle crash injuries can be accomplished by identifiable interventions.

**Occupants**

Injuries to passenger vehicle occupants are the predominant cause of motor
vehicle deaths among children and adolescents. The peak injury and death rate for both males and females in the pediatric age-group occurs between 15 and 19 yr (see Table 13.1). Proper restraint use in vehicles is the single most effective method for preventing serious or fatal injury. Table 13.3 shows the recommended restraints at different ages. Fig. 13.5 provides examples of car safety seats.

Data from [http://www.safercar.gov/parents/CarSeats.htm](http://www.safercar.gov/parents/CarSeats.htm).
Much attention has been given to child occupants <8 yr old. Use of child-restraint devices, infant car seats, and booster seats can be expected to reduce fatalities by 71% and the risk of serious injuries by 67% in this age-group. All 50
states and the District of Columbia have laws mandating their use, although the upper age limit for booster seat requirements varies by state. Physician reinforcement of the positive benefits of child seat restraints has been successful in improving parent acceptance. Pediatricians should point out to parents that toddlers who normally ride restrained behave better during car trips than children who ride unrestrained.

A detailed guide and list of acceptable devices is available from the American Academy of Pediatrics (AAP)* and the National Highway Traffic Safety Administration (NHTSA). † Children weighing <20 lb may use an infant seat or may be placed in a convertible infant-toddler child-restraint device. Infants and toddlers <4 yr should be placed in the rear seat facing backward; older toddlers and young children can be placed in the rear seat in a forward-facing child harness seat until it is outgrown. Emphasis must be placed on the correct use of these seats, including placing the seat in the right direction, routing the belt properly, and ensuring that the child is buckled into the seat correctly.

Government regulations specific to automobile and product design have made the fit between car seats and the car easier, quicker, and less prone to error. **Children <13 yr old should never sit in the front seat. Inflating airbags can be lethal to infants in rear-facing seats and to small children in the front passenger seat.**

Older children are often not adequately restrained. Many children ride in the rear seat restrained with lap belts only. **Booster seats** have been shown to decrease the risk of injury by 59% and should be used by children who weigh between 40 lb (about 4 yr of age) and 80 lb, are <8 yr of age, and are <4 ft 9 in (145 cm) tall. Many states have extended their car seat laws to include children of booster seat age as well. Shoulder straps placed behind the child or under the arm do not provide adequate crash protection and may increase the risk of serious injury. The use of lap belts alone has been associated with an increased risk of seatbelt-related injuries, especially fractures of the lumbar spine and hollow-viscus injuries of the abdomen. These flexion-distraction injuries of the spine are often accompanied by injuries to the abdominal organs.

The rear seat is clearly much safer than the front seat for both children and adults. One study of children <15 yr old found that the risk of injury in a crash was 70% lower for children in the rear seat compared with those sitting in the front seat. **Frontal airbags** present a risk of serious or fatal injury from the airbag itself for children <13 yr. Side airbags also pose a risk for children who are in the front seat and are leaning against the door at the time of a crash. The safest place
for children is in the rear middle seat, properly restrained for their age and size. Educational and legislative interventions to increase the number of children traveling in the rear seat have been successful.

Transportation of premature infants presents special problems. The possibility of oxygen desaturation, sometimes associated with bradycardia, among premature infants while in child seat restraints has led the AAP to recommend an observed trial of infants born at <37 wk of gestational age in the seat before discharge and the use of oxygen or alternative restraints for infants who experience desaturation or bradycardia, such as seats that can be reclined and used as a car bed.

Children riding in the rear bed of pickup trucks are at special risk for injury because of the possibility of ejection from the truck and resultant serious injury.

**Teenage Drivers**

Drivers 15-17 yr old have more than twice the rate of collisions compared with motorists 18 yr and older. Formal driver education courses for young drivers appear to be ineffective as a primary means of decreasing the number of collisions, and in fact may increase risk by allowing younger teens to drive. The risk of serious injury and mortality is directly related to the speed at the time of the crash and inversely related to the size of the vehicle. Small, fast cars greatly increase the risk of a fatal outcome in the event of a crash.

The number of passengers traveling with teen drivers influences the risk of a crash. The risk of death for 17 yr old drivers is 50% greater when driving with 1 passenger compared with driving alone; this risk is 2.6-fold higher with 2 passengers and 3-fold higher with 3 or more passengers.

Teens driving at night are overrepresented in crashes and fatal crashes, with nighttime crashes accounting for >33% of teen motor vehicle fatalities. Almost 50% of fatal crashes involving drivers <18 yr old occur in the 4 hours before or after midnight. Teens are 5-10 times more likely to be in a fatal crash while driving at night compared with driving during the day. The difficulty of driving at night combined with the inexperience of teen drivers appears to be a deadly combination.

Another risk factor for motor vehicle crashes for people of all ages, including teens, is **distracted driving**. Distracting events can include visual distraction (taking eyes from the forward roadway), manual distraction (removing hands from vehicle controls), or cognitive distraction (taking attention from navigating the vehicle or responding to critical events). **Electronic devices** present all 3
modes of distraction in combination and are increasingly recognized as a major threat to driver safety, especially among teens. The uptick in motor vehicle fatality rates per vehicle mile driven is generally believed to be caused by distracted driving.

In 2017, 39.2% of teen drivers reported they had texted or emailed while driving in the last 30 days. Dialing on a cell phone increases the risk of a crash almost 3-fold, and texting may increase the risk as much as 6-fold. Although most states have banned text messaging for all drivers, the effect of state laws on prohibiting such behavior while driving is unknown. Parents should set limits on the use of these devices by their teens; technologic interventions that can block cell phone signals in a moving vehicle are also be available and should be considered by parents for their teens.

**Graduated driver's licensing (GDL) programs** consist of a series of steps over a designated period before a teen can receive full, unrestricted driving privileges. In a 3-stage graduated license, the student driver must first pass vision and knowledge-based tests, followed by obtaining a learner's permit, and once a specific age has been achieved and driving skills advanced, the student driver is eligible to take the driving test. Once given a provisional license, the new driver will have a specified time to do low-risk driving. GDL usually places initial restrictions on the number of passengers (especially teenage) allowed in the vehicle and limits driving at night. The number of crashes decreased 10–30% among the youngest drivers in states with a GDL system. The characteristics of GDL programs vary substantially across states. Optimal safety benefits depend on parent monitoring and engagement with teens around driving restrictions and responsibilities. Parent-teen driving contracts are available and help to facilitate these discussions.

**Alcohol use** is a major cause of motor vehicle trauma among adolescents. The combination of inexperience in driving and inexperience with alcohol is particularly dangerous. Approximately 20% of all deaths from motor vehicle crashes in this age-group are the result of alcohol intoxication, with impairment of driving seen at blood alcohol concentrations (BACs) as low as 0.05 g/dL. In 2017, approximately 16.5% of adolescents reported riding with a driver who had been drinking, and 5.5% reported driving after drinking. All states have adopted a **zero tolerance policy** to adolescent drinking while driving, which defines any measurable alcohol content as legal intoxication. All adolescent motor vehicle injury victims should have their BAC measured in the ED and should be screened for high-risk alcohol use with a validated screening test (e.g., CRAFFT,
Alcohol Use Disorders Identification Test [AUDIT]) to identify those with alcohol abuse problems (see Chapter 140.1). Individuals who have evidence of alcohol abuse should not leave the ED or hospital without plans for appropriate alcohol abuse treatment. Interventions for problem drinking can be effective in decreasing the risk of subsequent motor vehicle crashes. Even brief interventions in the ED using motivational interviewing can be successful in decreasing adolescent problem drinking.

Another cause of impaired driving is marijuana use. In 2017, nearly 20% of high school students reported using marijuana in the prior 30 days. Marijuana is currently legal (2018) for adult use in 9 U.S. states and for medical use in 30 states, while being considered in many others; the effects of this on adolescent injury remains to be determined. Marijuana is often co-ingested with alcohol or other drugs, and blood thresholds for biologic impairment have not been standardized. It is therefore difficult to estimate the independent effect of marijuana on crash risk.

**All-Terrain Vehicles**

All-terrain vehicles (ATVs) in many parts of the United States are an important cause of injuries to children and adolescents. These vehicles can attain high speeds, especially with low-weight children, and are prone to rollover because of their high center of gravity. Orthopedic and head injuries are the most common serious injuries seen among children involved in ATV crashes. Helmets can significantly decrease the risk and severity of head injuries among ATV riders, but current use is very low. Voluntary industry efforts to decrease the risk of injuries appear to have had little effect in making ATVs safer. The AAP recommends that children <16 yr old should not ride on ATVs.

**Bicycle Injuries**

Each year in the United States, approximately 161,000 children and adolescents are treated in EDs for bicycle-related injuries, making this one of the most common reasons that children with trauma visit EDs. The majority of severe and fatal bicycle injuries involve head trauma. A logical step in the prevention of these head injuries is the use of helmets. Helmets are very effective, reducing the risk of all head injury by 85% and the risk of traumatic brain injury by 88%. Helmets also reduce injuries to the mid and upper face by as much as 65%. Pediatricians can be effective advocates for the use of bicycle helmets and
should incorporate this advice into their anticipatory guidance schedules for parents and children. Appropriate helmets are those with a firm polystyrene liner that fit properly on the child's head. Parents should avoid buying a larger helmet to give the child “growing room.”

Promotion of helmet use can and should be extended beyond the pediatrician's office. Community education programs spearheaded by coalitions of physicians, educators, bicycle clubs, and community service organizations have been successful in promoting the use of bicycle helmets to children across the socioeconomic spectrum, resulting in helmet use rates of ≥70% with a concomitant reduction in the number of head injuries. Passage of bicycle helmet laws also leads to increased helmet use.

Consideration should also be given to other types of preventive activities, although the evidence supporting their effectiveness is limited. Bicycle paths are a logical method for separating bicycles and motor vehicles.

**Pedestrian Injuries**

Pedestrian injuries are a major cause of traumatic death for children and adolescents in the United States and in most high-income countries. In low-income countries, a much higher proportion of road traffic fatalities are pedestrians, especially among 5-14 yr olds. Although case fatality rates are <5%, serious nonfatal injuries constitute a much larger problem, resulting in 34,498 ED visits annually for children and adolescents. Pedestrian injuries are the most important cause of traumatic coma in children and a frequent cause of serious lower-extremity fractures, particularly in school-age children.

Most injuries occur during the day, with a peak in the after-school period. Improved lighting or reflective clothing would be expected to prevent few injuries. Surprisingly, approximately 30% of pedestrian injuries occur while the individual is in a marked crosswalk, perhaps reflecting a false sense of security and decreased vigilance in these areas. The risk of pedestrian injury is greater in neighborhoods with high traffic volumes, speeds >25 miles/hr, absence of play space adjacent to the home, household crowding, and low socioeconomic status.

One important risk factor for childhood pedestrian injuries is the developmental level of the child. Children <5 yr old are at risk for being run over in the driveway. Few children <9 or 10 yr of age have the developmental skills to successfully negotiate traffic 100% of the time. Young children have poor ability to judge the distance and speed of traffic and are easily distracted by playmates.
or other factors in the environment. Many parents are not aware of this potential mismatch between the abilities of the young school-age child and the skills needed to cross streets safely. The use of mobile phones and devices has become increasingly common while walking and can increase the risk of being struck by a motor vehicle.

Prevention of pedestrian injuries is difficult but should consist of a multifaceted approach. Education of the child in pedestrian safety should be initiated at an early age by the parents and continue into the school-age years. Younger children should be taught never to cross streets when alone; older children should be taught (and practice how) to negotiate quiet streets with little traffic. Major streets should not be crossed alone until the child is at least 10 yr of age and has been observed to follow safe practices.

Legislation and police enforcement are important components of any campaign to reduce pedestrian injuries. Right-turn-on-red laws increase the hazard to pedestrians. In many cities, few drivers stop for pedestrians in crosswalks, a special hazard for young children. Engineering changes in roadway design are extremely important as passive prevention measures. Most important are measures to slow the speed of traffic and to route traffic away from schools and residential areas; these efforts are endorsed by parents and can decrease the risk of injuries and death by 10–35%. Other modifications include networks of 1-way streets, proper placement of transit or school bus stops, sidewalks in urban and suburban areas, striping in rural areas to delineate the edge of the road, and curb parking regulations. Comprehensive traffic “calming” schemes using these strategies have been very successful in reducing child pedestrian injuries in Sweden, The Netherlands, Germany, and increasingly, the United States.

**Ski- and Snowboard-Related Head Injuries**

The increasing use of helmets in snow sports, such as skiing and snowboarding, is encouraging since head injuries are the most common cause of death in these sports, and helmets reduce the risk of head injury by ≥50%. Use of helmets does not result in skiers or snow boarders taking more risks and should be encouraged in all snow sports at all ages, not just for young children.

**Fire- and Burn-Related Injuries**

See Chapter 92.
Poisoning

Drowning
See Chapter 91.

Traumatic Brain Injury
See Chapter 85.

Firearm Injuries
Injuries to children and adolescents involving firearms occur in 3 different situations: unintentional injury, suicide attempt, and assault. The injury may be fatal or may result in permanent sequelae. **Unintentional firearm injuries** and deaths have continued to decrease and accounted for 127 deaths in 2016, representing only a very small fraction of all firearm injuries among children and adolescents. The majority of these deaths occur to teens during hunting or recreational activities. **Suicide** is the 2nd most common cause of death from all causes in both males and females age 10-19 yr. During the 1950s to 1970, suicide rates for children and adolescents more than doubled; firearm suicide rates peaked in 1994 and decreased by 59% from this peak by 2010 before gradually increasing, paralleling increases in the overall suicide rate. The difference in the rate of suicide death between males and females is related to the differences in method used during attempts. Girls die less often in suicide attempts because they use less lethal means (mainly drugs) and perhaps have a lower degree of intent. The use of firearms in a suicidal act confers an approximately 90% case fatality rate.

**Homicides** are 3rd only to motor vehicle crashes and suicide among causes of death in teenagers >15 yr old. In 2016, 1816 adolescents age 15-19 yr were homicide victims; African American teenagers accounted for 63% of the total, making homicides the most common cause of death among black teenagers. Over 85% of homicides among teenage males involved firearms, mostly handguns.

In the United States, approximately 36% of households owned guns in 2016. Handguns account for approximately 30% of the firearms in use today, yet they are involved in 80% of criminal and other firearm misuse. Home ownership of
guns increases the risk of adolescent suicide 3- to 10-fold and the risk of adolescent homicide up to 4-fold. In homes with guns, the risk to the occupants is far greater than the chance that the gun will be used against an intruder; for every death occurring in self-defense, there may be 1.3 unintentional deaths, 4.6 homicides, and 37 suicides.

Of all firearms, **handguns** pose the greatest risk to children and adolescents. Access to handguns by adolescents is surprisingly common and is not restricted to those involved in gang or criminal activity. Stricter approaches to reduce youth access to handguns, rather than all firearms, would appear to be the most appropriate focus of efforts to reduce shooting injuries in children and adolescents.

Locking and unloading guns as well as storing ammunition locked in a different location substantially reduces the risk of a suicide or unintentional firearm injury among youth by up to 73%. Because up to 30% of handgun-owning households have at least 1 firearm stored unsafely, one potential approach to reducing these injuries could focus on improving household firearm storage practices where children and youth reside or visit. The evidence regarding the effectiveness of office-based counseling to influence firearm storage practice is mixed; the most effective programs are those in which devices are dispensed along with advice.

Adolescents with mental health conditions and alcoholism are at particularly high risk for firearm injury. In the absence of conclusive evidence, physicians should continue to work with families to eliminate access to guns in these households.

**Falls**

Falls are the leading cause of **nonfatal injury** in children and adolescents. Altogether, there were 2.3 million falls that led to ED visits in 2016 for children and adolescents; approximately 2.9% of these visits led to a hospitalization or transfer. There have been relatively few in-depth analytic studies of falls, except in particular circumstances, such as playground injuries. Strategies to prevent falls depend on the environmental circumstances and social context in which they occur. **Window falls** have been successfully prevented with the use of devices that prevent egress, and injuries from **playground falls** can be mitigated through the use of proper surfacing, such as woodchips or other soft, energy-absorbing materials. Alcohol may also contribute to falls among teenagers, and
these injuries can be reduced by general strategies to reduce teen alcohol use.

**Violent Behavior and Aggression**

Although the current rates of homicide are much lower than at their peak in the late 1980s and early 1990s, the problem of violence and assault remains large. The origins of adult and teen violence occur during childhood. Almost all adults who commit violent acts have a history of violent behavior during childhood or adolescence. Longitudinal studies following groups of individuals from birth have found that aggression occurs early and that most children learn to control this aggression in childhood. Children who later become violent adolescents and adults do not learn to control this aggressive behavior.

The most successful interventions for violence target young children and their families. These include home visits by nurses and paraprofessionals beginning in the prenatal period and continuing for the 1st few yr of life to provide support and guidance to parents, especially parents without other resources. Enrollment in early childhood education programs (e.g., Head Start) beginning at age 3 yr has been shown to be effective in improving school success, keeping children in school, and decreasing the chance that the child will be a delinquent adolescent. School-based interventions, including curricula to increase the social skills of children and improve the parenting skills of caregivers, have long-term effects on violence and risk-taking behavior. Early identification of behavior problems by primary care pediatricians can best be accomplished through the routine use of formal screening tools. Interventions in adolescence, such as family therapy, multisystemic therapy, and therapeutic foster care, can decrease problem behavior and a subsequent decline into delinquency and violence.

**Psychosocial Consequences of Injuries**

Many children and their parents have substantial psychosocial sequelae from trauma. Studies in adults indicate that 10–40% of hospitalized injured patients will have **posttraumatic stress disorder** (PTSD; see Chapter 38). Among injured children involved in motor vehicle crashes, 90% of families will have symptoms of acute stress disorder after the crash, although the diagnosis of acute stress disorder is poorly predictive of later PTSD. Standardized questionnaires that collect data from the child, the parents, and the medical record at the time of initial injury can serve as useful screening tests for later development of PTSD.
Early mental health intervention, with close follow-up, is important for the treatment of PTSD and for minimizing its effect on the child and family.

Bibliography

Centers for Disease Control and Prevention. Firearm homicides and suicides in major metropolitan areas—United States,

The reach of violence, whether as the victim, perpetrator, or witness, whether in person or through the media, is far, deep, and long-standing across the globe. In the home, it is estimated that 80–95% of such aggression is witnessed by a child. Exposure to violence disrupts the healthy development of children in a myriad of ways. Pediatric clinicians must be competent to address these issues in impacted children and families under their care (trauma-informed care). Clinicians also have a wider responsibility to advocate on local, state, national, and international levels for safer environments in which all children can grow and thrive.

Witnessing violence is detrimental to children. Because their scars as bystanders are emotional and not physical, the pediatric clinician may not fully appreciate their distress and thereby miss an opportunity to provide needed interventions. For children not living in war zones, the source of first exposure to violence is often intimate partner violence (IPV). In the United States alone, >1 in 15 children witness IPV each year, and worldwide approximately 275 million children are exposed to IPV yearly. Exposure to IPV in infancy and toddlerhood impacts attachment relationships, and school-age children who witness IPV have difficulties in developing and maintaining friendships, as well as an increased likelihood of developing maladaptive peer relations.

Another source of witnessed violence is community violence, a serious problem in the United States that disproportionately affects children from low-income areas. Approximately 22% of children witness violence in their family or in their community each year; witnessed violence includes assaults and bullying, sexual victimization, maltreatment by a caregiver, and theft or vandalism. Almost 60% of children will experience or witness violence during childhood. Witnessing acts of violence may be a significant stressor in children's lives. Witnessed community violence is related to internalizing problems such as
depression and posttraumatic stress disorder (PTSD) as well as externalizing problems, including delinquent behavior, aggression, and substance abuse. The most ubiquitous source of witnessing violence for U.S. children is media violence, sometimes referred to as virtual violence. This form of violence is not experienced physically; rather it is experienced in realistic ways through technology and ever more intense and realistic games. There is an ever-widening array of screens that are part of children's everyday lives, including computers, tablets, and cell phones, in addition to long-standing platforms, such as televisions and movies. Recent tragic events, including mass shootings and acts of terrorism, have increased the specter of fear among children as these events are reenacted for them on the multiple screens they encounter. Although exposure to media/virtual violence cannot be equated to exposure to real-life violence, many studies confirm that media/virtual violence desensitizes children to the meaning and impact of violent behavior. Violent video game exposure is associated with: an increased composite aggression score; increased aggressive behavior; increased aggressive cognitions; increased aggressive affect, increased desensitization, and decreased empathy; and increased physiological arousal. Violent video game use is a risk factor for adverse outcomes; however, insufficient data exist to examine any potential link between violent video game use and delinquency or criminal behavior. Table 14.1 lists interventions to reduce exposure to media violence.

Table 14.1

Public Health Recommendations to Reduce Effects of Media Violence on Children and Adolescents

<table>
<thead>
<tr>
<th>Parents should:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Be made aware of the risks associated with children viewing violent imagery, as it promotes aggressive attitudes, antisocial behavior, fear, and desensitization.</td>
</tr>
<tr>
<td>• Review the nature, extent, and context of violence in media available to their children before children view.</td>
</tr>
<tr>
<td>• Assist children's understanding of violent imagery appropriate to their developmental level.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Professionals should:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>
• Offer support and advice to parents who allow their children unsupervised access to extreme violent imagery, as this could be seen as a form of emotional abuse and neglect.
• Educate all young people in critical film appraisal, in terms of realism, justification, and consequences.
• Exercise greater control over access to inappropriate violent media entertainment by young people in secure institutions.
• Use violent film material in anger management programs under guidance.

**Media producers should:**
• Reduce violent content, and promote antiviolence themes and publicity campaigns.
• Ensure that when violence is presented, it is in context and associated with remorse, criticism, and penalty.
• Ensure that violent action is not justified, or its consequences understated.

**Policymakers should:**
• Monitor the nature, extent, and context of violence in all forms of media, and implement appropriate guidelines, standards, and penalties.
• Ensure that education in media awareness is a priority and a part of school curricula.

**Impacts of Violence**

All types of violence have a profound impact on health and development both psychologically and behaviorally; it may influence how children view the world and their place in it. Children can come to see the world as a dangerous and unpredictable place. This fear may thwart their exploration of the environment, which is essential to learning in childhood. Children may experience overwhelming terror, helplessness, and fear, even if they are not immediately in danger. Preschoolers are most vulnerable to threats that involve the safety (or perceived safety) of their caretakers. High exposure to violence in older children
correlates with poorer performances in school, symptoms of anxiety and depression, and lower self-esteem. Violence, particularly IPV, can also teach children especially powerful early lessons about the role of violence in relationships. Violence may change the way that children view their future; they may believe that they could die at an early age and thus take more risks, such as drinking alcohol, abusing drugs, not wearing a seatbelt, and not taking prescribed medication.

Some children exposed to severe and/or chronic violence may suffer from PTSD, exhibiting constricted emotions, difficulty concentrating, autonomic disturbances, and reenactment of the trauma through play or action (see Chapter 38). Based on Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria for PTSD in children ≤6 yr old, >50% of preschoolers may experience clinically significant symptoms of PTSD after exposure to IPV. Although young children may not fully meet these criteria, certain behavioral changes are associated with exposure to trauma, such as sleep disturbances, aggressive behavior, new fears, and increased anxiety about separations (clinginess). A challenge in treating and diagnosing pediatric PTSD is that a child's caregiver exposed to the same trauma may be suffering from it as well.

**Diagnosis and Follow-Up**

*The simplest way to recognize whether violence has become a problem in a family is to screen both the parents and the children (after approximately 8 yr of age) on a regular basis.* This practice is particularly important during pregnancy and the immediate postpartum period, when women may be at highest risk for being abused. It is important to assure families that they are not being singled out, but that all families are asked about their exposure to violence. A direct approach may be useful: “Violence is a major problem in our world today and one that impacts everyone in our society. So I ask all my patients and families about violence that they are experiencing in their lives. …” In other cases, beginning with general questions and then moving to the specific may be helpful: “Do you feel safe in your home and neighborhood? Has anyone ever hurt you or your child?” When violence has impacted the child, it is important to gather details about symptoms and behaviors.

The pediatric clinician can effectively counsel many parents and children who have been exposed to violence. Regardless of the type of violence to which the child has been exposed, the following components are part of the guidance: (1)
careful review of the facts and details of the event, (2) gaining access to support services, (3) providing information about the symptoms and behaviors common in children exposed to violence, (4) assistance in restoring a sense of stability to the family in order to enhance the child's feelings of safety, and (5) helping parents talk to their children about the event. When the symptoms are chronic (>6 mo) or not improving, if the violent event involved the death or departure of a parent, if the caregivers are unable to empathize with the child, or if the ongoing safety of the child is a concern, it is important that the family be referred to mental health professionals for additional treatment.

Bullying and Cyberbullying

Bullying behavior affects people throughout the life span, but much of the focus
Bullying has been on children and adolescents. In the past, bullying was sometimes considered a rite of passage, or was written off as “kids being kids.” It is now recognized that bullying can have profound short- and long-term negative consequences on all those involved, including perpetrators, targets, and bystanders. The consequences of bullying can affect a child's social experiences, academic progress, and health.

**Bullying** is defined as any unwanted aggressive behavior by another youth or group of youths that involves an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated. Generally, sibling aggression and dating violence are excluded, but research has associated these problems with *peer bullying*. Digital technology was initially viewed as a context in which bullying can occur. Further research studies have suggested that **cyberbullying** is not merely bullying that occurs through electronic communications, but rather a type of bullying with distinct elements, such as the potential for a single event to “go viral” and the use of technology as a tool to achieve power imbalance.

It is thought that bullying and cyberbullying are more alike than dissimilar, and that surveillance efforts, as well as prevention and intervention approaches, should address both types of bullying.

## Bullying Roles and Nomenclature

Bullying represents a dynamic social interaction in which an individual may play different roles at different stages. A child can be a perpetrator of bullying, a target of bullying, a witness or bystander, or simply a child whose environment is affected by pervasive bullying. In any bullying experience, the roles that each child plays may be fluid; such that a target of bullying may then become a perpetrator, or vice versa. Thus, common nomenclature has evolved to refer to children as *perpetrators* of bullying or *targets* of bullying to represent a present state, rather than labeling a child as a bully or a victim, which suggests a static role and may impact that child's self-image.

## Epidemiology

Bullying is a widespread problem during childhood and adolescence. Current estimates suggest that school-based bullying likely affects 18–31% of children and youth and that cyberbullying affects 7–15% of youth. Apparent rates of
bullying are influenced by the questions that are asked; the word “bully” is stigmatized, and absent that label, youth are more willing to acknowledge having engaged in activities that can be categorized as bullying. Estimates of bullying prevalence are typically based on self-reported victimization (not perpetration), but here too, language can influence results. Targets of other types of social conflict may overestimate or underestimate their bullying victimization unless precise language is used during assessment.

**Risk Factors**

Certain groups are more vulnerable to bullying, including youth who are lesbian, gay, bisexual, transgender, and questioning (LGBTQ); immigrant and racial minority youth; obese youth; and youth with disabilities. However, it is important to recognize that while these individual risk factors exist, the context and situation can also present unique risk factors. Some studies have found that African Americans are bullied more often than Latinos, whereas other studies have found no group differences. Contextual factors, such as the school climate or prevalence of a particular ethnic group in a school setting, may be important factors in a given bullying situation. The 2015 *Youth Risk Behavior Survey* found that white students were much more likely than black teens to report being bullied at school or online. Thus, it is important to recognize that in any bullying situation, an individual is embedded within a situation that is within a larger social context. This *person by situation by context* approach is useful to consider in identifying why bullying takes place in some situations but not others.

Bullying may occur with other high-risk behaviors. Students who carry weapons, smoke, and drink alcohol >5-6 days/wk are at greatest risk for moderate bullying. Those who carry weapons, smoke, have >1 alcoholic drink/day, have above-average academic performance, moderate/high family affluence, and feel irritable or bad-tempered daily are at greatest risk for engaging in frequent bullying. Negative parenting behavior is related to a moderately increased risk of becoming a *bully/victim* (youth who are both perpetrators and targets) and small to moderate effects on being targeted for bullying at school.

Some risk factors may be specific to cyberbullying. Among preadolescent children, more access to technology (e.g., cell phone ownership) predicts cyberbullying behaviors and some types of digital victimization. Also, communications through digital technology can be misperceived as hostility, and
those misperceptions can in turn increase electronic forms of bullying.

**Consequences of Bullying**

Involvement in any type of bullying is associated with poorer psychosocial adjustment; perpetrators, targets, and those both perpetrator and target report greater health problems and poorer emotional and social adjustment. Bullying consequences of both traditional and cyber forms of bullying are particularly significant in the areas of physical health, mental health, and academic achievement. Being the target of bullying is typically viewed as particularly stressful. The impact of this stress has been shown to affect the developing brain and to be associated with changes to the stress response system, which confers an increased risk for future health and academic difficulties. The long-term consequences of being bullied as a child include increased risk for depression, poor self-esteem, and abusive relationships. Negative outcomes for perpetrating bullying include higher risks of depression as well as substance abuse. Mental health consequences for both perpetrator and target include, across types of bullying, increased risks of depression, poor-self-esteem, increased suicidality, and anxiety. Academic difficulties include increased risk of poor school performance, school failure, and dropping out.

**School Violence**

**Epidemiology**

School violence is a significant problem in the United States. Almost 40% of U.S. schools report a least 1 violent incident to police, with >600,000 victims of violent crime per year. Among 9th to 12th graders, 8% were threatened or injured on school property in the last 12 mo, and 14% were involved in a physical fight over the last year. Still, school-associated violent deaths are rare. Seventeen homicides of children age 5-18 yr occurred at school during the 2009–2010 school year. Of all youth homicides, <2% occur at school. While urban schools experience more episodes of violence, the rare rampage gun violence that happens in rural and suburban schools demonstrates that no region is immune to lethal violence.

**Risk Factors**
Bullying and weapon carrying may be important precursors to more serious school violence. Among perpetrators of violent deaths at school, 20% had been bullying victims, and 6% carried a weapon to school in the last 30 days. Nonlethal violence, mental health problems, racial tensions, student attacks on teachers, and the effects of rapid economic change in communities can all lead to school violence. Individual risk factors for violence include prior history of violence, drug, alcohol, or tobacco use, association with delinquent peers, poor family functioning, poor grades in school, and poverty in the community.

Family risk factors include early childbearing, low parental attachment and involvement, authoritarian or permissive parenting styles (see Chapter 19), and poverty. There is more school violence in areas with higher crime rates and more street gangs, which take away students’ ability to learn in a safe environment and leave many children with traumatic stress and grief reactions.

Treatment and Prevention of Bullying and School Violence

Pediatric providers are in a unique position to screen, treat, and advocate for reducing the impact of bullying and school violence by assisting those affected and seeking to prevent further occurrences.

Signs and Symptoms

Signs of a child being involved in bullying or exposed to school violence include physical complaints such as insomnia, stomachaches, headaches, and new-onset enuresis. Psychological symptoms, such as depression (see Chapter 39), loneliness, anxiety (see Chapter 38), and suicidal ideation, may occur. Behavioral changes, such as irritability, poor concentration, school avoidance, and substance abuse, are common. School problems, such as academic failure, social problems, and lack of friends, can also occur. Additional vigilance is warranted for those children who represent vulnerable groups for bullying and aggression, including youth with disabilities, obesity, or minority, immigrant, or LGBTQ status.

Screening for Bullying
Assessing bullying and cyberbullying involvement is an important part of pediatric visits. Several tools can be helpful for clinicians, including the *Bright Futures Guidelines*, which recommend screening at each well-child visit. In these discussions, begin by normalizing the discussion; for example, practitioners can let the patient know that bullying is a topic they discuss with all their patients. It is advisable to define bullying based on the Uniform Definition, but using readily understandable and developmentally appropriate language. Physicians can ask patients if they have had experiences where there was repeated cruelty between peers, either as a target of that cruelty or seeing the cruelty, or even being angry or mean toward others. Asking a patient if he or she is a bully is not likely to generate either trust or an honest answer. Asking about exposures to peer victimization or school violence is also important. Throughout these discussions, it is critical to provide support and empathy while engaging a patient.

One tool to help providers begin and navigate these discussions is a *Practice Enhancement Tool* developed by the *Massachusetts Aggression Reduction Center* (MARC) and Children's Hospital Boston (Fig. 14.1). It begins by defining bullying in readily understandable language and then asks, “Is there any one kid, or a bunch of kids, that pick on you or make feel bad over and over again?” The Tool also guides the practitioner in asking about problematic digital experiences and asks whom the child has spoken to about the problem, and whether that has helped. Finally, it guides the practitioner through emphasizing the usefulness of talking about social problems and discusses how the physician can assist the patient.
MARC/BACPAC Pediatric Questionnaire: Bullying & Cyberbullying

Date of office visit: ____________________________

Child's name: ____________________________

Gender:  ☐ Male  ☐ Female

Child's grade: ____________________________

Child's age: ____________________________

☐ IEP?  ☐ Yes  ☐ No

Parent present during interview?  ☐ Yes  ☐ No

Subjective complaints (eg. H/A, tics, sleep):
______________________________

Neurodev / Psych Dx (if established):
______________________________

BEGIN BY STATING:

“You probably know that grownups today are very worried about bullying. I’d like to ask you a little bit about that, but I want to make sure you understand what I mean. When I ask about bullying, I mean another kid (or group of kids) who picks on someone or is mean to them on purpose, over and over again – not just one time.”

1. Do you see bullying happen at your school?

☐ Yes  ☐ No

2. Is there any one kid or a bunch of kids that pick on you or make you feel bad over and over again?

☐ Yes (inquire as to the frequency):

( ______ times daily; ______ times a week; ______ times a month; ______ times a year).

☐ If NO, SKIP TO #3

If YES: Where does this happen? (check all that apply):

☐ classroom  ☐ lunchroom  ☐ hallways

☐ stairwell  ☐ bathroom  ☐ locker-room

☐ playground  ☐ bus  ☐ other: ____________________________

What did he or she do to you? (check all that apply):

☐ made fun of me  ☐ kids laughed  ☐ name-calling

☐ rumors  ☐ made up lies  ☐ got me in trouble

☐ pushed, shoved, hit, threw stuff  ☐ other: ____________________________

3. How about on the computer at home? Has anyone been mean to you or made fun of you on the internet?

☐ Yes (Details):

______________________________

If NO to both #2 and #3, END HERE. Otherwise, continue.
4. It’s very important that you understand that if you are being bullied that it is never your fault. Bullying is wrong and people should never bully others. Have you told any adults about the kids that are bothering you?

☐ Yes (Who have you told?)
  ☐ Parent
  ☐ Teacher
  ☐ Other: ___________________________

If Yes.....Were the adults able to stop the bullying?
  ☐ Yes ☐ No

If Yes.....Did talking about it make you feel better?
  ☐ Yes ☐ No (“That’s ok. Sometimes talking does help though.”)

5. “Sometimes it feels good just to talk about things. I wish you and I had more time to talk about it today. Would you like to have a chance to talk about it sometime soon?”

☐ Yes (if YES, refer to):

______________________________________________________________

☐ No

IF NO...

...“Would you like me to try to help? As your doctor, I can talk with the school officials and try to make sure that the bullying stops. While I cannot promise that everything will be better, I know that if we do nothing the bullying will likely continue and probably get worse. I want you to be happy and safe at school — is it okay with you if I talk to your school about this?”

☐ Yes
  (Who would you like me to talk to? Principal / Nurse / Counselor / Teacher / Other: ________________)

☐ No
Guide to the bullying/cyberbullying checklist/interview

“Warm up” questions: briefly acknowledge these but do not discuss at length. No need to note the child’s answers.

› Are the kids in your school friendly?
› Tell me about one child at your school who you like.
› Tell me about one child at your school who is not friendly.

(Brief acknowledgement, e.g.: “Ok” or “that’s good.”)

Note: It’s fine to skip the warm-up questions if you have already chatted with the child.

When a child is being bullied

There are three venues through which you can help this child:

1. By giving them a “SAFE ADULT” at school they can always speak with (e.g., the school nurse, the school adjustment counselor);

2. By giving their parents guidance about how to cope (through handouts, websites); and

3. By offering them support from yourself.

If child consents to your involvement, seek written parental consent to share information with the school in writing. The more details the child can provide as to who, what, where, how, the more power the school will have to act. Explain this to the child/parent and do your best to gently get details for your letter to the school. If child or parent will not consent to communication with school, provide advice/handouts (MARCcenter.org) to help the parent advocate themselves for their child with the school. Always document in your note the conversation in the office.

Bullying and Cyberbullying Prevention and Advocacy Collaborative (BACPAC) at Boston Children’s Hospital: bostonchildrens.org/BACPAC

Stop Bullying Now from the U.S. government: stopbullying.gov
Children who are aggressive, overly confident, lacking in empathy, or having persistent conduct problems may need careful screening. It is important to bear in mind that bullying is a dynamic process, and a child may be involved as both a perpetrator and a target at different time points. The physical, behavioral, psychological, and academic symptoms of bullying may overlap with other conditions, such as medical illness, learning problems, and psychological disorders. Thus, labeling the behavior as *bullying* rather than the child as a “bully” is recommended.

Management of bullying and school violence involves several steps. First, ensure that all parties understand the relevant information (the patient, parents, and school). Second, assess a child's need for specialized counseling or social skills interventions. Extracurricular activities, (e.g., drama clubs, mentoring programs, sports) can be discussed as avenues to help to increase the child's social skills and self-esteem. Third, ensure that the patient has adequate support, including at home and at school. Peers are a particularly effective source of support, and patients can be encouraged to spend time with friends, but parents and educators are also important sources of emotional support. Many children benefit from planning their actions in unstructured settings (e.g., discussing where they could sit during lunch), while some benefit from role-playing. Finally, the clinician should identify safety issues, such as suicidal ideation and plans, substance abuse, and other high-risk behaviors.

When bullying or cyberbullying is suspected or confirmed, the parents and child should be offered education and resources. Some resources include the government-supported website [www.stopbullying.gov](http://www.stopbullying.gov), as well as MARC. Both provide free downloadable literature that can be offered to parents and families.

Addressing cases of bullying or exposure to violence in clinic often requires a cross-disciplinary approach. Involving teachers or school counselors, as well as outside referrals to psychologists, social workers, or counselors, may be warranted. Parental mental health and resource risk factors should also be addressed.

**Prevention**

Pediatric clinicians can reasonably expect their patients’ schools to provide
violence and bullying prevention programs. Rather than focusing on only changing a target of bullying, successful interventions use whole school approaches that involve multiple stakeholders. School climate has been shown to have significant effects on bullying prevalence, so these approaches are essential to primary prevention. These broad-based programs simultaneously include school-wide rules and sanctions, teacher training, classroom curriculum, and high levels of student engagement. Addressing access to firearms, involving community organizations and parents, and supporting youth mental health are important in creating a safe school climate.

Prevention programs for cyberbullying are at a nascent stage, reflecting uncertainty about the prevalence of the practice, who is perpetrating it and from where, and how students respond when they are victimized. Many schools have established cyberbullying policies and are increasingly involved with teaching youth about guidelines for appropriate online interactions and monitoring for cyberbullying problems. As of 2016, 23 states included cyberbullying in their state antibullying laws, while 48 states included “electronic harassment.” Although legal remedies are frequently not the most productive answer to bullying and cyberbullying incidents, pediatric physicians should be aware of local laws and be prepared to refer parents to more information about these laws when necessary. Studies suggest that preventive interventions designed to address bullying have effects on cyberbullying, and vice versa.

The American Academy of Pediatrics (AAP) provides a free online Family Media Use Plan that allows families to develop rules for digital media use and prompts for discussions about safety and online relationships with the goal of preventing negative consequences of online behavior and interactions. The tool is designed for ongoing discussions with family members about online experiences and family rules and values.

**Media Violence**

* Megan A. Moreno*
Today's youth are growing up in a media-rich environment of both traditional and digital media. Traditional media includes television (TV), radio, and periodicals; digital media includes online content that promote interactive and social engagement. The online world allows youth instant access to entertainment, information, and knowledge; social contact; and marketing. Social and interactive media allow media users to act as both creators and consumers of content. Examples include applications (apps), multiplayer video games, YouTube videos, and video blogs (vlogs).

One of the earliest studies that has been linked to media effects on aggression and violence was the “bobo doll” experiment in which children who observed an aggressive adult model were more likely to be aggressive toward a doll afterward. It has been widely accepted that media exposure can affect behavior; the advertising industry is grounded in the concept that media exposure can change purchasing behavior. Exposure to sexual content in media has been linked to earlier sexual initiation. However, applying these same constructs to media violence has been controversial. Some suggest that other concepts may be important to consider, such as “dose-response” effects of media, or gene-environment interactions.

There are 3 main types of media in which children may be exposed to violence: video games, traditional media, and social media. Violent video game exposure is associated with several outcomes, including increases in composite aggression score, aggressive behavior, aggressive cognitions, aggressive affect, and desensitization; decreased empathy; and increased physiological arousal.

Movies and TV often model violent behavior for the purposes of entertainment. Media violence does not always portray the real human cost or suffering caused by violence. Special effects can make virtual violence more believable and appealing than in the real world. For some children, exposure to media violence can lead to anxiety, depression, posttraumatic stress disorder, or
sleep disorders and nightmares. Repeated exposure to the behavioral scripts provided by entertainment media can lead to increased feelings of hostility, expectations for aggression, desensitization to violence, and increased likelihood of interacting and responding to others with violence.

**Social media** presents similar risks of exposure to virtual violence, but because of the interactive nature of the medium, this content can feel more personal or targeted. Social media combines peer and media effects and thereby represents a powerful motivator of behavior, whether content created by adolescents themselves or content they find and share with peers. The Facebook Influence Model describes 13 distinct constructs in which social media may influence users, such as establishing *social norms* and connection to identity. Thus, exposure to violent content on social media may have influence in promoting a social norm, or connecting this type of content to one's own identity.

**Screening**

It is important for pediatricians to screen and counsel patients and families about media use and exposure to violent content. Both the quantity and the quality of media are critical factors in media effects on children. When heavy media use by a child is identified, pediatricians should evaluate the child for aggressive behaviors, fears, or sleep disturbances and intervene appropriately.

**Recommendations (see Table 14.1)**

Pediatricians can counsel parents to help their children *avoid exposure to any form of media violence under age 8 yr*. These younger children do not have the capacity to distinguish fantasy from reality.

Parents should *select and co-view media with their children*, including playing video games with them, watching movies together, and co-viewing social media content. Parents can then assess these games and shows in regard to what they are teaching about communication and interactions with others.

Parents should *feel empowered to place restrictions* on games or shows that reward shooting, killing, or harming other people. Media are powerful teachers, and parents can make choices about how much violence they want their children to learn. Parents can use industry ratings, such as from the Motion Picture Association of America and the Entertainment Software Ratings Board, as well
as resources such as Commonsense Media, to guide media selections.

14.3
Effects of War on Children

Isaiah D. Wexler, Eitan Kerem

Keywords

biologic warfare
chemical warfare
child exploitation
gang warfare
posttraumatic stress disorder
terrorism
violence
war

The adverse consequences of war on children are devastating and long-lasting—death, injury, disfigurement, pain and other physical and cognitive disabilities, acute and chronic psychological suffering, temporary and permanent loss of family members, abduction, rape, conscription into armed service, forced relocation, epidemics, famine, drought, and residual trauma lasting decades after hostilities have ceased. The impact of war on children is detailed annually by the Secretary General of the United Nations, and in the 2016 report he described the increasing intensity of human rights violations in a large number of armed conflict situations throughout the world that included mass abduction of children, coercive conscription, death of children or their parents, attacks on schools, and sexual violence. Exploitation in the form of human trafficking has significantly increased in areas of conflict. Slavery, forced marriages, prostitution, and child labor are often a consequence of displacement, which has seen an increase in the past decade due to the increasing number of intrastate conflicts, especially in the Middle East and Northern Africa. In 2017, UNHCR (Office of the United Nations High Commissioner for Refugees), the UN
Refugee Agency, reported the astounding statistic of 65.6 million people forcibly displaced worldwide.

Mortality and morbidity related to the long-term effects of war and civil strife are often higher than that occurring during actual fighting. War and violence are not listed as leading causes of childhood mortality, but the regions with the highest levels of child mortality, especially among children <5 yr of age, are the same locations involved in military conflicts. Nations experiencing conflict devote substantial portions of their budgets to military expenditures at the expense of the healthcare infrastructure; a substantial proportion of deaths attributed to malnutrition, environmentally related infectious disease, or inadequate immunization are related to the effects of war. Children experiencing the trauma of wartime violence are at risk for long-term health sequelae, with greater risk for obesity, hypertension, stroke, and cardiovascular disease.

During wartime, customary patterns of behavior are forced to change, overcrowding is frequent, and essential resources, such as water and food staples, may be polluted or contaminated. War is associated with plagues and epidemics, and novel disease entities can develop. Reemergence of polio or cholera and the increased virulence of tuberculosis have been associated with conflict-affected regions and large population displacements.

The morbidity of children exposed to conflicts is significant (Table 14.2). Many more children are physically harmed than killed. Children bear the psychological scars of war resulting from exposure to violent events, loss of primary caregivers, and forced removal from their homes. Impressment of children into service as soldiers or agents is a form of exploitation associated with long-term problems of adjustment, because child soldiers often lack the appropriate education and socialization and thus their moral compass is often misaligned. They are often incapable of understanding the sources of conflict or why they have been targeted. Their thought processes are more concrete; it is easier for them to dehumanize their adversaries. Children, who themselves are exposed to violence and cruelty, frequently become the worst perpetrators of atrocities.

Conscription as soldiers
Coerced involvement in terrorist activities
Prostitution
Slavery
Forced adoption

After cessation of hostilities, children are still at risk for life-endangering injuries from landmines, unexploded ordnance, and other explosive remnants of war. Prior to the signing of the international treaty to ban landmines in 1997, an
estimated 20,000-25,000 casualties occurred annually from landmines. Since the ban, the number of casualties from landmines and explosive devices had been declining until 2015, when there was a significant increase in causalities attributed to the increasing number of conflicts. Approximately 40% of these casualties occur in children. Injuries and death tended to occur while children were either playing or involved in household chores, and in contrast to adults, a large proportion of the injuries involved upper-extremity amputation. After the end of armed conflict, the continued proliferation of small arms and light weapons, which are easily handled by children, continues to take its toll on human life and hinders stabilization in postconflict societies.

**Susceptibility of Children in Times of War**

Children do not have the physical or intellectual capabilities to defend themselves. It is easier for adults to victimize children than other adults. Older children's curiosity, desire for adventure, and imperfect assessment of risk often lead them to participate in dangerous behavior. Younger children, because of their small size and immature physiology, are more susceptible to disease and starvation and are more likely to sustain fatal injuries from ballistic projectiles and explosive devices such as mines. Blast injuries, a common cause of violence-related injuries, have a more devastating impact on children than adults. Specific types of military engagement can have a disproportionate effect on children. In a survey of war-related mortality in Iraq from 2003–2008, it was found that approximately 10% of the violence-related fatalities were children. Most children succumbed to either small arms gunfire or suicide bombs (35%). Compared with adults, a proportionately higher rate of children died as a result of the indiscriminant use of weaponry such as mortars, missiles, and aircraft-delivered bombs; 40% of the total casualties in these types of attacks were children.

During times of war, there is a breakdown of social inhibitions and cultural norms. Exploitation of children, such as forced marriages or involuntary conscription, are rationalized as being beneficial for the greater cause. Aberrant behavior such as rape, torture, and pillaging, which would be inconceivable in times of peace, is common during war. Children may be attacked, kidnapped, or used as human shields.
The changing nature of war has adversely affected children. Conventional warfare in which armies of professional soldiers representing different countries battle each other has become less common. Intrastate conflicts in the form of civil war are more frequent. In 2013, there were 33 active intrastate armed conflicts in the world as documented by the Uppsala Conflict Data Program (UCDP). These conflicts are often rooted in factious ethnic, political, or religious ideologies, and the participants are frequently nonprofessional irregulars who lack discipline and accountability to higher echelons, and are directed by those who do not acknowledge or respect international accords governing warfare. Often the military resources of the antagonists are disproportionate, leading the weaker protagonist to develop compensatory tactics that can include guerrilla, paramilitary, and terrorist activities, while the stronger side often resorts to the disproportionate use of force. Low-intensity conflicts have become more common. These types of conflicts are often characterized by military activities targeting civilian populations with the goal of disrupting normal routines and generating publicity for the perpetrators. Sites of violence can be remote from the battleground when one or both parties to a conflict resort to terrorist activities.

Terrorism and organized urban-based gang warfare have become prevalent. Violence perpetrated by terrorists groups or gangs is designed to coerce and intimidate both individuals and entire societies. Children are often intended victims of political- or religious-motivated violence because this serves to maximize the impact of terrorism. The destruction of the New York City World Trade Center Towers in 2001 and the nearly 3,000 fatalities showed that highly organized and motivated terrorists have few inhibitions and can strike anywhere. Biologic and chemical weapons of mass destruction have been employed, with the most recent example being the use of poisonous gases in the Syrian civil war. Children are more susceptible to chemical and biologic toxins because of their higher respiratory rates, more permeable skin, and other developmental vulnerabilities (see Chapter 741).

The media and internet have had a significant role in exacerbating the effects of war on children. Media coverage of war and terrorist events is extensive and visual, and social media promulgated via the internet is a convenient tool for disseminating propaganda and graphic video material designed to recruit volunteers and shock opponents. Children, more impressionable than adults, often view this material uncontrolled. Uncensored pictures of victims, unbridled violence, people in shock, or family members searching through ruins for
relatives may traumatize children and even encourage inappropriate behavior. Overt broadcast propaganda glorifying war and violence may sway children to participate in militaristic or antisocial activities.

**Psychological Impact of War**

Exposure to war and violence can have a significant impact on a child's psychosocial development. Displacement, loss of caregivers, physical suffering, and the lack of appropriate socialization all contribute to abnormal child development (see Table 14.2). Often the reactions are age specific (Table 14.3). Preschoolers may have an increase in somatic complaints and sleep disturbances and display acting-out behaviors such as tantrums or excessively clinging behavior. School-age children may show regressive behavior such as enuresis and thumb sucking. They, too, have an increase in somatic complaints; there is often a negative impact on school performance. For teenagers, psychological withdrawal and depression are common. Adolescents often exhibit trauma-stimulated acting-out behavior. Motivated by the desire for revenge, they may be quick to join in the violence and contribute to the continuation of conflict.

Substance abuse
Revenge fantasies
Suicidal ideation
Withdrawal

There is an increased incidence of both acute stress reactions and posttraumatic stress disorder (PTSD; see Chapter 38). The true incidence is difficult to assess because of the heterogeneous nature of war, degree of exposure to violence, and methodologic challenges related to the precise characterization of PTSD. Risk factors for having a more serious psychological response to a violent event include severity of the incident, personal involvement (physical injury, proximity, loss of a relative), prior history of exposure to traumatic events, female gender, and a dysfunctional parental response to the same event. Children may develop PTSD many years after the traumatic event. Children do not have to be directly exposed to violent activity, and media coverage of terrorist events may be sufficient to trigger PTSD.

The trauma experienced by children during war can have lifelong effects. Studies on children imprisoned in concentration camps or evacuated from their homes in London during the Battle of Britain show that these individuals were at
greater risk for PTSD, anxiety disorders, and a higher level of dissatisfaction with life when surveyed decades after the traumatic events. Trauma may have a transgenerational effect with epigenetic alterations and environmental influences causing children of PTSD victims to display a wide variety of psychological disorders. On the positive side, children are more resilient than adults. With appropriate support from family and community, together with timely and intensive psychological intervention, children can recover and lead normal, productive lives despite the searing trauma that they may have experienced.

**Efforts to Protect Children From the Effects of War**

**International Conventions**

War and terror violate the human rights of children, including the right to life, the right to be nurtured and protected, the right to develop appropriately, the right to be with family and community, and the right to a healthy existence. Several international treaties and conventions have been ratified, beginning with the **Fourth Geneva Convention** (1949) that set forth guidelines regarding appropriate treatment of children in times of war. The **United Nations Convention on the Rights of the Child** (1990) delineated specific human rights inherent to every child (defined as any individual younger than 18 yr), and the subsequent **First Optional Protocol** (2000), which prohibits conscripting or recruiting children for military activities. The **Third Optional Protocol** in 2014 established methods for communicating complaints of human rights violations involving children to the United Nations Committee on the Rights of the Child and sets up procedures by which the Committee can conduct inquiries into alleged human rights violations among signatory nations. The **Rome Statute of the International Criminal Court** enacted in 2002 declared that the conscription or enlistment of children younger than 15 yr is a prosecutable war crime. A decade since the ratification of the Rome Statute, the number of armed conflicts in which children were serving as soldiers had decreased from 36 to 16 worldwide.

Although these treaties and conventions define the extent of protection afforded to children, the means of enforcement available to the international
community is limited. Individuals, motivated by religious fervor, nationalistic zeal, or ethnic xenophobia, are unlikely to curb their activities because of fear of prosecution. These treaties better serve in heightening awareness regarding the protected status of children in wartime, and perhaps deter high-ranking leaders who fear being held accountable for war crimes.

Humanitarian Efforts

Several organizations, either nongovernmental or under UN auspices, are involved in mitigating the effects of war on children. The International Red Cross, UNICEF, UNHCR, International Rescue Committee, World Health Organization, and Médicins Sans Frontières (Doctors Without Borders), have had a significant impact on reducing violence-related casualties in war-torn regions. The infusion of humanitarian aid into developing countries often improves overall mortality and morbidity by increasing the level of medical and social services available to the general population. Other organizations, such as Amnesty International, Stockholm International Peace Research Institute, and Physicians for Human Rights, actively monitor human rights abuses involving children and other civilian groups. In 2005 the UN Security Council approved the establishment of a monitoring and reporting system designed to protect children exposed to war. UN-led task forces conduct active surveillance in war-stricken regions reporting on the 6 grave violations against children during armed conflict: the killing or injuring of children, recruitment of child soldiers, attacks directed against schools or hospitals, sexual violence against children, abduction of children, and denial of humanitarian access for children.

Role of Pediatricians and Allied Health Professionals

War is a chronic condition, and health providers need to be prepared to treat childhood casualties resulting from military or terrorist activity, as well as caring for children suffering from the aftermath of war or related violence. Community and hospital pediatricians need to be involved in community disaster planning. General disaster planning should not ignore the unique needs and requirements of children; in planning for a possible chemical attack, appropriate resuscitation equipment suitable for children needs to be stockpiled. The signs of biologic
infection, chemical intoxication, or radiation injury are different for children, and pediatricians and emergency personnel need to be aware of these differences (see Chapters 736 and 741). Surveys of pediatricians and other healthcare providers indicate that many feel unprepared for bioterrorism attacks. Professional organizations (e.g., AAP, CDC) have published position papers; there is a special section in the AAP Red Book that presents guidelines for treating specific pathogens likely to be used in biologic warfare. In regions where violent terrorist activity is likely, pediatricians, nurses, and rescue personnel should consider becoming certified in the Red Cross Basic and Advanced Trauma Life Support programs.

Pediatricians need to be aware of the potential effects of war and terror on parents and children. Loss or separation from parents or caregivers has a devastating impact on children (see Chapter 30). Parents, who themselves are under tremendous strain, may not be sensitive to the effects that the same stressors have on their children. Parents and caregivers must be made cognizant of the effect that media coverage can have on their children and their role in the intermediation of the repetitive broadcast of real-time acts of violence and incendiary communications designed to enlist support for specific causes. Pediatricians should draw out both parents and children and encourage them to talk freely about their feelings. Child healthcare providers can be instrumental in educating parents to be more aware of inappropriate responses by children to war and violence. When necessary, pediatricians can serve their families by referring them to appropriate support services.

Just as it is important to administer first aid for physical trauma, it is also critical to provide psychologic first aid to victims of trauma. An excellent source of online information for both providers and caregivers is the National Child Traumatic Stress Network (www.nctsn.org). In day-to-day patient interactions, a pediatrician is most likely to confront situations related to stress reactions such as PTSD or depressive disorders. Recognition of PTSD is essential so that early treatment can be initiated. The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) stipulates that for a diagnosis of PTSD, there has to be manifestations from each of 4 symptom clusters: intrusion, avoidance, negative alterations in cognitions and mood, and alterations in arousal and reactivity. DSM-5 also established a special preschool subtype of PTSD that has the same 4 symptom clusters but with specific manifestations typical of preschoolers exposed to trauma. Clues to the presence of PTSD and acute anxiety reactions include changes in behavior, school performance, affect, and
sleep patterns and an increase in somatic complaints. Even when the triggering event is neither temporally nor physically proximate, it should not dissuade the pediatrician from making an appropriate referral to mental health professionals who are expert in childhood stress disorders.

Medical professional standards demand that the physician treat all patients equitably without regard to their background. Both international law and professional medical societies ban physicians from actively participating in torture or other activities that infringe on human rights, including those of children. It is difficult to countenance any situation in which a health professional, even acting as a representative of his country, might directly or indirectly injure a minor. On the positive side, many pediatricians and other physicians have treated children during war either as members of the armed services or volunteers, often under adverse conditions, refusing to abandon their patients even when it has put their own life at risk. Pediatricians and pediatric organizations have been at the forefront in advocating for peaceful coexistence, assisting in relief efforts, and attempting to alleviate the disparities in healthcare resulting from war.

Health professionals have an important role in preventing the atrocities that occur to children. In their role as advocates for the rights of children, pediatricians can be instrumental in focusing public attention on the precarious situation of children exposed to the brutality and mayhem of organized violence. They can promulgate the message that war and terror should not be allowed to rob children of their childhood.

Human trafficking violates the fundamental human rights of child and adult victims and impacts families, communities, and societies. Trafficked persons originate from countries worldwide and may belong to any racial, ethnic, religious, socioeconomic, or cultural group. They may be of any gender. According to the United Nations Protocol to Prevent, Suppress and Punish Trafficking in Persons, child trafficking refers to the “recruitment, transportation, transfer, harboring or receipt of a person” under 18 yr old for purposes of exploitation. Two major types of trafficking involve forced labor and sexual exploitation (Table 15.1). While adult sex trafficking requires demonstration of force, fraud, coercion, deception, or the abuse of power as a means of exploitation, these are not required for persons younger than 18 yr. Interpretation of the international protocol varies across the globe; U.S. law does not require movement of a victim to qualify as human trafficking. In addition, minors who “consent” to commercial sex in the absence of a third party (trafficker) are victims of commercial sexual exploitation, because their age precludes true informed consent.

Live online sexual abuse

**Labor Exploitation**

Occurs in a variety of sectors, such as agriculture, manufacturing, textiles, food/hospitality services; domestic work; construction, magazine sales, health and beauty, and cleaning services

**Forced Begging**

**Forced Criminality**

**Forced Engagement in Armed Conflict**

**Illegal Adoption**

The word *victim* is used in this chapter in the legal sense and refers to a person who has been harmed as a result of a crime or other event. It is not intended to imply any subjective interpretation of the person's feelings about his/her situation or imply any judgment about that person's resilience.

Child trafficking may occur within the confines of the child's home country (*domestic* trafficking) or may cross national borders (*international*, or *transnational*, trafficking). Globally, victims tend to be trafficked within their own country or to a country in the same region. In the United States, most identified *child sex trafficking* victims are U.S. citizens or legal residents; few statistical data exist on victims of child labor trafficking. Variations in definitions of terms, problems with data collection, and underrecognition of victims complicate estimates of the prevalence of human trafficking, but the International Labour Organization estimates that 5.5 million of the world's children are victims of forced labor (this includes human trafficking). In a study of 55,000 officially identified trafficking victims, the United Nations Office on Drugs and Crime estimated that approximately 17% were girls and 10% boys. However, laws that define sexual exploitation in terms of girls and women, as well as cultural views regarding gender roles, lead to underreporting of boys, especially as victims of sex trafficking, so their numbers may be higher than estimated.

Factors creating vulnerability to human trafficking exist at the individual, family, community, and societal levels (*Table 15.2*). *Age* is an important risk
factor for adolescents since they are at a stage in their development at which they have limited life experience, a desire to demonstrate their independence from parental control, and a level of brain maturation that favors risk-taking and impulsive behaviors over careful situational analysis and other executive functions. They are also very interested in social media and are savvy at internet use, which render them susceptible to online recruitment and solicitation.

**Societal**

Cultural beliefs about roles and rights of children  
Gender bias/discrimination  
Tolerance of marginalization, exploitation  
Sexual objectification of girls  
Tolerance of violence  
Economic disparities

Recruitment of child victims for labor or sex trafficking often involves false promises of romance, job opportunities, or a better life. Children may remain in their exploitative situation for a number of reasons, including **fear of violence** to themselves or their loved ones should they attempt escape; **guilt and shame** for believing the fraudulent recruitment scheme or engaging in illegal and/or socially condemned activities; **humiliation** and fear of criticism by authorities; **debt bondage** (believing they owe the trafficker exorbitant amounts of money and cannot leave until the debt is paid), and fear of **arrest** and/or deportation. Many children do not recognize their victimization. Girls who believe their trafficker is a boyfriend may view their commercial sexual activities as demonstrations of their love; boys engaging in commercial sex to obtain shelter or food while living on the street may feel they are exploiting buyers rather than being victimized. Traffickers may use violence, economic manipulation, and psychological manipulation to control their victims.

**Clinical Presentation**

Trafficked persons may seek medical care for any of the myriad physical and emotional consequences of exploitation. They may present with traumatic injuries inflicted by traffickers, buyers, or others or injuries related to unsafe working conditions. They may present with a history of sexual assault, or symptoms/signs of sexually transmitted infections (STIs) and infections related to overcrowded, unsanitary conditions. They may request testing for HIV or complain of signs/symptoms of HIV or infections endemic to the victim's home country (e.g., malaria, schistosomiasis, tuberculosis). Other clinical presentations
may involve pregnancy and complications of pregnancy or abortion; malnutrition and/or dehydration; exhaustion; conditions related to exposure to toxins, chemicals, and dust; and signs and symptoms of posttraumatic stress disorder (PTSD), major depression, suicidality, behavioral problems with aggression, and somatization. Some children may have preexisting chronic medical conditions that have been inadequately treated before or during the exploitation (e.g., diabetes, seizure disorder, asthma). Trafficked persons may also seek care for medical issues related to their children.

Many of the same factors that keep victims trapped in their exploitative conditions also preclude them from disclosing their situation to others. Most victims presenting for medical care at clinics, hospitals, and emergency departments do not self-identify as trafficked persons. Consequently, it is incumbent on the medical professional to be aware of risk factors so that potential victims may be recognized and offered services. A trafficked child may present to a medical facility alone, in the company of a parent/guardian (who may or may not be aware of the trafficking situation), a friend or other person not involved in the trafficking, a person working for the trafficker (who may pose as a friend or relative), or the trafficker. Traffickers may be male or female, adult or juvenile, and they may be family members, acquaintances, friends, or strangers. On occasion, children are brought in by law enforcement or child protective services, as known or suspected victims. Table 15.3 lists possible indicators of labor or sex trafficking. In some cases, the best indicator is the chief complaint, which may be a condition frequently associated with trafficking (e.g., teen pregnancy, STI symptoms/signs (especially with history of prior STI), preventable work-related injury). The practitioner may become concerned about possible trafficking on recognizing the presence of 1 or more risk factors (runaway status; recent migration and current work in sector known for labor trafficking).

**Table 15.3**

**Possible Indicators of Child Trafficking**

**Indicators at Presentation**

- Chief complaint of acute physical or sexual assault
- Chief complaint of suicide attempt
- Child accompanied by unrelated adult or juvenile
Child or parent accompanied by domineering person who appears in hurry to leave; child/parent appears intimidated, fearful
Child or accompanying person provides inconsistent or unlikely history of events
Child does not know city he or she is in, or address where staying

Physical Findings

Child withdrawn and with flat affect; fearful; very anxious; intoxicated; or with inappropriate affect
Motel key(s), multiple cell phones, large amounts of cash, or a few expensive items (clothing, nails, etc.)
Tattoos (especially with street names or sexual innuendo)
Evidence of remote or acute inflicted injury (suspicious burns, bruising, signs of strangulation, fractures, closed head injury, thoracoabdominal trauma)
Malnutrition and/or poor hygiene
Poor dentition and/or dental trauma
Late presentation of illness/injury

Approach to the Potentially Trafficked Child

When interacting with a possible victim of trafficking, the medical provider should use a trauma-informed, human rights–based, culturally appropriate, and gender-sensitive approach (Table 15.4). This involves being aware that trauma experienced by children may influence their thoughts about themselves and others, their beliefs and perceptions of the world, and their behavior. Hostility, withdrawal, or distrust may be reactions to trauma and should be met with a sensitive, nonjudgmental, empathic response by the provider. Physical safety of the patient and staff are critical, and protocols should be in place to address security issues that may arise if the trafficker is on the premises. Psychological safety of the patient may be facilitated by separating them from any accompanying person when obtaining the medical history, conducting the visit in a warm, child-friendly environment, taking adequate time to build rapport and begin to establish trust, and ensuring that any interpreter used is not
from the same community as the patient and is trained in human trafficking.

### Table 15.4

**Elements of Human Rights–Based, Trauma-Informed Approach to Patient Care**

#### Basic Rights

- Best interest of the child to be primary concern in all actions involving the child
- Protection from discrimination because of gender, race, ethnicity, culture, socioeconomic status, disability, religion, language, country of origin, or other status
- Right to express views and be heard, appropriate to child's age and development
- Right to obtain information relevant to child, to be given in a way that children understand
- Right to privacy and confidentiality
- Right to highest attainable standard of health and to access healthcare services
- Right to dignity, self-respect
- Right to consideration of special needs (age, disability, etc.)
- Right to respect of cultural and religious beliefs and practices

#### Trauma-Informed Care

- Strength-based approach; facilitate patient resilience and empowerment.
- Obtain medical history in private, safe place, outside presence of persons accompanying child to visit.
- Explain all processes in way child understands, and obtain assent for each step; discuss limits of confidentiality and mandated reporting.
- Encourage patient to express views and to participate in decision-making regarding referrals and care.
- Foster patient's sense of control during evaluation.
- Ask only the questions needed to assess safety, health, and well-being.
- Avoid asking irrelevant questions about trauma, to avoid unnecessarily
triggering anxiety and distress. Minimize retraumatization during history, examination, and diagnostic testing (avoid triggers of stress when possible). Monitor for signs of distress, both verbal and nonverbal. Allow patient option to choose gender of provider, if feasible. Have trained personnel present during examination to assist with providing support and reassurance. Avoid making promises provider cannot fulfill. Put information gathered to good use. Conduct safety assessment and create plan.

Respect for the patient's rights is essential, including the right to an explanation of the purpose of the questions being asked, and the reasons for, and elements of, the examination and diagnostic evaluation. Informed assent by the patient for all steps of the process should be obtained when possible. The limits of confidentiality should be explained in a way the child understands so that they are able to choose what information to disclose. A risk assessment should include a discussion with the patient of safety concerns (involving current risks and perceived risks after discharge). While many trafficked persons have committed crimes during their period of exploitation, it is critical to treat the child with respect and compassion, viewing the patient as a victim of exploitation rather than a criminal offender. Every attempt should be made to understand and respect cultural and religious influences that may affect the child's views of their bodies, their condition, and their desired treatment.

In some cases the provider may become concerned about the possibility of human trafficking only after speaking with the child and obtaining the medical history. Social or other vulnerability factors may come to light, prompting concern about exploitation. In such cases the provider may consider asking additional questions, if this can be done in a nontraumatizing manner. Such questions might include the following:

◆ “Many children who have to live on the street have a hard time getting money for food and shelter. Sometimes they have to exchange sex to get what
they need. Has this ever happened to you or anyone you know?”
◆ When asking about sexual history: “Has anyone ever asked you or forced you to have sex when you really didn't want to? Do you feel comfortable telling me about it?”
◆ “If you feel comfortable, can you tell me a little bit about your job? Who offered you the job? Is the work you do what you expected when you agreed to the job? Are you allowed to keep all of the money you earn, or send it home? Where, and with whom, do you live? When you are not working, are you allowed to come and go from the place you stay?”

Such questions may open the door to a discussion of exploitation and facilitate the provider identifying appropriate resources and referrals.

All elements of the medical history and review of systems are important, but special attention should be paid to reproductive history (including sexual orientation and identity, prior history of sex partners, STIs, pregnancy/abortions, condom use); injury history; substance use/misuse; and mental health history and current symptoms. Rates of substance misuse, depression, PTSD, depression, and suicidality are very high, and questioning may highlight the need for emergency care or nonurgent referrals. It also provides an opportunity for anticipatory guidance aimed at harm reduction: a discussion of condom use, STIs, HIV/AIDS, and substance use may prove invaluable, since many victims lack accurate information on these topics. It is important to identify any chronic conditions, especially if untreated, and to assess vaccination status. Many trafficked persons have had very poor healthcare in the past and lack basic primary care. It is important to ask questions about signs/symptoms of infections endemic to the child's home country or to countries in which the child has been trafficked (e.g., tuberculosis, dengue, malaria; see Chapter 10 ).
Examination and Diagnostic Testing

A thorough physical examination allows the provider to assess and treat acute and chronic medical conditions, collect forensic evidence (as appropriate), assess nutritional and developmental status, and document recent and remote injuries. Diagnostic testing may identify pregnancy, STIs, HIV, non–sexually transmitted infections, vitamin and mineral deficiencies, anemia, toxic exposures, drugs, or alcohol. A sexual assault evidence kit may reveal trace evidence or DNA from offenders. Informed assent for the exam, assault kit, and diagnostic tests is important, as is careful explanation of each step during the process, and monitoring of the patient for signs of distress and anxiety. Those who have been sex-trafficked may experience particular distress during the anogenital examination, the oral exam, and when injuries are photographed. A trauma-trained chaperone is very helpful in providing comfort and support to the patient. The examination should be conducted outside the presence of anyone suspected of being involved in the trafficking situation. After the exam the provider should explain the results, ask the child if they have any questions about the exam, and give them the opportunity to discuss concerns about their bodies. Trafficked persons may harbor anxiety about a variety of issues, including possible infertility, future health, or possible permanent damage from work-related injuries and toxic conditions.

Providers may follow U.S. Centers for Disease Control and Prevention (CDC) guidelines on STI testing and prophylaxis. Additional resources on laboratory testing for sexually and non–sexually transmitted diseases may be obtained from the CDC (https://www.cdc.gov/) or World Health Organization (WHO) websites (http://www.who.int/en/). In general, STIs of greatest relevance include *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, *Trichomonas vaginalis*, HIV, syphilis, and hepatitis B and C viruses. Methods of testing and decisions to treat (e.g., positive test results vs prophylaxis vs syndromic treatment) will depend on national guidelines as well as on medical resources, which may be limited in some countries or regions. However, consideration should be given to the high likelihood that the patient may be lost to follow-up after the visit, so the decision to delay treatment until test results are available may lead to lack of needed medication. Testing and treatment decisions need to be outlined in a protocol. Emergency contraception and other methods of birth control (especially long-acting reversible contraception) should be discussed with the patient as feasible.

Many child victims of trafficking (and children of trafficked adults) have
experienced nutritional deprivation, lack of immunizations, and general poor health, especially if they are from low-resource countries or are born into the trafficking situation. Guidance on medical screening and care for immigrant children (see Chapter 10) may also be obtained from the CDC or American Academy of Pediatrics (AAP) Red Book or Immigrant Child Health Toolkit.* Consideration should be given to vaccine-preventable diseases (including tetanus if there are open wounds) and common diseases in the child's home country. Domestic or international victims may have iron deficiency, hemoglobinopathies, vitamin D deficiency, and undiagnosed vision or hearing problems. Crowded, unhygienic living conditions during the trafficking period raise the risks of tuberculosis, scabies, and diarrheal illnesses. Toxic levels of lead or chemicals may be present, and vitamin/mineral deficiencies should be considered. A developmental assessment is important, given the high likelihood of poor primary care in the past and possible harsh living conditions.

Documentation of health and injuries is extremely important and should be detailed and accurate. Body diagrams and photographs (if not traumatizing to the child) are helpful, as are written descriptions of injury location, type (e.g., contusion, laceration), size, shape, and color. All photographs should include patient identifiers and a measuring instrument when possible. Distance photographs to establish injury location may be supplemented with close-up photographs from various angles. Physical signs of untreated illness, malnutrition, and other conditions need to be documented carefully. When documenting the medical history, direct quotes should be used when possible (quotes of provider and of victim statements). Records, including written, video, audio, and photographic records, should be stored in a secure health information system, with limited access and password protection. Strict protocols for patient confidentiality and privacy should be established and followed.

**Referrals and Resources**

Healthcare providers must comply with mandatory reporting laws in their state or country, but in doing so, should make every effort to avoid causing harm to the child or their family. In the event the parent is the trafficking victim rather than the child, care should be taken to make reports and referrals only with the victim's consent (unless child's safety/health are at risk). For those practicing within the United States, assistance on interpreting laws, working with suspected victims, making reports to authorities, and identifying local referral sources may
be obtained by contacting the **National Human Trafficking Resource Center** (1-888-3737-888). The NHTRC has trained staff to assist victims and professionals alike, including interpreters for over 100 languages. Additional assistance may be obtained by contacting state or local law enforcement and antitrafficking task forces or local child advocacy centers. In some countries, “helplines” and “hotlines” may be used to seek assistance for suspected trafficking victims. It is important for the healthcare provider to be aware of local, state, and national resources for trafficking victims. Exploited persons have numerous needs that extend beyond the range of the healthcare provider's ability to respond. A multidisciplinary team approach is needed to ensure the child is provided with necessary food, shelter, crisis management, language interpretation, immigration assistance, mental health and medical care, educational needs, and other services. Such a team may include local victim service providers, shelter staff, behavioral health professionals, child protective services (CPS) workers, law enforcement, child advocacy center staff, sexual assault providers, and victim advocates. Table 15.5 lists potential health-related referrals.

* Appropriate therapy may differ with victims from varied cultures; there is a very limited evidence-base for effectiveness of behavioral health therapy for trafficked children. However, therapies with an evidence base for child sexual assault/abuse are often used in the U.S.

Trafficked victims may face considerable **social stigma** and **discrimination**. They may be viewed as consenting participants, illegal immigrants who deserve maltreatment, or “bad kids” who are responsible for their own actions. In some countries, laws on sexual exploitation do not include boys, and cultural beliefs foster the attitude that males cannot be victimized. Variations in the age of consent may result in a child being considered an adult in one country and a child in another. For these reasons and others, it is important for the healthcare provider to advocate for the child's victim status when interacting with other professionals and emphasize the need for comprehensive, sustained, trauma-informed services.

Prior to discharge, the provider should ensure the patient understands the results of the evaluation and the treatment plan, has a safety plan, and is aware of options for future care. When referrals are being made, it is helpful for the provider to take steps to ensure services are actually obtained by following up with the referral staff, sending medical records (as appropriate and with victim consent), and assisting the victim with arrangements as feasible. It is also helpful to counsel the victim on their basic human rights, including their right to medical care. If responsible for long-term care of the child, the provider should consider that treatment needs change over time, so treatment plans must be reevaluated periodically. Continuity of care is important but can be challenging when the child is moved to another city, is transported back to the home country, or is re-trafficked. Communication and collaboration with external agencies and healthcare providers can be extremely helpful, along with assignment of a case
manager to help ensure referrals are in place in destination towns or villages.

Abused and Neglected Children

Howard Dubowitz, Wendy G. Lane

The abuse and neglect (maltreatment) of children are pervasive problems worldwide, with short- and long-term physical and mental health and social consequences. Child healthcare professionals have an important role in helping address this problem. In addition to their responsibility to identify maltreated children and help ensure their protection and health, child healthcare professionals can also play vital roles related to prevention, treatment, and advocacy. Rates and policies vary greatly among nations and, often, within nations. Rates of maltreatment and provision of services are affected by the overall policies of the country, province, or state governing recognition and responses to child abuse and neglect. Two broad approaches have been identified: a child and family welfare approach and a child safety approach. Although overlapping, the focus in the former is the family as a whole, and in the latter, on the child perceived to be at risk. The United States has primarily had a child safety approach.

Definitions

Abuse is defined as acts of commission and neglect as acts of omission. The U.S. government defines child abuse as “any recent act or failure to act on the part of a parent or caretaker, which results in death, serious physical or emotional harm, sexual abuse or exploitation, or an act or failure to act which presents an imminent risk of serious harm.” Some states also include other household members. Children may be found in situations in which no actual harm has occurred, and no imminent risk of serious harm is evident, but potential harm may be a concern. Many states include potential harm in their child abuse laws. Consideration of potential harm enables preventive
intervention, although predicting potential harm is inherently difficult. Two aspects should be considered: the likelihood of harm and the severity of that harm.

**Physical abuse** includes beating, shaking, burning, and biting. **Corporal punishment**, however, is increasingly being prohibited. The Global Initiative to End All Corporal Punishment of Children reported that 52 countries have prohibited corporal punishment in all settings, including the home. Governments in 55 other countries have expressed a commitment to full prohibition. In the United States, corporal punishment in the home is lawful in all states, but 31 states have banned corporal punishment in public.

The threshold for defining corporal punishment as abuse is unclear. One can consider any injury beyond transient redness as abuse. If parents spank a child, it should be limited to the buttocks, should occur over clothing, and should never involve the head and neck. When parents use objects other than a hand, the potential for serious harm increases. Acts of serious violence (e.g., throwing a hard object, slapping an infant’s face) should be seen as abusive even if no injury ensues; significant risk of harm exists. While some child healthcare professionals think that hitting is acceptable under limited conditions, almost all know that more constructive approaches to discipline are preferable. The American Academy of Pediatrics clearly opposed the use of corporal punishment in a recent policy statement. Although many think that hitting a child should never be accepted, and many studies have documented the potential harm, there remains a reluctance in the United States to label hitting as abuse, unless there is an injury. It is clear that the emotional impact of being hit may leave the most worrisome scar, long after the bruises fade and the fracture heals.

**Sexual abuse** has been defined as “the involvement of dependent, developmentally immature children and adolescents in sexual activities which they do not fully comprehend, to which they are unable to give consent, or that violate the social taboos of family roles.” Sexual abuse includes exposure to sexually explicit materials, oral-genital contact, genital-to-genital contact, genital-to-anal contact, and genital fondling. Any touching of private parts by parents or caregivers in a context other than necessary care is inappropriate.

**Neglect** refers to omissions in care, resulting in actual or potential harm. **Omissions** include inadequate healthcare, education, supervision, protection from hazards in the environment, and unmet physical needs (e.g., clothing, food) and emotional support. A preferable alternative to focusing on caregiver omissions is to instead consider the basic needs (or rights) of children (e.g.,
adequate food, clothing, shelter, healthcare, education, nurturance). Neglect occurs when a need is not adequately met and results in actual or potential harm, whatever the reasons. A child whose health is jeopardized or harmed by not receiving necessary care experiences **medical neglect**. Not all such situations necessarily require a report to child protective services (CPS); less intrusive initial efforts may be appropriate.

**Psychological abuse** includes verbal abuse and humiliation and acts that scare or terrorize a child. Although this form of abuse may be extremely harmful to children, resulting in depression, anxiety, poor self-esteem, or lack of empathy, CPS seldom becomes involved because of the difficulty in proving such allegations. Child healthcare professionals should still carefully consider this form of maltreatment, even if the concern fails to reach a legal or agency threshold for reporting. These children and families can benefit from counseling and social support. Many children experience more than one form of maltreatment; CPS are more likely to address psychological abuse in the context of other forms of maltreatment.

Within the United States and internationally, problems of **trafficking** in children, for purposes of cheap labor and sexual exploitation, expose children to all the forms of abuse just noted (see Chapter 15).

**Incidence and Prevalence**

**Global**

Child abuse and neglect are not rare and occur worldwide. Based on international studies, the World Health Organization (WHO) has estimated that 18% of girls and 8% of boys experience sexual abuse as children, while 23% of children report being physically abused (**Figs. 16.1** and **16.2**). In addition, many children experience emotional abuse and neglect. Surveys reported by United Nations Children's Fund (UNICEF) confirm these reports; one survey conducted in the Middle East reported that 30% of children had been beaten or tied up by parents, and in a survey in a Southeast Asian country, 30% of mothers reported having hit their child with an object in the past 6 mo.
United States

Abuse and neglect mostly occur behind closed doors and often are a well-kept secret. Nevertheless, there were 4 million reports to CPS involving 7.2 million children in the United States in 2015. Of the 683,000 children with substantiated reports (9.2 per 1,000 children), 78.3% experienced neglect (including 1.9%
medical neglect), 17.2% physical abuse, 8.4% sexual abuse, and 6.2% psychological maltreatment. While there had been a decline in rates beginning in the early 1990s, rates increased in 2014 and 2015 from prior years. Likewise, the rate of hospitalized children with serious physical abuse has not declined in recent years. Medical personnel made 9.1% of all reports.

Other sources independent from the official CPS statistics cited above confirm the prevalence of child maltreatment. In a community survey, 3% of parents reported using very severe violence (e.g., hitting with fist, burning, using gun or knife) against their child in the prior year. Considering a natural disinclination to disclose socially undesirable information, such rates are both conservative and alarming.

**Etiology**

Child maltreatment seldom has a single cause; rather, multiple and interacting biopsychosocial **risk factors** at 4 levels usually exist. To illustrate, at the *individual level*, a child's disability or a parent's depression or substance abuse predispose a child to maltreatment. At the *familial level*, intimate partner (or domestic) violence presents risks for children. Influential *community factors* include stressors such as dangerous neighborhoods or a lack of recreational facilities. Professional inaction may contribute to neglect, such as when the treatment plan is not clearly communicated. Broad *societal factors*, such as poverty and its associated burdens, also contribute to maltreatment. WHO estimates the rate of homicide of children is approximately 2-fold higher in low-income compared to high-income countries (2.58 vs 1.21 per 100,000 population), but clearly homicide occurs in high-income countries too. Children in all social classes can be maltreated, and child healthcare professionals need to guard against biases concerning low-income families.

In contrast, **protective factors**, such as family supports, or a mother's concern for her child, may buffer risk factors and protect children from maltreatment. Identifying and building on protective factors can be vital to intervening effectively. One can say to a parent, “I can see how much you love [child's name]. What can we do to keep her out of the hospital?” Child maltreatment results from a complex interplay among risk and protective factors. A single mother who has a colicky baby and who recently lost her job is at risk for maltreatment, but a loving grandmother may be protective. A good understanding of factors that contribute to maltreatment, as well as those that are
Clinical Manifestations

Child abuse and neglect can manifest in many ways. A critical element of physical abuse is the lack of a plausible history other than inflicted trauma. The onus is on the clinician to carefully consider the differential diagnosis and not jump to conclusions.

**Bruises** are the most common manifestation of physical abuse. Features suggestive of inflicted bruises include (1) bruising in a preambulatory infant (occurring in just 2% of infants), (2) bruising of padded and less exposed areas (buttocks, cheeks, ears, genitalia), (3) patterned bruising or burns conforming to shape of an object or ligatures around the wrists, and (4) multiple bruises, especially if clearly of different ages (Fig. 16.3 and Table 16.1). Earlier suggestions for estimating the age of bruises have been discredited. It is very difficult to precisely determine the ages of bruises.

**FIG. 16.3** A variety of instruments may be used to inflict injury on a child. Often the choice of an instrument is a matter of convenience. Marks tend to silhouette or outline the shape of the instrument. The possibility of intentional trauma should prompt a high degree of suspicion when injuries to a child are geometric, paired, mirrored, of various ages or types, or on relatively protected parts of the body. Early recognition of intentional trauma is important to provide therapy and prevent escalation to more serious injury.

* Punishment by kneeling on salt or other rough substance.

Other conditions such as birthmarks and congenital dermal melanocytosis (e.g., mongolian spots) can be confused with bruises and abuse. These skin markings are not tender and do not rapidly change color or size. An underlying medical explanation for bruises may exist, such as blood dyscrasias (hemophilia) or connective tissue disorders (Ehlers-Danlos syndrome). The history or examination usually provides clues to these conditions. Henoch-Schönlein purpura, the most common vasculitis in young children, may be confused with abuse. The pattern and location of bruises caused by abuse are usually different from those due to a coagulopathy. Noninflicted bruises are characteristically anterior and over bony prominences, such as shins and forehead. The presence of a medical disorder does not preclude abuse.

Cultural practices can cause bruising. Cao gio, or coinage, is a Southeast Asian folkloric therapy. A hard object is vigorously rubbed on the skin, causing petechiae or purpura. Cupping is another approach, popular in the Middle East. A heated glass is applied to the skin, often on the back. As it cools, a vacuum is
formed, leading to perfectly circular bruises. The context here is important, and such circumstances should not be considered abusive (see Chapter 11).

A careful history of bleeding problems in the patient and first-degree relatives is needed. If a bleeding disorder is suspected, a complete blood count including platelet count, prothrombin time, and partial thromboplastin time should be obtained. More extensive testing, such as factors VIII, IX and XIII activity and von Willebrand evaluation, should be considered in consultation with a hematologist.

**Bites** have a characteristic pattern of 1 or 2 opposing arches with multiple bruises. They can be inflicted by an adult, another child, an animal, or the patient. Forensic odontologists have previously developed guidelines for distinguishing adult from child and human from animal bites. However, several studies have identified problems with the accuracy and consistency of bite mark analysis.

**Burns** may be inflicted or caused by inadequate supervision. Scalding burns may result from immersion or splash. *Immersion burns*, when a child is forcibly held in hot water, show clear delineation between the burned and healthy skin and uniform depth. They may have a sock or glove distribution. Splash marks are usually absent, unlike when a child inadvertently encounters hot water. Symmetric burns are especially suggestive of abuse, as are burns of the buttocks and perineum (Fig. 16.4). Although most often accidental, splash burns may also result from abuse. Burns from hot objects such as curling irons, radiators, steam irons, metal grids, hot knives, and cigarettes leave patterns representing the object (Fig. 16.5). A child is likely to draw back rapidly from a hot object; thus burns that are extensive and deep reflect more than fleeting contact and are suggestive of abuse.
FIG. 16.4 Marks from heated objects cause burns in a pattern that duplicates that of the object. Familiarity with the common heated objects that are used to traumatize children facilitates recognition of possible intentional injuries. The location of the burn is important in determining its cause. Children tend to explore surfaces with the palmar surface of the hand and rarely touch a heated object repeatedly for long.

Several conditions mimic abusive burns, such as brushing against a hot radiator, car seat burns, hemangiomas, and folk remedies such as moxibustion. Impetigo may resemble cigarette burns. *Cigarette burns* are usually 7-10 mm across, whereas impetigo has lesions of varying size. Noninflicted cigarette burns are usually oval and superficial.

Neglect frequently contributes to childhood burns. Children, home alone, may
be burned in house fires. A parent taking drugs may cause a fire and may be unable to protect a child. Exploring children may pull hot liquids left unattended onto themselves. Liquids cool as they flow downward so that the burn is most severe and broad proximally. If the child is wearing a diaper or clothing, the fabric may absorb the hot water and cause burns worse than otherwise expected. Some circumstances are difficult to foresee, and a single burn resulting from a momentary lapse in supervision should not automatically be seen as neglectful parenting.

Concluding whether a burn was inflicted depends on the history, burn pattern, and the child's capabilities. A delay in seeking healthcare may result from the burn initially appearing minor, before blistering or becoming infected. This circumstance may represent reasonable behavior and should not be automatically deemed neglectful. A home investigation is often valuable (e.g., testing the water temperature).

**Fractures** that strongly suggest abuse include classic metaphyseal lesions, posterior rib fractures, and fractures of the scapula, sternum, and spinous processes, especially in young children (Table 16.2). These fractures all require more force than would be expected from a minor fall or routine handling and activities of a child. Rib and sternal fractures rarely result from cardiopulmonary resuscitation (CPR), even when performed by untrained adults. The recommended 2-finger or 2-thumb technique recommended for infants since 2005 may produce anterolateral rib fractures. In abused infants, rib (Fig. 16.6), metaphyseal (Fig. 16.7), and skull fractures are most common. Femoral and humeral fractures in nonambulatory infants are also very worrisome for abuse. With increasing mobility and running, toddlers can fall with enough rotational force to cause a spiral, femoral fracture. Multiple fractures in various stages of healing are suggestive of abuse; nevertheless, underlying conditions need to be considered. Clavicular, femoral, supracondylar humeral, and distal extremity fractures in children older than 2 yr are most likely noninflicted unless they are multiple or accompanied by other signs of abuse. Few fractures are pathognomonic of abuse; all must be considered in light of the history and the child's developmental level. Fractures may present as an irritable fussy child.

<tr>
<td>Specificity of Radiologic Findings for Fractures</td>
</tr>
</tbody>
</table>
High Specificity*

Classic metaphyseal lesions
Rib fractures, especially posteromedial
Scapular fractures
Spinous process fractures
Sternal fractures

Moderate Specificity

Multiple fractures, especially bilateral
Fractures of different ages
Epiphyseal separations
Vertebral body fractures and subluxations
Digital fractures
Complex skull fractures
Pelvic fractures

Common but Low Specificity

Subperiosteal new bone formation
Clavicular fractures
Long-bone shaft fractures
Linear skull fractures

* Highest specificity applies in infants.

FIG. 16.6  High-detail oblique view of the ribs of a 6 mo old infant shows multiple healing posteromedial rib fractures (arrowheads). The level of detail in this image is far greater than what would be present on a standard chest radiograph. (From Dwek JR: The radiographic approach to child abuse, Clin Orthop Relat Res 469:776–789, 2011, p 780, Fig 4.)

FIG. 16.7  A, Metaphyseal fracture of the distal tibia in a 3 mo old infant admitted to the hospital with severe head injury. There is also periosteal new bone formation of the tibia, perhaps from previous injury. B, Bone scan
of same infant. Initial chest radiograph showed a single fracture of the right posterior 4th rib. A radionuclide bone scan performed 2 days later revealed multiple previously unrecognized fractures of the posterior and lateral ribs. C, Follow-up radiographs 2 wk later showed multiple healing rib fractures. This pattern of fracture is highly specific for child abuse. The mechanism of these injuries is usually violent squeezing of the chest.

The differential diagnosis includes conditions that increase susceptibility to fractures, such as osteopenia and osteogenesis imperfecta, metabolic and nutritional disorders (e.g., scurvy, rickets), renal osteodystrophy, osteomyelitis, congenital syphilis, and neoplasia. Some have pointed to possible rickets and low but subclinical levels of vitamin D as being responsible for fractures thought to be abusive. The evidence to date does not support this supposition. Features of congenital or metabolic conditions associated with nonabusive fractures include family history of recurrent fractures after minor trauma, abnormally shaped cranium, dentinogenesis imperfecta, blue sclera, craniotabes, ligamentous laxity, bowed legs, hernia, and translucent skin. *Subperiosteal new bone formation* is a nonspecific finding seen in infectious, traumatic, and metabolic disorders. In young infants, new bone formation may be a normal physiologic finding, usually bilateral, symmetric, and <2 mm in depth.

The evaluation of a fracture should include a skeletal radiologic survey in children <2 yr old when abuse seems possible (Table 16.3). Multiple radiographs with different views are needed; “babygrams” (1 or 2 films of the entire body) should be avoided. If the survey is normal, but concern for an occult injury remains, a radionucleotide bone scan should be performed to detect a possible acute injury. Follow-up films after 2 wk may also reveal fractures not apparent initially.

**Table 16.3**

**Radiologic Skeletal Survey for Infants and Children Under 2 Yr of Age***

- Anteroposterior (AP) and lateral views of skull (Townes view optional; add if any fracture seen)
- Lateral spine (cervical spine [C-spine] may be included on skull radiographs; AP spine is included on AP chest and AP pelvis views to include entire spine)
- AP view, right posterior oblique, left posterior oblique view of chest—rib
technique
• AP pelvis
• AP view of each femur
• AP view of each leg
• AP view of each humerus
• AP view of each forearm
• Posteroanterior (PA) view of each hand
• AP (dorsoventral) view of each foot

* Images are checked by a radiologist before the patient leaves. Poorly positioned or otherwise suboptimal images should be repeated. Lateral views are added for positive or equivocal findings in the extremities. Coned views of positive or equivocal findings (i.e., at ends of long bones, ribs) may be obtained.

Adapted from Coley BD: Caffey's pediatric diagnostic imaging, ed 12, vol 2, Philadelphia, 2013, Mosby/Elsevier, p 1588 (Box 144-1).

In corroborating the history and the injury, the age of a fracture can be crudely estimated (Table 16.4). Soft tissue swelling subsides in 2-21 days. Subperiosteal new bone is visible within 6-21 days. Loss of definition of the fracture line occurs in 10-21 days. Soft callus can be visible after 9 days and hard callus at 14-90 days. These ranges are shorter in infancy and longer in children with poor nutritional status or a chronic underlying disease. Fractures of flat bones such as the skull do not form callus and cannot be aged, although soft tissue swelling indicates approximate recency (within the prior week).

Repetitive injuries may prolong all categories. The time points tend to increase from early infancy into childhood.

**Abusive head trauma** (AHT) results in the most significant morbidity and mortality. Abusive injury may be caused by direct impact, asphyxia, or shaking. Subdural hematomas (Fig. 16.8), retinal hemorrhages, especially when extensive and involving multiple layers, and diffuse axonal injury strongly suggest AHT, especially when they occur together. The poor neck muscle tone and relatively large heads of infants make them vulnerable to acceleration-deceleration forces associated with shaking, leading to AHT. Children may lack external signs of injury, even with serious intracranial trauma. Signs and symptoms may be nonspecific, ranging from lethargy, vomiting (without diarrhea), changing neurologic status or seizures, and coma. In all preverbal children, an index of suspicion for AHT should exist when children present with these signs and symptoms.

![FIG. 16.8 CT scan indicating intracranial bleeding. A arrow, Older blood. B arrow, New blood.](image)

Acute intracranial trauma is best evaluated by initial and follow-up CT. MRI is helpful in differentiating extra axial fluid, determining timing of injuries,
assessing parenchymal injury, and identifying vascular anomalies. MRI is best obtained 5-7 days after an acute injury. Glutaric aciduria type 1 can present with intracranial bleeding and should be considered. Other causes of subdural hemorrhage in infants include arteriovenous malformations, coagulopathies, birth trauma, tumor, and infections. When AHT is suspected, injuries elsewhere—skeletal and abdominal—should be ruled out.

**Retinal hemorrhages** are an important marker of AHT (Fig. 16.9). Whenever AHT is being considered, a dilated indirect eye examination by a pediatric ophthalmologist should be performed. Although retinal hemorrhages can be found in other conditions, hemorrhages that are multiple, involve >1 layer of the retina, and extend to the periphery are very suspicious for abuse. The mechanism is likely repeated acceleration-deceleration from shaking. Traumatic retinoschisis points strongly to abuse.

![Retinal hemorrhages](image)

With other causes of retinal hemorrhages, the pattern is usually different than seen in child abuse. After birth, many newborns have them, but they disappear in 2-6 wk. Coagulopathies (particularly leukemia), retinal diseases, carbon monoxide poisoning, or glutaric aciduria may be responsible. Severe, noninflicted, direct crush injury to the head can rarely cause an extensive hemorrhagic retinopathy. CPR rarely, if ever, causes retinal hemorrhage in infants and children; if present, there a few hemorrhages in the posterior pole.
Hemoglobinopathies, diabetes mellitus, routine play, minor noninflicted head trauma, and vaccinations do not appear to cause retinal hemorrhage in children. Severe coughing or seizures rarely cause retinal hemorrhages that could be confused with AHT.

The dilemma frequently posed is whether minor, everyday forces can explain the findings seen in AHT. Simple linear skull fractures in the absence of other suggestive evidence can be explained by a short fall, although even that is rare (1-2%), and underlying brain injury from short falls is exceedingly rare. Timing of brain injuries in cases of abuse is not precise. In fatal cases, however, the trauma most likely occurred very soon before the child became symptomatic.

Other manifestations of AHT may be seen. Raccoon eyes occur in association with subgaleal hematomas after traction on the anterior hair and scalp, or after a blow to the forehead. Neuroblastoma can present similarly and should be considered. Bruises from attempted strangulation may be visible on the neck. Choking or suffocation can cause hypoxic brain injury, often with no external signs.

**Abdominal trauma** accounts for significant morbidity and mortality in abused children. Young children are especially vulnerable because of their relatively large abdomens and lax abdominal musculature. A forceful blow or kick can cause hematomas of solid organs (liver, spleen, kidney) from compression against the spine, as well as hematoma (duodenal) or rupture (stomach) of hollow organs. Intraabdominal bleeding may result from trauma to an organ or from shearing of a vessel. More than 1 organ may be affected. Children may present with cardiovascular failure or an acute condition of the abdomen, often after a delay in care. Biliary vomiting without fever or peritoneal irritation suggests a duodenal hematoma, often caused by abuse.

The manifestations of abdominal trauma are often subtle, even with severe injuries. Bruising of the abdominal wall is unusual, and symptoms may evolve slowly. Delayed perforation may occur days after the injury; bowel strictures or a pancreatic pseudocyst may occur weeks or months later. Child healthcare professionals should consider screening for occult abdominal trauma when other evidence of physical abuse exists. Screening should include liver and pancreatic enzyme levels, and testing urine for blood. Children with lab results indicating possible injury should have abdominal CT performed. CT or ultrasound should also be performed if there is concern about possible splenic, adrenal, hepatic, or reproductive organ injury.

**Oral lesions** may present as bruised lips, bleeding, torn frenulum, and dental
trauma or caries (neglect).

**Neglect**

Neglect is the most prevalent form of child maltreatment, with potentially severe and lasting sequelae. It may manifest in many ways, depending on which needs are not adequately met. Nonadherence to medical treatment, for example, may aggravate the condition, as may a delay in seeking care. Inadequate food may manifest as impaired growth; inattention to obesity may compound that problem. Poor hygiene may contribute to infected cuts or lesions. Inadequate supervision contributes to injuries and ingestions. Children's needs for mental healthcare, dental care, and other health-related needs may be unmet, manifesting as neglect in those areas. Educational needs, particularly for children with learning disabilities, are often not met.

The evaluation of possible neglect requires addressing critical questions: “Is this neglect?” and “Have the circumstances harmed the child, or jeopardized the child's health and safety?” For example, suboptimal treatment adherence may lead to few or no clear consequences. Inadequacies in the care that children receive naturally fall along a continuum, requiring a range of responses tailored to the individual situation. Legal considerations or CPS policies may discourage physicians from labeling many circumstances as neglect. Even if neglect does not meet a threshold for reporting to CPS, child healthcare professionals can still help ensure children's needs are adequately met.

**General Principles for Assessing Possible Abuse and Neglect**

The heterogeneity of circumstances in situations of child maltreatment precludes specific detailing of varied assessments. The following are useful general principles.

◆ Given the complexity and possible ramifications of determining child maltreatment, an **interdisciplinary assessment** is optimal, with input from all involved
professionals. Consultation with a physician expert in child maltreatment is recommended.
◆ A thorough **history** should be obtained from the parent(s) optimally via separate interviews.
◆ Verbal children should be interviewed separately, in a developmentally appropriate manner. **Open-ended questions** (e.g., “Tell me what happened”) are best. Some children need more directed questioning (e.g., “How did you get that bruise?”); others need multiple-choice questions. Leading questions must be avoided (e.g., “Did your daddy hit you?”).
◆ A thorough **physical examination** is necessary.
◆ Careful **documentation** of the history and physical is essential. Verbatim quotes are valuable, including the question that prompted the response. Photographs are helpful.
◆ For **abuse** : What is the evidence for concluding abuse? Have other diagnoses been ruled out? What is the likely mechanism of the injury? When did the injury likely occur?
◆ For **neglect** : Do the circumstances indicate that the child’s needs have not been adequately met? Is there evidence of actual harm? Is there evidence of potential harm and on what basis? What is the nature of the neglect? Is there a pattern of neglect?
◆ Are there indications of other forms of maltreatment? Has there been prior CPS
involvement?
◆ A child's safety is a paramount concern. What is the risk of imminent harm, and of what severity?
◆ What is contributing to the maltreatment? Consider the categories described in the section on etiology.
◆ What strengths/resources are there? This is as important as identifying problems.
◆ What interventions have been tried, with what results? Knowing the nature of these interventions can be useful, including from the parent's perspective.
◆ What is the prognosis? Is the family motivated to improve the circumstances and accept help, or resistant? Are suitable resources, formal and informal, available?
◆ Are there other children in the home who should be assessed for maltreatment?

General Principles for Addressing Child Maltreatment

The heterogeneity of circumstances also precludes specific details regarding how to address different types of maltreatment. The following are general principles.

◆ Treat any medical problems.
◆ Help ensure the child's safety, often in conjunction with CPS; this is a priority.
◆ Convey concerns of maltreatment to parents, kindly but forthrightly. Avoid blaming. It is natural to feel
anger toward parents of maltreated children, but they need support and deserve respect.
◆ Have a means of addressing the difficult emotions child maltreatment can evoke.
◆ Be empathic, and state interest in helping or suggest another pediatrician.
◆ Know your national and state laws and/or local CPS policies on reporting child maltreatment. In the United States, the legal threshold for reporting is typically “reason to believe” (or similar language such as “reason to suspect”); one does not need to be certain. Physical abuse and moderate to severe neglect warrant a report. In less severe neglect, less intrusive interventions may be an appropriate initial response. For example, if an infant's mild failure to thrive is caused by an error in mixing the formula, parent education and perhaps a visiting nurse should be tried. In contrast, severe failure to thrive may require hospitalization, and if the contributing factors are particularly serious (e.g., psychotic mother), out-of-home placement may be needed. CPS can assess the home environment, providing valuable insights.
◆ Reporting child maltreatment is never easy. Parental inadequacy or culpability is at least implicit, and parents may express considerable anger. Child healthcare professionals should supportively inform families directly of the report; it can be explained as
an effort to clarify the situation and provide help, as well as a professional (and legal) responsibility. Explaining what the ensuing process is likely to entail (e.g., a visit from a CPS worker and sometimes a police officer) may ease a parent's anxiety. Parents are frequently concerned that they might lose their child. Child healthcare professionals can cautiously reassure parents that CPS is responsible for helping children and families and that, in most instances, children remain with their parents. When CPS does not accept a report or when a report is not substantiated, they may still offer voluntary supportive services such as food, shelter, parenting resources, and childcare. Child healthcare professionals can be a useful liaison between the family and the public agencies and should try to remain involved after reporting to CPS.

◆ Help address contributory factors, prioritizing those most important and amenable to being remedied. Concrete needs should not be overlooked; accessing nutrition programs, obtaining health insurance, enrolling children in preschool programs, and help finding safe housing can make a valuable difference. Parents may need their own problems addressed to enable them to provide adequate care for their children.

◆ Establish specific objectives (e.g., no hitting, diabetes will be adequately controlled), with
measurable outcomes (e.g., urine dipsticks, hemoglobin A1c). Similarly, advice should be specific and limited to a few reasonable steps. A written contract can be very helpful.

◆ Engage the family in developing the plan, solicit their input and agreement.
◆ Build on strengths; there are always some. These provide a valuable way to engage parents.
◆ Encourage informal supports (e.g., family, friends; invite fathers to office visits). This is where most people get their support, not from professionals. Consider support available through a family's religious affiliation.
◆ Consider children's specific needs. Too often, maltreated children do not receive direct services.
◆ Be knowledgeable about community resources, and facilitate appropriate referrals.
◆ Provide support, follow-up, review of progress, and adjust the plan if needed.
◆ Recognize that maltreatment often requires long-term intervention with ongoing support and monitoring.

Outcomes of Child Maltreatment

Child maltreatment often has significant short- and long-term medical, mental health, and social sequelae. Physically abused children are at risk for many problems, including conduct disorders, aggressive behavior, posttraumatic stress
disorder (PTSD), anxiety and mood disorders, decreased cognitive functioning, and poor academic performance. Neglect is similarly associated with many potential problems. Even if a maltreated child appears to be functioning well, healthcare professionals and parents need to be sensitive to the possibility of later problems. Maltreatment is associated with increased risk in adolescence and adulthood for health risk behaviors (e.g., smoking, alcohol/drug abuse), mental health problems (e.g., anxiety, depression, suicide attempt), physical health problems (e.g., heart disease, arthritis), and mental health problems. Maltreated children are at risk for becoming abusive parents. The neurobiologic effects of child abuse and neglect on the developing brain may partly explain some of these sequelae.

Some children appear to be resilient and may not exhibit sequelae of maltreatment, perhaps because of protective factors or interventions. The benefits of intervention have been found in even the most severely neglected children, such as those from Romanian orphanages, who were adopted—the earlier the better.

Prevention of Child Abuse and Neglect

An important aspect of prevention is that many of the efforts to strengthen families and support parents should promote children's health, development, and safety, as well as prevent child abuse and neglect. Medical responses to child maltreatment have typically occurred after the fact; preventing the problem is preferable. Child healthcare professionals can help in several ways. An ongoing relationship offers opportunities to develop trust and knowledge of a family's circumstances. Astute observation of parent–child interactions can reveal useful information.

Parent and child education regarding medical conditions helps to ensure implementation of the treatment plan and to prevent neglect. Possible barriers to treatment should be addressed. Practical strategies such as writing down the plan can help. In addition, anticipatory guidance may help with child rearing, diminishing the risk of maltreatment. Hospital-based programs that educate parents about infant crying and the risks of shaking the infant may help prevent abusive head trauma.

Screening for major psychosocial risk factors for maltreatment (depression, substance abuse, intimate partner violence, major stress), and helping address identified problems, often through referrals, may help prevent maltreatment. The
primary care focus on prevention offers excellent opportunities to screen briefly for psychosocial problems. The traditional organ system–focused review of systems can be expanded to probe areas such as feelings about the child, the parent’s own functioning, possible depression, substance abuse, intimate partner violence, disciplinary approaches, stressors, and supports. The Safe Environment for Every Kid (SEEK) model offers a promising approach for pediatric primary care to identify and help address prevalent psychosocial problems. This can strengthen families; support parents; promote children’s health, development, and safety; and help prevent child maltreatment.

Obtaining information directly from children or youth is also important, especially given that separate interviews with teens have become the norm. Any concerns identified on such screens require at least brief assessment and initial management, which may lead to a referral for further evaluation and treatment. More frequent office visits can be scheduled for support and counseling while monitoring the situation. Other key family members (e.g., fathers) might be invited to participate, thereby encouraging informal support. Practices might arrange parent groups through which problems and solutions are shared.

Child healthcare professionals also need to recognize their limitations and facilitate referrals to other community resources. Finally, the problems underpinning child maltreatment, such as poverty, parental stress, substance abuse, and limited child-rearing resources, require policies and programs that enhance families’ abilities to care for their children adequately. Child healthcare professionals can help advocate for such policies and programs.

**Advocacy**

Child healthcare professionals can assist in understanding what contributed to the child's maltreatment. When advocating for the best interest of the child and family, addressing risk factors at the individual, family, and community levels is optimal. At the individual level, an example of advocating on behalf of a child is explaining to a parent that an active toddler is behaving normally and not intentionally challenging the parent. Encouraging a mother to seek help dealing with a violent spouse (e.g., saying, “You and your life are very important”), asking about substance abuse, and helping parents obtain health insurance for their children are all forms of advocacy.

Efforts to improve family functioning, such as encouraging fathers’ involvement in child care, are also examples of advocacy. Remaining involved
after a report to CPS and helping ensure appropriate services are provided is advocacy as well. In the community, child health professionals can be influential advocates for maximizing resources devoted to children and families. These include parenting programs, services for abused women and children, and recreational facilities. Lastly, child healthcare professionals can play an important role in advocating for policies and programs at the local, state, and national levels to benefit children and families. Child maltreatment is a complex problem that has no easy solutions. Through partnerships with colleagues in child protection, mental health, education, and law enforcement, child health professionals can make a valuable difference in the lives of many children and families.

16.1

Sexual Abuse

Wendy G. Lane, Howard Dubowitz

Keywords

chlamydia
hymen
nucleic acid amplification testing
NAAT
sexual abuse
sexual assault
sexually explicit behavior
sexually transmitted infection
STI

See also Chapter 145 .

Approximately 18% of females and 7% of males in the United States will be
sexually abused at some point during their childhood. Whether children and families share this information with their pediatrician will depend largely on the pediatrician's comfort with and openness to discussing possible sexual abuse with families. Pediatricians may play a number of different roles in addressing sexual abuse, including identification, reporting to child protective services (CPS), testing for and treating sexually transmitted infections (STIs), and providing support and reassurance to children and families. Pediatricians may also play a role in the prevention of sexual abuse by advising parents and children about ways to help keep safe from sexual abuse. In many U.S. jurisdictions, general pediatricians will play a triage role, with the definitive medical evaluation conducted by a child abuse specialist.

**Definition**

Sexual abuse may be defined as any sexual behavior or action toward a child that is unwanted or exploitative. Some legal definitions distinguish sexual abuse from sexual assault: abuse being committed by a caregiver or household member, and assault being committed by someone with a noncustodial relationship or no relationship with the child. For this chapter, the term sexual abuse will encompass both abuse and assault. It is important to note that sexual abuse does not have to involve direct touching or contact by the perpetrator. Showing pornography to a child, filming or photographing a child in sexually explicit poses, and encouraging or forcing one child to perform sex acts on another all constitute sexual abuse.

**Presentation of Sexual Abuse**

Children who have been sexually abused sometimes provide a clear, spontaneous disclosure to a trusted adult. Often the signs of sexual abuse are subtle. For some children, behavioral changes are the first indication that something is amiss. **Nonspecific behavior changes** such as social withdrawal, acting out, increased clinginess or fearfulness, distractibility, and learning difficulties may be attributed to a variety of life changes or stressors. Regression in developmental milestones, including new-onset bed-wetting or encopresis, is another behavior that caregivers may overlook as an indicator of sexual abuse. Teenagers may respond by becoming depressed, experimenting with drugs or alcohol, or
running away from home. Because nonspecific symptoms are very common among children who have been sexually abused, it should almost always be included in one's differential diagnosis of child behavior changes.

Some children may not exhibit behavioral changes or provide any other indication that something is wrong. For these children, sexual abuse may be discovered when another person witnesses the abuse or discovers evidence such as sexually explicit photographs or videos. Pregnancy may be another way that sexual abuse is identified. Other children, some with and some without symptoms, will not be identified at any point during their childhood.

Caregivers may become concerned about the possibility of sexual abuse when children exhibit **sexually explicit behavior**. This behavior includes that which is outside the norm for a child's age and developmental level. For preschool and school-age children, sexually explicit behavior may include compulsive masturbation, attempting to perform sex acts on adults or other children, or asking adults or children to perform sex acts on them. Teenagers may become sexually promiscuous and even engage in prostitution. Older children and teenagers may respond by sexually abusing younger children. It is important to recognize that this behavior could also result from accidental exposure (e.g., child enters parents’ bedroom at night and sees them having sex), or from neglect (e.g., adults watching pornographic movies where a child can see them).

**Role of General Pediatrician in Assessment and Management of Possible Sexual Abuse**

Before determining where and how a child with suspected sexual abuse is evaluated, it is important to assess for and rule out any medical problems that can be confused with abuse. A number of **genital findings** may raise concern about abuse but often have alternative explanations. Genital redness in a prepubertal child is more often caused by nonspecific vulvovaginitis, eczema, or infection with staphylococcus, group A streptococcus, *Haemophilus*, or yeast. Lichen sclerosis is a less common cause of redness. Vaginal discharge can be caused by STIs, but also by poor hygiene, vaginal foreign body, early in the onset of puberty, or infection with *Salmonella*, *Shigella*, or *Yersinia*. Genital ulcers can be caused by herpes simplex virus (HSV) and syphilis, but also by
Epstein-Barr virus, varicella-zoster virus, Crohn disease, and Behçet disease. Genital bleeding can be caused by urethral prolapse, vaginal foreign body, accidental trauma, and vaginal tumor.

Although other medical conditions may need to be evaluated, any possible sexual abuse should be investigated (Fig. 16.10). Where and how a child with suspected sexual abuse is evaluated should be determined by duration since the last incident of abuse likely occurred, and whether the child is prepubertal or postpubertal. For the prepubertal child, if abuse has occurred in the previous 72 hr, and history suggests direct contact, forensic evidence collection (e.g., external genital, vaginal, anal, and oral swabs, sometimes referred to as a “rape kit”) is indicated, and the child should be referred to a site equipped to collect forensic evidence. Depending on the jurisdiction, this site may be an emergency department (ED), a child advocacy center, or an outpatient clinic. If the last incident of abuse occurred >72 hr prior, the likelihood of recovering forensic evidence is extremely low, making forensic evidence collection unnecessary. For postpubertal females, many experts recommend forensic evidence collection up to 120 hr following the abuse—the same time limit as for adult women. The extended time frame is justified because some studies have demonstrated that semen can remain in the postpubertal vaginal vault for >72 hr.
FIG. 16.10 Triage protocol for children with suspected sexual abuse.

The site to which a child is referred may be different when the child does not present until after the cutoff for an acute examination. Because EDs may not have a child abuse expert and can be busy, noisy, and lacking in privacy, examination at an alternate location such as a child advocacy center or outpatient clinic is recommended. If the exam is not urgent, waiting until the next morning is recommended because it is easier to interview and examine a child who is not tired and cranky. Referring physicians should be familiar with the triage procedures in their communities, including the referral sites for both acute and chronic exams, and whether there are separate referral sites for prepubertal and postpubertal children.

Children with suspected sexual abuse may present to the pediatrician's office with a clear disclosure of abuse or subtler indicators. A private, brief conversation between pediatrician and child can provide an opportunity for the child to speak in his or her own words without the parent speaking for the child. Doing this may be especially important when the caregiver does not believe the child, or is unwilling or unable to offer emotional support and protection. Telling caregivers that a private conversation is part of the routine assessment for the child’s concerns can help comfort a hesitant parent.
When speaking with the child, experts recommend establishing rapport by starting with general and open-ended questions, such as, “Tell me about school,” and “What are your favorite things to do?” Questions about sexual abuse should be nonleading (e.g., “Who touched you there?”). A pediatrician should explain that sometimes children are hurt or bothered by others, and that he or she wonders whether that might have happened to the child. Open-ended questions, such as, “Can you tell me more about that?” allow the child to provide additional information and clarification in his or her own words. It is not necessary to obtain extensive information about what happened because the child will usually have a forensic interview once a report is made to CPS and an investigation begins. Very young children and those with developmental delay may lack the verbal skills to describe what happened. In this situation the caregiver's history may provide enough information to warrant a report to CPS without interviewing the child.

All 50 U.S. states mandate that professionals report suspected maltreatment to CPS. The specific criteria for “reason to suspect” are generally not defined by state law. It is clear that reporting does not require certainty that abuse has occurred. Therefore, it may be appropriate to report a child with sexual behavior concerns when no accidental sexual exposure can be identified, and when the child does not clearly confirm or deny abuse.

Physical Examination of the Child With Suspected Sexual Abuse

Unfortunately, many physicians are unfamiliar with genital anatomy and examination, particularly in the prepubertal child (Figs. 16.11 and 16.12). Because about 95% of children who undergo a medical evaluation following sexual abuse have normal examinations, the role of the primary care provider is often simply to be able to distinguish a normal exam from findings indicative of common medical concerns or trauma. The absence of physical findings can often be explained by the type and timing of sexual contact that has occurred. Abusive acts such as fondling, or even digital penetration, can occur without causing injury. In addition, many children do not disclose abuse until days, weeks, months, or even years after the abuse has occurred. Because genital injuries usually heal rapidly, injuries are often completely healed by the time a child presents for medical evaluation. A normal genital examination does not rule out
the possibility of abuse and should not influence the decision to report to CPS.

FIG. 16.11  Congenital anomalies of the hymen. A-F, Different types of hymen abnormalities. Photograph shows a normal hymen, as in A. (From Moore KL, Persaud TVN. The developing human, ed 7, Philadelphia, 2003, Elsevier.)
Even with the high proportion of normal genital exams, there is value in conducting a thorough physical examination. Unsuspected injuries or medical
problems, such as labial adhesions, imperforate hymen, or urethral prolapse, may be identified. In addition, reassurance about the child's physical health may allay anxiety for the child and family.

*Few findings on the genital examination are diagnostic for sexual abuse.* In the acute time frame, lacerations or bruising of the labia, penis, scrotum, perianal tissues, or perineum are indicative of trauma. Likewise, hymenal bruising and lacerations and perianal lacerations extending deep to the external anal sphincter indicate penetrating trauma. In the nonacute time frame, perianal scars and scars of the posterior fourchette or fossa indicate trauma and/or sexual activity. A complete transection of the hymen to the base between the 4 and 8 o'clock in the supine position (i.e., absence of hymenal tissue in the posterior rim) is considered diagnostic for trauma ([Fig. 16.12](#)). For these findings, the cause of injury must be elucidated through the child and caregiver history. If there is any concern that the finding may be the result of sexual abuse, CPS should be notified and a medical evaluation performed by an experienced child abuse pediatrician.

Testing for STIs is not indicated for all children but is warranted in certain situations ([Table 16.5](#)). *Culture* was once considered the gold standard for the diagnosis of vaginal gonorrhea (see Chapter 219) and chlamydia (Chapter 252) infections in children. However, several studies demonstrated that *nucleic acid amplification testing* (NAAT) for gonorrhea and chlamydia by either vaginal swab or urine in prepubertal females is as sensitive, and possibly more sensitive, than culture. Current guidelines from the Centers for Disease Control and Prevention (CDC) allow for NAAT testing by vaginal swab or urine as an alternative to culture in females. Because obtaining vaginal swabs can be uncomfortable for prepubertal children, urine testing is preferable. *Culture* remains the preferred method for testing of rectal and pharyngeal specimens in males and females. Few data are available on the use of urine NAAT testing in prepubertal boys. Therefore the CDC continues to recommend urine or urethral culture for boys. Many child abuse experts perform urine NAAT testing on prepubertal boys because urethral swabs are uncomfortable, and good data support urine NAAT testing in females. For all NAAT testing in both genders, the child should *not* receive presumptive treatment at testing. Instead, a positive NAAT test should be confirmed by culture or an alternate NAAT test before treatment. Because gonorrhea and chlamydia in prepubertal children do not typically cause ascending infection, waiting for a definitive diagnosis before treatment will not increase the risk for pelvic inflammatory disease. Testing for
*Trichomonas vaginalis* is by culture (Diamond media or InPouch; Biomed Diagnostics, White City, OR) or wet mount. *Wet mount* requires the presence of vaginal secretions, viewing must be immediate for optimal results, and sensitivity is only 44–68%; therefore false-negative tests are common. Experts have determined that insufficient data exist to recommend commercially available *Trichomonas* NAATs for prepubertal children. However, there is also no reason to suspect that test performance in children would be different from adults.

**Table 16.5**

**Indications for STI Screening in Children With Suspected Sexual Abuse**

1. Child has experienced penetration or has evidence of recent or healed penetrative injury to the genitals, anus, or oropharynx.
2. Child has been abused by a stranger.
3. Child has been abused by a perpetrator known to be infected with a sexually transmitted infection (STI) or at high risk for STIs (e.g., intravenous drug abusers, men who have sex with men, persons with multiple sexual partners, those with a history of STIs).
4. Child has a sibling, other relative, or another person in the household with an STI.
5. Child lives in an area with a high rate of STI in the community.
6. Child has signs or symptoms of STIs (e.g., vaginal discharge or pain, genital itching or odor, urinary symptoms, genital lesions or ulcers).
7. Child or parent requests STI testing.

A number of STIs should raise concern for abuse (Table 16.6). In a prepubertal child, *gonorrhea* or *syphilis* beyond the neonatal period indicates that the child has had some contact with infected genital secretions, almost always as a result of sexual abuse. There is some evidence to indicate that *chlamydia* in children up to 3 yr of age may be perinatally acquired. Chlamydia in children >3 yr old is diagnostic of contact with infected genital secretions,
almost always a result of sexual abuse. In children <3 yr old, sexual abuse should still be strongly considered beyond the neonatal period. HIV is diagnostic for sexual abuse if other means of transmission have been excluded. Because of the potential for transmission either perinatally or through nonsexual contact, the presence of genital warts has a low specificity for sexual abuse. The possibility of sexual abuse should be considered and addressed with the family, especially in children whose warts first appear beyond 5 yr of age. Type 1 or 2 genital herpes is concerning for sexual abuse, but not diagnostic given other possible routes of transmission. For human papillomavirus (HPV) and HSV, the American Academy of Pediatrics (AAP) recommends reporting to CPS unless perinatal or horizontal transmission is considered likely.

Additional Management

Because HIV testing identifies antibodies to the virus and not the human immunodeficiency virus itself, and because it may take several months for seroconversion, repeat testing at 6 wk and 3 mo after the last suspected exposure is indicated. Repeat testing for syphilis is also recommended. Hepatitis B and HPV vaccination (for children ≥9 yr) should be given if the child has not been previously vaccinated or vaccination is incomplete.

Sexual Abuse Prevention

Pediatricians can play a role in the prevention of sexual abuse by educating parents and children about sexual safety at well-child visits. During the genital exam the pediatrician can inform the child that only the doctor and select adult caregivers should be permitted to see their private parts, and that a trusted adult should be told if anyone else attempts to do so. Pediatricians can raise parental awareness that older kids or adults may try to engage in sexual behavior with children. The pediatrician can teach parents how to minimize the opportunity for perpetrators to access children, for example, by limiting one-adult/one-child situations and being sensitive to any adult's unusual interest in young children. In addition, pediatricians can help parents talk to children about what to do if confronted with a potentially abusive situation. Some examples include telling children to say “no,” to leave, and to tell a parent and/or another adult. If abuse does occur, the pediatrician can tell parents how to recognize possible signs and symptoms, and how to reassure the child that she or he was not at fault. Lastly, pediatricians can provide parents with suggestions about how to maintain open communication with their children so that these conversations can occur with minimal parent and child discomfort.

Medical Child Abuse (Factitious Disorder by Proxy, Munchausen Syndrome by Proxy)

Howard Dubowitz, Wendy G. Lane

Keywords

apnea
bleeding
factitious disorder by proxy
MCA
medical child abuse
Munchausen syndrome by proxy
recurrent sepsis
seizures

The term Munchausen syndrome is used to describe situations in which adults falsify their own symptoms. In Munchausen syndrome by proxy, a parent, typically a mother, simulates or causes disease in her child. Several terms have been suggested to describe this phenomenon: factitious disorder by proxy, pediatric condition falsification, and currently, medical child abuse (MCA). In some instances, such as partial suffocation, child abuse may be most appropriate. The core dynamic of MCA is that a parent falsely presents a child for medical
attention. This may occur by fabricating a history, such as reporting seizures that never occurred. A parent may directly cause a child's illness, by exposing a child to a toxin, medication, or infectious agent (e.g., injecting stool into an intravenous line). Signs or symptoms may also be manufactured, such as when a parent smoothes a child, or alters laboratory samples or temperature measurements. Each of these actions may lead to unnecessary medical care, sometimes including intrusive tests and surgeries. The “problems” often recur repeatedly over several years. In addition to the physical concomitants of testing and treatment, there are potentially serious and lasting social and psychological sequelae.

Child healthcare professionals are typically misled into thinking that the child really has a medical problem. Parents, sometimes working in a medical field, may be adept at constructing somewhat plausible presentations. A convincing seizure history may be offered, and a normal electroencephalogram (EEG) cannot fully rule out the possibility of a seizure disorder. Even after extensive testing fails to lead to a diagnosis or treatment proves ineffective, health professionals may think they are confronting a new or rare disease. Unwittingly, this can lead to continued testing (leaving no stone unturned) and interventions, thus perpetuating the MCA. Pediatricians generally rely on and trust parents to provide an accurate history. As with other forms of child maltreatment, an accurate diagnosis of MCA requires that the pediatrician maintain a healthy skepticism under certain circumstances.

Clinical Manifestations

The presentation of MCA may vary in nature and severity. Consideration of MCA should be triggered when the reported symptoms are repeatedly noted by only 1 parent, appropriate testing fails to confirm a diagnosis, and seemingly appropriate treatment is ineffective. At times, the child's symptoms, their course, or the response to treatment may be incompatible with any recognized disease. Preverbal children are usually involved, although older children may be convinced by parents that they have a particular problem and become dependent on the increased attention; this may lead to feigning symptoms.

Symptoms in young children are mostly associated with proximity of the offending caregiver to the child. The mother may present as a devoted or even model parent who forms close relationships with members of the healthcare team. While appearing very interested in her child's condition, she may be
relatively distant emotionally. She may have a history of Munchausen syndrome, although not necessarily diagnosed as such.

**Bleeding** is a particularly common presentation. This may be caused by adding dyes to samples, adding blood (e.g., from the mother) to the child's sample, or giving the child an anticoagulant (e.g., warfarin).

**Seizures** are another common manifestation, with a history easy to fabricate, and the difficulty of excluding the problem based on testing. A parent may report that another physician diagnosed seizures, and the myth may be continued if there is no effort to confirm the basis for the “diagnosis.” Alternatively, seizures may be induced by toxins, medications (e.g., insulin), water, or salts. Physicians need to be familiar with the substances available to families and the possible consequences of exposure.

**Apnea** is also a common presentation. The observation may be falsified or created by partial suffocation. A history of a sibling with the same problem, perhaps dying from it, should be cause for concern. Parents of children hospitalized for brief resolved unexplained events (or apparent life-threatening events) have been videotaped attempting to suffocate their child while in the hospital.

**Gastrointestinal** signs or symptoms are another common manifestation. Forced ingestion of medications such as ipecac may cause chronic vomiting, or laxatives may cause diarrhea.

The skin, easily accessible, may be burned, dyed, tattooed, lacerated, or punctured to simulate acute or chronic skin conditions. **Recurrent sepsis** may be caused by infectious agents being administered; intravenous lines during hospitalization may provide a convenient portal. Urine and blood samples may be contaminated with foreign blood or stool.

**Diagnosis**

In assessing possible MCA, several explanations should be considered in addition to a true medical problem. Some parents may be extremely anxious and genuinely concerned about possible problems. This anxiety may result from a personality trait, the death of neighbor's child, or something read on the internet. Alternatively, parents may believe something told to them by a trusted physician despite subsequent evidence to the contrary and efforts to correct the earlier misdiagnosis. Physicians may unwittingly contribute to a parent's belief that a real problem exists by, perhaps reasonably, persistently pursuing a medical
There is a need to discern commonly used hyperbole (e.g., exaggerating height of fever) in order to evoke concern and perhaps justify an ED visit. In the end, a diagnosis of MCA rests on clear evidence of a child repeatedly being subjected to unnecessary medical tests and treatment, primarily stemming from a parent's actions. Determining the parent's underlying psychopathology is the responsibility of mental health professionals.

Once MCA is suspected, gathering and reviewing all the child's medical records from all sources is an onerous but critical first step. It is often important to confer with other treating physicians about what specifically was conveyed to the family. A mother may report that the child's physician insisted that a certain test be done, when instead it was the mother who demanded the test. It is also necessary to confirm the basis for a given diagnosis, rather than simply accepting a parent's account.

Pediatricians may face the dilemma of when to accept that all plausible diagnoses have been reasonably ruled out, the circumstances fit MCA, and further testing and treatment should cease. The likelihood of MCA must be balanced with concerns about possibly missing an important diagnosis. Consultation with a pediatrician expert in child abuse is recommended. In evaluating possible MCA, specimens should be carefully collected, with no opportunity for tampering with them. Similarly, temperature measurements should be closely observed.

Depending on the severity and complexity, hospitalization may be needed for careful observation to help make the diagnosis. In some instances, such as repeated apparent life-threating events, covert video surveillance accompanied by close monitoring (to rapidly intervene in case a parent attempts to suffocate a child) can be valuable. Close coordination among hospital staff is essential, especially since some may side with the mother and resent even the possibility of MCA being raised. Parents should not be informed of the evaluation for MCA until the diagnosis is made. Doing so could naturally influence their behavior and jeopardize establishing the diagnosis. All steps in making the diagnosis and all pertinent information should be very carefully documented, perhaps using a “shadow chart” to which the parent does not have access.

**Treatment**

Once the diagnosis is established, the medical team and CPS should determine the treatment plan, which may require out-of-home placement and should
include mental healthcare for the offending parent as well as for other affected children. Further medical care should be carefully organized and coordinated by one primary care provider. CPS should be encouraged to meet with the family only after the medical team has informed the offending parent of the diagnosis; their earlier involvement may hamper the evaluation. Parents often respond with resistance, denial, and threats. It may be prudent to have hospital security in the vicinity.

To improve the health of children, pediatricians often ask patients and caregivers to make behavioral changes. These may be lifestyle changes to manage a chronic condition (e.g., obesity, asthma), adherence with the recommended timing and frequency of medications, or recommendations to seek assistance from other health providers (e.g., dieticians, mental health providers, physical, occupational, or speech therapists). However, change is difficult and can cause distress, and families often express reluctance or ambivalence to change due to perceived barriers. When families do not believe change is needed or possible, pediatricians may become discouraged or uncomfortable in providing care. This can make it difficult for clinicians to form an alliance with families, which is central to finding a solution to most problems identified in the medical setting.

Many healthcare problems may require complex, multifaceted interventions, but the first step is always to engage the family in identifying the healthcare problem driving the need for behavior change. Once a problem is identified and agreed on, clinicians and families need to set an achievable goal and identify specific behaviors that can help families reach their goal. It is important to be specific and precise about the actual behavior and not simply identify the category of the behavior. When counseling a patient on weight loss for obesity, for example, one might discuss 3 possible approaches: making dietary changes, increasing exercise, and decreasing screen time. The choice of which behavior to focus on should come from the patient but needs to be specific. It is not enough for the patient to state he will exercise more. Instead, the clinician should help the patient identify a more specific goal, such as playing basketball with his friends 3 times a week at the park near home. This takes into account the action, context, setting, and time of the new behavioral goal. Specific examples of
problems that would necessitate a behavior change to improve outcomes are used throughout the chapter.

Unified Theory of Behavior Change

There are several theories of health-related behavior change. Each highlights a different concept, but frameworks that unite these theories suggest that the factor most predictive of whether one will perform a behavior is the intention to do so. The unified theory of behavior change examines behavior along 2 dimensions: influences on intent and moderators of the intention-behavior relationship (Fig. 17.1 ). Five main factors that influence one’s decision to perform a behavior are expectancies, social norms/normative influences, self-concept/self-image, emotions, and self-efficacy. Table 17.1 provides specific examples on how to explore influences of intent when guiding families in decision-making, such as deciding to start a stimulant medication for a child diagnosed with attention-deficit/hyperactivity disorder (ADHD). It is not necessary to ask about each influence, but these principles are particularly useful when guiding patients who may be resistant to change.

![Diagram](image)

**FIG. 17.1** The 5 constructs that influence one’s intent to perform a behavior and the 4 influences that determine whether an intent will lead to performing the behavior. Problem identification (box at upper right) is where the process of thinking about health behavior changes begins. A clinician can then help the patient decide on which behavior can help the patient to meet the health goal. Once this is decided, to help with behavior change, clinicians should think about intent, influences of intent, and the factors that may facilitate or impede intent from leading to action.

strategize ways to overcome obstacles. “Do you feel confident you will be able to get your child to take the medication?” “Let's brainstorm how we can prevent any of the side effects.” “Many of my patients have a large breakfast before taking the medication. Can I help you figure out how to fit that into your schedule?”

“Will I be able to make sure my child has a large breakfast in the morning before taking her medication?”

ADHD, Attention-deficit/hyperactivity disorder.

Once a decision to make a change is made, 4 factors determine whether an intention leads to carrying out the behavior: knowledge and skills, environmental facilitators and constraints, salience of the behavior, and habits. The pediatrician can help ensure intent leads to behavior change by addressing these factors during the visit. In the ADHD example, the clinician can help the family build their knowledge by providing handouts on stimulants, nutritional pamphlets on how to minimize the appetite-suppressant effects of the medication on weight, and information on how the family can explain to others the need for medication. Asking about morning routines will help identify potential barriers in remembering to take the medication. Lastly, clinicians can help families think about cues for remembering to give the medication in the morning, since their morning routines, or habits, will have to be adjusted to adhere to this medication.

By using these principles of behavior change, pediatricians can guide their patients toward change during an encounter by ensuring they leave with (1) a strong positive intention to perform the behavior; (2) the perception that they have the skills to accomplish it; (3) a belief that the behavior is socially acceptable and consistent with their self-image; (4) a positive feeling about the behavior; (5) specific strategies in overcoming potential barriers in performing the behavior; and (6) a set of identified cues and enablers to help build new habits.

**Transtheoretical Model of Health Behavior Change**

It is difficult to counsel families to change a behavior when they may not agree there is a problem or when they are not ready to build an intention to change. The **transtheoretical model of health behavior change** places an individual's motivation and readiness to change on a continuum. The premise of this model is that behavior change is a process, and as someone attempts to change, they move...
through 5 stages (although not always in a linear fashion): precontemplation (no current intention of making a change), contemplation (considering change), preparation (creating an intention, planning, and committing to change), action (has changed behavior for a short time), and maintenance (sustaining long-term change). Assessing a patient's stage of change and then targeting counseling toward that stage can help build a therapeutic alliance, in contrast to counseling a patient to do something she is not ready for, which can disrupt therapeutic alliance and lead to resistance. Table 17.2 further describes stages of change and gives examples for counseling that targets the adolescent's stage of change in reducing marijuana smoking.

**Common Factors Approach**

Conversations around behavior change are most effective when they take place in a context of a trusting, mutually respectful relationship. The traditional medical model assumes that patients and their families come with questions and needs, and that the pediatrician's job is to offer specific advice and advocate for its acceptance. This approach fails when families are reluctant, ambivalent, demoralized, or unfamiliar with the healthcare system or the treatment choices offered. A context more supportive of behavior change can be developed when pediatricians use communication strategies that facilitate collaboration and
building therapeutic alliance.

The **common factors approach** is an evidence-based communication strategy that is effective in facilitating behavior change. The skills central to a common factors approach are consistent across multiple forms of psychotherapy and can be viewed as generic aspects of treatment that can be used across a wide range of symptoms to build a therapeutic alliance between the physician and patient. This alliance predicts outcomes of counseling more than the specific modality of treatment. The common factors approach has been implemented and studied in pediatric primary care for children with mental health problems. Children who were treated by pediatricians trained in the common factors approach had improved functioning compared to those who saw pediatricians without this training.

A common factors approach distinguishes between the impact of the patient–provider alliance and the pediatrician's use of skills that influence patient behavior change across a broad range of conditions. Interpersonal skills that help build alliances with patients include showing empathy, warmth, and positive regard. Skills that influence behavior change include a clinician's ability to provide optimism, facilitate treatment engagement, and maintain the focus on achievable goals. This can be done by clearly explaining the condition and treatment approaches while keeping the discussion focused on immediate and practical concerns.

**Interpersonal Skills: HEL\(^2\) P\(^3\)**

The interpersonal skills that facilitate an affective bond between the patient and clinician can be remembered by the HEL\(^2\) P\(^3\) mnemonic (Table 17.3). These skills include providing **hope**, **empathy**, and **loyalty**; using the patient's **language**; **partnering** with the family; asking **permission** to raise more sensitive questions or to give advice; and creating a **plan** that is initiated by the family. These interpersonal skills should help operationalize the common factors approach by increasing a patient's optimism, feelings of well-being, and willingness to work toward improved health, while also targeting feelings of anger, ambivalence, and hopelessness.

</tr>
<tr>
<td><strong>Empathy:</strong> Listen attentively.</td>
<td>“It must be hard for you that you no longer get pleasure in playing soccer.”</td>
</tr>
<tr>
<td><strong>Language:</strong> Use family’s language. Check understanding.</td>
<td>“Let me make sure I understand what you are saying. You no longer feel like doing things that make you happy in the past?”</td>
</tr>
<tr>
<td><strong>Loyalty:</strong> Express support and commitment.</td>
<td>“You are free to talk to me about anything while we work through this.”</td>
</tr>
<tr>
<td><strong>Permission:</strong> Ask permission to explore sensitive subjects. Offer advice.</td>
<td>“I would like to ask more questions that you may find more sensitive, is that okay?”</td>
</tr>
<tr>
<td><strong>Partnership:</strong> Identify and overcome barriers.</td>
<td>“Is it okay with you if I give you my opinion on what may be the problem here?”</td>
</tr>
<tr>
<td><strong>Plan:</strong> Establish a plan, or at least a first step family can take.</td>
<td>“If we work together, maybe we can think through solutions for the problems you identified.”</td>
</tr>
</tbody>
</table>

* This table illustrates the interperson al skills highlighted in the common factors approach. In this example the clinician is responding to an adolescent struggling with depression and resistant to seeking help.

Structuring a patient encounter using common factors to facilitate behavior change uses these steps: eliciting concerns while setting an agenda and agreeing on the nature of the problem; establishing a plan; and responding to anger and demoralization and emphasizing hope.

**Elicit Concerns: Set the Agenda and Agree on the Problem**

The first step of the visit is to elicit both the child's and the parent's concerns and agree on the focus for the visit. This can be accomplished by using open-ended questions and asking “anything else?” until nothing else is disclosed. It is important to show you have time and are interested in their concerns by making eye contact, listening attentively, minimizing distractions, and responding with empathy and interest. Engage both the child and the parent by taking turns eliciting their concerns. It is helpful to summarize their story to reassure them you have heard and understand what they are saying. Keep the session organized, and manage rambling by gently interrupting, paraphrasing, asking for additional concerns, and refocusing the conversation.

By the end of this step in the visit, all parties should feel reassured that their problems were heard and accurately described. The next step is to agree on the
problem to be addressed during that visit. If the parent and child do not agree on the issue, try to find a common thread that will address the concerns of both.

**Establish a Plan**

Once a problem is agreed on, the pediatrician can partner with families to develop acceptable and achievable plans for treatment or further evaluation. Families should take the lead in developing goals and the strategies to attain them, and information should be given in response to patients’ expressed needs. Pediatricians can involve families by offering choices and asking for feedback. Advice should be given only after asking a family’s permission to do so. If the family asks for advice, the clinician should respond by considering principles of behavior change, as described earlier. Advice should be tailored toward the family’s willingness to act, concerns for barriers, and attitudes and should be as specific and practical as possible. Once an initial plan is established, it is important to partner in monitoring responses and to provide continued support.

**Respond to Anger and Demoralization and Emphasize Hope**

The common factors approach is particularly helpful in engaging families in situations where anger and demoralization could prevent patients from being able to use the clinician's advice. Focusing the conversation on goals for the future and how to achieve them is more productive than discussing how problems began. This “solution-focused therapy” approach grew out of the need for clinicians to help people in a brief encounter. Hopelessness can be relieved by pediatricians helping patients to identify and build on strengths and past success, reframing events and feelings, and breaking down overwhelming goals into small, concrete steps that are more readily accomplished. In general, pediatricians can use the **elicit-provide-elicit model**. First, ask if they want to hear your thoughts about the situation. Provide guidance in a neutral way, and then ask the family what they think about what you just stated.

**Table 17.4** provides an example of how to use common factors in practice using a scenario of an adolescent female who has been teased for using albuterol before physical education class for her exercise-induced asthma. The clinician in the scenario attempts to address both the patient's and her mother's concerns.

<tr>
<td>Elicit child and parents' concerns.</td>
<td>Use open-ended questions and ask, “What else?” until nothing else is listed, while engaging both parties and demonstrating empathy.</td>
<td>“Hi, Jacqueline and Mrs. Smith. How have things been since last time? What are your biggest concerns for today?” “What else do you think we should put on the agenda for today?” “I am sorry to hear that you have had more asthma symptoms around gym time, Jacqueline. I’d like to ask you a few more questions to get a better understanding of what has changed, if that’s okay with you.” “I understand this is upsetting you, Mrs. Smith, and that you worry that Jacqueline is not going to the nurse before gym to use her inhaler pump anymore. Let’s hear from Jacqueline.”</td>
</tr>
<tr>
<td>Agree on the problem.</td>
<td>“Can we all agree that managing the asthma symptoms around gym time is the most pressing issue for today? Should we focus on that today?”</td>
<td></td>
</tr>
<tr>
<td>Manage rambling.</td>
<td>“What you’re saying is really important, but I want to be sure we have time to talk about controlling your daughter's asthma symptoms during gym. Is it okay if we go back to that topic?”</td>
<td></td>
</tr>
<tr>
<td>Partner with families to find acceptable forms of treatment.</td>
<td>Develop acceptable plans for treatment of further diagnoses.</td>
<td>“I believe we can develop a plan to help deal with this. Is it okay to start talking about next steps?” “I know these asthma symptoms are concerning to your mom. But, Jacqueline, is this something you can act on now?” “I am happy to give suggestions on how to more easily use your inhaler before gym, without the other kids noticing. But what were you thinking, Jacqueline?” “Let’s make a specific plan on where you can keep your inhaler so the other kids don’t see it.”</td>
</tr>
<tr>
<td>Address barriers to treatment.</td>
<td>“Is there anything that makes you worry that this may not work?”</td>
<td></td>
</tr>
<tr>
<td>Increase expectations that treatment will be helpful.</td>
<td>Respond to hopelessness, anger, and frustration.</td>
<td>“I realize it wasn’t your choice to come here, Jacqueline, but I’m interested in hearing how you feel about this issue.” “It must be really hard for you, Jacqueline, when the kids tease you about your inhaler.” “It must be frustrating for the school nurse to call you in the middle of the day at work, Mrs. Smith.” “I would be angry, too, if I felt my mom didn’t understand how it felt when I got teased for going to the nurse’s office.”</td>
</tr>
<tr>
<td>Emphasize hope.</td>
<td>“We’ve managed difficult things before. Remember when Jacqueline kept getting admitted for her asthma when she was younger? We have come a long way since then, and I’m sure we can manage this as well.”</td>
<td></td>
</tr>
</tbody>
</table>

* Jacqueline is an adolescent female who has had asthma since she was an infant. Despite
multiple hospitalizations as an infant, her asthma had been under control except for during exercise, including physical education (PE) class. She had been going to the nurse’s office to take albuterol before PE class, but recently she had been teased for having to take medication before PE. She has begun to skip treatments to avoid the teasing. However, her mother has now been called a few times to pick her up from school due to her asthma symptoms. Mrs. Smith is a single mother who cannot miss work and is very frustrated. She was not aware of the bullying Jacqueline has undergone.

**Motivational Interviewing**

Motivational interviewing (MI) is a goal-oriented, supportive counseling style that complements the HEL² P³ framework and is useful when patients or families remain ambivalent about making health-related behavior changes. MI is designed to enhance intrinsic motivation in patients by exploring their perspectives and ambivalence. It is also aligned with the transtheoretical model's continuum of change, where the pediatrician not only tailors counseling to a patient's stage of change, but does so with the goal of moving the patient toward the next stage. It is particularly effective for those not interested in change or not ready to make a commitment. MI has been shown to be an effective intervention strategy for decreasing high-risk behaviors, improving chronic disease control, and increasing adherence to preventive health measures.

MI is a collaborative approach in which the pediatrician respects patients’ perspective and treats them as the “expert” on their values, beliefs, and goals. **Collaboration, acceptance, compassion, and evocation** are the foundation of MI and are referred to as the “spirit” of the approach. The clinician is a “guide,” respecting patients’ autonomy and their ability to make their own decision to change. The pediatrician expresses genuine concern and demonstrates that he or she understands and validates the patient's or family's struggle. Using open-ended questions, the pediatrician evokes the patient's own motivation for change.

Expressing empathy facilitates behavior change by accepting the patient's beliefs and behaviors. This contrasts to direct persuasion, which often leads to resistance. The pediatrician must reinforce that ambivalence is normal and use skillful reflective listening, showing the patient an understanding of the situation.

Developing a discrepancy between current behaviors (or treatment choices) and treatment goals motivates change and helps move the patient from the
precontemplative stage to the contemplative stage or from the contemplative stage to preparation, as described in the transtheoretical model. Through MI the clinician can guide patients in understanding that their current behaviors may not be consistent with their stated goals and values.

Rolling with resistance, or not pushing back when suggestions are declined, is a strategy again to align with the patient. Resistance is usually a sign that a different approach is needed. As necessary, the clinician can ask permission to give new perspectives.

Self-efficacy, or a patient's belief in her ability to perform the behavior, is a key element for change and a powerful motivator. Clinicians can express confidence in the patient's ability to achieve change and support the patient's self-efficacy.

The process by which MI is used in a patient encounter involves the following 4 parts:

1. **Engagement** is the rapport-building part of the encounter. In addition to using the skills presented in the HEL² P³ framework, the MI approach highlights the use of open-ended questions, affirmations, reflective listening, and summaries (OARS). **Open-ended questions** should be inviting and probing enabling the patient to think through and come to a better understanding of the problem and elicit their internal motivation. **Affirmations** provide positive feedback, express appreciation about a patient's strengths and can reinforce autonomy and self-efficacy. **Reflective listening** demonstrates that the clinician understands the patient's thoughts and feelings without judgement or interruption. It should be done frequently and can encourage the patient to be more open. **Summarizing** the conversation in a succinct way reinforces that you are listening, pulls together all information, and allows the patient to hear his own motivations and ambivalence.

2. **Focusing** the visit is done to clarify the patient's priorities, stage of readiness, and to identify the problem where there is ambivalence. If a patient remains resistant to change, ask permission to give information or share ideas and then ask for feedback on what they think about what you said. In the **elicit-ask-elicit model**, a clinician can deliver information about an unhealthy behavior or lifestyle decision in a nonpaternalistic manner.

3. **Evocation** is when the clinician assesses their patients’ reasons for
change and helps them to explore advantages, disadvantages, and barriers to change. It is important to reinforce the patient's change talk. Examples of change talk include an expression of desire ("I want to…"), ability ("I can…"), reasons ("There are good reasons to…"), or a need for change ("I need to…"). Clinician can use "readiness rulers" by asking their patients to rate on a scale from 1 to 10 how important and confident they are in making change. The clinician should then respond by asking why the patient did not choose a lower number and should follow up asking what it would take to bring it to a higher number.

4. The planning stage is similar to that described in the discussion of a common factors approach and occurs once a patient is in the preparation stage on the continuum of change. A clinician can guide their patient through this stage by having them write down responses to statements such as, “The changes I want to make are…,” “The most important reasons to make this change are…,” “Some people who can support me are…,” and “They can help me by ….” A concrete plan should include specific actions and a way to factor in accountability and rewards. Table 17.5 uses a visit for counseling about obesity to demonstrate the process of motivational interviewing.

statements | lose weight and make changes for the whole family, but you are willing to consider some simple changes.”
---|---
**Focusing** | Set the agenda. | “We could talk about increasing the amount of exercise Jimmy has every week, reducing screen time, or making a dietary change. What do you think would work best?”
 |  | “Great, so we will talk about soda. What do you like about it? How many times a week do you drink it?”
**Evocation** | Reinforce any change talk. Change ruler. | “Those are great reasons for thinking about cutting back on soda.”
 |  | “On a scale of 1 to 10, how confident are you (or important is it) that you can cut back on soda?”
 |  | “A 5. Why didn't you answer a 3?”
 |  | “What would it take to bring it to a 7?”
**Planning** | Focus on how to make the change, not “why” anymore. Be concrete. | “Maybe completely eliminating soda is too difficult right now. Do you want to think of a couple of times during the week where you can reward yourself with a soda?”
 |  | “What will you drink after school instead of soda?”

*OARS is used to engage the patient and build rapport.*

## Shared Decision-Making

Shared decision-making has many similarities to the processes previously described in that it emphasizes moving physicians away from a paternalistic approach in dictating treatment to one where patients and clinicians collaborate in making a medical decision, particularly when multiple evidence-based treatments options exist. The pediatrician or clinician offers different treatment options and describes the risks and benefits for each one. The patient or caregiver expresses their values, preferences, and treatment goals, and a decision is made together.

Shared decision-making is often facilitated by using evidence-based decision aids such as pamphlets, videos, web-based tools, or educational workshops. Condition-specific or more generic decision aids have been created and facilitate the process of shared decision-making. Studies in adults show that such aids improve knowledge and satisfaction, reduce decisional conflict, and increase the alignment between patient preferences and treatment options. More study is needed to assess behavioral and physiologic outcomes specifically when
involving children in the decision-making process.

The field of pediatrics is dedicated to optimizing the growth and development of each child. Pediatricians require knowledge of normal growth, development, and behavior in order to effectively monitor children's progress, identify delays or abnormalities in development, help obtain needed services, and counsel parents and caretakers. To alter factors that increase or decrease risk, pediatricians need to understand how biologic and social forces interact within the parent–child relationship, within the family, and between the family and the larger society. Growth is an indicator of overall well-being, status of chronic disease, and interpersonal and psychologic stress. By monitoring children and families over time, pediatricians are uniquely situated to observe the interrelationships between physical growth and cognitive, motor, and emotional development. Observation is enhanced by familiarity with developmental and behavioral theories that inform one about typical patterns of development and provide guidance for prevention or intervention for behavior problems. Familiarity with theories of health behavior may assist in guiding patients and families in disease management and wellness care.

Biopsychosocial Model and Ecobiodevelopmental Framework: Models of Development

The medical model presumes that a patient presents with signs and symptoms and a physician focuses on diagnosing and treating diseases of the body. This
model neglects the psychologic aspect of a person who exists in the larger realm of the family and society. In the biopsychosocial model, societal and community systems are simultaneously considered along with more proximal systems that make up the person and the person's environment (Fig. 18.1). A patient's symptoms are examined and explained in the context of the patient's existence. This basic model can be used to understand health and both acute and chronic disease.

![Biopsychosocial Model Diagram](image)

**FIG. 18.1** Continuum and hierarchy of natural systems in the biopsychosocial model. (From Engel GL: The clinical application of the biopsychosocial model, Am J Psychiatry 137:535–544, 1980.)

With the advances in neurology, genomics (including epigenetics), molecular biology, and the social sciences, a more accurate model, the ecobiodevelopmental framework, has emerged. This framework emphasizes how the ecology of childhood (social and physical environments) interacts with biologic processes to determine outcomes and life trajectories. Early influences, particularly those producing toxic levels of stress, affect the individual through modification of gene expression, without change in DNA sequencing. These
epigenetic changes, such as DNA methylation and histone acetylation (see Chapter 100), are influenced by the early life experiences (the environment). Stress responses may produce alterations in brain structure and function, leading to disruption of later coping mechanisms. These changes will produce long-lasting effects on the health and well-being of the individual and may be passed on to future generations (Fig. 18.2).

Critical to learning and remembering (and therefore development) is neuronal plasticity, which permits the central nervous system to reorganize neuronal networks in response to environmental stimulation, both positive and negative. An overproduction of neuronal precursors eventually leads to about 100 billion neurons in the adult brain. Each neuron develops on average 15,000 synapses by 3 yr of age. During early childhood, synapses in frequently used pathways are preserved, whereas less-used ones atrophy, a process termed “pruning.” Changes in the strength and number of synapses and reorganization of neuronal circuits also play important roles in brain plasticity. Increases or decreases in synaptic activity result in persistent increases or decreases in synaptic strength. Thus experience (environment) has a direct effect on the physical and therefore functional properties of the brain. Children with different talents and
temperaments (already a combination of genetics and environment) further elicit different stimuli from their (differing) environments.

Periods of rapid development generally correlate with periods of great changes in synaptic numbers in relevant areas of the brain. Accordingly, sensory deprivation during the time when synaptic changes should be occurring has profound effects. For example, the effects of strabismus leading to amblyopia in one eye may occur quickly during early childhood; likewise, patching the eye with good vision to reverse amblyopia in the other eye is less effective in late childhood (see Chapter 641 ). Early experience is particularly important because learning proceeds more efficiently along established synaptic pathways.

Early traumatic experiences modify the expression of stress mediators (in particular the hypothalamic-pituitary-adrenal axis) and neurotransmitters, leading to changes in brain structure and function. These effects may be persistent, leading to alterations and dysfunction in the stress response throughout life. Chronic stress has negative effects on cognitive functions, including memory and emotional regulation. Positive and negative experiences do not determine the ultimate outcome, but shift the probabilities by influencing the child's ability to respond adaptively to future stimuli. The plasticity of the brain continues into adolescence, with further development of the prefrontal cortex, which is important in decision-making, future planning, and emotional control; neurogenesis persists in adulthood in certain areas of the brain.

**Biologic Influences**

Biologic influences on development include genetics, in utero exposure to teratogens, the long-term negative effects of low birthweight (neonatal morbidities plus increased rates of subsequent adult-onset obesity, coronary heart disease, stroke, hypertension, and type 2 diabetes), postnatal illnesses, exposure to hazardous substances, and maturation. Adoption and twin studies consistently show that heredity accounts for approximately 40% of the variance in IQ and in other personality traits, such as sociability and desire for novelty, whereas shared environment accounts for another 50%. The negative effects on development of prenatal exposure to teratogens, such as mercury and alcohol, and of postnatal insults, such as meningitis and traumatic brain injury, have been extensively studied (see Chapters 115 and 120 ). Any chronic illness can affect growth and development, either directly or through changes in nutrition, parenting, school attendance, or peer interactions.
Most children follow similar motor developmental sequences; the age at which children walk independently is similar around the world, despite great variability in child-rearing practices. The attainment of other skills, such as the use of complex sentences, is less tightly bound to a maturational schedule. Maturational changes also generate behavioral challenges at predictable times. Decrement in growth rate and sleep requirements around 2 yr of age often generate concern about poor appetite and refusal to nap. Although it is possible to accelerate many developmental milestones (toilet-training a 12 mo old or teaching a 3 yr old to read), *the long-term benefits of such precocious accomplishments are questionable.*

In addition to physical changes in size, body proportions, and strength, maturation brings about hormonal changes. Sexual differentiation, both somatic and neurologic, begins in utero. Both stress and reproductive hormones affect brain development as well as behavior throughout development. Steroid production by the fetal gonads leads to differences in brain structures between males and females.

**Temperament** describes the stable, early-appearing individual variations in behavioral dimensions, including emotionality (crying, laughing, sulking), activity level, attention, sociability, and persistence. The classic theory proposes 9 dimensions of temperament (Table 18.1). These characteristics lead to 3 common constellations: (1) the easy, highly adaptable child, who has regular biologic cycles; (2) the difficult child, who is inflexible, moody, and easily frustrated; and (3) the slow-to-warm-up child, who needs extra time to adapt to new circumstances. Various combinations of these clusters also occur. Temperament has long been described as biologic or “inherited.” Monozygotic twins are rated by their parents as temperamentally similar more often than are dizygotic twins. Estimates of heritability suggest that genetic differences account for approximately 20–60% of the variability of temperament within a population. The remainder of the variance is attributed to the child's environment. Maternal prenatal stress and anxiety is associated with child temperament, possibly through stress hormones. However, certain polymorphisms of specific genes moderate the influence of maternal stress on infant temperament. Children who are easily frustrated, fearful, or irritable may elicit negative parental reactions, making these children even more susceptible to negative parenting behaviors and to poor adjustment to adversity. Longitudinal twin studies of adult personality indicate that changes in personality over time largely result from nonshared environmental influences, whereas stability of
temperament appears to result from genetic factors.

* Typical statements of parents, reflecting the range for each characteristic from very little to very much.

The concept of temperament can help parents understand and accept the characteristics of their children without feeling responsible for having caused them. Children who have difficulty adjusting to change may have behavior problems when a new baby arrives or at the time of school entry. In addition, pointing out the child’s temperament may allow for adjustment in parenting styles. Behavioral and emotional problems may develop when the temperamental characteristics of children and parents are in conflict. For example, if parents who keep an irregular schedule have a child who is not readily adaptable, behavioral difficulties are more likely than if the child has parents who have predictable routines.

### Psychologic Influences: Attachment and
Contingency

The influence of the child-rearing environment dominates most current models of development. Infants in hospitals and orphanages, devoid of opportunities for attachment, have severe developmental deficits. Attachment refers to a biologically determined tendency of a young child to seek proximity to the parent during times of stress and also to the relationship that allows securely attached children to use their parents to reestablish a sense of well-being after a stressful experience. Insecure attachment may be predictive of later behavioral and learning problems.

At all stages of development, children progress optimally when they have adult caregivers who pay attention to their verbal and nonverbal cues and respond accordingly. In early infancy, such contingent responsiveness to signs of overarousal or underarousal helps maintain infants in a state of quiet alertness and fosters autonomic self-regulation. Contingent responses (reinforcement depending on the behavior of the other) to nonverbal gestures create the groundwork for the shared attention and reciprocity that are critical for later language and social development. Children learn best when new challenges are just slightly more difficult than what they have already mastered, a degree of difficulty dubbed the “zone of proximal development.” Psychologic forces, such as attention problems (see Chapter 49) or mood disorders (see Chapter 39), will have profound effects on many aspects of an older child's life.

Social Factors: Family Systems and the Ecologic Model

Contemporary models of child development recognize the critical importance of influences outside the mother–child dyad. Fathers play critical roles, both in their direct relationships with their children and in supporting mothers. As traditional nuclear families become less dominant, the influence of other family members (grandparents, foster and adoptive parents, same-sex partners) becomes increasingly important. Children are increasingly raised by unrelated caregivers while parents work or while they are in foster care.

Families function as systems, with internal and external boundaries, subsystems, roles, and rules for interaction. In families with rigidly defined parental subsystems, children may be denied any decision-making, exacerbating rebelliousness. In families with poorly defined parent–child boundaries, children
may be required to take on responsibilities beyond their years or may be recruited to play a spousal role.

Family systems theory recognizes that individuals within systems adopt implicit roles. Although birth order does not have long-term effects on personality development, within families the members take on different roles. One child may be the troublemaker, whereas another is the negotiator and another is quiet. Changes in one person's behavior affects every other member of the system; roles shift until a new equilibrium is found. The birth of a new child, attainment of developmental milestones such as independent walking, the onset of nighttime fears, and the death of a grandparent are all changes that require renegotiation of roles within the family and have the potential for healthy adaptation or dysfunction.

The family system, in turn, functions within the larger systems of extended family, subculture, culture, and society. Bronfenbrenner's ecologic model depicts these relationships as concentric circles, with the parent–child dyad at the center (with associated risks and protective factors) and the larger society at the periphery. Changes at any level are reflected in the levels above and below. The shift from an industrial economy to one based on service and information is an obvious example of societal change with profound effects on families and children.

**Unifying Concepts: The Transactional Model, Risk, and Resilience**

The *transactional model* proposes that a child's status at any point in time is a function of the interaction between biologic and social influences. The influences are bidirectional: biologic factors, such as temperament and health status, both affect the child-rearing environment and are affected by it. A premature infant may cry little and sleep for long periods; the infant's depressed parent may welcome this behavior, setting up a cycle that leads to poor nutrition and inadequate growth. The child's failure to thrive may reinforce the parent's sense of failure as a parent. At a later stage, impulsivity and inattention associated with early, prolonged undernutrition may lead to aggressive behavior. The cause of the aggression in this case is not the prematurity, the undernutrition, or the maternal depression, but the interaction of all these factors (Fig. 18.3). Conversely, children with biologic risk factors may nevertheless do well developmentally if the child-rearing environment is supportive. Premature
infants with electroencephalographic evidence of neurologic immaturity may be at increased risk for cognitive delay. This risk may only be realized when the quality of parent–child interaction is poor. When parent–child interactions are optimal, prematurity carries a reduced risk of developmental disability.

An estimate of developmental risk can begin with risk factors, such as low income, limited parental education, and lack of neighborhood resources. Stress and anxiety in pregnancy are associated with cognitive, behavioral, and emotional problems in the child. Early stress may have effects on aging mediated by shortening of telomere length, a link to health disparities. Risk for negative outcomes over time increases exponentially as a result of declining plasticity and accumulation of risk factors (both behavioral and environmental). Interventions are most effective in young children; over time, risk increases as the ability to change decreases.

Children growing up in poverty experience multiple levels of developmental risk: increased exposure to biologic risk factors, such as environmental lead and undernutrition; lack of stimulation in the home; and decreased access to interventional education and therapeutic experiences. As they respond by withdrawal or acting out, they further discourage positive stimulation from those around them. Children of adolescent mothers are also at risk. When early intervention programs provide timely, intensive, comprehensive, and prolonged
services, at-risk children show marked and sustained upswings in their developmental trajectory. Early identification of children at developmental risk, along with early intervention to support parenting, is critically important.

Children can have appropriate developmental trajectories despite childhood trauma. Resilience is the ability to withstand, adapt to, and recover from adversities. There are several resilience factors that can be modified: a positive appraisal or outlook and good executive functioning (see Chapter 48); nurturing parenting (see Chapter 19); good maternal mental health, good self-care skills, and consistent household routines; and an understanding of trauma. The personal histories of children who overcome poverty often include at least one trusted adult (parent, grandparent, teacher) with whom the child has a special, supportive, close relationship. Pediatric providers are positioned to target and bolster resilience in their patients and families.

Developmental Domains and Theories of Emotion and Cognition

Child development can also be tracked by the child's developmental progress in particular domains, such as gross motor, fine motor, social, emotional, language, and cognition. Within each of these categories are developmental lines or sequences of changes leading up to particular attainments. Developmental lines in the gross motor domain, from rolling to creeping to independent walking, are clear. Others, such as the line leading to the development of conscience, are subtler.

The concept of a developmental line implies that a child passes through successive stages. Several psychoanalytic theories are based on stages as qualitatively different epochs in the development of emotion and cognition (Table 18.2). In contrast, behavioral theories rely less on qualitative change and more on the gradual modification of behavior and accumulation of competence.

### Psychoanalytic Theories

At the core of **Freudian theory** is the idea of body-centered (or broadly, “sexual”) drives; the emotional health of both the child and the adult depends on adequate resolution of these conflicts. Although Freudian ideas have been challenged, they opened the door to subsequent theories of development.

**Erikson** recast Freud's stages in terms of the emerging personality (see Table 18.2). The child's sense of basic trust develops through the successful negotiation of infantile needs. As children progress through these psychosocial stages, different issues become salient. It is predictable that a toddler will be preoccupied with establishing a sense of autonomy, whereas a late adolescent may be more focused on establishing meaningful relationships and an occupational identity. Erikson recognized that these stages arise in the context of Western European societal expectations; in other cultures, the salient issues may be quite different.

Erikson's work calls attention to the intrapersonal challenges facing children at different ages in a way that facilitates professional intervention. Knowing that the salient issue for school-age children is industry vs inferiority, pediatricians inquire about a child's experiences of mastery and failure and (if necessary) suggest ways to ensure adequate successes.

### Cognitive Theories

Cognitive development is best understood through the work of **Piaget**. A central tenet of Piaget's work is that cognition changes in *quality*, not just quantity (see Table 18.2). During the sensorimotor stage, an infant's thinking is tied to immediate sensations and a child's ability to manipulate objects. The concept of “in” is embodied in a child's act of putting a block into a cup. With the arrival of language, the nature of thinking changes dramatically; symbols increasingly take the place of objects and actions. Piaget described how children actively construct knowledge for themselves through the linked processes of *assimilation* (taking in new experiences according to existing schemata) and *accommodation*
(creating new patterns of understanding to adapt to new information). In this way, children are continually and actively reorganizing cognitive processes.

Piaget's basic concepts have held up well. Challenges have included questions about the timing of various stages and the extent to which context may affect conclusions about cognitive stage. Children's understanding of cause and effect may be considerably more advanced in the context of sibling relationships than in the manipulation and perception of inanimate objects. In many children, logical thinking appears well before puberty (even in toddlers), the age postulated by Piaget. Of undeniable importance is Piaget's focus on cognition as a subject of empirical study, the universality of the progression of cognitive stages, and the image of a child as actively and creatively interpreting the world.

Piaget's work is of special importance to pediatricians for 3 reasons: (1) Piaget's observations provide insight into many puzzling behaviors of infancy, such as the common exacerbation of sleep problems at 9 and 18 mo of age; (2) Piaget's observations often lend themselves to quick replication in the office, with little special equipment; and (3) open-ended questioning, based on Piaget's work, can provide insights into children's understanding of illness and hospitalization.

Based on cognitive development, Kohlberg developed a theory of moral development in 6 stages, from early childhood through adulthood. Preschoolers' earliest sense of right and wrong is egocentric, motivated by externally applied controls. In later stages, children perceive equality, fairness, and reciprocity in their understanding of interpersonal interactions through perspective taking. Most youth will reach stage 4, conventional morality, by mid- to late adolescence. The basic theory has been modified to distinguish morality from social conventions. Whereas moral thinking considers interpersonal interactions, justice, and human welfare, social conventions are the agreed-on standards of behavior particular to a social or cultural group. Within each stage of development, children are guided by the basic precepts of moral behavior, but they also may take into account local standards, such as dress code, classroom behavior, and dating expectations. Additional studies have even demonstrated some protomorality in infants.

**Behavioral Theory**

This theoretical perspective distinguishes itself by its lack of concern with a child's inner experience. Its sole focus is on observable behaviors and measurable factors that either increase or decrease the frequency with which
these behaviors occur. No stages are implied; children, adults, and indeed animals all respond in the same way. In its simplest form, the behaviorist orientation asserts that behaviors that are reinforced occur more frequently; behaviors that are punished or ignored occur less frequently. Reinforcement may be further divided into positive reinforcement, when a reward or attention increases the chance of a behavior occurring, and negative reinforcement, when removal of an aversive stimulus increases the frequency of the behavior. For example, a teacher who allows students who do the homework Monday through Thursday not to do the assignment on Friday, is using negative reinforcement to motivate homework completion during the week.

The strengths of behavioral theory are its simplicity, wide applicability, and conduciveness to scientific verification. A behavioral approach lends itself to interventions for various common problems, such as temper tantrums, aggressive preschool behavior, and eating disorders in which behaviors are broken down into discrete units. In cognitively limited children and children with autism spectrum disorder, behavioral interventions using applied behavior analysis approaches have demonstrated the ability to teach new, complex behaviors. Applied behavior analysis has been particularly useful in the treatment of early-diagnosed autism (see Chapter 54). However, when misbehavior is symptomatic of an underlying emotional, perceptual, or family problem, an exclusive reliance on behavior therapy risks leaving the cause untreated. Behavioral approaches can be taught to parents for application at home.

**Theories Used in Behavioral Interventions**

An increasing number of programs or interventions (within and outside the physician's office) are designed to influence health behaviors; some of these models are based on behavioral or cognitive theory or may have attributes of both. The most commonly employed models are the Health Belief Model, Theory of Reasoned Action, Theory of Planned Behavior, Social Cognitive Theory, and Transtheoretical Model, also known as Stages of Change Theory (see Chapter 17). Pediatricians should be aware of these models and their similarities and differences (Table 18.3). Interventions based on these theories have been designed for children and adolescents in community, clinic, and hospital-based settings.

**RISK-RELATED BELIEFS AND EMOTIONAL RESPONSES**

| Belief that one is at risk if one does not engage in the behavior, and that the consequences may be severe; may include actually experiencing negative emotions or symptoms and coping with them | One feels at risk with regard to a negative outcome or disease. | Perceived susceptibility/severity (perceived threat) | — | — | Emotional coping responses/expectancies about environmental cues |

**INTENTION/COMMITMENT/PLANNING**

| Intending or planning to perform the behavior; setting goals or making a commitment to perform the behavior | One has formed strong behavioral intentions to engage in the behavior; one has set realistic goals or made a firm commitment to engage in the behavior. | — | Behavioral intentions | Behavioral intentions | Self-control/self-regulation |

**Motivational interviewing** is a technique often used in clinical settings to bring about behavior change, as discussed in detail in Chapter 17. Briefly, the goal is to enhance an individual's motivation to change behavior by exploring and overcoming ambivalence. The therapist is a partner rather than an authority figure and recognizes that, ultimately, the patient has control over his or her choices.

**Statistics Used in Describing Growth and Development**

(See Chapter 27.)

In everyday use, the term *normal* is synonymous with *healthy*. In a statistical
sense, *normal* means that a set of values generates a normal (bell-shaped or gaussian) distribution. This is the case with anthropometric quantities, such as height and weight, and with many developmental measures, such as intelligence quotient (IQ). For a **normally distributed measurement**, a histogram with the quantity (height, age) on the x axis and the frequency (the number of children of that height, or the number who stand on their own at that age) on the y axis generates a bell-shaped curve. In an ideal bell-shaped curve, the peak corresponds to the arithmetic **mean** (average) of the sample, as well as to the median and the mode. The **median** is the value above and below which 50% of the observations lie; the **mode** is the value having the highest number of observations. Distributions are termed **skewed** if the mean, median, and mode are not the same number.

The extent to which observed values cluster near the mean determines the width of the bell and can be described mathematically by the **standard deviation** (SD). In the ideal normal curve, a range of values extending from 1 SD below the mean to 1 SD above the mean includes approximately 68% of the values, and each “tail” above and below that range contains 16% of the values. A range encompassing ±2 SD includes 95% of the values (with the upper and lower tails each comprising approximately 2.5% of the values), and ±3 SD encompasses 99.7% of the values (Table 18.4 and Fig. 18.4).

### Table 18.4

</tr>
<tr>
<td>±3</td>
<td>99.7</td>
</tr>
</tbody>
</table>
For any single measurement, its distance away from the mean can be expressed in terms of the number of SDs (also called a z score); one can then consult a table of the normal distribution to find out what percentage of measurements fall within that distance from the mean. Software to convert anthropometric data into z scores for epidemiologic purposes is available. A measurement that falls “outside the normal range”—arbitrarily defined as 2, or sometimes 3, SDs on either side of the mean—is atypical, but not necessarily indicative of illness. The further a measurement (height, weight, IQ) falls from the mean, the greater is the probability that it represents not simply normal variation, but rather a different, potentially pathologic condition.

Another way of relating an individual to a group uses percentiles. The **percentile** is the percentage of individuals in the group who have achieved a certain measured quantity (e.g., height of 95 cm) or a developmental milestone (e.g., walking independently). For anthropometric data, the percentile cutoffs can be calculated from the mean and SD. The 5th, 10th, and 25th percentiles correspond to −1.65 SD, −1.3 SD, and −0.7 SD, respectively. **Fig. 18.4** demonstrates how frequency distributions of a particular parameter (height) at different ages relate to the percentile lines on the growth curve.

Chen Y, Baram TZ. Toward understanding how early-life stress

No force may be more important to a child's development than the family. Many factors contribute to the family's influence, including family structure, functioning, economics, and stress. Parenting provides the foundation to promote healthy child development and to protect against adverse outcomes. The term positive parenting describes an approach to parenting that achieves these goals.

The Importance of Parenting

Interactions between parents and their children provide stimulation that promotes the development of language, early cognitive skills, and school readiness. Less frequent participation in interactive parenting practices, such as reading aloud to children, eating family meals, and participating in family outings, predicts an increased risk of developmental delay in low-income families. Interventions that increase parents' reading to children promote positive developmental outcomes such as early language and literacy development.

The affective nature of the parent–child interaction is important for both cognitive and social emotional development. Persistent maternal depression has been linked to decreases in child IQ scores at school entry. Early exposure to positive parenting has been associated with lower rates of childhood depression, risky behavior, delinquency, injuries, behavior problems, and bullying, with increased likelihood of empathy and prosocial behavior. The beneficial effects of early maternal sensitivity on social competence have been found to persist into adulthood, suggesting that early life experiences have a long-term impact.

Positive parenting practices, such as using a warm, supporting approach during conflict, and negative practices, such as maternal aggression, have been associated with MRI changes in adolescent brain development in boys. Animal
models have been used to demonstrate the detrimental effects of stressful early life experiences, characterized by maternal separation or decreased maternal responsiveness. Offspring raised in these environments were more likely to exhibit fearful behavior. Differences were noted in brain architecture and epigenetic changes that alter gene expression (see Chapter 100). Importantly in these animal models, increased maternal nurturing could protect against these changes.

The Role of the Family

Parenting occurs in the context of a family unit, and there is significant diversity among families. Family makeup has changed greatly over the last several decades in the United States, with increases in cultural, ethnic, and spiritual diversity and in single-parent families. In 2014, based on U.S. Census Bureau data, 26% of children lived in single-parent families, and 62% lived in households with 2 married parents. These patterns differ when race and ethnicity are considered; the majority of children in white and Asian American families live in households with married parents, whereas only 31% of black children do, with about half (57%) living in single-parent households. Although children can thrive in all types of family environments, data suggest that, on average, children living in single-parent families fare less well than their counterparts. Children in single-parent households are 3 times more likely to be living below the poverty line than those in families with 2 married parents. Mothers are the primary breadwinner in 40% of families, an increase from 10% in 1960, yet families led by unmarried mothers tend to fare worse than those led by unmarried fathers.

Families are also changing how they spend time together. Media use for both parents and children has increased dramatically with the advent of tablets and smartphones. Over the last several decades, as women have entered the workforce, increasing numbers of children participate in childcare, and in after-school activities. Racial, ethnic, and economic disparities are found in those participating in these activities as well. More children from economically advantaged families participate in extracurricular activities; low-income and black families worry more about the availability of high-quality programming for their children.

The U.S. Census Bureau projects that by 2040 the majority of the U.S. population will consist of minorities, with steady increases in foreign-born populations and individuals reporting 2 or more ethnicities. This diversity will
impact family composition, as well as family values and approaches to parenting. Culture refers to a pattern of social norms, values, language, and behavior shared by a group of individuals, and parents are thus affected by their culture. Parenting approaches to self-regulation vary across cultures with respect to promoting attention, compliance, delayed gratification, executive function, and effortful control.

Parenting Styles

Three styles of parenting are authoritative, authoritarian, and permissive, each with varying approaches to parental control and responsiveness. A fourth style, neglectful parenting, has also been suggested. Authoritative parenting describes a parenting style that is warm, responsive, and accepting but that also sets expectations for behavior and achievement. Differences are approached with reasoning and discussion rather than by exerting control. Authoritarian parenting is characterized by a high degree of parental control in which obedience is expected. Punishment is often employed to foster compliance rather than verbal discussion. Permissive parenting refers to an approach characterized by warmth and acceptability but with few rules or expectations, and the child's autonomy is highly valued. This contrasts with neglectful parenting, similarly characterized by few rules or expectations, but also by limited parental warmth or responsiveness.

Studies have found that an authoritative parenting style is most likely to be associated with positive child outcomes across multiple domains, including educational achievement and social-emotional competence. Parental supervision, consistency, and open communication reduce risky behaviors in adolescents. Harsh, inconsistent, and coercive discipline and physical punishment have been associated with increases in emotional and behavioral problems and may be a risk factor for child maltreatment. Much of the initial research on parenting styles was based on select U.S. populations (white middle-class families). Some suggest that an authoritarian parenting style may be beneficial in certain environments, and further work is needed to account for the economic and demographic changes in U.S. families.

Child Temperament
As evidenced by the effects of family structure, culture/ethnicity, and economics, parenting does not occur in isolation. The child also brings to the parent–child relationship their own personality, or temperament, a collection of traits that stay relatively constant over time (see Chapter 18). Nine traits have been identified in child temperament: activity level, predictability of behavior, reaction to new environments, adaptability, intensity, mood, distractibility, persistence, and sensitivity. Most infants (65%) fit into 1 of 3 groups: easy (40%), difficult (10%), and slow to warm up (15%), and these patterns are relatively stable over time. Although variations in temperament traits are part of normal human variations, certain behavioral difficulties have been associated with certain temperament types. For example, a difficult temperament has been associated with the development of externalizing behavior (e.g., acting-out, disruptive, and aggressive behavior) and not surprisingly, a slow-to-warm-up temperament with internalizing behavior (e.g., anxious and moody behavior).

Temperament traits are relatively stable, but how the child functions is affected by the environment, especially by parenting and the “goodness of fit” between the parent and child. Children with difficult temperament characteristics respond more negatively to neglectful parenting, and children of all temperament groups respond positively to responsive and sensitive parenting. Moreover, childhood traits such as low adaptability, impulsivity, and low frustration tolerance may lead some parents to engage in more negative parenting practices. These findings illustrate the interactive nature between parent and child, with parental behavior shaping child behavior, and vice versa.

**Child Behavioral Problems**

Emotional and behavioral problems are common in childhood. Indeed, many patterns of challenging behavior are normative in childhood, such as the tantrums and negativism seen in toddlers. Approximately 7.4% of children 4-17 yr of age have emotional and behavioral problems, defined as either elevated symptoms or serious overall difficulties. Emotional and behavioral problems have been associated with mother-only households, poverty, and developmental disorders. In preschool children, rates of clinically significant challenging behavior have been estimated at 8–17%, again with an increased prevalence among children living in poverty. The association between challenging behavior and poverty is likely multifactorial, mediated by increases in family stress, more negative parenting behaviors, lower-quality childcare, parental mental health
issues, and community violence. Evidence also suggests that some types of challenging behavior apparent at a young age may persist. In one study, a high percentage of preschoolers identified as having both internalizing and externalizing behavior at age 3 yr continued to have similar difficulties at 6 yr.

Other risk factors for the development of challenging behavior include trauma and developmental problems. **Adverse childhood experiences (ACEs)**, defined as abuse and neglect, caregiver substance use, caregiver depression, and domestic violence or criminality, are often present during childhood. In the National Survey of Child and Adolescent Well-Being, 42% of children under 6 yr of age in the child welfare system had experienced 4 or more ACEs. Further, there was a cumulative relationship between emotional and behavioral problems and ACE exposure, with children exposed to 4 or more ACEs almost 5 times more likely to have internalizing problems than children not exposed to ACEs. A similar relationship was found for externalizing problems. Studies involving children with developmental disabilities suggest emotional and behavioral problems occur more frequently in this group than in typically developing children. These children may have delays in self-regulation and communication skills as well as increased family stress, which contribute to the increased likelihood of behavioral challenges.

### Defining Positive Parenting

The precise definition of the components of positive parenting are lacking. Positive parenting must ensure the child's safety, health, and nutrition as well as developmental promotion. Common attributes of positive parenting include: caring, leading, providing, teaching, and communicating with the child in a consistent and unconditional manner. To account for the long-term goals of successful parenting in promoting optimal emotional, behavioral, and developmental outcomes, some suggest the term **purposeful parenting** and related characteristics (**Table 19.1**). The characterization of an ideal approach to parenting will evolve with ever-changing societal norms, but key components such as those in **Table 19.1** will likely remain fundamental.

</table>
Parenting as an Intervention

The influence of parenting practices on child behavior, development, and overall adjustment has led to efforts to teach parenting as a method of primary prevention. The Video Interaction Project (VIP) uses a coaching and education model with recorded parent–child interactions to foster positive parenting behavior. These parenting behaviors range from reading aloud to encouraging interactive play. In an urban, low-income, primary care setting, parent and child outcomes for the VIP group were compared to those from a lower-intensity intervention (parent mailings encouraging positive parenting behaviors) and a control group. VIP produced the most robust impacts on socioemotional outcomes, including increased attention and decreased distress with separation, hyperactivity, and externalizing behavior in toddlers.

Positive parenting as a public health intervention has resulted in decreased rates of substantiated child maltreatment cases, out-of-home placements, and child maltreatment injuries. Other effective public health approaches include home-visiting programs, which have been deployed to at-risk families in an effort to improve maternal and child outcomes. The Maternal, Infant and Early Childhood Home Visiting Program, authorized as part of the Affordable Care
Act of 2010 and again in 2015, is part of the Medicare Access and Children's Health Insurance Program (CHIP) Reauthorization Act. A key component of home-visiting programs is the promotion of positive parenting behavior to foster child developmental and school readiness. Group parenting programs have been deployed as primary prevention to promote emotional and behavioral adjustment in young children. There is moderate-quality evidence that group-based parenting programs may improve parent–child interactions. These programs typically employ praise, encouragement, and affection and have been associated with improved self-esteem and social and academic competence.

Parenting behaviors have also been employed as an intervention to treat emotional and behavioral problems in young children. Parenting interventions such as Incredible Years, Triple P Positive Parenting Program, and New Forrest Parenting Program are effective for at least short-term improvements in child conduct problems, parental mental health, and parenting practices. Also called parent training programs, most teach the importance of play, rewards, praise, and consistent discipline and allow parents to practice new skills. This active-learning component distinguishes parent training programs from educational programs, which have been shown to be less effective.

Teaching emotional communication skills and positive parent–child interaction skills are associated with parent training programs that demonstrate a greater increase in parenting skills (Table 19.2). Several components are associated with programs that show greater improvements in child externalizing behavior: teaching parents to use time-out correctly, respond consistently, and interact positively with their children. All successful programs require parents to practice parenting skills during the program.

Helping children identify and express emotion

**Disciplinary communication**
- Setting clear, appropriate, and consistent expectations
- Establishing limits and rules
- Choosing and following through with appropriate consequences

**Discipline and behavior management**
- Understanding child misbehavior
- Understanding appropriate discipline strategies
- Using safe and appropriate monitoring and supervision practices
- Using reinforcement techniques
- Using problem solving for challenging behavior
- Being consistent

**Promoting children's social skills and prosocial behavior**
- Teaching children to share, cooperate, and get along with others
- Using good manners

**Promoting children's cognitive or academic skills**
- Fostering language and literacy development
- Promoting school readiness

Adapted from US Centers for Disease Control and Prevention: Parent training programs: insight for practitioners, Atlanta, 2009, CDC.

Parents have been found to benefit from participation in parenting programs. Before their participation, parents experienced a loss of control, self-blame, social isolation, and difficulty dealing with their child's emotional and behavioral problems, all of which improved after participation. The few studies that have assessed the long-term efficacy of parent-training programs suggest overall positive child outcomes, but also periods of relapse during which the use of positive parenting skills decreased. Use of social supports is associated with positive child outcomes and may be an important program component when considering long-term success.

**The Role of the Pediatrician**

Pediatricians and other pediatric practitioners have a primary responsibility to support the needs of parents and their children. Numerous programs and interventions have been developed to be delivered effectively and efficiently in the primary care setting.

The American Academy of Pediatrics published Bright Futures and the associated Guidelines for Preventive Care to standardize child health promotion and prevention in primary care. A substantial amount of the content in Bright Futures maps to the positive-parenting domains of safety, feeding, developmental promotion, and protection. Implementing Bright Futures guidelines in health supervision visits is an important way for pediatric practitioners to support the promotion of positive parenting in practice.
Reading aloud to children is a powerful strategy to promote language development, early literacy, and positive parent–child interaction. The Reach Out and Read program is a primary care–based intervention that trains practitioners to encourage parents to read with their child and provides books to at-risk families. In the absence of a formal partnership with Reach Out and Read, practitioners should promote the benefits of reading aloud to children and support parents in their efforts to develop habits that incorporate reading into daily routines.

In addition to VIP described earlier, other primary care models to promote parenting have been studied. The Healthy Steps for Young Children program is a strengths-based approach delivered in the primary care setting from infancy to age 3 yr. Healthy Steps promotes changes in parents' knowledge, beliefs, and psychologic health and changes in parenting behaviors using a variety of methods delivered in the office setting by the practitioner and Healthy Steps specialists and through home visits. Extensive evaluations have shown improvements in parental well-being, parenting practices, and parent–child attachment and decreased child behavior problems. Another promising approach uses community health workers and nurses to provide parenting education and allow mothers to practice parenting skills outside the office setting.

If participation in a formal parenting program is not possible, pediatric practitioners can still implement a systematic approach to support the needs of parents and their children. Practitioners can take advantage of materials in the public domain from national organizations devoted to child and family health, such as ZERO TO THREE (https://www.zerotothree.org/) and the American Academy of Pediatrics https://www.aap.org/). The U.S. Centers for Disease Control and Prevention (CDC) also provides evidenced-based parenting resources (https://www.cdc.gov/parents/essentials/index.html). Additional components include early identification of parents' concerns, addressing concerns in a supportive and nonjudgmental way, and providing linkage to treatment services when appropriate.

Parents want more information about child development, but parents of children with behavior problems often feel stigmatized and isolated. Practitioners are encouraged to be supportive and optimistic in their interactions with families, to develop a partnership aimed at promoting parent and child health (see Chapter 17). Practitioners may also encourage parents to practice new skills briefly in the office setting before trying a new skill at home. Active modeling by the practitioner using “teachable moments” may also be effective.
Bibliography

The developing fetus is affected by social and environmental influences, including maternal nutritional status; substance use (both legal and illicit); and psychologic trauma. Correspondingly, the psychologic alterations experienced by the parents during the gestation profoundly impact the lives of all members of the family. Growing evidence implicates the importance of these and other maternal and paternal experiences that occur during and prior to the pregnancy (and even among members of earlier generations) on the subsequent development of the individual (epigenetic effects; see Chapter 100). The complex interplay among these forces and the somatic and neurologic transformations occurring in the fetus influence growth and behavior at birth, through infancy, and potentially throughout the individual's life.

**Somatic Development**

**Embryonic Period**

Table 20.1 lists milestones of prenatal development. By 6 days postconception age, as implantation begins, the embryo consists of a spherical mass of cells with a central cavity (the blastocyst). By 2 wk, implantation is complete and the uteroplacental circulation has begun; the embryo has 2 distinct layers, endoderm and ectoderm, and the amnion has started to form. By 3 wk, the 3rd primary germ layer (mesoderm) has appeared, along with a primitive neural tube and blood vessels. Paired heart tubes have begun to pump.

During wk 4-8, lateral folding of the embryologic plate, followed by growth at the cranial and caudal ends and the budding of arms and legs, produces a human-like shape. Precursors of skeletal muscle and vertebrae (somites) appear, along with the branchial arches that will form the mandible, maxilla, palate, external ear, and other head and neck structures. Lens placodes appear, marking the site of future eyes; the brain grows rapidly. By the end of wk 8, as the embryonic period closes, the rudiments of all major organ systems have developed; the crown-rump length is 3 cm.

### Fetal Period

From the 9th wk on (fetal period), somatic changes consist of rapid body growth as well as differentiation of tissues, organs, and organ systems. Fig. 20.1 depicts changes in body proportion. By wk 10, the face is recognizably human. The midgut returns to the abdomen from the umbilical cord, rotating counterclockwise to bring the stomach, small intestine, and large intestine into their normal positions. By wk 12, the gender of the external genitals becomes clearly distinguishable. Lung development proceeds, with the budding of bronchi, bronchioles, and successively smaller divisions. By wk 20-24, primitive alveoli have formed and surfactant production has begun; before that time, the absence of alveoli renders the lungs useless as organs of gas exchange.
During the 3rd trimester, weight triples and length doubles as body stores of protein, fat, iron, and calcium increase.

**Neurologic Development**

During the 3rd wk, a neural plate appears on the ectodermal surface of the trilaminar embryo. Infolding produces a neural tube that will become the central nervous system and a neural crest that will become the peripheral nervous system. Neuroectodermal cells differentiate into neurons, astrocytes, oligodendrocytes, and ependymal cells, whereas microglial cells are derived from mesoderm. By the 5th wk, the 3 main subdivisions of forebrain, midbrain, and hindbrain are evident. The dorsal and ventral horns of the spinal cord have begun to form, along with the peripheral motor and sensory nerves. Myelinization begins at midgestation and continues for years.

By the end of the embryonic period (wk 8), the gross structure of the nervous system has been established. On a cellular level, neurons migrate outward to form the 6 cortical layers. Migration is complete by the 6th mo, but differentiation continues. Axons and dendrites form synaptic connections at a rapid pace, making the central nervous system vulnerable to teratogenic or hypoxic influences throughout gestation. Fig. 20.2 shows rates of increase in DNA (a marker of cell number), overall brain weight, and cholesterol (a marker
of myelinization). The prenatal and postnatal peaks of DNA probably represent rapid growth of neurons and glia, respectively. The glial cells are important in shaping the brain and neuronal circuits. The various types of glial cells are needed for the formation of axonal myelin sheaths, a range of functions in the formation and maintenance of neural pathways, and removal of waste (the brain has no lymphoid system for this task).

By the time of birth, the structure of the brain is complete. However, many cells will undergo apoptosis (cell death). Synapses will be pruned back substantially, and new connections will be made, largely as a result of experience. Many psychiatric and developmental disorders are thought to result at least in part from disruptions in the functional connectivity of brain networks. Disorders of connectivity may begin during fetal life; MRI studies provide a developmental timetable for such connections that lend support to the possible role of disruptions in the establishment of such connections.

**Behavioral Development**

No behavioral evidence of neural function is detectable until the 3rd mo. Reflexive responses to tactile stimulation develop in a craniocaudal sequence.
By wk 13-14, breathing and swallowing motions appear. The grasp reflex appears at 17 wk and is well developed by 27 wk. Eye opening occurs around 26-28 wk. By midgestation, the full range of neonatal movements can be observed.

During the 3rd trimester, fetuses respond to external stimuli with heart rate elevation and body movements, which can be observed with ultrasound (see Chapter 115). Reactivity to auditory (vibroacoustic) and visual (bright light) stimuli vary, depending on their behavioral state, which can be characterized as quiet sleep, active sleep, or awake. Individual differences in the level of fetal activity are usually noted by mothers. Fetuses will preferentially turn to light patterns in the configuration of the human face. Fetal movement is affected by maternal medications and diet, increasing after ingestion of caffeine. Behavior may be entrained to the mother's diurnal rhythms: asleep during the day, active at night. Abnormal fetal movement patterns are found in neonates with subsequent muscular or neurologic abnormalities.

Fetal movement increases in response to a sudden auditory tone but decreases after several repetitions. This demonstrates habituation, a basic form of learning in which repeated stimulation results in a response decrement. If the tone changes in pitch, the movement increases again, which is evidence that the fetus distinguishes between a familiar, repeated tone and a novel tone. Habituation improves in older fetuses and decreases in neurologically impaired or physically stressed fetuses. Similar responses to visual and tactile stimuli have been observed.

**Psychologic Changes in Parents**

Many psychologic changes occur during pregnancy. An unplanned pregnancy may be met with anger, denial, or depression. Ambivalent feelings are the norm, whether or not the pregnancy was planned. Elation at the thought of producing a baby and the wish to be the perfect parent compete with fears of inadequacy and of the lifestyle changes that parenting will impose. Parents of an existing child may feel protective of the child, worried that the child may feel less valued. Old conflicts may resurface as a woman psychologically identifies with her own mother and with herself as a child. The father-to-be faces similar mixed feelings, and problems in the parental relationship may intensify.

Tangible evidence that a fetus exists as a separate being, whether as a result of ultrasonic visualization or awareness of fetal movements known as quickening...
(at 16-20 wk), often heightens a woman's feelings. Parents worry about the fetus's healthy development and mentally rehearse what they will do if the child is malformed, including their response to evidence of abnormality through ultrasound, amniocentesis, or other fetal laboratory tests. Toward the end of pregnancy, a woman becomes aware of patterns of fetal activity and reactivity and begins to ascribe to her fetus an individual personality and an ability to survive independently. Appreciation of the psychologic vulnerability of the expectant parents and of the powerful contribution of fetal behavior facilitates supportive clinical intervention.

**Threats to Fetal Development**

Mortality and morbidity are highest during the prenatal period (see Chapter 112). An estimated 50% of all pregnancies end in spontaneous abortion, including 10–15% of all clinically recognized pregnancies. The majority occur in the 1st trimester. Some occur as a result of chromosomal or other abnormalities.

Teratogens associated with gross physical and mental abnormalities include various infectious agents (e.g., toxoplasmosis, rubella, syphilis, Zika virus); chemical agents (e.g., mercury, thalidomide, antiepileptic medications, ethanol), high temperature, and radiation (see Chapters 115.6 and 736).

Teratogenic effects may also result in decreased growth and cognitive or behavioral deficits that only become apparent later in life. Nicotine has vasoconstrictor properties and may disrupt dopaminergic and serotonergic pathways. Prenatal exposure to cigarette smoke is associated with lower birthweight, stunting, and smaller head circumference, as well as changes in neonatal neurodevelopmental assessments. Later, these children are at increased risk for learning problems, attention and behavior disorders, and long-term health effects. Alcohol is a significant teratogen affecting physical development, cognition, and behavior (see Chapter 126.3). The effects of prenatal exposure to cocaine, also occurring through alternations in placental blood flow and in direct toxic effects to the developing brain, have been followed in several cohorts and are less dramatic than previously believed. Exposed adolescents show small but significant effects in behavior and functioning but may not show cognitive impairment. The associated risk factors, including other prenatal exposures (alcohol and cigarette co-use) as well as “toxic” postnatal environments frequently characterized by instability, multiple caregivers, and violence exposure remain significant (see Chapters 14 and 16).
The association between an inadequate nutrient supply to the fetus and low birthweight has been recognized for decades; this adaptation on the part of the fetus presumably increases the likelihood that the fetus will survive until birth. For any potential fetal insult, the extent and nature of its effects are determined by characteristics of the host as well as the dose and timing of the exposure. Inherited differences in the metabolism of ethanol, timing of exposure, and the mother's diet may explain the variability in fetal alcohol effects. Organ systems are most vulnerable during periods of maximum growth and differentiation, generally during the 1st trimester (organogenesis) (http://www2.epa.gov/children/children-are-not-little-adults details critical periods and specific developmental abnormalities).

Fetal adaptations or responses to an adverse situation in utero, termed fetal programming or developmental plasticity, have lifelong implications for the individual. Fetal programming may prepare the fetus for an environment that matches that experienced in utero. Fetal programming in response to some environmental and nutritional signals in utero increases the risk of cardiovascular disease, diabetes, and obesity in later life. These adverse long-term effects appear to represent a mismatch between fetal and neonatal environmental conditions and the conditions that the individual will confront later in life; a fetus deprived of adequate calories may or may not as a child or teenager face famine. One proposed mechanism for fetal programming is epigenetic imprinting, in which 1 of 2 alleles is turned off through environmentally induced epigenetic modification (see Chapters 97 and 100). Exposure to psychoactive drugs in utero produces drug–protein receptor interactions, affecting both nervous system development and neurotransmitter function. This dysregulation causes long-lasting effects on fetal growth and adult function and may have effects on future generations through these epigenetic changes.

Just as the fetal adaptations to the in utero environment may increase the likelihood of later metabolic conditions, the fetus adapts to the mother's psychologic distress. In response to the stressful environment, physiologic changes involving the hypothalamic-pituitary-adrenal axis and the autonomic nervous system occur. Dysregulation of these systems may explain the associations observed in some but not all studies between maternal distress and negative infant outcomes, including low birthweight, spontaneous abortion, prematurity, and decreased head circumference. In addition, children born to mothers experiencing high stress levels have been found to have higher rates of
inattention, impulsivity, conduct disorders, and cognitive changes. Although these changes may have been adaptive in primitive cultures, they are maladaptive in modern societies, leading to psychopathology. Genetic variability, timing of stress during sensitive periods, and the quality of postnatal parenting can attenuate or exacerbate these associations.

Regardless of gestational age, the newborn (neonatal) period begins at birth and includes the 1st mo of life. During this time, marked physiologic transitions occur in all organ systems, and the infant learns to respond to many forms of external stimuli. Because infants thrive physically and psychologically only in the context of their social relationships, any description of the newborn's developmental status has to include consideration of the parents' role as well.

Parental Role in Mother–Infant Attachment

Parenting a newborn infant requires dedication because a newborn's needs are urgent, continuous, and often unclear. Parents must attend to an infant's signals and respond empathically. Many factors influence parents' ability to assume this role.

Prenatal Factors

Pregnancy is a period of psychologic preparation for the profound demands of parenting. Women may experience ambivalence, particularly (but not exclusively) if the pregnancy was unplanned. If financial concerns, physical illness, prior miscarriages or stillbirths, or other crises interfere with psychologic preparation, the neonate may not be welcomed. For adolescent mothers, the demand that they relinquish their own developmental agenda, such as an active social life, may be especially burdensome.
The early experience of being mothered may establish unconsciously held expectations about nurturing relationships that permit mothers to “tune in” to their infants. These expectations are linked with the quality of later infant–parent interactions. Mothers whose early childhoods were marked by traumatic separations, abuse, or neglect may find it especially difficult to provide consistent, responsive care. Instead, they may reenact their childhood experiences with their own infants, as if unable to conceive of the mother–child relationship in any other way. Bonding may be adversely affected by several risk factors during pregnancy and in the postpartum period that undermine the mother–child relationship and may threaten the infant's cognitive and emotional development (Table 21.1).

Social support during pregnancy, particularly support from the father and close family members, is also important. Conversely, conflict with or abandonment by the father during pregnancy may diminish the mother's ability
to become absorbed with her infant. Anticipation of an early return to work may make some women reluctant to fall in love with their babies because of anticipated separation. Returning to work should be delayed for at least 6 wk, by which time feeding and basic behavioral adjustments have been established.

Many decisions have to be made by parents in anticipation of the birth of their child. One important choice is that of how the infant will be nourished. Among the important benefits of breastfeeding is its promotion of bonding. Providing breastfeeding education for the parents at the prenatal visit by the pediatrician and by the obstetrician during prenatal care can increase maternal confidence in breastfeeding after delivery and reduce stress during the newborn period (see Chapter 56).

Peripartum and Postpartum Influences

The continuous presence during labor of a woman trained to offer friendly support and encouragement (a doula) results in shorter labor, fewer obstetric complications (including cesarean section), and reduced postpartum hospital stays. Early skin-to-skin contact between mothers and infants immediately after birth may correlate with an increased rate and longer duration of breastfeeding. Most new parents value even a brief period of uninterrupted time in which to get to know their new infant, and increased mother–infant contact over the 1st days of life may improve long-term mother–child interactions. Nonetheless, early separation, although predictably very stressful, does not inevitably impair a mother's ability to bond with her infant. Early discharge home from the maternity ward may undermine bonding, particularly when a new mother is required to resume full responsibility for a busy household.

Postpartum depression may occur in the 1st wk or up to 6 mo after delivery and can adversely affect neonatal growth and development. Screening tools, such as the Edinburgh Postnatal Depression Scale (EPDS), are available for use during neonatal and infant visits to the pediatric provider. On the EPDS, scores of 0-8 indicate a low likelihood of depression (Table 21.2). Cutoff-score recommendations for further evaluation of depression have ranged from 9 to 13; thus any woman scoring 9 or above should be evaluated further. If postpartum depression is present, referral for mental healthcare will greatly accelerate recovery.

Table 21.2
Edinburgh Postnatal Depression Scale

Instructions for Users

1. The mother is asked to underline the response that comes closest to how she has been feeling in the previous 7 days.
2. All 10 items must be completed.
3. Care should be taken to avoid the possibility of the mother discussing her answers with others.
4. The mother should complete the scale herself, unless she has limited English or has difficulty with reading.
5. The Edinburgh Postnatal Depression Scale may be used at 6-8 wk to screen postnatal women. The child health clinic, a postnatal checkup, or a home visit may provide a suitable opportunity for its completion.

Edinburgh Postnatal Depression Scale

Name:
Address:
Baby's age:

Because you have recently had a baby, we would like to know how you are feeling. Please underline the answer that comes closest to how you have felt in the past 7 days, not just how you feel today.

Here is an example, already completed.

I have felt happy:
Yes, all the time
Yes, most of the time
No, not very often
No, not at all

This would mean: “I have felt happy most of the time” during the past week. Please complete the other questions in the same way.

In the past 7 days:

1. I have been able to laugh and see the funny side of things
   As much as I always could
   Not quite so much now
   Definitely not so much now
Not at all

2. I have looked forward with enjoyment to things
   As much as I ever did
   Rather less than I used to
   Definitely less than I used to
   Hardly at all

*3. I have blamed myself unnecessarily when things went wrong
   Yes, most of the time
   Yes, some of the time
   Not very often
   No, never

4. I have been anxious or worried for no good reason
   No, not at all
   Hardly ever
   Yes, sometimes
   Yes, very often

*5. I have felt scared or panicky for no very good reason
   Yes, quite a lot
   Yes, sometimes
   No, not much
   No, not at all

*6. Things have been getting on top of me
   Yes, most of the time I haven't been able to cope at all
   Yes, sometimes I haven't been coping as well as usual
   No, most of the time I have coped quite well
   No, I have been coping as well as ever

*7. I have been so unhappy that I have had difficulty sleeping
   Yes, most of the time
   Yes, sometimes
   Not very often
   No, not at all

*8. I have felt sad or miserable
   Yes, most of the time
   Yes, quite often
   Not very often
   No, not at all

*9. I have been so unhappy that I have been crying
The thought of harming myself has occurred to me
    Yes, quite often
    Sometimes
    Hardly ever
    Never

Response categories are scored 0, 1, 2, and 3 according to increased severity of the symptom. Items marked with an asterisk (*) are reverse-scored (i.e., 3, 2, 1, and 0). The total score is calculated by adding the scores for each of the 10 items. Users may reproduce the scale without further permission provided they respect copyright (which remains with the British Journal of Psychiatry) by quoting the names of the authors, the title, and the source of the paper in all reproduced copies.

The Infant's Role in Mother–Infant Attachment

The in utero environment contributes greatly but not completely to the future growth and development of the fetus. Abnormalities in maternal-fetal placental circulation and maternal glucose metabolism or the presence of maternal infection can result in abnormal fetal growth. Infants may be small or large for gestational age as a result. These abnormal growth patterns not only predispose infants to an increased requirement for medical intervention, but also may affect their ability to respond behaviorally to their parents.

Physical Examination

Examination of the newborn should include an evaluation of growth (see Chapter 20) and an observation of behavior. The average term newborn
weighs approximately 3.4 kg (7.5 lb); boys are slightly heavier than girls. Average weight does vary by ethnicity and socioeconomic status. The average length and head circumference are about 50 cm (20 in) and 35 cm (14 in), respectively, in term infants. Each newborn's growth parameters should be plotted on growth curves specific for that infant's gestational age to determine the appropriateness of size. Likewise, specific growth charts for conditions associated with variations in growth patterns have also been developed. The infant's response to being examined may be useful in assessing its vigor, alertness, and tone. Observing how the parents handle their infant, their comfort and affection, is also important. The order of the physical examination should be from the least to the most intrusive maneuver. Assessing visual tracking and response to sound and noting changes of tone with level of activity and alertness are very helpful. Performing this examination and sharing impressions with parents is an important opportunity to facilitate bonding (see Chapter 113).

**Interactional Abilities**

Soon after birth, neonates are alert and ready to interact and nurse. This first alert-awake period may be affected by maternal analgesics and anesthetics or fetal hypoxia. Neonates are nearsighted, having a fixed focal length of 8-12 inches, approximately the distance from the breast to the mother's face, as well as an inborn visual preference for faces. Hearing is well developed, and infants preferentially turn toward a female voice. These innate abilities and predilections increase the likelihood that when a mother gazes at her newborn, the baby will gaze back. The initial period of social interaction, usually lasting about 40 minutes, is followed by a period of somnolence. After that, briefer periods of alertness or excitation alternate with sleep. If a mother misses her baby's first alert-awake period, she may not experience as long a period of social interaction for several days. The hypothalamic-midbrain-limbic-paralimbic-cortical circuit of the parents interacts to support responses to the infants that are critical for effective parenting (e.g., emotion, attention, motivation, empathy, decision-making).

**Modulation of Arousal**

Adaptation to extrauterine life requires rapid and profound physiologic changes, including aeration of the lungs, rerouting of the circulation, and activation of the
intestinal tract. The necessary behavioral changes are no less profound. To obtain nourishment, to avoid hypo- and hyperthermia, and to ensure safety, neonates must react appropriately to an expanded range of sensory stimuli. Infants must become aroused in response to stimulation, but not so overaroused that their behavior becomes disorganized. Underaroused infants are not able to feed and interact; overaroused infants show signs of autonomic instability, including flushing or mottling, perioral pallor, hiccupping, vomiting, uncontrolled limb movements, and inconsolable crying.

**Behavioral States**

The organization of infant behavior into discrete behavioral states may reflect an infant's inborn ability to regulate arousal. Six states have been described: quiet sleep, active sleep, drowsy, alert, fussy, and crying. In the alert state, infants visually fixate on objects or faces and follow them horizontally and (within a month) vertically; they also reliably turn toward a novel sound, as if searching for its source. When overstimulated, they may calm themselves by looking away, yawning, or sucking on their lips or hands, thereby increasing parasympathetic activity and reducing sympathetic nervous activity. The behavioral state determines an infant's muscle tone, spontaneous movement, electroencephalogram pattern, and response to stimuli. In active sleep, an infant may show progressively less reaction to a repeated heelstick (habituation), whereas in the drowsy state, the same stimulus may push a child into fussing or crying.

**Mutual Regulation**

Parents actively participate in an infant's state regulation, alternately stimulating and soothing. In turn, they are regulated by the infant's signals, responding to cries of hunger with a letdown of milk (or with a bottle). Such interactions constitute a system directed toward furthering the infant's physiologic homeostasis and physical growth. At the same time, they form the basis for the emerging psychologic relationship between parent and child. Infants come to associate the presence of the parent with the pleasurable reduction of tension (as in feeding) and show this preference by calming more quickly for their mother than for a stranger. This response in turn strengthens a mother's sense of efficacy and her connection with her baby.
Implications for the Pediatrician

The pediatrician can support healthy newborn development in several ways.

Optimal Practices

A prenatal pediatric visit allows pediatricians to assess potential threats to bonding (e.g., tense spousal relationship) and sources of social support. Supportive hospital policies include the use of birthing rooms rather than operating suites and delivery rooms; encouraging the father or a trusted relative or friend to remain with the mother during labor or the provision of a professional doula; the practice of giving the newborn infant to the mother immediately after drying and a brief assessment; placement of the newborn in the mother’s room rather than in a central nursery; and avoiding in-hospital distribution of infant formula. Such policies (“Baby Friendly Hospital”) have been shown to significantly increase breastfeeding rates (see Chapter 113.3). After discharge, home visits by nurses and lactation counselors can reduce early feeding problems and identify emerging medical conditions in either mother or baby. Infants requiring transport to another hospital should be brought to see the mother first, if at all possible. On discharge home, fathers can shield mothers from unnecessary visits and calls and take over household duties, allowing mothers and infants time to get to know each other without distractions. The first office visit should occur during the 1st 2 wk after discharge to determine how smoothly the mother and infant are making the transition to life at home. Babies who are discharged early, those who are breastfeeding, and those who are at risk for jaundice should be seen 1-3 days after discharge.

Assessing Parent–Infant Interactions

During a feeding or when infants are alert and face-to-face with their parents, it is normal for the dyad to appear absorbed in one another. Infants who become overstimulated by the parent's voice or activity may turn away or close their eyes, leading to a premature termination of the encounter. Alternatively, the infant may be ready to interact, but the parent may appear preoccupied. Asking a new mother about her own emotional state, and inquiring specifically about a history of depression, facilitates referral for therapy, which may provide long-term benefits to the child. Pediatricians may detect postpartum depression using
the EPDS at well-child visits during the 1st yr (see Table 21.2).

Teaching About Individual Competencies

The **Newborn Behavior Assessment Scale (NBAS)** provides a formal measure of an infant's neurodevelopmental competencies, including state control, autonomic reactivity, reflexes, habituation, and orientation toward auditory and visual stimuli. This examination can also be used to demonstrate to parents an infant's capabilities and vulnerabilities. Parents might learn that they need to undress their infant to increase the level of arousal or to swaddle the infant to reduce overstimulation by containing random arm movements. The NBAS can be used to support the development of positive early parent–infant relationships. Demonstration of the NBAS to parents in the 1st wk of life has been shown to correlate with improvements in the caretaking environment months later.

Bibliography

Hodnett ED. Caregiver support for women during childbirth. *Cochrane Database Syst Rev* . 2002;(1) [CD000199].

The prenatal period and the 1st yr of life provide the platform for remarkable growth and development, setting the trajectory for a child's life. **Neural plasticity**, the ability of the brain to be shaped by experience, both positive and negative, is at its peak. Total brain volume doubles in the 1st yr of life and increases by an additional 15% over the 2nd yr. Total brain volume at age 1 mo is approximately 36% of adult volume but by age 1 yr is approximately 72% (83% by 2 yr) (Fig. 22.1).
The acquisition of seemingly “simple” skills, such as swallowing, reflect a series of intricate and highly coordinated processes involving multiple levels of neural control distributed among several physiologic systems whose nature and relationships mature throughout the 1st yr of life. Substantial learning of the basic tools of language (phonology, word segmentation) occurs during infancy. Speech processing in older individuals requires defined and precise neuronal networks; the infant brain possesses a structural and functional organization similar to that of adults, suggesting that structural neurologic processing of speech may guide infants to discover the properties of their native language. Myelination of the cortex begins at 7-8 mo gestation and continues into adolescence and young adulthood. It proceeds posterior to anterior, allowing progressive maturation of sensory, motor, and finally associative pathways. Given the importance of iron, cholesterol, and other nutrients in myelination, adequate stores throughout infancy are critical (see Chapter 56). Insufficient
interactions with caregivers or the wider environment may alter experience-dependent processes that are critical to brain structure development and function during infancy. Although for some processes, subsequent stimulation may allow catch-up, as the periods of plasticity close during the rapid developmental changes occurring in infancy, more permanent deficits may result.

The infant acquires new competences in all developmental domains. The concept of developmental trajectories recognizes that complex skills build on simpler ones; it is also important to realize how development in each domain affects functioning in all the others. All growth parameters should be plotted using the World Health Organization charts, which show how children from birth through 72 mo “should” grow under optimal circumstances (see Chapter 23, Figs. 23.1 and 23.2). Table 22.1 presents an overview of key milestones by domain; Table 22.2 presents similar information arranged by age. Table 22.3 presents age at time of x-ray appearance of centers of ossification. Parents often seek information about “normal development” during this period and should be directed to reliable sources, including the American Academy of Pediatrics website (healthychildren.org).

**AT 1 MO**

| Prone: Legs more extended; holds chin up; turns head; head lifted momentarily to plane of body on ventral suspension |     |
| Supine: Tonic neck posture predominates; supple and relaxed; head lags when pulled to sitting position |     |
| Visual: Watches person; follows moving object            |     |
| Social: Body movements in cadence with voice of other in social contact; beginning to smile |     |

**AT 2 MO**

| Prone: Raises head slightly farther; head sustained in plane of body on ventral suspension |     |
| Supine: Tonic neck posture predominates; head lags when pulled to sitting position |     |
| Visual: Follows moving object 180 degrees                |     |
| Social: Smiles on social contact; listens to voice and coos |     |

**AT 3 MO**
| Prone:       | Lifts head and chest with arms extended; head above plane of body on ventral suspension |
| Supine:     | Tonic neck posture predominates; reaches toward and misses objects; waves at toy |
| Sitting:    | Head lag partially compensated when pulled to sitting position; early head control with bobbing motion; back rounded |
| Reflex:     | Typical Moro response has not persisted; makes defensive movements or selective withdrawal reactions |
| Social:     | Sustained social contact; listens to music; says “aah, ngah” |

**AT 4 MO**

| Prone:       | Rolls over; pivots; crawls or creep-crawls (Knobloch) |
| Supine:     | Lifts head; rolls over; squirms |
| Sitting:    | Sits briefly, with support of pelvis; leans forward on hands; back rounded |
| Standing:  | May support most of weight; bounces actively |
| Adaptive:  | Reaches out for and grasps large object; transfers objects from hand to hand; grasp uses radial palm; rakes at raisin |
| Language:  | Forms polysyllabic vowel sounds |
| Social:     | Prefers mother; babbles; enjoys mirror; responds to changes in emotional content of social contact |

**AT 7 MO**

| Sitting:    | Sits up alone and indefinitely without support, with back straight |
| Standing:  | Pulls to standing position; “cruises” or walks holding on to furniture |
| Motor:      | Creeps or crawls |
| Adaptive:  | Grasps objects with thumb and forefinger; pokes at things with forefinger; picks up pellet with assisted pincer movement; uncovers hidden toy; attempts to retrieve dropped object; releases object grasped by other person |
| Language:  | Repetitive consonant sounds (“mama,” “dada”) |
| Social:     | Responds to sound of name; plays peek-a-boo or pat-a-cake; waves bye-bye |

**AT 1 YR**

| Motor:      | Walks with one hand held; rises independently, takes several steps (Knobloch) |
| Adaptive:  | Picks up raisin with unassisted pincer movement of forefinger and thumb; releases object to other person on request or gesture |
| Language:  | Says a few words besides “mama,” “dada” |
| Social:     | Plays simple ball game; makes postural adjustment to dressing |

Values represent mean ± standard deviation, when applicable.

The norms present a composite of published data from the Fels Research Institute, Yellow
Age 0-2 Months

In the full-term infant, myelination is present by the time of birth in the dorsal brainstem, cerebellar peduncles, and posterior limb of the internal capsule. The cerebellar white matter acquires myelin by 1 mo of age and is well myelinated by 3 mo. The subcortical white matter of the parietal, posterior frontal, temporal, and calcarine cortex is partially myelinated by 3 mo of age. In this period the infant experiences tremendous growth. Physiologic changes allow the establishment of effective feeding routines and a predictable sleep–wake cycle. The social interactions that occur as parents and infants accomplish these tasks lay the foundation for cognitive and emotional development.

Physical Development

A newborn's weight may initially decrease 10% (vaginal delivery) to 12% (cesarean section) below birthweight in the 1st wk as a result of excretion of excess extravascular fluid and limited nutritional intake. Nutrition improves as colostrum is replaced by higher-fat content breast milk, and when infants learn to latch on and suck more efficiently, and as mothers become more comfortable with feeding techniques. Infants regain or exceed birthweight by 2 wk of age and should grow at approximately 30 g (1 oz) per day during the 1st mo (see Table 27.1). This is the period of fastest postnatal growth. Arms are held to the sides. Limb movements consist largely of uncontrolled writhing, with apparently purposeless opening and closing of the hands. Smiling occurs involuntarily. Eye gaze, head turning, and sucking are under better control and thus can be used to demonstrate infant perception and cognition. An infant's preferential turning toward the mother's voice is evidence of recognition memory.

Six behavioral states have been described (see Chapter 21). Initially, sleep and wakefulness are evenly distributed throughout the 24 hr day (Fig. 22.2). Neurologic maturation accounts for the consolidation of sleep into blocks of 5 or 6 hr at night, with brief awake, feeding periods. Learning also occurs; infants whose parents are consistently more interactive and stimulating during the day learn to concentrate their sleeping during the night.
Cognitive Development

Infants can differentiate among patterns, colors, and consonants. They can recognize facial expressions (smiles) as similar, even when they appear on different faces. They also can match abstract properties of stimuli, such as contour, intensity, or temporal pattern, across sensory modalities. Infants at 2 mo of age can discriminate rhythmic patterns in native vs non-native language. Infants appear to seek stimuli actively, as though satisfying an innate need to make sense of the world. These phenomena point to the integration of sensory inputs in the central nervous system. Caretaking activities provide visual, tactile, olfactory, and auditory stimuli, all of which support the development of cognition. Infants habituate to the familiar, attending less to repeated stimuli and increasing their attention to novel stimuli.
Emotional Development

The infant is dependent on the environment to meet his or her needs. The consistent availability of a trusted adult to meet the infant's urgent needs creates the conditions for secure attachment. Basic trust vs mistrust, the first of Erikson's psychosocial stages (see Chapter 18), depends on attachment and reciprocal maternal bonding. Crying occurs in response to stimuli that may be obvious (a soiled diaper) but are often obscure (see Chapter 22.1). Infants who are consistently picked up and held in response to distress cry less at 1 yr and show less aggressive behavior at 2 yr. Infants cry in response to the cry of another infant, which has been interpreted as an early sign of empathy.

Implications for Parents and Pediatricians

Success or failure in establishing feeding and sleep cycles influences parents' feelings of competence. When things go well, the parents' anxiety and ambivalence, as well as the exhaustion of the early weeks, decrease. Infant issues (e.g., colic) or familial conflict may prevent this from occurring. With physical recovery from delivery and hormonal normalization, the mild postpartum “blues” that affects many mothers passes. If the mother continues to feel sad, overwhelmed, and anxious, the possibility of moderate to severe postpartum depression, found in 10–15% of postpartum women, needs to be considered. Major depression that arises during pregnancy or in the postpartum period threatens the mother–child relationship and is a risk factor for later cognitive and behavioral problems. The pediatrician may be the first professional to encounter the depressed mother and should be instrumental in assisting her in seeking treatment (see Chapter 21).

Age 2-6 Months

At about age 2 mo, the emergence of voluntary (social) smiles and increasing eye contact mark a change in the parent–child relationship, heightening the parents' sense of being loved reciprocally. During the next months, an infant's range of motor and social control and cognitive engagement increases dramatically. Mutual regulation takes the form of complex social interchanges, resulting in strong mutual attachment and enjoyment. Routines are established. Parents are less fatigued.
Physical Development

Between 3 and 4 mo of age, the rate of growth slows to approximately 20 g/day (see Table 27.1 and Figs. 23.1 and 23.2). By age 4 mo, birthweight is doubled. Early reflexes that limited voluntary movement recede (e.g., primitive reflexes; see Chapter 608). Disappearance of the asymmetric tonic neck reflex means that infants can begin to examine objects in the midline and manipulate them with both hands. Waning of the early grasp reflex allows infants both to hold objects and to let them go voluntarily. A novel object may elicit purposeful, although inefficient, reaching. The quality of spontaneous movements also changes, from larger writhing to smaller, circular movements that have been described as “fidgety.” Abnormal or absent fidgety movements may constitute a risk factor for later neurologic abnormalities.

Increasing control of truncal flexion makes intentional rolling possible. Once infants can hold their heads steady while sitting, they can gaze across at things rather than merely looking up at them, opening up a new visual range. They can begin taking food from a spoon. At the same time, maturation of the visual system allows greater depth perception.

In this period, infants achieve stable state regulation and regular sleep–wake cycles. Total sleep requirements are approximately 14-16 hr/24 hr, with about 9-10 hr concentrated at night and 2 naps/day. Approximately 70% of infants sleep for a 6-8 hr stretch by age 6 mo (see Fig. 22.2). By 4-6 mo, the sleep electroencephalogram shows a mature pattern, with demarcation of rapid eye movement and 3 stages of non–rapid eye movement sleep. The sleep cycle remains shorter than in adults (50-60 min vs approximately 90 min). As a result, infants arouse to light sleep or wake frequently during the night, setting the stage for behavioral sleep problems (see Chapter 31).

Cognitive Development

The overall effect of these developments is a qualitative change. At 4 mo of age, infants are described as “hatching” socially, becoming interested in a wider world. During feeding, infants no longer focus exclusively on the mother, but become distracted. In the mother's arms, the infant may literally turn around, preferring to face outward.

Infants at this age also explore their own bodies, staring intently at their hands, vocalizing, blowing bubbles, and touching their ears, cheeks, and
genitals. These explorations represent an early stage in the understanding of cause and effect as infants learn that voluntary muscle movements generate predictable tactile and visual sensations. They also have a role in the emergence of a sense of self, separate from the mother. This is the 1st stage of personality development. Infants come to associate certain sensations through frequent repetition. The proprioceptive feeling of holding up the hand and wiggling the fingers always accompanies the sight of the fingers moving. Such “self” sensations are consistently linked and reproducible at will. In contrast, sensations that are associated with “other” occur with less regularity and in varying combinations. The sound, smell, and feel of the mother sometimes appear promptly in response to crying, but sometimes do not. The satisfaction that the mother or another loving adult provides continues the process of attachment.

Emotional Development and Communication

Babies interact with increasing sophistication and range. The primary emotions of anger, joy, interest, fear, disgust, and surprise appear in appropriate contexts as distinct facial expressions. When face-to-face, the infant and a trusted adult can match affective expressions (smiling or surprise) approximately 30% of the time. Initiating games (singing, hand games) increases social development. Such face-to-face behavior reveals the infant's ability to share emotional states, the 1st step in the development of communication. Infants of depressed parents show a different pattern, spending less time in coordinated movement with their parents and making fewer efforts to reengage. Rather than anger, they show sadness and a loss of energy when the parents continue to be unavailable.

Implications for Parents and Pediatricians

Motor and sensory maturation makes infants at 3-6 mo exciting and interactive. Some parents experience their 4 mo old child's outward turning as a rejection, secretly fearing that their infants no longer love them. For most parents, this is a happy period. Most parents excitedly report that they can hold conversations with their infants, taking turns vocalizing and listening. Pediatricians share in the enjoyment, as the baby coos, makes eye contact, and moves rhythmically. Infants who do not show this reciprocal language and movements are at risk for autism spectrum disorders or other developmental disabilities (see Chapters 52 and 54). If this visit does not feel joyful and relaxed, causes such as social stress, family
dysfunction, parental mental illness, or problems in the infant–parent relationship should be considered. Parents can be reassured that responding to an infant's emotional needs cannot spoil the infant. Giving vaccines and drawing blood while the child is seated on the parent's lap or nursing at the breast increases pain tolerance.

**Age 6-12 Months**

With achievement of the sitting position, increased mobility, and new skills to explore the world around them, 6-12 mo old infants show advances in cognitive understanding and communication, and new tensions arise in regard to attachment and separation. Infants develop will and intentions, characteristics that most parents welcome but still find challenging to manage.

**Physical Development**

Growth slows more (see Table 27.1 and Figs. 23.1 and 23.2). By the 1st birthday, birthweight has tripled, length has increased by 50%, and head circumference has increased by 10 cm (4 in). The ability to sit unsupported (6-7 mo) and to pivot while sitting (around 9-10 mo) provides increasing opportunities to manipulate several objects at a time and to experiment with novel combinations of objects. These explorations are aided by the emergence of a thumb–finger grasp (8-9 mo) and a neat pincer grasp by 12 mo. Voluntary release emerges at 9 mo. Many infants begin crawling and pulling to stand around 8 mo, followed by cruising. Some walk by 1 yr. Motor achievements correlate with increasing myelinization and cerebellar growth. These gross motor skills expand infants' exploratory range and create new physical dangers, as well as opportunities for learning. Tooth eruption occurs, usually starting with the mandibular central incisors. Tooth development reflects skeletal maturation and bone age, although there is wide individual variation (see Table 22.3 and Chapter 333).

**Cognitive Development**

The 6 mo old infant has discovered his hands and will soon learn to manipulate objects. At first, everything is mouthed. In time, novel objects are picked up, inspected, passed from hand to hand, banged, dropped, and then mouthed. Each
action represents a nonverbal idea about what things are for (in Piagetian terms, a *schema*; see Chapter 18). The complexity of an infant's play, how many different schemata are brought to bear, is a useful index of cognitive development at this age. The pleasure, persistence, and energy with which infants tackle these challenges suggest the existence of an intrinsic drive or mastery motivation. Mastery behavior occurs when infants feel secure; those with less secure attachments show limited experimentation and less competence.

A major milestone is the achievement by 9 mo of **object permanence (constancy)**, the understanding that objects continue to exist, even when not seen. At 4-7 mo of age, infants look down for a yarn ball that has been dropped but quickly give up if it is not seen. With object constancy, older infants persist in searching. They will find objects hidden under a cloth or behind the examiner's back. Peek-a-boo brings unlimited pleasure as the child magically brings back the other player. Events seem to occur as a result of the child's own activities.

**Emotional Development**

The advent of object permanence corresponds with qualitative changes in social and communicative development. Infants look back and forth between an approaching stranger and a parent and may cling or cry anxiously, demonstrating **stranger anxiety**. Separations often become more difficult. Infants who have been sleeping through the night for months begin to awaken regularly and cry, as though remembering that the parents are nearby or in the next room.

A new demand for **autonomy** also emerges. Poor weight gain at this age often reflects a struggle between an infant's emerging independence and parent's control of the feeding situation. Use of the 2-spoon method of feeding (1 for the child and 1 for the parent), finger foods, and a high chair with tray table can avert potential problems. Tantrums make their first appearance as the drives for autonomy and mastery come in conflict with parental controls and the infant's still-limited abilities.

**Communication**

Infants at 7 mo of age are adept at nonverbal communication, expressing a range of emotions and responding to vocal tone and facial expressions. About 9 mo of age, infants become aware that emotions can be shared between people; they
show parents toys as a way of sharing their happy feelings. Between 8 and 10 mo of age, babbling takes on a new complexity, with multisyllabic sounds (“ba-da-ma”) called **canonical babbling**. Babies can discriminate between languages. Infants in bilingual homes learn the characteristics and rules that govern 2 different languages. Social interaction (attentive adults taking turns vocalizing with the infant) profoundly influences the acquisition and production of new sounds. The first true word (i.e., a sound used consistently to refer to a specific object or person) appears in concert with an infant's discovery of object permanence. Picture books now provide an ideal context for verbal language acquisition. With a familiar book as a shared focus of attention, a parent and child engage in repeated cycles of pointing and labeling, with elaboration and feedback by the parent. The addition of sign language may support infant development while enhancing parent–infant communication.

**Implications for Parents and Pediatricians**

With the developmental reorganization that occurs around 9 mo of age, previously resolved issues of feeding and sleeping reemerge. Pediatricians can prepare parents at the 6 mo visit so that these problems can be understood as the result of developmental progress and not regression. Parents should be encouraged to plan ahead for necessary, and inevitable, separations (e.g., babysitter, daycare). Routine preparations may make these separations easier. Dual parent employment has not been consistently found to be harmful or beneficial for long-term cognitive or social-emotional outcomes. Introduction of a **transitional object** may allow the infant to self-comfort in the parents' absence. The object cannot have any potential for asphyxiation or strangulation.

Infants' wariness of strangers often makes the 9 mo examination difficult, particularly if the infant is temperamentally prone to react negatively to unfamiliar situations. Initially, the pediatrician should avoid direct eye contact with the child. Time spent talking with the parent and introducing the child to a small, washable toy will be rewarded with more cooperation. The examination can be continued on the parent's lap when feasible.

22.1
Crying or fussiness is present in all babies but reaches medical attention in about 20% of infants younger than 2 mo. Although usually a transient and normal infant behavior, crying is often associated with parental concern and distress. On average, babies cry 2 hr/day, peaking at 6 wk of age. Premature infants will have peak crying at 6 wk corrected age (Fig. 22.3). Small-for-gestational-age and premature babies may be at higher risk. The peak period of infant crying usually occurs in the evenings and early part of the night. Excessive crying or fussiness persisting longer than 3-5 mo may be associated with behavioral problems in an older child (anxiety, aggression, hyperactivity), decreased duration of breastfeeding, or postnatal depression, but it is uncertain which is the cause or effect. Most infants with crying/fussiness do not have gastroesophageal reflux, lactose intolerance, constipation, or cow's milk protein allergy.
**Acute-onset uncontrollable crying** could be caused by a medical condition. Potentially overlooked conditions to consider include corneal abrasion, tourniquet effect of a hair wrapped around a digit or penis, occult fracture, urinary tract infection, acute abdomen including inguinal hernia, or anomalous coronary artery. Breastfeeding mothers should be questioned about medications, drugs, and diet. Gastrointestinal distress can result from a maternal diet high in cruciferous vegetables. Most of the time, the etiology of a serious problem can be discovered with a careful history and physical examination.

Crying is a normal part of neurobehavioral development. Infants have various signals for their needs and for getting attention from a caregiver. These behaviors progressively increase in intensity in many infants, from changes in breathing and color, to postural and movement changes, and then to calm vocalizations. These precry cues, if not attended to, will eventually lead to active crying. Some infants may go directly to crying, perhaps based on temperament; these infants may be less easily consolable, more intense, or more responsive to sensory stimuli. Management of crying/fussiness should include teaching caregivers about precry cues and responding to the signal for feeding in a calm, relaxed manner. If sensory overstimulation is a factor, creating a nondistracting, calm environment may help, as well as swaddling. When lack of sensory stimulation is present, mother–infant skin-to-skin contact and carrying the infant may be beneficial. In all situations, reassurance that this is both normal and transient, with only 5% of infants persisting beyond 3 mo of age, helps the family cope. Teaching families about expectations for normal crying behavior can reduce emergency department visits.

The emotional significance of any experience depends on both the individual child's temperament and the parent's responses (see Table 18.1); differing feeding schedules produce differing reactions. Hunger generates increasing tension; as the urgency peaks, the infant cries, the parent offers the breast or bottle, and the tension dissipates. Infants fed “on demand” consistently experience this link among their distress, the arrival of the parent, and relief from hunger. Most infants fed on a fixed schedule quickly adapt their hunger cycle to the schedule. Those who cannot adapt, because they are temperamentally prone to irregular biologic rhythms, experience periods of unrelieved hunger as well as unwanted feedings when they already feel full. Similarly, infants who are fed at the parents' convenience, with neither attention
to the infant's hunger cues nor a fixed schedule, may not consistently experience feeding as the pleasurable reduction of tension. Infants with early dysregulation often show increased irritability and physiologic instability (spitting, diarrhea, poor weight gain) as well as later behavioral problems. Infants with excess crying after 4-6 mo may have neurobehavioral dysregulation and may be at higher risk of other behavior problems (sleep, behavior, feeding).

**Colic** is characterized by the “rule of 3.” It occurs in a healthy, thriving infant beginning in the 2nd or 3rd week of life, lasts about 3 hr/day, occurs 3 days/wk, lasts for more than 3 wk, and resolves by 3 or 4 mo of age. It is equally common in breast- and bottle-fed infants, although prevalence is variable (up to 20%). There is no racial, socioeconomic status, or gender risk for colic. Colic is a diagnosis of exclusion following a careful history and physical examination. Few cases will be found to have an organic etiology. Although all babies have crying episodes, colicky babies cry excessively and are difficult to settle. The fussiness is not associated with hunger or any other form of discomfort. Colicky babies may be more reactive to the same stimulus and may cry louder than other babies. Although crying periods are a normal developmental phenomenon, babies with colic can cause parents to become anxious, distraught, frustrated, and sleep deprived. Mothers are at higher risk for postpartum depression if they report inconsolable crying episodes lasting more than 20 min. Depression may lead to cessation of breastfeeding. The risk of abuse increases as parents may use aggressive means to quiet the child, resulting in the *shaken baby syndrome*.

There is no specific treatment for colic, but practitioners should provide advice and reassurance to parents. Parents must be counseled about the problem, the importance of implementing a series of calm, systematic steps to soothe the infant, and having a plan for stress relief, such as time-out for parents and substitute caregivers. Parents can be advised that that colic is self-limited with no adverse effects on the child. Public health programs, such as the **Period of PURPLE Crying** (http://purplecrying.info/ ) and **Take 5 Safety Plan for Crying**, are invaluable tools for parents. These programs inform parents that all babies go through periods of crying, deflecting parental guilt and self-recrimination. Most importantly, parents are reminded that it is better to allow the baby to cry than engage in shaking that leads to head trauma. Although babies with colic will have inconsolable periods when there is no relief, parents can try some simple steps. Predictable daily schedules may help, ensuring the baby has adequate sleep. Parents should provide appropriate stimulation throughout the day when baby is in an alert/awake period. The sleep
environment should be free of stimulation. Swaddling, rocking, white noise, and movement (e.g., stroller, car ride) help some babies settle. Infants who are carried by a parent show different physiologic changes than when held in a sitting position, although there is no evidence that continuous carrying is effective in colic management. A study in a hunter–gatherer society showed that children who are continuously carried by their mothers display similar crying periods as those in Western societies.

Some studies have found differences in fecal microflora between babies with excess crying and controls. Results include fewer bifidobacteria and lactobacilli and more coliform bacteria such as Escherichia coli. None has been conclusive, however, and each study was found to have limitations such as lack of precise inclusion criteria, lack of blinded observers, and variability in outcome measurements.

If the child appears to have gastrointestinal symptoms, breastfeeding mothers may try elimination of milk, beans, and cruciferous vegetables. In allergic families, mothers may try a stricter elimination of food allergens (milk, egg, wheat, nuts, soy, and fish), although nutritional status should be monitored. For formula-fed infants, changing from milk-based to soy-based or other lactose-free formulas had no effect in most studies. A protein hydrolysate formula may moderately improve symptoms.

The cause of colic is not known, and no medical intervention has been consistently effective. Colic has been described as a “functional gastrointestinal disorder” and has been associated with later development of migraine. Simethicone has not been shown to be better than placebo. Anticholinergic medications should not be used in infants younger than 6 mo. Early studies of probiotics look promising, but evidence is insufficient to recommend their routine use. Among various complementary therapies, certain herbal teas, sugar solutions, Gripe water (containing herbal supplements), and fennel extract may have benefit, but the evidence is weak. Baby massage may be helpful, but chiropractic manipulation should not be performed in young children. Acupuncture was effective in 1 trial, and singing while in utero may produce babies who cry less.

The 2nd year of life is a time of rapid growth of development, particularly in the realms of social-emotional and cognitive skills as well as motor development. The toddler's newly found ability to walk allows separation and independence; however, the toddler continues to need secure attachment to the parents. At approximately 18 mo of age, the emergence of symbolic thought and language causes a reorganization of behavior, with implications across many developmental domains.

Age 12-18 Months

Physical Development

While overall rate of growth continues to decline, the toddler continues to experience considerable brain growth and myelination in the 2nd yr of life, resulting in an increase in head circumference of 2 cm over the year (Figs. 23.1 and 23.2). Toddlers have relatively short legs and long torsos, with exaggerated lumbar lordosis and protruding abdomens.

Most children begin to walk independently at about 12-15 mo of age. Early walking is not associated with advanced development in other domains. Infants initially toddle with a wide-based gait, with the knees bent and the arms flexed at the elbow; the entire torso rotates with each stride; the toes may point in or out, and the feet strike the floor flat. The appearance is that of genu varum (bowleg). Subsequent refinement leads to greater steadiness and energy efficiency. After several months of practice, the center of gravity shifts back and the torso stabilizes, while the knees extend and the arms swing at the sides for balance. The feet are held in better alignment, and the child is able to stop, pivot, and stoop without toppling over (see Chapters 692 and 693).

Cognitive Development

Exploration of the environment increases in parallel with improved dexterity (reaching, grasping, releasing) and mobility. Learning follows the precepts of Piaget's sensorimotor stage (see Chapter 18). Toddlers manipulate objects in novel ways to create interesting effects, such as stacking blocks or filling and dumping buckets. Playthings are also more likely to be used for their intended purposes (combs for hair, cups for drinking). Imitation of parents and older siblings or other children is an important mode of learning. Make-believe play (symbolic play) centers on the child's own body, such as pretending to drink from an empty cup (Table 23.1; see also Table 22.1).

* Data derived from those of Gesell (as revised by Knobloch), Shirley, Provence, Wolf, Bailey, and others. After 6 yr, the Wechsler Intelligence Scales for Children (WISC-IV) and other scales offer the most precise estimates of cognitive development. To have their greatest value, they should be administered only by an experienced and qualified person.

### Emotional Development

Infants who are approaching the developmental milestone of taking their 1st steps may be irritable. Once they start walking, their predominant mood changes markedly. Toddlers are often elated with their new ability and with the power to control the distance between themselves and their parents. Exploring toddlers orbit around their parents, moving away and then returning for a reassuring touch before moving away again. A child with **secure attachment** will use the
parent as a secure base from which to explore independently. Proud of her or his accomplishments, the child illustrates Erikson’s **stage of autonomy and separation** (see Chapter 18). The toddler who is overly controlled and discouraged from active exploration will feel doubt, shame, anger, and insecurity. All children will experience tantrums, reflecting their inability to delay gratification, suppress or displace anger, or verbally communicate their emotional states. The quality of the parent–child relationship may moderate negative behavioral effects of childcare arrangements when parents work.

**Linguistic Development**

*Receptive* language precedes *expressive* language. By the time infants speak their first words around 12 mo of age, they already respond appropriately to several simple statements, such as “no,” “bye-bye,” and “give me.” By 15 mo, the average child points to major body parts and uses 4-6 words spontaneously and correctly. Toddlers also enjoy **polysyllabic jargoning** (see Tables 22.1 and 23.1) and do not seem upset that no one understands. Most communication of wants and ideas continues to be nonverbal.

**Implications for Parents and Pediatricians**

Parents who cannot recall any other milestone tend to remember when their child began to walk, perhaps because of the symbolic significance of walking as an act of independence and because of the new demands that the ambulating toddler places on the parent. All toddlers should be encouraged to explore their environment; however, a child's ability to wander out of sight also increases the risks of injury and the need for supervision, making **childproofing** an integral focus of physician visits.

In the office setting, many toddlers are comfortable exploring the examination room, but cling to the parents under the stress of the examination. Performing most of the physical examination in the parent's lap may help allay fears of separation. Infants who become more, not less, distressed in their parents' arms or who avoid their parents at times of stress may be insecurely attached. Young children who, when distressed, turn to strangers rather than parents for comfort are particularly worrisome. Children raised in **toxic stressful environments** have increased vulnerability to disease. The conflicts between independence and security manifest in issues of discipline, temper tantrums, toilet training, and
changing feeding behaviors. Parents should be counseled on these matters within the framework of normal development.

Parents may express concern about poor food intake as growth slows. The growth chart should provide reassurance. Many children still take 2 daytime naps, although the duration steadily decreases and may start to condense to 1 longer nap (see Fig. 22.2).

Age 18-24 Months

Physical Development

Motor development during this period is reflected in improvements in balance and agility and the emergence of running and stair climbing. Height and weight increase at a steady rate during this year, with a gain of 5 in and 5 lb. By 24 mo, children are about half their ultimate adult height. Head growth slows slightly, with 85% of adult head circumference achieved by age 2 yr, leaving only an additional 5 cm (2 in) gain over the next few years (see Fig. 23.1 and Table 27.1).

Cognitive Development

At approximately 18 mo of age, several cognitive changes coalesce, marking the conclusion of the sensorimotor period. These can be observed during self-initiated play. Object permanence is firmly established; toddlers anticipate where an object will end up, even though the object was not visible while it was being moved. Cause and effect are better understood, and toddlers demonstrate flexibility in problem solving (e.g., using a stick to obtain a toy that is out of reach, figuring out how to wind a mechanical toy). Symbolic transformations in play are no longer tied to the toddler's own body; thus a doll can be “fed” from an empty plate. As with the reorganization that occurs at 9 mo (see Chapter 22), the cognitive changes at 18 mo correlate with important changes in the emotional and linguistic domains (see Table 23.1).

Emotional Development

The relative independence of the preceding half-year often gives way to increased clingingness about 18 mo. This stage, described as “rapprochement,”
may be a reaction to growing awareness of the possibility of separation. Many parents report that they cannot go anywhere without having a small child attached to them. Separation anxiety will manifest at bedtime. Many children use a special blanket or stuffed toy as a transitional object, which functions as a symbol of the absent parent. The transitional object remains important until the transition to symbolic thought has been completed and the symbolic presence of the parent fully internalized. Despite the attachment to the parent, the child's use of “no” is a way of declaring independence. Individual differences in temperament, in both the child and the parents, play a critical role in determining the balance of conflict vs cooperation in the parent–child relationship. As effective language emerges, conflicts often become less frequent.

Self-conscious awareness and internalized standards of behavior first appear at this age. Toddlers looking in a mirror will, for the first time, reach for their own face rather than the mirror image if they notice something unusual on their nose. They begin to recognize when toys are broken and may hand them to their parents to fix. Language becomes a means of impulse control, early reasoning, and connection between ideas. When tempted to touch a forbidden object, they may tell themselves “no, no.” This is the very beginning of the formation of a conscience. The fact that they often go on to touch the object anyway demonstrates the relative weakness of internalized inhibitions at this stage.

Linguistic Development

Perhaps the most dramatic developments in this period are linguistic. Labeling of objects coincides with the advent of symbolic thought. After the realization occurs that words can stand for objects or ideas, a child's vocabulary grows from 10-15 words at 18 mo to between 50 and 100 at 2 yr. After acquiring a vocabulary of about 50 words, toddlers begin to combine them to make simple sentences, marking the beginning of grammar. At this stage, toddlers understand 2-step commands, such as “Give me the ball and then get your shoes.” Language also gives the toddler a sense of control over the surroundings, as in “night-night” or “bye-bye.” The emergence of verbal language marks the end of the sensorimotor period. As toddlers learn to use symbols to express ideas and solve problems, the need for cognition based on direct sensation and motor manipulation wanes.
Implications for Parents and Pediatricians

With children's increasing mobility, physical limits on their explorations become less effective; words become increasingly important for behavior control as well as cognition. Children with delayed language acquisition often have greater behavior problems and frustrations due to problems with communication. Language development is facilitated when parents and caregivers use clear, simple sentences; ask questions; and respond to children's incomplete sentences and gestural communication with the appropriate words. Television viewing, as well as television as background noise, decreases parent–child verbal interactions, whereas looking at picture books and engaging the child in 2-way conversations stimulates language development. In the world of constant access to tablets, phones, and screens, parents and children have more distractions from direct language engagement.

In the office setting, certain procedures may lessen the child's stranger anxiety. Avoid direct eye contact initially. Perform as much of the examination as feasible with the child on the parent's lap. Pediatricians can help parents understand the resurgence of problems with separation and the appearance of a transitional object as a developmental phenomenon. Parents must understand the importance of exploration. Rather than limiting movement, parents should place toddlers in safe environments or substitute one activity for another. Methods of discipline, including corporal punishment (which is not recommended), should be discussed; effective alternatives will usually be appreciated. Helping parents to understand and adapt to their children's different temperamental styles can constitute an important intervention (see Table 18.1). Developing daily routines is helpful to all children at this age. Rigidity in those routines reflects a need for mastery over a changing environment.

Bibliography

The emergence of language and exposure of children to an expanding social sphere represent the critical milestones for children ages 2-5 yr. As toddlers, children learn to walk away and come back to the secure adult or parent. As preschoolers, they explore emotional separation, alternating between stubborn opposition and cheerful compliance, between bold exploration and clinging dependence. Increasing time spent in classrooms and playgrounds challenges a child's ability to adapt to new rules and relationships. Emboldened by their growing array of new skills and accomplishments, preschool children also are increasingly cognizant of the constraints imposed on them by the adult world and their own limited abilities.

**Structural Development of the Brain**

The preschool brain experiences dramatic changes in its anatomic and physiologic characteristics, with increases in cortical area, decreases in cortical thickness, and changing cortical volume. These changes are not uniform across the brain and vary by region. Gray and white matter tissue properties change dramatically, including diffusion properties in the major cerebral fiber tracts. Dramatic increases occur in brain metabolic demands. In general, more brain regions are required in younger than in older children to complete the same cognitive task. This duplication has been interpreted as a form of “scaffolding,” which is discarded with increasing age. The preschool brain is characterized by growth and expansion that will be followed in later years by “pruning.”

**Physical Development**
Somatic and brain growth slows by the end of the 2nd yr of life, with corresponding decreases in nutritional requirements and appetite, and the emergence of “picky” eating habits (see Table 27.1). Increases of approximately 2 kg (4-5 lb) in weight and 7-8 cm (2-3 in) in height per year are expected. Birthweight quadruples by 2.5 yr of age. An average 4 yr old weighs 40 lb and is 40 in tall. The head will grow only an additional 5-6 cm between ages 3 and 18 yr. Current growth charts, with growth parameters, can be found on the U.S. Centers for Disease Control and Prevention website (http://www.cdc.gov/growthcharts/) and in Chapter 27. Children with early 

adiposity rebound (increase in body mass index) are at increased risk for adult obesity.

The preschooler has genu valgum (knock-knees) and mild pes planus (flatfoot). The torso slims as the legs lengthen. Growth of sexual organs is commensurate with somatic growth. Physical energy peaks, and the need for sleep declines to 11-13 hr/24 hr, with the child eventually dropping the nap (see Fig. 22.2). Visual acuity reaches 20/30 by age 3 yr and 20/20 by age 4 yr. All 20 primary teeth should have erupted by 3 yr of age (see Chapter 333).

Most children walk with a mature gait and run steadily before the end of their 3rd yr (see Table 23.1). Beyond this basic level, there is wide variation in ability as the range of motor activities expands to include throwing, catching, and kicking balls; riding on bicycles; climbing on playground structures; dancing; and other complex pattern behaviors. Stylistic features of gross motor activity, such as tempo, intensity, and cautiousness, also vary significantly. Although toddlers may walk with different styles, toe walking should not persist.

The effects of such individual differences on cognitive and emotional development depend in part on the demands of the social environment. Energetic, coordinated children may thrive emotionally with parents or teachers who encourage physical activity; lower-energy, more cerebral children may thrive with adults who value quiet play.

Handedness is usually established by the 3rd yr. Frustration may result from attempts to change children's hand preference. Variations in fine motor development reflect both individual proclivities and different opportunities for learning. Children who are restricted from drawing with crayons, for example, develop a mature pencil grasp later.

Bowel and bladder control emerge during this period, with “readiness” for toileting having large individual and cultural variation. Girls tend to potty “train” faster and earlier than boys. Bed-wetting is common up to age 5 yr (see Chapter
Many children master toileting with ease, particularly once they are able to verbalize their bodily needs. For others, toilet training can involve a protracted power struggle. Refusal to defecate in the toilet or potty is relatively common, associated with constipation, and can lead to parental frustration. Defusing the issue with a temporary cessation of training (and a return to diapers) often allows toilet mastery to proceed.

Implications for Parents and Pediatricians

The normal decrease in appetite at this age may cause parental concern about nutrition; growth charts should reassure parents that the child's intake is adequate. Children normally modulate their food intake to match their somatic needs according to feelings of hunger and satiety. Daily intake fluctuates, at times widely, but intake over a week is relatively stable. Parents should provide a predictable eating schedule, with 3 meals and 2 snacks per day, allowing the child to choose how much to eat in order to avoid power struggles and to allow the child to learn to respond to satiety cues. However, it is important to obtain thorough diet histories for children at this age to advise parents about healthy choices and encourage physical activity to decrease long-term obesity risks and improve learning and cognitive development.

Highly active children face increased risks of injury, and parents should be counseled about safety precautions. Parental concerns about possible hyperactivity may reflect inappropriate expectations, heightened fears, or true overactivity. Children who engage in ongoing impulsive activity with no apparent regard for personal safety or those harming others on a regular basis should be evaluated further.

Language, Cognition, and Play

These 3 domains all involve symbolic function, a mode of dealing with the world that emerges during the preschool period.

Language

Our understanding of the acquisition of language is evolving. Preschool children command significant computational skills and understanding of statistical patterns that allow them to learn about both language and causation. The 2 and 3
yr old child employs frequency distributions to identify phonetic units
distinguishing words in his or her native language from other languages.

Language development occurs most rapidly between 2 and 5 yr of age.
Vocabulary increases from 50-100 words to more than 2,000. Sentence structure
advances from telegraphic phrases (“Baby cry”) to sentences incorporating all
the major grammatical components. As a rule of thumb, between ages 2 and 5 yr,
the number of words the child puts in a typical sentence should, at a minimum,
equal the child's age (2 by age 2 yr, 3 by age 3 yr, and so on). By 21-24 mo, most
children are using possessives (“My ball”), progressives (the “-ing” construction,
as in “I playing”), questions, and negatives. By age 4 yr, most children can count
to 4 and use the past tense; by age 5 yr, they can use the future tense. Young
children do not use figurative speech; they will only comprehend the literal
meaning of words. Referring to an object as “light as a feather” may produce a
quizzical look on a child.

It is important to distinguish between speech (the production of intelligible
sounds) and language, which refers to the underlying mental act. Language
includes both expressive and receptive functions. Receptive language
(understanding) varies less in its rate of acquisition than does expressive
language; therefore, it has greater prognostic importance (see Chapters 28 and 52).

Language acquisition depends critically on environmental input. Key
determinants include the amount and variety of speech directed toward children
and the frequency with which adults ask questions and encourage verbalization.
Children raised in poverty typically perform lower on measures of language
development than children from economically advantaged families, who tend to
be exposed to many more words in the preschool period.

Although experience influences the rate of language development, many
linguists believe that the basic mechanism for language learning is “hard-wired”
in the brain. Children do not simply imitate adult speech; they abstract the
complex rules of grammar from the ambient language, generating implicit
hypotheses. Evidence for the existence of such implicit rules comes from
analysis of grammatical errors, such as the overgeneralized use of “-s” to signify
the plural and “-ed” to signify the past (“We seed lots of mouses.”).

Language is linked to both cognitive and emotional development. Language
delays may be the 1st indication of an intellectual disability, autism spectrum
disorder, or child neglect or maltreatment. Language plays a critical part in the
regulation of behavior through internalized “private speech” in which a child
repeats adult prohibitions, first audibly and then mentally. Language also allows children to express feelings, such as anger or frustration, without acting them out; consequently, language-delayed children show higher rates of tantrums and other externalizing behaviors.

Preschool language development lays the foundation for later success in school. Approximately 35% of U.S. children may enter school lacking the language skills that are the prerequisites for acquiring literacy. Children from socially and economically disadvantaged backgrounds have an increased risk of school problems, making early detection, along with referral and enrichment, highly crucial for later development. Although children typically learn to read and write in elementary school, critical foundations for literacy are established during the preschool years. Through repeated early exposure to written words, children learn about the uses of writing (telling stories or sending messages) and about its form (left to right, top to bottom). Early errors in writing, like errors in speaking, reveal that literacy acquisition is an active process involving the generation and revision of hypotheses. Programs such as Head Start are especially important for improving language skills for children from bilingual homes. Such parents should be reassured that although bilingual children may initially appear to lag behind their monolingual peers in acquiring language, they learn the differing rules governing both languages, and generally have the same number of total words between the languages. Bilingual children do not follow the same course of language development as monolingual children, but rather create a different system of language cues. Several cognitive advantages have been repeatedly demonstrated among bilingual compared to monolingual children.

Picture books have a special role in familiarizing young children with the printed word and in the development of verbal language. Children's vocabulary and receptive language improve when their parents or caregivers consistently read to them. Reading aloud with a young child is an interactive process in which a parent repeatedly focuses the child's attention on a particular picture, asks questions, and then gives the child feedback (dialogic reading). The elements of shared attention, active participation, immediate feedback, repetition, and graduated difficulty make such routines ideal for language learning. Programs in which physicians provide books to preschool children have shown improvement in language skills among the children (e.g., Reach Out and Read).

The period of rapid language acquisition is also when developmental
dysfluency and stuttering are most likely to emerge (see Chapter 52.1); these can be traced to activation of the cortical motor, sensory, and cerebellar areas. Common difficulties include pauses and repetitions of initial sounds. Stress or excitement exacerbates these difficulties, which generally resolve on their own. Although 5% of preschool children will stutter, it will resolve in 80% of those children by age 8 yr. Children with stuttering should be referred for evaluation if it is severe, persistent, or associated with anxiety, or if parental concern is elicited. Treatment includes guidance to parents to reduce pressures associated with speaking.

Cognition

The preschool period corresponds to Piaget's preoperational (prelogical) stage, characterized by magical thinking, egocentrism, and thinking that is dominated by perception, not abstraction (see Table 18.2). Magical thinking includes confusing coincidence with causality, animism (attributing motivations to inanimate objects and events), and unrealistic beliefs about the power of wishes. A child might believe that people cause it to rain by carrying umbrellas, that the sun goes down because it is tired, or that feeling resentment toward a sibling can actually make that sibling sick. Egocentrism refers to a child's inability to take another's point of view and does not connote selfishness. A child might try to comfort an adult who is upset by bringing the adult a favorite stuffed animal. After 2 yr of age, the child develops a concept of herself or himself as an individual and senses the need to feel “whole.”

Piaget demonstrated the dominance of perception over logic. In one experiment, water is poured back and forth between a tall, thin vase and a low, wide dish, and children are asked which container has more water. Invariably, they choose the one that looks larger (usually the tall vase), even when the examiner points out that no water has been added or taken away. Such misunderstandings reflect young children's developing hypotheses about the nature of the world, as well as their difficulty in attending simultaneously to multiple aspects of a situation.

Recent work indicating that preschool children do have the ability to understand causal relationships has modified our understanding of the ability of preschool children to engage in abstract thinking (see Chapter 18).

Imitation, central to the learning experience of preschool children, is a complex act because of differences in the size of the operators (the adult and the
child), different levels of dexterity, and even different outcomes. A child who watches an adult unsuccessfully attempt a simple act (unscrew a lid) will imitate the action—but often with the intended outcome, not the demonstrated but failed outcome. Thus “imitation” goes beyond the mere repetition of observed movements.

By age 3, children have self-identified their sex and are actively seeking understanding of the meaning of gender identification. There is a developmental progression from rigidity (boys and girls have strict gender roles) in the early preschool years to a more flexible realistic understanding (boys and girls can have a variety of interests).

**Play**

Play involves learning, physical activity, socialization with peers, and practicing adult roles. Play increases in complexity and imagination, from simple imitation of common experiences, such as shopping and putting baby to bed (2 or 3 yr of age), to more extended scenarios involving singular events, such as going to the zoo or going on a trip (3 or 4 yr of age), to the creation of scenarios that have only been imagined, such as flying to the moon (4 or 5 yr of age). By age 3 yr, cooperative play is seen in activities such as building a tower of blocks together; later, more structured role-play activity, as in playing house, is seen. Play also becomes increasingly governed by rules, from early rules about asking (rather than taking) and sharing (2 or 3 yr of age), to rules that change from moment to moment, according to the desires of the players (4 and 5 yr of age), to the beginning of the recognition of rules as relatively immutable (5 yr of age). Electronic forms of play (games) are best if interactive and educational and should remain limited in duration.

Play also allows for resolution of conflicts and anxiety and for creative outlets. Children can vent anger safely (spanking a doll), take on superpowers (dinosaur and superhero play), and obtain things that are denied in real life (an imaginary friend or stuffed animal). Creativity is particularly apparent in drawing, painting, and other artistic activities. Themes and emotions that emerge in a child's drawings often reflect the emotional issues of greatest importance for the child.

Difficulty distinguishing fantasy from reality colors a child's perception of what the child views in the media, through programming and advertising. One fourth of young children have a television set in their bedroom; a TV in the
bedroom is associated with more hours of watching. The number of hours that most preschoolers watch TV exceeds guidelines (1 hr/day for 2-5 year olds). Interactive quality educational programming in which children develop social relationships with the characters can increase learning if paired with adult interaction around the storyline. However, exposure to commercial TV with violent content is associated with later behavior problems, and because children younger than 8 yr are not able to comprehend the concept of persuasive intent, they are more vulnerable to TV advertising.

**Implications for Parents and Pediatricians**

The significance of language as a target for assessment and intervention cannot be overestimated, because of its central role as an indicator of cognitive and emotional development and a key factor in behavioral regulation and later school success. As language emerges, parents can support emotional development by using words that describe the child's feeling states (“You sound angry right now”) and urging the child to use words to express rather than act out feelings. Active imaginations will come into play when children offer explanations for misbehavior. A parent's best way of dealing with untruths is to address the event, not the child, and have the child participate in “making things right.”

Parents should have a regular time each day for reading or looking at books with their children. Programs such as **Reach Out and Read**, in which pediatricians give out picture books along with appropriate guidance during primary care visits, have been effective in increasing reading aloud and thereby promoting language development, particularly in lower-income families. TV and similar media should be limited to 1 hr/day of quality programming for children aged 2-5 yr, and parents should be watching the programs with their children and debriefing their young children afterward. At-risk children, particularly those living in poverty, can better meet future school challenges if they have early high-quality child care and learning experiences (e.g., Head Start).

Preoperational thinking constrains how children understand experiences of illness and treatment. Children begin to understand that bodies have “insides” and “outsides.” Children should be given simple, concrete explanations for medical procedures and given some control over procedures if possible. Children should be reassured that they are not to blame when receiving a vaccine or venipuncture. An adhesive bandage will help to make the body “whole” again in a child's mind.
The active imagination that fuels play and the magical, animist thinking characteristic of preoperational cognition can also generate intense fears. More than 80% of parents report at least 1 fear in their preschool children. Refusal to take baths or to sit on the toilet may arise from the fear of being washed or flushed away, reflecting a child's immature appreciation of relative size. Attempts to demonstrate rationally that there are no monsters in the closet often fail, inasmuch as the fear arises from preoperational thinking. However, this same thinking allows parents to be endowed with magical powers that can banish the monsters with “monster spray” or a night-light. Parents should acknowledge the fears, offer reassurance and a sense of security, and give the child some sense of control over the situation. Use of the Draw-a-Person, in which a child is asked to draw the best person he or she child can, may help elucidate a child's viewpoint.

**Emotional and Moral Development**

Emotional challenges facing preschool children include accepting limits while maintaining a sense of self-direction, reigning in aggressive and sexual impulses, and interacting with a widening circle of adults and peers. At 2 yr of age, behavioral limits are predominantly external; by 5 yr of age, these controls need to be internalized if a child is to function in a typical classroom. Success in achieving this goal relies on prior emotional development, particularly the ability to use internalized images of trusted adults to provide a secure environment in times of stress. The love a child feels for important adults is the main incentive for the development of self-control.

Children learn what behaviors are acceptable and how much power they wield vis-à-vis important adults by testing limits. **Limit testing** increases when it elicits attention, even though that attention is often negative, and when limits are inconsistent. Testing often arouses parental anger or inappropriate solicitude as a child struggles to separate, and it gives rise to a corresponding parental challenge: letting go. Excessively tight limits can undermine a child's sense of initiative, whereas overly loose limits can provoke anxiety in a child who feels that no one is in control. **Control** is a central issue. Young children cannot control many aspects of their lives, including where they go, how long they stay, and what they take home from the store. They are also prone to lose internal control, that is, to have temper tantrums. Fear, overtiredness, hunger, inconsistent expectations, or
physical discomfort can also evoke tantrums. Tantrums normally appear toward the end of the 1st yr of life and peak in prevalence between 2 and 4 yr of age. Tantrums lasting more than 15 min or regularly occurring more than 3 times/day may reflect underlying medical, emotional, developmental, or social problems.

Preschool children normally experience complicated feelings toward their parents that can include strong attachment and possessiveness toward the parent of the opposite sex, jealousy and resentment of the other parent, and fear that these negative feelings might lead to abandonment. These emotions, most of which are beyond a child's ability to comprehend or verbalize, often find expression in highly labile moods. The resolution of this crisis (a process extending over years) involves a child's unspoken decision to identify with the parents rather than compete with them. Play and language foster the development of emotional controls by allowing children to express emotions and role-play.

Curiosity about genitals and adult sexual organs is normal, as is masturbation. Excessive masturbation interfering with normal activity, acting out sexual intercourse, extreme modesty, or mimicry of adult seductive behavior all suggest the possibility of sexual abuse or inappropriate exposure (see Chapter 16.1). Modesty appears gradually between 4 and 6 yr of age, with wide variations among cultures and families. Parents should begin to teach children about “private” body areas before school entry.

Moral thinking is constrained by a child's cognitive level and language abilities but develops as the child continues her or his identity with the parents. Beginning before the 2nd birthday, the child's sense of right and wrong stems from the desire to earn approval from the parents and avoid negative consequences. The child's impulses are tempered by external forces; the child has not yet internalized societal rules or a sense of justice and fairness. Over time, as the child internalizes parental admonitions, words are substituted for aggressive behaviors. Finally, the child accepts personal responsibility. Actions will be viewed by damage caused, not by intent. Empathic responses to others' distress arise during the 2nd yr of life, but the ability to consider another child's point of view remains limited throughout this period. In keeping with a child's inability to focus on more than one aspect of a situation at a time, fairness is taken to mean equal treatment, regardless of circumstance. A 4 yr old will acknowledge the importance of taking turns, but will complain if he or she “didn't get enough time.” Rules tend to be absolute, with guilt assigned for bad outcomes, regardless of intentions.
Implications for Parents and Pediatricians

The importance of the preschooler's sense of control over his or her body and surroundings has implications for practice. Preparing the patient by letting the child know how the visit will proceed is reassuring. Tell the child what will happen, but do not ask permission unless you are willing to deal with a “no” answer. A brief introduction to “private parts” is warranted before the genital examination.

The visit of the 4 or 5 yr old should be entertaining, because of the child's ability to communicate, as well as the child's natural curiosity. Physicians should realize that all children are occasionally difficult. Guidance emphasizing appropriate expectations for behavioral and emotional development and acknowledging normal parental feelings of anger, guilt, and confusion should be part of all visits at this time. Parents should be queried about daily routines and their expectations of child behavior. Providing children with acceptable choices (all options being acceptable to the parent) and encouraging independence in self-care activities (feeding, dressing, and bathing) will reduce conflicts.

Although some cultures condone the use of corporal punishment for disciplining of young children, it is not a consistently effective means of behavioral control. As children habituate to repeated spanking, parents have to spank ever harder to achieve the desired response, increasing the risk of serious injury. Sufficiently harsh punishment may inhibit undesired behaviors, but at great psychologic cost. Children mimic the corporal punishment that they receive; children who are spanked will have more aggressive behaviors later. Where spanking is the use of force, externally applied, to produce behavior change, discipline is the process that allows the child to internalize controls on behavior. Alternative discipline strategies should be offered, such as the “countdown” for transitions along with consistent limit setting, “time-outs” or “time-ins” (breaks from play with caregiver present and interacting), clear communication of rules, and frequent approval with positive reinforcement of productive play and behavior (see Chapter 19 ). Punishment should be immediate, specific to the behavior, and time-limited. Time-out for approximately 1 min/yr of age is very effective. A kitchen timer allows the parent to step back from the situation; the child is free when the timer rings. Although one strategy might not work for all children uniformly, consistency is integral to healthy learning and growth.
Bibliography

Middle childhood (6-11 yr of age) is the period in which children increasingly separate from parents and seek acceptance from teachers, other adults, and peers. Children begin to feel under pressure to conform to the style and ideals of the peer group. Self-esteem becomes a central issue, as children develop the cognitive ability to consider their own self-evaluations and their perception of how others see them. For the first time, they are judged according to their ability to produce socially valued outputs, such as getting good grades, playing a musical instrument, or hitting home runs.

Physical Development

Growth occurs discontinuously, in 3-6 irregularly timed spurts each year, but varies both within and among individuals. Growth during the period averages 3-3.5 kg (6.6-7.7 lb) and 6-7 cm (2.4-2.8 in) per year (Fig. 25.1). The head grows only 2 cm in circumference throughout the entire period, reflecting a slowing of brain growth. Myelination continues into adolescence, with peak gray matter at 12-14 yr. Body habitus is more erect than previously, with long legs compared with the torso.
Stature-for-age and Weight-for-age percentiles

For boys age 2-20 yr.

To Calculate BMI: Weight (kg) = Stature (cm) - Stature (cm) x 10,000 or Weight (lb) = Stature (in) - Stature (in) x 703.

(Courtesy National Center for Health Statistics, 2000.)
Growth of the midface and lower face occurs gradually. Loss of deciduous (baby) teeth is a more dramatic sign of maturation, beginning around 6 yr of age. Replacement with adult teeth occurs at a rate of about 4 per year, so that by age 9 yr, children will have 8 permanent incisors and 4 permanent molars. Premolars erupt by 11-12 yr of age (see Chapter 333). Lymphoid tissues hypertrophy and reach maximal size, often giving rise to impressive tonsils and adenoids.

Muscular strength, coordination, and stamina increase progressively, as does the ability to perform complex movements, such as dancing or shooting baskets. Such higher-order motor skills are the result of both maturation and training; the degree of accomplishment reflects wide variability in innate skill, interest, and opportunity.

Physical fitness has declined among school-age children. Sedentary habits at this age are associated with increased lifetime risk of obesity, cardiovascular disease, lower academic achievement, and lower self-esteem. The number of overweight children and the degree of overweight have been increasing, although recently at a slower rate (see Chapter 60). Only 15% of middle and junior high schools require physical education class at least 3 days/wk. One quarter of youth do not engage in any free-time physical activity, despite the recommendation for at least 1 hr of physical activity per day.

Perceptions of body image develop early during this period; children as young as 5 and 6 yr express dissatisfaction with their body image; by ages 8 and 9 yr many of these youth report trying to diet, often using ill-advised regimens. Loss-of-control (binge) eating occurs among approximately 6% of children at this age.

Prior to puberty, the sensitivity of the hypothalamus and pituitary changes, leading to increased gonadotropin synthesis. Interest in gender differences and sexual behavior increases progressively until puberty. Although this is a period when sexual drives are limited, masturbation is common, and children may be interested in differences between genders. Rates of maturation differ by geography, ethnicity, and country. Sexual maturity occurs earlier for both genders in the United States. Differences in maturation rates have implications for differing expectations of others based on sexual maturation.

Implications for Parents and Pediatricians
Middle childhood is generally a time of excellent health. However, children have variable sizes, shapes, and abilities. Children of this age compare themselves with others, eliciting feelings about their physical attributes and abilities. Fears of being “abnormal” can lead to avoidance of situations in which physical differences might be revealed, such as gym class or medical examinations. Children with actual physical disabilities may face special stresses. Medical, social, and psychologic risks tend to occur together.

Children should be asked about risk factors for obesity. Participation in physical activity, including organized sports or other organized activities, can foster skill, teamwork, and fitness as well as a sense of accomplishment, but pressure to compete when the activity is no longer enjoyable has negative effects. Counseling on establishing healthy eating habits and limited screen time should be given to all families. Prepubertal children should not engage in high-stress, high-impact sports, such as power lifting or tackle football, because skeletal immaturity increases the risk of injury (see Chapter 713).

**Cognitive Development**

The thinking of early elementary school-age children differs qualitatively from that of preschool children. In place of magical, egocentric, and perception-bound cognition, school-age children increasingly apply rules based on observable phenomena, factor in multiple dimensions and points of view, and interpret their perceptions using physical laws. Piaget documented this shift from preoperational to **concrete (logical) operations**. When 5 yr olds watch a ball of clay being rolled into a snake, they might insist that the snake has “more” because it is longer. In contrast, 7 yr olds typically reply that the ball and the snake must weigh the same because nothing has been added or taken away or because the snake is both longer and thinner. This cognitive reorganization occurs at different rates in different contexts. In the context of social interactions with siblings, young children often demonstrate an ability to understand alternate points of view long before they demonstrate that ability in their thinking about the physical world. Understanding time and space constructs occurs in the later part of this period.

The concept of **school readiness** has evolved. The American Academy of Pediatrics recommends following an “interactional relational” model in which the focus is on the child, the environment, and the resulting interactions. This model explicitly asserts that all children can learn and that the educational
process is reciprocal between the child and the school. It is developmentally based, recognizing the importance of early experiences for later development. Rather than delaying school entry, high-quality early-education programs may be the key to ultimate school success.

School makes increasing cognitive demands on the child. Mastery of the elementary curriculum requires that many perceptual, cognitive, and language processes work efficiently (Table 25.1), and children are expected to attend to many inputs at once. The 1st 2-3 yr of elementary school are devoted to acquiring the fundamentals: reading, writing, and basic mathematics skills. By 3rd grade, children need to be able to sustain attention through a 45 min period, and the curriculum requires more complex tasks. The goal of reading a paragraph is no longer to decode the words, but to understand the content; the goal of writing is no longer spelling or penmanship, but composition. The volume of work increases along with the complexity.

when, only, except), nuances of speech, and extended blocks of language (e.g., paragraphs) | comprehension; problems with peer relationships

| Expressive language | Ability to recall required words effortlessly (word finding), control meanings by varying position and word endings, and construct meaningful paragraphs and stories | Difficulty expressing feelings and using words for self-defense, with resulting frustration and physical acting out; struggling during “circle time” and in language-based subjects (e.g., English) |

Cognitive abilities interact with a wide array of attitudinal and emotional factors in determining classroom performance. These factors include external rewards (eagerness to please adults and approval from peers) and internal rewards (competitiveness, willingness to work for a delayed reward, belief in one's abilities, and ability to risk trying when success is not ensured). Success predisposes to success, whereas failure impacts self-esteem and reduces self-efficacy, diminishing a child's ability to take future risks.

Children's intellectual activity extends beyond the classroom. Beginning in the 3rd or 4th grade, children increasingly enjoy strategy games and wordplay (puns and insults) that exercise their growing cognitive and linguistic mastery. Many become experts on subjects of their own choosing, such as sports trivia, or develop hobbies, such as special card collections. Others become avid readers or take on artistic pursuits. Whereas board and card games were once the usual leisure-time activity of youth, video, computer, and other electronic games currently fill this need.

**Implications for Parents and Pediatricians**

Pediatricians have an important role in preparing their patients for school entrance by promoting health through immunizations, adequate nutrition, appropriate recreation, and screening for physical, developmental, and cognitive disorders. The American Academy of Pediatrics recommends that pediatric providers promote the “5 Rs” of early education: (1) reading as a daily family activity; (2) rhyming, playing, and cuddling together; (3) routines and regular times for meals, play, and sleep; (4) reward through praise for successes; and (5) reciprocal nurturing relationships.

Concrete operations allow children to understand simple explanations for illnesses and necessary treatments, although they may revert to prelogical thinking when under stress. A child with pneumonia may be able to explain about white cells fighting the “germs” in the lungs, but may still secretly harbor the belief that the sickness is a punishment for disobedience.

As children are faced with more abstract concepts, academic and classroom
behavior problems emerge and come to the pediatrician's attention. Referrals may be made to the school for remediation or to community resources (medical or psychologic) when appropriate. The causes may be one or more of the following: deficits in perception (vision and hearing); specific learning disabilities (see Chapters 50 and 51); global cognitive delay (intellectual disability; Chapter 53); deficits in attention and executive function (Chapters 48 and 49); and attention deficits secondary to family dysfunction, depression, anxiety, or chronic illness. Children whose learning style does not fit the classroom culture may have academic difficulties and need assessment before failure sets in. Simply having a child repeat a failed grade rarely has any beneficial effect and often seriously undercuts the child's self-esteem. In addition to finding the problem areas, identifying each child's strengths is important. Educational approaches that value a wide range of talents (“multiple intelligences”) beyond the traditional reading, writing, and mathematics may allow more children to succeed.

The change in cognition allows the child to understand “if/when” clauses. Increased responsibilities and expectations accompany increased rights and privileges. Discipline strategies should move toward negotiation and a clear understanding of consequences, including removal of privileges for infringements.

Social, Emotional, and Moral Development

Social and Emotional Development

In middle childhood, energy is directed toward creativity and productivity. Changes occur in 3 spheres: the home, the school, and the neighborhood. Of these, the home and family remains the most influential. Increasing independence is marked by the first sleepover at a friend's house and the first time at overnight camp. Parents should make demands for effort in school and extracurricular activities, celebrate successes, and offer unconditional acceptance when failures occur. Regular chores, associated with an allowance, provide an opportunity for children to contribute to family functioning and learn the value of money. These responsibilities may be a testing ground for psychologic separation, leading to conflict. Siblings have critical roles as competitors, loyal
supporters, and role models.

The beginning of school coincides with a child's further separation from the family and the increasing importance of teacher and peer relationships. Social groups tend to be same-sex, with frequent changing of membership, contributing to a child's growing social development and competence. Popularity, a central ingredient of self-esteem, may be won through possessions (having the latest electronic gadgets or the right clothes), as well as through personal attractiveness, accomplishments, and actual social skills. Children are aware of racial differences and are beginning to form opinions about racial groups that impact their relationships. Gender identification, which began in early childhood, continues to evolve and can have significant implications for peer relationships and self-awareness.

Some children conform readily to the peer norms and enjoy easy social success. Those who adopt individualistic styles or have visible differences may be teased or bullied. Such children may be painfully aware that they are different, or they may be puzzled by their lack of popularity. Children with deficits in social skills may go to extreme lengths to win acceptance, only to meet with repeated failure. Attributions conferred by peers, such as funny, stupid, bad, or fat, may become incorporated into a child's self-image and affect the child's personality, as well as school performance. Parents may have their greatest effect indirectly, through actions that change the peer group (moving to a new community or insisting on involvement in structured after-school activities). Children who identify with a gender different from their sex of birth, or whose manner and dress reflect those more typically seen as “opposite” their birth sex, may be subject to teasing or, bullying. This can magnify the confusion for these children, who are formulating their own concept of “self.”

In the neighborhood, real dangers, such as busy streets, bullies, violence, and strangers, tax school-age children's common sense and resourcefulness (see Chapter 14). Interactions with peers without close adult supervision call on increasing conflict resolution skills. Media exposure to adult materialism, sexuality, substance use, and violence may be frightening, reinforcing children's feeling of powerlessness in the larger world. Compensatory fantasies of being powerful may fuel the fascination with heroes and superheroes. A balance between fantasy and an appropriate ability to negotiate real-world challenges indicates healthy emotional development.
Moral Development

Although by age 6 yr most children will have a conscience (internalized rules of society), they vary greatly in their level of moral development. For the younger youth, many still subscribe to the notion that rules are established and enforced by an authority figure (parent or teacher), and decision-making is guided by self-interest (avoidance of negative and receipt of positive consequences). The needs of others are not strongly considered in decision-making. As they grow older, most will recognize not only their own needs and desires but also those of others, although personal consequences are still the primary driver of behavior. Social behaviors that are socially undesirable are considered wrong. By age 10-11 yr, the combination of peer pressure, a desire to please authority figures, and an understanding of reciprocity (treat others as you wish to be treated) shapes the child's behavior.

Implications for Parents and Pediatricians

Children need unconditional support as well as realistic demands as they venture into a world that is often frightening. A daily query from parents over the dinner table or at bedtime about the good and bad things that happened during the child's day may uncover problems early. Parents may have difficulty allowing the child independence or may exert excessive pressure on their children to achieve academic or competitive success. Children who struggle to meet such expectations may have behavior problems or psychosomatic complaints.

Many children face stressors that exceed the normal challenges of separation and success in school and the neighborhood. Divorce affects almost 50% of children. Domestic violence, parental substance abuse, and other mental health problems may also impair a child's ability to use home as a secure base for refueling emotional energies. In many neighborhoods, random violence makes the normal development of independence extremely dangerous. Older children may join gangs as a means of self-protection and a way to attain recognition and to belong to a cohesive group. Children who bully others and those who are victims of bullying should be evaluated, since bullying is associated with mood disorders, family problems, and school adjustment problems. Parents should reduce exposure to hazards where possible. Because of the risk of unintentional firearm injuries to children, parents should be encouraged to ask parents of playmates whether a gun is kept in their home and, if so, how it is secured.
high prevalence of adjustment disorders among school-age children attests to the effects of such overwhelming stressors on development.

Pediatrician visits are infrequent in this period; therefore each visit is an opportunity to assess children's functioning in all contexts (home, school, neighborhood). Maladaptive behaviors, both internalizing and externalizing, occur when stress in any of these environments overwhelms the child's coping responses. Because of continuous exposure and the strong influence of media (programming and advertisements) on children's beliefs and attitudes, parents must be alert to exposures from television and Internet. An average American youth spends over 6 hr/day with a variety of media, and 65% of these children have a TV in their bedrooms. Parents should be advised to remove the TV from their children's rooms, limit viewing to 2 hr/day, and monitor what programs children watch. The **Draw-a-Person** (for ages 3-10 yr, with instructions to “draw a complete person”) and **Kinetic Family Drawing** (beginning at age 5 yr, with instructions to “draw a picture of everyone in your family doing something”) are useful office tools to assess a child's functioning.

CHAPTER 26

Adolescence

See Part XII, Chapter 132, Adolescent Physical and Social Development.
Growth can be considered a vital sign in children, and aberrant growth may be the first sign of an underlying pathologic condition. The most powerful tool in growth assessment is the growth chart (Figs. 23.1, 23.2, 25.1, and 27.1), used in combination with accurate measurements of height, weight, head circumference, and calculation of the body mass index.

**Techniques to Measure Growth**

Growth assessment requires accurate and precise measurements. For infants and toddlers age <2 yr, weight, length, and head circumference are obtained. Head circumference is measured with a flexible tape measure starting at the supraorbital ridge around to the occipital prominence in the back of the head, locating the maximal circumference. Height and weight measures should be performed with the infant naked, and ideally, repeated measures will be performed on the same equipment. Recumbent length is most accurately measured by two examiners (one to position the child). Hair ornaments and hairstyles that interfere with measurements and positioning should be removed. The child's head is positioned against an inflexible measuring board in the Frankfort plane, in which the outer canthi of the eyes are in line with the external auditory meatus and are perpendicular to the long axis of the trunk. Legs should be fully extended, and feet are maintained perpendicular to the plane of the supine infant. For older children (>2 yr) who can stand unassisted, standing heights should be obtained without shoes, using a stadiometer with the head in the Frankfort plane, and the back of the head, thoracic spine, buttocks, and heels approximating the vertical axis of one another and the stadiometer.

Measurements obtained using alternative means, such as marking examination
paper at the foot and head of a supine infant or using a tape measure or wall growth chart with a book or ruler on the head can lead to inaccuracy and render the measurement useless.

Measurements for height and weight should be plotted on the age-appropriate growth curve. Comparing measurements with previous growth trends, repeating measures that are inconsistent, and plotting results longitudinally are essential for monitoring growth. Calculation of interim linear height velocity, such as centimeters per year (cm/yr), allows more precise comparison of growth rate to the norm (Table 27.1).

If a child is growing faster or more slowly than expected, measurement of body proportions, which follow a predictable sequence of changes with development, are useful. The head and trunk are relatively large at birth, with progressive lengthening of the limbs throughout development, particularly during puberty. The upper-to-lower body segment ratio (U/L ratio) provides an assessment of truncal growth relative to limb growth. The lower-body segment is defined as the length from the top of the symphysis pubis to the floor, and the upper-body segment is the total height minus the lower-body segment. The U/L ratio equals approximately 1.7 at birth, 1.3 at 3 yr, and 1.0 after 7 yr. Higher U/L ratios are characteristic of short-limb dwarfism, as occurs with Turner syndrome or bone disorders, whereas lower ratios suggest hypogonadism or Marfan syndrome.

Arm span also provides assessment of proportionality and is measured as the distance between the tips of the middle fingers while the patient stands with the back against the wall with arms outstretched horizontally at a 90-degree angle to the trunk. This span should be close to height, although the proportion changes with age.
Growth Curves

The American Academy of Pediatrics (AAP) and the U.S. Centers for Disease Control and Prevention (CDC) recommend use of the 2006 World Health Organization (WHO) growth curves for children age 0-24 mo and the 2000 CDC growth curves for children age 2-19 yr ([https://www.cdc.gov/growthcharts](https://www.cdc.gov/growthcharts)). There are 5 standard gender-specific charts: (1) weight for age, (2) height (length and stature) for age, (3) head circumference for age, (4) weight for height (length and stature) for infants, and (5) body mass index for age (Fig. 27.1 ; see also Figs. 23.1, 23.2, and 25.1 ). Clinicians should confirm that the correct CDC and WHO growth charts are used in electronic medical records to ensure accurate characterization of growth.
Body mass index-for-age percentiles for boys, age 2-20 yr. (Official Centers for Disease Control [CDC] growth charts, as described in this chapter. The 85th to 95th percentile is at risk for overweight; >95th percentile is overweight; <5th percentile is underweight. Technical information and interpretation and management guides are available at [CDC website](http://www.cdc.gov/growthcharts).
B, Body mass index (BMI) percentiles for girls, age 2-20 yr.

FIG. 27.1
The WHO curves describe growth differently than the CDC curves (Fig. 27.2). The WHO curves are growth standards that describe how children grow under optimal conditions, whereas the CDC curves are growth references that describe how children grew in a specific time and place. The WHO growth curves are based on longitudinal growth studies in which cohorts of newborns were chosen from six countries (Brazil, Ghana, India, Norway, Oman, United States) using specific inclusion and exclusion criteria; all infants were breastfed for at least 12 months and were predominantly breastfed for the first 4 mo of life. They were measured regularly from birth to 23 mo during 1997–2003. In contrast, the CDC curves are based on cross-sectional data from different studies during different time points. Growth curves for children age 2-59 mo were based on the National Health and Nutrition Examination Survey (NHANES), which included a cross section of the U.S. population. These data were supplemented with additional participants in a separate nutrition surveillance study.

**FIG. 27.2** Comparison of WHO and CDC growth chart prevalence of low length for age, low weight for age, and high weight for length among children age <24 mo, United States, 1999–2004. *, ≤5th percentile on the CDC charts; ≤2.3rd percentile on the WHO charts. †, ≥95th percentile on the CDC charts; ≥97.7th percentile on the WHO charts. (Data from the National Health and Nutrition Examination Survey, 1999–2004; from Grummer-Strawn LM, Reinold C, Krebs NF; Centers for Disease Control and Prevention: Use of World Health Organization and CDC growth charts for children aged 0-59 months in the United States, *MMWR Recomm Rep* 59(RR-9):1–15, 2010.)
Several deficiencies of the older charts have been corrected, such as the overrepresentation of bottle-fed infants and the reliance on a local dataset for the infant charts. The disjunction between length and height when transitioning from the infant curves to those for older children is improved.

Each chart is composed of percentile curves, which indicate the percentage of children at a given age on the x axis whose measured value falls below the corresponding value on the y axis. The 2006 WHO growth curves include values that are 2 standard deviations (SD) above and below median (2nd and 98th percentiles), whereas the 2000 CDC growth curves include 3rd and 97th percentiles. On the WHO weight chart for boys age 0-24 mo (see Fig. 23.2A), the 9 mo age line intersects the 25th percentile curve at 8.3 kg, indicating that 25% of 9 mo old boys in the WHO cohorts weigh less than 8.3 kg (75% weigh more). Similarly, a 9 mo old boy weighing more than 11 kg is heavier than 98% of his peers. The median or 50th percentile is also termed the standard value, in the sense that the standard length for a 7 mo old girl is 67.3 cm (see Fig. 23.2B). The weight-for-length charts (see Fig. 23.1) are constructed in an analogous fashion, with length or stature in place of age on the x axis; the median or standard weight for a girl measuring 100 cm is 15 kg.

Extremes of height or weight can also be expressed in terms of the age for which they would represent the standard or median. For instance, an 18 mo old girl who is 74.9 cm (2nd percentile) is at the 50th percentile for a 13 mo old. Thus the height age is 13 mo. Weight age can also be expressed this way.

In assessing adolescents, caution must be used in applying cross-sectional charts. Growth during adolescence is linked temporally to the onset of puberty, which varies widely. Normal variations in the timing of the growth spurt can lead to misdiagnosis of growth abnormalities. By using cross-sectional data based on chronological age, the charts combine youth who are at different stages of maturation. Data for 12 yr old boys include both earlier-maturing boys who are at the peak of their growth spurts and later-maturing ones who are still growing at their prepubertal rate. The net results are an artificially blunted growth peak, and the appearance that adolescents grow more gradually and for a longer duration than in actuality.

When additional insight is necessary, growth charts derived from longitudinal data, such as the height velocity charts of Tanner and colleagues, are recommended. The longitudinal component of these velocity curves are based on British children from the 1950s–1960s, and cross-sectional data from U.S. children were superimposed. More recently, height velocity curves based on
longitudinal data from a multiethnic study conducted at five U.S. sites included standard deviation scores for height velocity for earlier- and later-maturing adolescents to facilitate the identification of poor or accelerated linear growth. Specialized growth charts have been developed for U.S. children with various conditions, including very low birthweight, small for gestational age, trisomy 21, Turner syndrome, and achondroplasia, and should be used when appropriate.

Facilitating identification of obesity, the charts include curves for plotting body mass index (BMI) for ages 2-20 yr rather than weight for height (see Fig. 27.1). Methodological steps have ensured that the increase in the prevalence of obesity has not unduly raised the upper limits of normal. BMI can be calculated as weight in kilograms/(height in meters)$^2$ or weight in pounds/(height in inches)$^2 \times 703$, with fractions of pounds and inches expressed as decimals. Because of variable weight and height gains during childhood, BMI must be interpreted relative to age and sex; BMI percentile provides a more standardized comparison. For example, a 6 yr old girl with BMI of 19.7 kg/m$^2$ (97th percentile) is obese, whereas a 15 yr old girl with BMI of 19.7 kg/m$^2$ (50th percentile) is normal weight.

**Normal Growth**

Height is highly correlated with genetics, specifically parental height. Calculation of sex-adjusted midparental height is important when assessing growth in a child to avoid misclassification of abnormal growth. The average difference in stature between men and women is 5 inches (13 cm); therefore 5 inches (13 cm) is subtracted from father's height before averaging with mother's height in a female, whereas 5 inches (13 cm) is added to mother's height before averaging with father's height in a male:

- **Boys:** $\frac{(\text{Maternal height} + 5 \text{ inches}) + \text{Paternal height}}{2}$
- **Girls:** $\frac{\text{Maternal height} + (\text{Paternal height} - 5 \text{ inches})}{2}$

Furthermore, generally 4 inches (2 SD) is applied above and below this value.
to provide a *genetic target height range*. For example, if the mother is 63 inches tall and the father 70 inches tall, the daughter's sex-adjusted midparental height is 64 inches ± 4 inches, for a target height range of 60-68 inches. The son of these same parents would have a sex-adjusted midparental height of 69 inches, with a range of 65-73 inches. Note that these general guidelines do not address extreme differences between parental heights that may affect individual target height range.

Growth can be divided into four major phases: fetal, infantile, childhood, and adolescence. Growth rate varies by age (see Table 27.1). Different factors are of different importance in each phase, and the various contributors to poor growth may feature more in one phase than another. Long-term height may be permanently compromised if one entire phase is characterized by poor growth. Therefore, early detection and prevention are critical. **Fetal growth** is the fastest growth phase, with maternal, placental, fetal, and environmental factors playing key roles. Birthweight does not necessarily correlate with adult height, although factors that inhibit fetal growth may have long-lasting effects, as seen in children with intrauterine growth retardation. **Infantile growth** is particularly sensitive to nutrition as well as congenital conditions. Genetic height gradually becomes influential; indeed, crossing of percentiles in the 1st 2 yr of life is common as children begin to approach their genetic potential. **Childhood growth** is often the most steady and predictable. During this phase the height percentile channel is fairly consistent in otherwise healthy children.

**Adolescent growth** is associated with a decrease in growth velocity prior to the onset of puberty; this deceleration tends to be more pronounced in males. During pubertal development, sex hormones (testosterone and estrogen) are the primary drivers of growth and enhance growth hormone secretion, thereby facilitating pubertal growth acceleration. Girls typically experience growth acceleration during Tanner Stage 3 for breast development, whereas this acceleration occurs during Tanner Stage 4 for pubic hair development in boys. Boys not only achieve greater height velocities than girls during puberty, but also grow approximately 2 yr longer than girls, both of which contribute to the taller average height of adult men compared with adult women.

**Abnormal Growth**

Growth is a dynamic process. A child measured at the 5th percentile for stature may be growing normally, may be failing to grow, or may be recovering from
growth failure, depending on the trajectory of the growth curve (Fig. 27.3). Growth failure must be distinguished from short stature. **Growth failure** is defined as achievement of height velocity that is less than expected for a child's age and sex (and pubertal development if relevant) or a downward crossing of more than 2 percentile lines for height on the growth chart. **Short stature** is defined as growing either below expected genetic potential or growing below $-2$ SD for age and sex. For some children, however, growth parameters $<-2$ SD may be normal, and differentiating appropriately small vs pathologically small is crucial. Midparental height, ethnicity, and other factors that may be inherent in the child's genetic potential for growth are important considerations in the assessment of growth. For children with particularly tall or short parents, overdiagnosing and underdiagnosing growth disorders are risks if parental heights are not taken into account. In the setting of familial short stature or tall status, more specialized charts can help determine if a child is even shorter or taller than expected for parental heights, to prevent misdiagnosis of growth disorders.

**FIG. 27.3** Height-for-age curves of the 4 general causes of proportional...
For premature infants, overdiagnosis of growth failure can be avoided by using growth charts developed specifically for this population. A cruder method, subtracting the weeks of prematurity from the postnatal age when plotting growth parameters, does not capture the variability in growth velocity that very-low-birthweight (VLBW) infants demonstrate. Although VLBW infants may continue to show catch-up growth through early school age, most achieve weight catch-up during the 2nd year and height catch-up by 3-4 yr, barring medical complications (see Chapter 117).

Abnormal growth may be caused by a variety of factors, including congenital conditions, systemic disease, endocrine disorders, nutritional deficiency (see Chapter 57), psychosocial conditions, constitutional delay, or familial disorders (Tables 27.2 and 27.3). In congenital pathologic short stature, an infant may or may not be born small, but growth gradually tapers throughout infancy (Fig. 27.3). Causes include chromosome or genetic abnormalities (Turner syndrome, skeletal dysplasia, trisomy 21; see Chapter 98), perinatal infection, extreme prematurity, and teratogens (phenytoin, alcohol) (see Chapter 115.5). Linear growth deceleration with or without changes in weight can occur at the onset or as a result of a systemic illness or chronic inflammation. Medications such as high-dose glucocorticoids may also impact growth. Analysis of growth patterns requires consideration of weight status. Poor linear growth in the setting of decreasing BMI suggests a nutritional or gastrointestinal issue, whereas poor linear growth in the context of good or robust BMI suggests a hormonal condition (hypothyroidism, growth hormone deficiency, cortisol excess).

Table 27.3
Common Causes of Increased Growth and Tall Stature

Variation of normal
Constitutional tall stature
Familial tall stature

Endocrine conditions
Growth hormone excess
Precocious puberty
Congenital adrenal hyperplasia
Not all decreased growth is abnormal; variations of growth include constitutional growth (and pubertal) delay and familial short stature. In constitutional growth delay, weight and height decrease near the end of infancy, parallel the norm through middle childhood, and accelerate toward the end of adolescence with achievement of normal adult height. In familial short stature, both the infant/child and the parent(s) are small; growth runs parallel to and just below the normal curves.

Although tall or accelerated growth may be a variation of normal, unexpected increase in growth may also signal an underlying condition (Table 27.3). Typically, obese individuals grow more quickly than their peers because of peripheral aromatization of estrogen and effects on bone maturation. Despite early taller stature, obese children are not ultimately taller than anticipated for genetic height. Early onset of puberty, growth hormone excess, and sex steroid exposure can also lead to accelerated growth. Several of these conditions may ultimately lead to short stature in adulthood. Genetic conditions associated with tall stature and overgrowth include Sotos, Klinefelter, and Marfan syndromes (see Chapter 576).

**Evaluation of Abnormal Growth**

Evaluation of abnormal growth should include confirmation that the data are accurate and plotted correctly. Comparisons should be made with previous measurements. If poor or rapid growth or short or tall stature is a concern, a radiograph of the left hand and wrist, the bone age, can provide information about skeletal maturation. Skeletal development represents physiologic rather than chronological age. Reference standards for bone maturation facilitate estimation of bone age (see Table 22.3). A delayed bone age (skeletal age younger than chronological age) suggests catch-up potential for linear growth. Advanced bone age suggests a rapid maturation of the skeleton that may lead to earlier cessation of growth. Bone age should be interpreted with the guidance of a pediatric endocrinologist. Skeletal age correlates well with stage of pubertal
development and may be helpful in predicting adult height in early- or late-maturing adolescents. In familial short stature the bone age is normal (comparable to chronological age), whereas constitutional delay, endocrinologic short stature, and undernutrition may be associated with delay in bone age comparable to the height age.

Laboratory testing is also useful in assessment of growth and may be tailored to suspected etiology based on the patient history and physical examination. Initial assessment includes comprehensive metabolic panel, complete blood count, sedimentation rate, C-reactive protein, thyroid-stimulating hormone, thyroxine, celiac panel, and insulin-like growth factor (IGF)-I and IGF-BP3, which are surrogate markers for growth hormone secretion (see Chapter 573). A karyotype to exclude Turner syndrome is an essential component of the evaluation of short stature in females and should be performed even in the absence of characteristic physical features (see Chapter 604). If there is concern for abnormal timing of puberty contributing to growth pattern, gonadotropins (luteinizing hormone, follicle-stimulating hormone), and estradiol or testosterone may also be assessed. A urinalysis can provide additional information about renal function. Evaluation by a (pediatric) nutritionist for caloric needs assessment may be useful in patients with malnutrition, underweight status, or slow weight gain. Additional testing and referral to specialists should be performed as indicated.

**Other Growth Considerations**

**Obesity**

Obesity affects large numbers of children (see Chapter 60). The CDC defines obesity as BMI ≥95th percentile for age and sex, and overweight as BMI 85th to <95th percentile for age and sex. Although widely accepted as the best clinical measure of underweight and overweight, BMI may not provide an accurate index of adiposity because it does not differentiate lean tissue and bone from fat. In otherwise healthy individuals, lean body mass is largely represented by BMI at lower percentiles. BMI >80–85% largely reflects increased body fat with a nonlinear relationship between BMI and adiposity. In the setting of chronic illness, increased body fat may be present at low BMI, whereas in athletes, high BMI may reflect increased muscle mass. Measurement of the triceps, subscapular, and suprailiac skinfold thickness have been used to estimate
adiposity. Other methods of measuring fat, such as hydrodensitometry, bioelectrical impedance, and total body water measurement, are used in research, but not in clinical evaluation, but whole body dual-energy x-ray absorptiometry (DXA) is beginning to emerge as a tool for measuring body fat and lean body mass.

Dental Development

Dental development includes mineralization, eruption, and exfoliation (Table 27.4). Initial mineralization begins as early as the 2nd trimester (mean age for central incisors, 14 wk) and continues through 3 yr of age for the primary (deciduous) teeth and 25 yr of age for the secondary (permanent) teeth. Mineralization begins at the crown and progresses toward the root. Eruption begins with the central incisors and progresses laterally. Exfoliation begins at about 6 yr of age and continues through 12 yr. Eruption of the permanent teeth may follow exfoliation immediately or may lag by 4-5 mo. The timing of dental development is poorly correlated with other processes of growth and maturation. Delayed eruption is usually considered when no teeth have erupted by approximately 13 mo of age (mean ± 3 SD). Common causes include congenital or genetic disorders, endocrine disorders (e.g., hypothyroidism, hypoparathyroidism), familial conditions, and (the most common) idiopathic conditions. Individual teeth may fail to erupt because of mechanical blockage (crowding, gum fibrosis). Causes of early exfoliation include hypophosphatasia, histiocytosis X, cyclic neutropenia, leukemia, trauma, and idiopathic factors. Nutritional and metabolic disturbances, prolonged illness, and certain medications (tetracycline) frequently result in discoloration or malformations of the dental enamel. A discrete line of pitting on the enamel suggests a time-limited insult.

## Bibliography

Tanner JM, Davies PSW. Clinical longitudinal standards for

In healthy development, a child will acquire new skills beginning prenatally and extending into at least young adulthood. The roots of this acquisition of skills lie in the development of the nervous system, with additional influences from the health status of other organ systems and the physical and social environment in which the development occurs. Development and its milestones are divided into the “streams” of gross motor, fine motor, verbal language (expressive and receptive), social language, and self-help. Behavior can be categorized into observable, spontaneous, and responsive behaviors in the settings of home, school, and community.

Although typical development is associated with a wide variability of skill acquisition in each of these streams, specific developmental and behavioral disorders are seen in approximately 1 of every 6 children and may affect the health, function, and well-being of the child and family for a lifetime. These disorders include rare conditions that often cause severe impairments, such as cerebral palsy and autism, and relatively common conditions such as attention-deficit/hyperactivity disorder, speech language disorders, and behavioral and emotional disorders that affect as many as 1 in 4 children. The more common conditions are generally perceived as “less severe,” but these too can have major short-term and long-term impact on the child's health and daily functioning in the home, school, and community and can affect lifelong well-being. Because of their high prevalence in children; their impact on health, social, and economic status; and their effect on the child, the home, and the community, these disorders require the attention of the pediatrician throughout childhood. In addition, both the child and the family benefit from the early identification and treatment of many of these conditions, including the most severe. It is therefore
incumbent on the pediatric clinician to conduct regular **developmental surveillance** and periodic **developmental screening** at primary care health supervision visits aimed at early identification and treatment.

Among the many types of developmental or behavioral conditions, the most common include *language problems*, affecting at least 1 in 10 children (see Chapter 52); *behavior or emotional disorders*, affecting up to 25% of children, with 6% considered serious; *attention-deficit/hyperactivity disorder*, affecting 1 in 10 children (Chapter 49); and *learning disabilities*, affecting up to 10% (Chapters 50 and 51). Less common and more disabling are the *intellectual disabilities* (1–2%; Chapter 53); *autism spectrum disorders* (1 in 59 children; Chapter 54); *cerebral palsy* and related *motor impairments* (0.3%, or 1 in 345 children; Chapter 616); *hearing impairment*, also referred to as deafness, hard-of-hearing, or hearing loss (0.12%; Chapter 655); and *nonrefractive vision impairment* (0.8%; Chapter 639).

## Developmental and Behavioral Surveillance

General health surveillance is a critical responsibility of the primary care clinician and is a key component of health supervision visits. Regular developmental and behavioral surveillance should be performed at every health supervision visit from infancy through young adulthood. Surveillance of a child's development and behavior includes both obtaining historical information on the child and family and making observations at the office visit (Tables 28.1 and 28.2).

### Table 28.1

**Key Components of Developmental and Behavioral Surveillance**

**History**

1. Parental developmental concerns
2. Developmental history
   - a. Streams of developmental milestone achievement
     i. Gross motor
ii. Fine motor

iii. Verbal speech and language
   (1) Expressive
   (2) Receptive

iv. Social language and self-help

b. Patterns of abnormality
   i. Delay
   ii. Dissociation
   iii. Deviancy or deviation
   iv. Regression

3. Behavior history
   a. Interactions
      i. Familiar settings (e.g. home, school): parents, siblings, other familiar people, peers, other children
      ii. Interaction in unfamiliar settings (e.g., community): unfamiliar adults and children
   b. Patterns of abnormality
      i. Noncompliance, disruption (including tantrums), aggression, impulsivity, increased activity, decreased attention span, decreased social engagement, decreased auditory or visual attention
      ii. Deviation or atypical behaviors
         (1) Repetitive play, rituals, perseverative thought or action, self-injury

4. Risk factor identification: medical, family, and social history (including social determinants of health)

5. Protective factor identification (also including social determinants)

**Developmental Observation**

1. Movement: gross and fine motor skills
2. Verbal communication: expressive speech and language, language understanding
3. Social engagement and response
4. Behavior: spontaneous and responsive with caregiver and with staff
5. Related neurologic function on physical examination
Table 28.2
“Red Flags” in Developmental Screening and Surveillance*

These indicators suggest that development is seriously disordered and that the child should be promptly referred to a developmental or community pediatrician.

Positive Indicators

Presence of Any of the Following:

- Loss of developmental skills at any age
- Parental or professional concerns about vision, fixing, or following an object or a confirmed visual impairment at any age (simultaneous referral to pediatric ophthalmology)
- Hearing loss at any age (simultaneous referral for expert audiologic or ear, nose, and throat assessment)
- Persistently low muscle tone or floppiness
- No speech by 18 mo, especially if the child does not try to communicate by other means, such as gestures (simultaneous referral for urgent hearing test)
- Asymmetry of movements or other features suggestive of cerebral palsy, such as increased muscle tone
- Persistent toe walking
- Complex disabilities
- Head circumference above the 99.6th centile or below 0.4th centile; also, if circumference has crossed 2 centiles (up or down) on the appropriate chart or is disproportionate to parental head circumference
- An assessing clinician who is uncertain about any aspect of assessment but thinks that development may be disordered

Negative Indicators

Activities That the Child Cannot Do:

- Sit unsupported by 12 mo
- Walk by 18 mo (boys) or 2 yr (girls) (check creatine kinase urgently)
Walk other than on tiptoes
Run by 2.5 yr
Hold object placed in hand by 5 mo (corrected for gestation)
Reach for objects by 6 mo (corrected for gestation)
Point at objects to share interest with others by 2 yr

* Most children do not have “red flags” and thus require quality screening to detect any problems.

Key historical elements include (1) eliciting and attending to the parents' or caregivers' concerns around the child's development or behavior; (2) obtaining a history of the child's developmental skills and behavior at home, with peers, in school, and in the community; and (3) identifying the risks, strengths, and protective factors for development and behavior in the child and family, including the social determinants of health. During the office visit, the clinician should make and document direct observations of the child's developmental skills and behavioral interactions. Skills in all streams of development should be considered along with observations of related neurologic functioning made on physical examination.

With this history and observation, the clinician should create and maintain a longitudinal record of the child's development and behavior for tracking the child across visits. It is often helpful to obtain information from and share information with other professionals involved with the child, including childcare professionals, home visitors, teachers, after-school providers, and developmental therapists. This provides a complete picture of the child's development and behavior and allows collaborative tracking of the child's progress.

The Developmental and Behavioral Histories

Developmental surveillance includes tracking a child's achievement of milestones, which represent key readily recognizable skills that usually occur in a predictable sequence and at predictable age ranges during childhood. The
developmental skill areas can be divided into gross motor, fine motor, verbal speech and language (expressive and receptive), social language, and self-help. Tracking milestones will reveal that most children achieve the milestones in a typical pattern and within typical age ranges. However, the pediatrician or the parent may recognize concerning patterns of development, such as delay, dissociation, deviancy or deviation, or regression.

Developmental delay occurs when development is occurring in its usual sequence but at a slower rate, with milestones achieved later than the normal range (see Chapter 53). Delay can occur in a single area of development or across several streams and can be expressed as a developmental quotient (DQ). The DQ is calculated by dividing the age at which the child is functioning developmentally (developmental age; DA) by chronologic age (CA) and multiplying by 100 (DQ = DA/CA × 100). A DQ of 100 indicates that the child is developing at the mean or average rate, whereas a DQ below 70 is approximately 2 standard deviations (SD) below the mean and suggests a significant delay that requires further evaluation.

Developmental dissociation indicates delay in a single stream with typical development in other streams. A child with autism may have delays in verbal or social language but normal motor skills. Deviancy or deviation is defined by development occurring out of sequence, as when a child stands before sitting (as in diplegic cerebral palsy) or has better expressive vocabulary than receptive understanding of words (language and autism spectrum disorders). Regression refers to a loss of skills. It may also be identified earlier or more subtly by a slowing or lack of advancement in skills. Although uncommon, regression is described in as many as 1 in 4 children with autism and is also seen in rarer neurologic disorders, such as Rett syndrome and Duchenne muscular dystrophy (see Chapter 53.1).

Behavioral surveillance is conducted by obtaining a history of a child's behavior and interactions across settings, including home, daycare, school, and community, and in situations such as eating, sleeping, and play. In addition, interactions may differ based on who the child is with (parent or guardian, sibling, peers, strangers). Concerns may include limited engagement or socializing, compliance, tantrums, aggression, impulsivity, activity level, auditory or visual attention, and attention span. Deviations from usual behavior may also occur, including repetitive play, ritualistic behaviors, perseverative thoughts or actions, and self-injury.
Observation

Observations of the child's developmental skills and behavioral interactions should be made in the examining room, with documentation in the medical record, and combined with the examination of other neurologic functioning, such as muscle tone, reflexes, and posture.

Developmental observations may include a child's gross and fine motor movements, both on the floor and on the examination table. Spoken language and response to others' communications, as well as interactions and engagement with the parent or guardian, should be noted. If siblings are in the room, the interaction between the child and a sibling may also be informative. Impulsivity, attention problems, tantrums, noncompliance, oppositionality, and aggression may be observed along with interactions with the clinician, but one should inquire about whether these behaviors are seen in other settings, given the possible unfamiliarity or discomfort of the child with the healthcare professional or in healthcare settings.

If inquiring about and observing the child's development and behavior suggests normal or typical patterns of development and behavior, discussions can be held about future milestones and usual behavior management strategies employable at home. If problems or concerns are identified by the parent or clinician, however, formal developmental screening, evaluation, or management should be considered, along with early follow-up and review.

Developmental and Behavioral Screening

Periodic episodic screening for developmental and behavioral conditions should be conducted on every child, as done for other health conditions such as anemia, lead poisoning, hearing, and congenital metabolic disorders. Developmental and behavioral screenings are centered on administration of low-cost, brief, and standardized tests designed for such purposes in the primary care office setting. These tests can be implemented by health assistants at age-determined visits, with interpretation of the results and referral or treatment initiation by the pediatric healthcare clinician as indicated.

The American Academy of Pediatrics provides recommendations and guidelines on age-specific developmental screening for implementation in the primary care medical home. Developmental screening using a formal, validated, and standardized test is recommended during the 1st 3 yr of life at the preventive
care visit at 9 m, 18 mo, and 30 mo. Tests recommended at these ages screen development across all the streams. In addition, an autism screening test is recommended at the 18 and 24 mo visits. Table 28.3 provides recommended screening tests for general development and for autism. It is also recommended that a child have a screening test administered any time that a parent, guardian, or child health or early childhood professional has concerns identified during developmental surveillance, or through screening performed at early childhood programs. Although routine formal screening before the child's entry into elementary school is not included in current guidelines, the primary care clinician should be vigilant about surveillance regarding development at the 4 or 5 yr old visit and perform formal screening if concerns are identified, because of the potential impact on learning and school services.

† Initial validation studies have been completed. Further validation on large populations is currently in progress. Dev, Development.

Each of the screening visits offers special opportunities to identify specific developmental conditions. At the 9 mo screening, critical areas of development are vision, hearing, gross motor, fine motor, and receptive language. It is at this age that disabilities may be identified in vision or hearing, as well as cerebral palsy and other neuromotor disorders. At 18 mo, expressive language and social language development are particularly important areas. Conditions identified at this age may include those considered at 9 mo, although in milder forms, as well as autism spectrum, language, and intellectual disorders. By the 30 mo visit, the child's behavioral interactions become an additional area of focus, with problems emerging tied to attention and disruptive behavior disorders. While universal screening is not recommended at later ages, developmental surveillance may
identify children in need of screening or evaluation for problems in learning, attention, and behavior.

Additional screening for behavioral conditions should be considered, although there is currently no recommended consensus on the ages at which behavioral screening should occur. One possibility would be to provide behavioral screening at the 30 mo, 4 or 5 yr, and 8 yr visits to identify problems emerging in the toddler, preschool, and early elementary years. For older children, visits during preadolescent or adolescent ages also offer an opportunity for surveillance and possible screening for behavioral and emotional problems meriting professional assistance or intervention. Table 28.4 provides recommended behavior screening tools.

**Evidence-Based Tools**

Tables 28.3, 28.4, and 28.5 show a range of measures useful for early identification of developmental and behavioral problems, including autism spectrum disorders. Because well-child visits are brief and with broad agendas (health surveillance and screening, physical examination, immunization,
anticipatory guidance, safety and injury prevention, and developmental promotion), tools relying on parent completion with office staff administration and scoring are well suited for primary care settings. Such tests may be completed in advance of appointments, either online or in writing, whether at home or while waiting for the pediatric visit to begin. If a test is scored in advance of the visit, the pediatric clinician can enter the room with results in hand for review and discussion, including a description of the child's development and behavior compared with peers, general information on child development and behavior, any areas of concern, referrals needed, and information to share with the child's daycare, preschool, or other community providers, when applicable.

Screening Test Properties

Each of the tests provided in Tables 28.3 to 28.5 meets accepted psychometric test criteria. The test has norms, with standardized questions or milestones based on administration to parents of a large sample of children with typical development. These norms are used for comparing an individual child's performance on the test with that of the large sample of typically developing children. In addition, the tests demonstrate accepted standards of reliability, or the ability to produce consistent results; predictive validity, or the ability to predict later test performance or development; sensitivity, or accuracy in the identification of delayed development or disability; and specificity, or accuracy in the identification of children who are not delayed. Some of the screening tests are general, evaluating multiple areas of development or behavior (sometimes referred to as “broad band”). Others are domain specific, evaluating one area of development (e.g., language), or disorder specific, aimed at identifying a specific developmental disorder (sometimes referred to as “narrow band”).

Beyond Surveillance and Screening

Comprehensive Evaluation

When a developmental or behavioral concern is identified through surveillance or screening, the primary care physician's role is to ensure that the child receives an appropriate diagnostic evaluation, related medical testing, and indicated
developmental interventions and medical treatment. When a concern is identified, a full diagnostic evaluation should be performed by a professional with appropriate training and experience. In the case of developmental concerns, this may be a pediatric specialist, such as a neurodevelopmental pediatrician/neurologist or a developmental-behavioral pediatrician, or a related developmental professional, depending on resources in the local community. Related professionals may include early childhood educators, psychologists, speech/language pathologists, audiologists, physical therapists, and occupational therapists, many of whom are available through the local early intervention system. Such an evaluation would typically include more detailed standardized developmental testing. The primary care physician should ensure that hearing and vision assessments are completed. For the child with motor concerns, the physician should pay particular attention to the motor and neurologic evaluation. Children with language delays should have hearing, speech, language, and learning skills (e.g., reading, phonics) evaluated.

The primary care pediatrician should also perform a comprehensive medical evaluation of the child to identify any related health conditions. Physical examination including head circumference should be reviewed to identify growth abnormalities and dysmorphic features. For the child with motor delay and decreased or normal muscle tone, serum creatine kinase and thyroid function testing are recommended to rule out muscular dystrophy and thyroid disease, respectively. When there is increased tone, MRI or referral to a neurologist should be considered. For the child with suspected autism or intellectual disability (or global developmental delay), chromosomal microarray and fragile X testing are recommended (see Chapter 53).

**Referral and Intervention**

Children with significant developmental delays or an identified developmental disability are entitled to and usually benefit from early intervention with therapy services directed at delayed or atypical development. The U.S. Individuals with Disabilities Education Act (IDEA) entitles any child with a disability or developmental delay to receive local education and related services, including therapy, from as early as birth, for known or high-risk conditions that lead to such delay or disability, through age 21 yr. These interventions enhance the child's development through early intervention and family support as well as individualized public education with the goal of reducing public costs. The
pediatric clinician should therefore refer every child with developmental concerns to the local early intervention program or agency (ages 0-3 yr), public school program (≥3 yr), or local therapy providers. Typical service needs include special education for the child with intellectual or learning concerns, physical or occupational therapy for children with motor delays, speech language therapy for the child with language or social communication difficulties, and behavioral therapy services for the child with social engagement or other behavior problems.

Likewise, the child with specific behavior concerns should be referred to an appropriate pediatric or mental health professional who can perform a thorough evaluation and assist the family to alleviate the problems or concerns. Such professionals may include those trained in developmental-behavioral pediatrics, neurodevelopmental disabilities, adolescent medicine, child and adolescent psychiatry, pediatric psychology, psychiatric advanced practice nursing, and social work. Such an evaluation is similar to developmental evaluation in its aim of determining a diagnosis, as well as developing a treatment program that may include psychotherapeutic and medication management. Associated medical or developmental disorders should be considered and further evaluated as needed.

**Ongoing Management**

Children with developmental or behavioral disorders should be identified as *children with special healthcare needs* in the medical home, with a program of chronic condition management initiated by the clinical program staff, including its medical and nonmedical staff. In doing so, the clinician and family should work together to outline the child's short- and long-term goals and management plan. This includes a program of regular monitoring and follow-up of the child's development and behavior, referrals, treatment, and surveillance for identification and treatment of related medical, developmental, or behavioral comorbidities that may arise. Some children and families may warrant assignment of a case manager either within the medical home or in a related local agency. The pediatric clinician or other medical home staff should participate in care coordination activities as needed and assist the family and other professionals in decision-making on medical care, therapies, and educational services.

The family can be further assisted during the screening and referral phases or later with ongoing care by referral to support service programs, such as respite
care, parent-to-parent programs, and advocacy organizations. Some children may qualify for additional state or federal benefit programs, including insurance, supplemental security income, and state programs for children with special healthcare needs. Families often seek out information, support, or connection to other families with similarly affected children and find benefit in local or national networks (e.g., Family Voices, Family to Family Health Information centers) and condition-specific associations.

**Implementation**

The principles and professional guidelines for developmental-behavioral surveillance and screening have been solidified to identify children with developmental disabilities, including the specific conditions of intellectual disability, autism, motor disorders, and behavioral-emotional problems. Specific algorithms are included in these guidelines to assist the clinician with implementation. However, pediatricians have reported difficulties in putting these into practice, with obstacles and barriers identified and policy changes made to ensure that screening and referral can be implemented. (See **Bibliography** online for specific guidelines.)

Implementation projects have identified key factors for successful incorporation of developmental surveillance and screening into practice. Successful office-based screening requires development of a comprehensive office-based system that extends from the child's home to the front office and into the clinic visit, rather than solely centered on the time in the clinic room. This requires utilizing office and medical support staff for scheduling, advance test distribution, and initiation of the surveillance and screening procedures before the preventive care visit. The pediatric staff must choose screening tests that are not only valid for screening of the specific condition at the recommended ages, but also appropriate to the population being served (including reading level and language). The tests chosen should be able to be completed by the caregiver in a short time and at low cost. Staff training on billing and coding for these procedures ensures appropriate payment.

Practice systems should also be developed for referral and tracking of children who have problems identified through screening. This should include systems for referral to early intervention, community therapy, developmental professionals, and medical consultants. Office representatives or the clinician should establish working relationships with local community programs and
resources to assist the child and family.

**Resources**

In the United States, approximately half of all children under the age of 3 yr and 60–75% of children age 3-5 yr had at least 1 regular nonparental childcare arrangement in 2012. Young children of employed mothers spend on average 36 hr per week in a childcare arrangement.

Childcare provision is affected by many factors, derived from family demand, childcare supply, and child/family policy. With increasing movement of mothers into the workplace across the globe, the prime reason most families use childcare is to support employment of both parents. At childbirth, unpaid maternity leave is the typical solution among U.S. mothers. The U.S. Federal leave program allows for 12 wk of unpaid job-protected leave during pregnancy or after childbirth, but only covers approximately 50% of the workforce because companies with <50 employees, with part-time employees, and those working in informal labor markets are exempt. Four states and several cities have passed paid family leave laws.

In part because of the financial burden of an unpaid maternity leave, many mothers return to work, and their children may begin childcare in the 1st few weeks after birth. In a 2000 Family and Medical Leave Act survey, only 10% of respondents reported taking more than 60 days for maternity leave. Approximately 44% of mothers in 2005–2007 were working by the time their 1st child was 3-4 mo of age, and approximately 63% of mothers were working by the time their 1st child was 12 mo. Some mothers face work requirements if they are receiving public benefits because of the reforms to welfare passed by the U.S. Congress in 1996. Many mothers feel strong financial motivation or even pressure to work, especially in single-parent households, or have strong incentive to work for short- and long-term financial security, or because interest and preference, or all these. Employment is not the only factor driving childcare
use; young children of unemployed mothers spend on average 21 hr/wk in childcare. Many parents want their children to have childcare experiences for the potential benefits that early learning environments can give to their children, particularly preschoolers. Given these realities, childcare quality is of great concern, yet the quality of childcare and early education environments varies widely, and the supply of high-quality childcare is largely deemed inadequate.

**Provision, Regulation, and Use of Childcare in America**

**Childcare Settings**

Childcare settings vary widely and fall into 4 broad categories, listed here from the least to the most formal: (1) relative care; (2) in-home nonrelative care, such as nannies, babysitters, or au pairs; (3) family childcare, in which the caregiver provides care in her own home for up to 6 young children, often including children of mixed ages, siblings, or the provider's own children; and (4) center-based care, provided in nonresidential facilities for children grouped by age.

Parents more often use home-based care for infants and toddlers, partly because of greater preference, flexibility, and availability, and sometimes because of lower cost. Use of center-based childcare is greater among preschoolers (children 3-5 yr old). Childcare centers and early education programs are administered by a wide array of businesses and organizations, including for-profit independent companies and chains, religious organizations, public and private schools, nonprofit community organizations, cooperatives, and public agencies. **Preschool** programs (e.g., Head Start, **prekindergarten**) also may play an important role in childcare. Although early education programs may have a greater focus on educational activities and often provide only limited hours of care daily, the health and safety issues involved with preschool programs are similar to those presented by other group childcare settings.

**Childcare Licensing, Regulation, and Accreditation**

Poor-quality childcare settings and unsafe environments that do not meet children's basic physical and emotional needs can result in neglect, toxic stress,
injury, or even death. Licensing and regulatory requirements establish the minimum requirements necessary to protect the health and safety of children in childcare. For the most part, licensing standards mandate basic health and safety standards, such as sanitary practices, child and provider vaccinations, access to a healthcare professional, and facilities and equipment safety, as well as basic structural and caregiver characteristics, such as the ratio of children to staff, group sizes, and minimum caregiver education and training requirements. Most childcare centers and preschools and many family daycare providers are subject to state licensing and regulation. All states regulate centers, as does the District of Columbia, and most states regulate family childcare providers.* Childcare programs that are subject to licensing must comply with their state's requirements to legally operate. Many early care and education providers are subject to monitoring by multiple agencies and organizations.

Many providers are legally exempt from licensing standards. However, the 2014 Child Care Development Block Grant (CCDBG) reauthorization required states and territories to expand their monitoring of legally exempt providers to protect the health and safety of children receiving subsidized childcare. Exemptions for various types of programs vary by state. The smallest homes (3-4 children in care) are typically license exempt, encompassing relative, friend, and neighbor caregivers as well as babysitters, nannies, and au pairs. These providers may fall outside of any regulatory scrutiny, and some may not even think of themselves as offering “childcare.” Fewer children (≥4) are cared for in large home-based settings, typically by nonrelatives. Depending on the state, small family childcare homes may be exempt if there are few children in care, and large/group family childcare homes may be exempt if they are open part-day. Unlike exemption rules for homecare providers, which typically are based on size, centers are often exempted if overseen by other organizations such as schools, churches, or local governments, and thus have some external oversight. Many of these entities provide part-day or part-week Head Start or preschool programs, and about half the states also explicitly exempt such part-time programs.

Homes and centers that fall under state-licensing guidelines face different requirements, which can have a direct impact on the quality of children's experiences. Size differs greatly between the 2 types of contexts, and such size differences are built into regulations in terms of the maximum number of children who can be cared for in a group and the number of adults that must be present. The most common state-required maximum group size in centers is 8
for infants, 12 for toddlers, and 20 for preschoolers; centers may have numerous classrooms of these sizes. For centers, regulations explicitly state an allowable ratio of children to adults. The most common ratios are 4 : 1 for infants, 6 : 1 for toddlers, and 10 : 1 for preschoolers, meaning that typically there would be 2 adults in a group. However, other states permit ratios that are 5 : 1 or 6 : 1 for infants ≤9 mo of age. Furthermore, most states' child/staff ratio requirements increase as children age; for children 27 mo old, only a handful of states have ratios of 4 : 1.

States license homes in 2 categories, small and large, with typical maximums of 6 and 12, respectively (including the provider's own children). More than 75% of licensed homes fall within the small category. Thus the total size of a typical home is smaller than just 1 classroom in a center. States less often explicitly lay out child/adult ratios for homes, given that many homes involve one provider caring for all the children. Some states restrict the number of younger children who may be in care or explicitly provide ratios (especially for large homes), although these restrictions vary greatly across states.

Health and safety conditions may be unsatisfactory in unlicensed settings. In most states, licensing and regulatory standards have been found to be inadequate to promote optimal child development, and in many states, standards are so low as to endanger child health and safety. Therefore, even licensed providers may be providing care at quality levels far below professional recommendations. A small portion of providers become accredited by National Association for the Education of Young Children (NAEYC), National Association for Family Child Care (NAFCC), or other organizations by voluntarily meeting high-quality, developmentally appropriate, professionally recommended standards. The accreditation process goes well beyond health and safety practices and structural and caregiver characteristics, to examine the quality of child–caregiver interactions, which are crucial for child development, as described in the next section. Evidence indicates that childcare programs that complete voluntary accreditation through NAEYC improve in quality and provide an environment that better facilitates children's overall development. Only 10% of childcare centers and 1% of family childcare homes are accredited. This is partly the result of a lack of knowledge, resources, and incentives for providers to improve quality, but also because of expenses providers incur in the process of becoming accredited.

State childcare licensing agencies are playing a larger role in various initiatives designed to improve the quality of childcare, working through the
infrastructure of the early care and education system. Several states have quality initiatives called *quality ratings and improvement systems (QRIS)*, such as tiered quality strategies (e.g., tiered reimbursement systems for participating providers who achieve levels of quality beyond basic licensing requirements), public funding to facilitate accreditation, professional development systems, and program assessments and technical assistance.

**Childcare's Role in Child Health and Development**

**Characteristics of Childcare and Associations With Child Developmental Outcomes**

*High-quality childcare* is characterized by warm, responsive, and stimulating interactions between children and caregivers. In high-quality interactions, caregivers express positive feelings toward their children; are emotionally involved, engaged, and aware of the child's needs and sensitive and responsive to their initiations; speak directly with children in a manner that is elaborative and stimulating while being age appropriate; and ask questions and encourage children's ideas and verbalizations. Structural quality features of the setting, including ratio of children to adults, group size, and caregiver education and training, act indirectly on child outcomes by facilitating high-quality child–caregiver interactions. It would be difficult for even the most sensitive and stimulating provider to engage in high-quality interactions with each child, if the provider was the sole caregiver of 10 toddlers.

Practices in childcare centers can support or undermine the potential for caregivers to provide high-quality individualized interactions with young children in their care and support development. **Primary caregiving** is the practice of assigning 1 teacher the primary responsibility for the care of a small group of children within a larger group setting; this teacher takes the lead role in providing intentional and individual care for the child's routine needs and establishes relationships with the children and families in their care. This practice is consistent with research showing that infants who experience stable, consistent, sensitive, and responsive care from their primary caregivers develop more **secure attachment** relationships (see Chapters 18, 19, and 22) and more
positive developmental outcomes. To enact primary caregiving, centers need to have child-to-staff ratios and staffing arrangements consistent with this practice. Several states' child/staff ratio licensing requirements (e.g., 4 : 1 for 6 or 9 mo old infants) are consistent with staffing arrangements conducive to creating and maintaining primary caregiving relationships, but other states' ratios are much larger and rise even higher during the infant/toddler years.

The quality, quantity, type of setting, and stability of childcare experienced by young children contribute to child development. Childcare use by itself does not affect mother–child attachment. Only when combined with low maternal sensitivity and responsiveness does poor-quality childcare, larger quantities of childcare, or multiple childcare arrangements predict greater likelihood of insecure attachment.

Adjusting for family factors (parental income, education, race/ethnicity, family structure, parental sensitivity), the quality of childcare has a unique and consistent but small association with child outcomes across most domains of development. The type of childcare setting has unique effects, controlling for quality, with results from numerous studies demonstrating that center-based care is associated with better language and preacademic performance than home-based care. Quantity of care (hours per week) may also have unique effects, but findings are mixed, with some studies demonstrating small associations between greater quantity and elevated behavior problems, and other studies finding no associations for most children. Instability in childcare—over the course of a day, such as with rotating staff or multiple arrangements, or over time, with frequent staff turnover or changes in arrangements—does have negative effects on children's language and internalizing problems. Also, since childcare settings naturally have packages of quality characteristics, which are a mix of lower- and higher-quality indicators, the bundle of features in a childcare arrangement may be another meaningful way for a parent to consider the potential effects of an arrangement on their child.

When a healthcare provider talks with a parent about the childcare arrangement, it is also important to consider the individual child's characteristics, health concerns, dispositions, and even physiologic responses to the environment. As with all environments, childcare is experienced differently by different children. An average environment can often sufficiently compensate for the typical regulatory capacities of most children, but when an environment lacks adequate support for a child's unique needs, healthy development can be further compromised. Some children may be more vulnerable to poor childcare
(or particularly responsive to good childcare), such as children with difficult or fearful temperaments, especially if their home environments are characterized by more risk factors, such as poverty or high conflict with a parent.

Several large studies have found that most U.S. childcare is of “poor to mediocre” quality. In one study, only 14% of centers (8% of center-based infant care) were found to provide developmentally appropriate care, while 12% scored at minimal levels that compromised health and safety (40% for infant care). In another study, 58% of family daycare homes provided adequate or custodial care, and only 8% provided good care. Children with the greatest amount of family risk may be the most likely to receive childcare that is substandard in quality. Many children from lower-risk families also receive lower-quality care, and despite their advantages at home, these children may not be protected from the negative effects of poor-quality care.

Affordable, accessible, high-quality childcare is difficult to find. Middle-class families spend approximately 6% of their annual income on childcare expenses, whereas poor families spend approximately 33% (on par with housing expenses). Infant and toddler care is particularly expensive, with fewer available slots. For a married couple with children, the average cost of full-time center care for 1 infant ranges from 7% to approximately 19% of the state median income, depending on the state. In 38 states the cost of infant care exceeds 10% of the state's median income for a 2-parent family. The average cost of center care for one 4 yr old exceeds 10% of the median household income in 21 states and the District of Columbia. For single parents, the average cost of center-based infant care exceeds 25% of median income in every state. The average cost of family childcare is only slightly lower.

In addition to the stress of meeting such a high expense, many parents worry that their child will feel unhappy in group settings, will suffer from separation from the parents, or will be subjected to neglect or abuse. This worry is especially likely among low-income parents with more risk factors, fewer resources, and fewer high-quality options available. Parents are the purchasers but not the recipients of care and are not in the best position to judge its quality. Many parents are 1st-time purchasers of childcare with little experience and very immediate needs, selecting care in a market that does little to provide them with useful information about childcare arrangements. In many states, efforts are underway to improve quality and provide parents with this information, but several states do not have a quality rating and information system, and programs in states that do are still emerging, and testing of effectiveness is still underway.
To inform their care decisions, parents may turn to their child's pediatrician as the only professional with expertise in child development with whom they have regular and convenient contact.

Pediatricians may frequently be asked to provide input regarding child health in out-of-home childcare settings. Standards and guidelines are provided by the American Academy of Pediatrics, the American Public Health Association, and the National Resource Center for Health and Safety in Child Care and Early Education, in Stepping Stones to Caring for Our Children: National Health and Safety Performance Standards—Guidelines for Early Care and Education Programs (3rd edition, 2013). Caring for our Children Basics (2014), which is based on the larger resource document, represents the minimum health and safety standards experts believe should be in place where children are cared for outside their homes. The intent is for the guidelines to serve as a resource for states and other entities as they work to improve health and safety standards in licensing and quality rating improvement systems. The guidelines include sections on program activities for healthy development (e.g., monitoring children's development, obtaining consent for age-appropriate developmental and behavioral screenings), health promotion and protection (e.g., active opportunities for physical activity; safe sleep practices and SIDS risk reduction; diaper-changing and hand hygiene procedures; emergency procedures; recognizing and reporting suspected child abuse, neglect, and exploitation), and nutrition and food service (e.g., care for children with food allergies; preparing, feeding, and storing human milk).

Pediatricians most often may encounter questions from parents and caregivers regarding sick children, exposure to and prevention of risks in childcare, and support for children with special needs in childcare. Guidelines in these areas are summarized in the next sections.

**Sick Children**

When children are ill, they may be excluded from out-of-home arrangements, and settings under state licensure are required to exclude children with certain conditions. Stepping Stones offers guidelines and recommendations regarding the conditions under which sick children should and should not be excluded from group programs. State laws typically mirror these guidelines but may be stricter in some states. Caring for Our Children Basics (2014) summarizes guidelines for inclusion, exclusion, or dismissal of children based on signs or
symptoms or illness (Table 29.1).

Table 29.1
Conditions That Do and Do Not Require Exclusion From Group Childcare Settings

<table>
<thead>
<tr>
<th>CONDITIONS THAT REQUIRE EXCLUSION</th>
<th>COMMENTS</th>
</tr>
</thead>
</table>
| If any of these 3 key criteria for exclusion of children who are ill are met, the child should be temporarily excluded, regardless of the type of illness: | Providers should specify in their policies, approved by the facility's healthcare consultant, what severity level of illness the facility can manage, and how much and what types of illness will be addressed:  
• Severity level 1 consists of children whose health condition is accompanied by high interest and complete involvement in activity, associated with an absence of symptoms of illness (e.g., children recovering from pinkeye, rash, or chickenpox) but who need further recuperation time.  
• Severity level 2 encompasses children whose health condition is accompanied by a medium activity level because of symptoms (e.g., children with low-grade fever, children at beginning of illness, children in early recovery period of illness)  
• Severity level 3 consists of children whose health condition is accompanied by a low activity level because of symptoms that preclude much involvement. |
| Illness preventing the child from participating comfortably in activities, as determined by the childcare provider |  |
| Illness resulting in a greater need for care than the childcare staff can provide without compromising the health and safety of the other children, as determined by the childcare provider |  |
| Illness that poses a risk of spread of harmful diseases to others |  |
| In addition to the above key criteria, temporary exclusion is recommended when the child has any of the following conditions: |  |
| Fever (temperature above 38°C [101°F] orally, above 38.9°C [102°F] rectally, or above 37.8°C [100°F] or higher taken axillary [armpit] or measured by an equivalent method) and behavior change or other signs and symptoms (e.g., sore throat, rash, vomiting, diarrhea) | Accompanied by behavior changes or other signs or symptoms of illness until medical professional evaluation finds the child able to be included at the facility |
| Acute change in behavior including lethargy/lack of responsiveness, inexplicable irritability or persistent crying, difficult breathing, or having a quickly spreading rash | Until evaluation by a medical professional finds the child able to be included at the facility |
| Diarrhea (defined by watery stools or decreased form of stool that is not associated with changes of diet). Exclusion is required for all diapered children whose stool is not contained in the diaper and toilet-trained children if the diarrhea is causing soiled pants or clothing. | Readmission after diarrhea can occur when diapered children have their stool contained by the diaper (even if the stools remain loose) and when toilet-trained children are continent. Special circumstances that require specific exclusion criteria include the following: |
- Toxin-producing *Escherichia coli* or *Shigella* infection, until stools are formed and test results of 2 stool cultures obtained from stools produced 24 hr apart do not detect these organisms
- *Salmonella* serotype *Typhi* infection, until diarrhea resolves and, in children <5 yr old, 3 negative stool cultures obtained at 24 hr intervals

Fever without any signs or symptoms of illness in children >6 mo old regardless of whether acetaminophen or ibuprofen was given

If the child is behaving normally but has fever <38.9°C (102°F) rectally or the equivalent, child should be monitored but does not need to be excluded for fever alone.

Rash without fever and without behavioral changes

Lice or nits

Exclusion for treatment of an active lice infestation may be delayed until end of the day.

Ringworm

Exclusion for treatment may be delayed until end of the day.

Molluscum contagiosum

Do not require exclusion or covering of lesions

Thrush (i.e., white spots or patches in mouth or on cheeks or gums)

Fifth disease

Once the rash has appeared

Methicillin-resistant *Staphylococcus aureus* (MRSA) without an infection or illness that would otherwise require exclusion

Known MRSA carriers or colonized individuals should not be excluded.

Cytomegalovirus infection

Chronic hepatitis B infection

HIV infection

Asymptomatic children who have been previously evaluated and found to be shedding potentially infectious organisms in the stool

Children who are continent of stool or who are diapered with formed stools that can be contained in the diaper may return to care

Children with chronic infections conditions who can be accommodated in the program according to federal legal requirement in Americans with Disabilities Act (ADA)

ADA requires that childcare programs make reasonable accommodations for children with disabilities and/or chronic illnesses, considering each child individually.

The caregiver/teacher should determine if the illness (1) prevents the child from participating comfortably in activities; (2) results in a need for care that is greater than the staff can provide without compromising the health and safety of other children; (3) poses a risk of spread of harmful diseases to others; or (4) causes a fever and behavior change or other signs and symptoms (e.g., sore throat, rash, vomiting, diarrhea). An unexplained temperature above 100°F (37.8°C) (armpit) in a child <6 mo old should be medically evaluated. Any infant <2 mo old with fever should receive immediate medical attention.

Most families need to arrange to keep sick children at home, such as staying home from work or having backup plans with an alternative caregiver.

Alternative care arrangements outside the home for sick children are relatively rare but may include either (1) care in the child's own center, if it offers special provisions designed for the care of ill children (sometimes called the infirmary model or sick daycare), or (2) care in a center that serves only children with
illness or temporary conditions. Although it is important that such arrangements emphasize preventing further spread of disease, one study found no occurrence of additional transmission of communicable disease in children attending a sick center. The impact of group care of ill children on their subsequent health and on the health of their families and community is unknown.

*Caring for Our Children Basics* also provides guidelines for control of infectious disease outbreaks and for exclusion of any child or staff member who is suspected of contributing to transmission of the illness, who is not adequately immunized when there is an outbreak of a vaccine-preventable disease, or when the circulating pathogen poses an increased risk to the individual.

**Childcare and Child Health**

A disproportionate number of sudden infant death syndrome (SIDS) deaths occur in childcare centers or family-based childcare homes (approximately 20%). Infants who are back-sleepers at home but are put to sleep on their front in childcare settings have a higher risk of SIDS. Providers and parents should be made aware of the importance of placing infants on their backs to sleep (see Chapter 402).

Children enrolled in childcare are also of an age that places them at increased risk for acquiring infectious diseases. Participation in group settings elevates exposure. Children enrolled in such settings have a higher incidence of illness (upper respiratory tract infections, otitis media, diarrhea, hepatitis A infections, skin conditions, and asthma) than those cared for at home, especially in the preschool years; these illnesses have no long-term adverse consequences. Childcare providers who follow childcare licensure guidelines for handwashing, diapering, and food handling, and who manage child illness appropriately, can reduce communicable illnesses.

Debate surrounds whether childcare exposure serves as a risk or protective factor for asthma. One cross-sectional study found that preschoolers in childcare had increased risk of the common cold and otitis media, and children who began childcare before age 2 yr had increased risk of developing recurrent otitis media and asthma. However, a longitudinal study found that children exposed to older children at home or to other children at childcare during the 1st 6 mo of life were less likely to have frequent wheezing from ages 6-13 yr, suggesting that childcare exposure may protect against the development of asthma and frequent wheezing later in childhood. A 10 yr follow-up of a birth cohort found no
association between childcare attendance and respiratory infections, asthma, allergic rhinitis, or skin-prick test reactivity. Another study found that in the 1st yr of elementary school, children who had attended childcare had fewer absences from school, half as many episodes of asthma, and less acute respiratory illness than their peers who had never attended childcare. These results may be related to protection against respiratory illness as a result of early exposure or a shift in the age-related peak of illness, although selection of illness-prone children into homecare may play a role. Other factors may also be relevant to this issue, such as children in childcare potentially being less exposed to passive smoking than children at home.

**Childcare and Children With Special Needs**

The needs of children with mental, physical, or emotional disabilities who, because of their chronic illness, require special care and instruction may require particular attention when it comes to their participation in most childcare settings. Guiding principles of services for children with disabilities advocate supporting children in natural environments, including childcare. Furthermore, the Americans with Disabilities Act and Section 504 of the Rehabilitation Act of 1973 prohibit discrimination against children and adults with disabilities by requiring equal access to offered programs and services.

Although many childcare providers and settings are unprepared to identify or administer services for children with special needs, childcare could be utilized for delivery of support services to these children and for linking families to services, such as early intervention and physician referrals. Furthermore, pediatricians can draw on childcare providers for important evaluative data regarding a child's well-being, since these providers have extensive daily contact with the child and may have broad, professional understanding of normative child development. A childcare provider may be the first to identify a child's potential language delay. Childcare providers are also necessary and valuable partners in the development and administration of early intervention service plans.

Children with special needs may be eligible for services under the **Individuals with Disabilities Education Act (IDEA)**; see Chapters 48 and 51). The purpose of this law is to provide “free appropriate public education,” regardless of disability or chronic illness, to all eligible children, birth to 21 yr, in a natural and/or least restrictive environment. Eligible children include those with mental,
physical, or emotional disabilities who, because of their disability or chronic illness, require special instruction to learn. As a part of these services, a formal plan of intervention is to be developed by the service providers, families, and the children's healthcare providers. Federal funds are available to implement a collaborative early intervention system of services for eligible infants and toddlers from birth to 3 yr and their families. These services include screening, assessment, service coordination, and collaborative development of an **individualized family service plan (IFSP)**. The IFSP describes early intervention services for the infant or toddler and family, including family support and the child's health, therapeutic, and educational needs. An understanding of the child's routines and real-life opportunities and activities, such as eating, playing, interacting with others, and working on developmental skills, is crucial to enhancing a child's ability to achieve the functional goals of the IFSP. Therefore it is critical that childcare providers be involved in IFSP development or revision, with parental consent. Childcare providers should also become familiar with the child's IFSP and understand the providers' role and the resources available to support the family and childcare provider.

Additionally, IDEA provides support for eligible preschool-age children to receive services through the local school district. This includes development of a written **individualized education program (IEP)**, with implementation being the responsibility of the local education agency in either a public or a private preschool setting. As with IFSPs, childcare providers should become familiar with the preschooler's special needs as identified in the IEP and may become involved, with parental consent, in IEP development and review meetings. For children who have or may be at risk for developmental delay, a diagnosis is important for obtaining and coordinating services and further evaluation. To this end, pediatricians can partner with childcare providers to screen and monitor children's behavior and development.

### Role of Pediatric Providers in Childcare

#### Advising Parents on Childcare Selection

Organized professional guidance in choosing childcare is insufficient. Pediatricians can help parents understand the importance of high-quality care for their child's development by describing this care and providing referrals and advice on finding and selecting high-quality childcare (Table 29.2). In addition,
pediatricians can help parents determine how to adjust childcare arrangements to best meet their child's specific needs (e.g., allergies, eating and sleeping habits, temperament and stress-regulation capacities). For most parents, finding childcare that they can afford, access, manage, and accept as a good environment for their child is a difficult and often distressing process. Many parents also worry about how their child will fare in childcare (e.g., Will their child feel distressed by group settings, suffer from separation from the parents, or even be subjected to neglect or abuse?). These worries are especially likely among low-income parents with fewer family and community resources. A few parents may think of childcare only as “babysitting” and may not consider the consequences for their child's cognitive, linguistic, and social development, focusing solely on whether the child is safe and warm. These parents may be less likely to select a high-quality childcare arrangement, which is especially problematic if the family is facing socioeconomic challenges that already place them at risk of receiving lower-quality care for their children. For these parents, it is vital to stress the importance of quality and its implications for their child's cognitive, language, and behavioral development and school readiness.

Advising Parents on Childcare Health Issues

Parents of infants should be advised to ensure that childcare providers put infants on their back to sleep to prevent SIDS. Also, pediatricians should emphasize the importance of following vaccination schedules; most states require compliance for children to participate in licensed group childcare settings.

When children are ill, parents should be advised to follow guidelines for inclusion and exclusion (see Table 29.1). Parents may disagree with childcare staff about whether a child meets or does not meet the exclusion criteria. However, professional guidelines state that “if … the reason for exclusion relates to the child's ability to participate or the caregiver's/teacher's ability to provide care for the other children, the caregiver/teacher should not be required to accept responsibility for the care of the child.” *

Helping Children With Special Needs

Pediatricians should work with parents and communicate with other service providers and early intervention staff to identify problems, remove access barriers, and coordinate service delivery for children with special needs. They should also encourage involvement of parents and childcare providers in IFSP or IEP plan development.

Consulting and Partnering With Childcare Providers

Most state regulations mandate that licensed programs have a formal relationship
with a healthcare provider. Additional state efforts include mental health consultation models to support providers, who are often not well trained in managing child behavior, and build capacity to raise quality for all children. Early childhood mental health consultation links a mental health professional with an early education and care provider in an ongoing problem-solving and capacity-building relationship.

Pediatricians can provide consultation to childcare providers about measures to protect and maintain the health and safety of children and staff. This may include consultation regarding promoting practices to prevent SIDS; preventing and reducing the spread of communicable disease; reducing allergen, toxin, and parasite exposure; ensuring vaccinations for children and staff; removing environmental hazards; and preventing injuries.

All children will experience involuntary separations, whether from illness, death, or other causes, from loved ones at some time in their lives. Relatively brief separations of children from their parents, usually produce minor transient effects, but more enduring and frequent separation may cause sequelae. The potential impact of each event must be considered in light of the age, stage of development, and experiences of the child, the particular relationship with the absent person, and the nature of the situation.

Separation and Loss

Separations may be from temporary causes, such as vacations, parental job requirements, natural disasters or civil unrest, or parental or sibling illness requiring hospitalization. More long-term separations occur as a result of divorce, placement in foster care, or immigration, whereas permanent separation may occur because of death. The initial reaction of young children to separation of any duration may involve crying, either of a tantrum-like, protesting type, or of a quieter, sadder type. Children's behavior may appear subdued, withdrawn, fussy, or moody, or they may demonstrate resistance to authority. Specific problems may include poor appetite, behavior issues such as acting against caregiver requests, reluctance to go to bed, sleep problems, or regressive behavior, such as requesting a bottle or bed-wetting. School-age children may experience impaired cognitive functioning and poor performance in school. Some children may repeatedly ask for the absent parent and question when the absent parent will return. The child may go to the window or door or out into the neighborhood to look for the absent parent; a few may even leave home or their place of temporary placement to search for their parents. Other children may not
refer to the parental absence at all.

A child's response to reunion may surprise or alarm an unprepared parent. A parent who joyfully returns to the family may be met by wary or cautious children. After a brief interchange of affection, children may seem indifferent to the parent's return. This response may indicate anger at being left or wariness that the event will happen again, or the young child may feel, as a result of magical thinking (see Chapter 24), as if the child caused the parent's departure. For example, if the parent who frequently says “Stop it, or you'll give me a headache” is hospitalized, the child may feel at fault and guilty. Because of these feelings, children may seem more closely attached to the present parent than to the absent one, or even to the grandparent or babysitter who cared for them during their parent's absence. Some children, particularly younger ones, may become more clinging and dependent than they were before the separation, while continuing any regressive behavior that occurred during the separation. Such behavior may engage the returned parent more closely and help to reestablish the bond that the child felt was broken. Such reactions are usually transient, and within 1-2 wk, children will have recovered their usual behavior and equilibrium. Recurrent separations may tend to make children wary and guarded about reestablishing the relationship with the repeatedly absent parent, and these traits may affect other personal relationships. Parents should be advised not to try to modify a child's behavior by threatening to leave.

**Divorce**

More sustained experiences of loss, such as divorce or placement in foster care, can give rise to the same kinds of reactions noted earlier, but they are more intense and possibly more lasting. Currently in the United States, approximately 40% of marriages end in divorce. Divorce has been found to be associated with negative parent functioning, such as parental depression and feelings of incompetence; negative child behavior, such as noncompliance and whining; and negative parent–child interaction, such as inconsistent discipline, decreased communication, and decreased affection. Greater childhood distress is associated with greater parental distress. Continued parental conflict and loss of contact with the noncustodial parent, usually the father, is common.

Two of the most important factors that contribute to morbidity of the children in a divorce include parental psychopathology and disrupted parenting before the separation. The year following the divorce is the period when problems are
most apparent; these problems tend to dissipate over the next 2 yr. Depression may be present up to 5 yr later, and educational or occupational decline may occur even 10 yr later. It is difficult to sort out all confounding factors. Children may suffer when exposed to parental conflict that continues after divorce and that in some cases may escalate. The degree of interparental conflict may be the most important factor associated with child morbidity. A continued relationship with the noncustodial parent when there is minimal interparental conflict is associated with more positive outcomes.

School-age children may become depressed, may seem indifferent, or may be extremely angry. Other children appear to deny or avoid the issue, behaviorally or verbally. Most children cling to the hope that the actual placement or separation is not real and only temporary. The child may experience guilt by feeling that the loss, separation, or placement represents rejection and perhaps punishment for misbehavior. Children may protect a parent and assume guilt, believing that their own “badness” caused the parent to depart. Children who feel that their misbehavior caused their parents to separate may have the fantasy that their own trivial or recurrent behavioral patterns caused their parents to become angry at each other. A child might perceive that outwardly blaming parents is emotionally risky; parents who discover that a child harbors resentment might punish the child further for these thoughts or feelings. Some children have behavioral or psychosomatic symptoms and unwittingly adopt a “sick” role as a strategy for reuniting their parents.

In response to divorce of parents and the subsequent separation and loss, older children and adolescents usually show intense anger. Five years after the breakup, approximately 30% of children report intense unhappiness and dissatisfaction with their life and their reconfigured family; another 30% show clear evidence of a satisfactory adjustment; and the remaining children demonstrate a mixed picture, with good achievement in some areas and faltering achievement in others. After 10 yr, approximately 45% do well, but 40% may have academic, social, or emotional problems. As adults, some are reluctant to form intimate relationships, fearful of repeating their parents' experience.

Parental divorce has a moderate long-term negative impact on the adult mental health status of children, even after controlling for changes in economic status and problems before divorce. Good adjustment of children after a divorce is related to ongoing involvement with two psychologically healthy parents who minimize conflict and to the siblings and other relatives who provide a positive support system. Divorcing parents should be encouraged to avoid adversarial
processes and to use a trained mediator to resolve disputes if needed. Joint-custody arrangements may reduce ongoing parental conflict, but children in joint custody may feel overburdened by the demands of maintaining a strong presence in two homes.

When the primary care provider is asked about the effects of divorce, parents should be informed that different children may have different reactions, but that the parents' behavior and the way they interact will have a major and long-term effect on the child's adjustment. The continued presence of both parents in the child's life, with minimal interparental conflict, is most beneficial to the child.

**Move/Family Relocation**

A significant proportion of the U.S. population changes residence each year. The effects of this movement on children and families are frequently overlooked. For children, the move is essentially involuntary and out of their control. When changes in family structure such as divorce or death precipitate moves, children face the stresses created by both the precipitating events and the move itself. Parental sadness surrounding the move may transmit unhappiness to the children. Children who move lose their old friends, the comfort of a familiar bedroom and house, and their ties to school and community. They not only must sever old relationships, but also are faced with developing new ones in new neighborhoods and new schools. Children may enter neighborhoods with different customs and values, and because academic standards and curricula vary among communities, children who have performed well in one school may find themselves struggling in a new one. Frequent moves during the school years are likely to have adverse consequences on social and academic performance.

**Migrant children** and children who emigrate from other countries present with special circumstances. These children not only need to adjust to a new house, school, and community, but also need to adjust to a new culture and in many cases a new language. Because children have faster language acquisition than adults, they may function as translators for the adults in their families. This powerful position may lead to role reversal and potential conflict within the family. In the evaluation of migrant children and families, it is important to ask about the circumstances of the migration, including legal status, violence or threat of violence, conflict of loyalties, and moral, ethical, and religious differences.

Parents should prepare children well in advance of any move and allow them
to express any unhappy feelings or misgivings. Parents should acknowledge their own mixed feelings and agree that they will miss their old home while looking forward to a new one. Visits to the new home in advance are often useful preludes to the actual move. Transient periods of regressive behavior may be noted in preschool children after moving, and these should be understood and accepted. Parents should assist the entry of their children into the new community, and whenever possible, exchanges of letters and visits with old friends should be encouraged.

**Separation Because of Hospitalization**

Potential challenges for hospitalized children include coping with separation, adapting to the new hospital environment, adjusting to multiple caregivers, seeing very sick children, and sometimes experiencing the disorientation of intensive care, anesthesia, and surgery. To help mitigate potential problems, a preadmission visit to the hospital can help by allowing the child to meet the people who will be offering care and ask questions about what will happen. Parents of children <5-6 yr old should room with the child if feasible. Older children may also benefit from parents staying with them while in the hospital, depending on the severity of their illness. Creative and active recreational or socialization programs with child life specialists, chances to act out feared procedures in play with dolls or mannequins, and liberal visiting hours, including visits from siblings, are all helpful. Sensitive, sympathetic, and accepting attitudes toward children and parents by the hospital staff are very important. Healthcare providers need to remember that parents have the best interest of their children at heart and know their children the best. Whenever possible, school assignments and tutoring for hospitalized children should be available to engage them intellectually and prevent them from falling behind in their scholastic achievements.

The psychologic aspects of illness should be evaluated from the outset, and physicians should act as a model for parents and children by showing interest in a child's feelings, allowing them a venue for expression, and demonstrating that it is possible and appropriate to communicate about discomfort. Continuity of medical personnel may be reassuring to the child and family.

**Military Families**
More than 2 million children live in military families in the United States, and approximately 50% of them obtain medical care in the community rather than at a military medical facility. Children whose parents are serving in the military may experience loss and separation in multiple ways. These include frequent relocations, relocation to foreign countries, and duty-related separation from parents. In recent years the most impactful experiences have been repeated wartime deployments of parents and the death of parents during military service. All branches of the military have increased their focus on preparing and supporting military families for a service member's deployment in order to improve family coping. Military families composed of young parents and young children are at risk for child maltreatment in the context of repeated or prolonged deployments.

**Parental/Sibling Death**

Approximately 5–8% of U.S. children will experience parental death; rates are much higher in other parts of the world more directly affected by war, AIDS, and natural disasters. Anticipated deaths from chronic illness may place a significant strain on a family, with frequent bouts of illness, hospitalization, disruption of normal home life, absence of the ill parent, and perhaps more responsibilities placed on the child. Additional strains include changes in daily routines, financial pressures, and the need to cope with aggressive treatment options.

Children can and should continue to be involved with the sick parent or sibling, but they need to be prepared for what they will see in the home or hospital setting. The stresses that a child will face include visualizing the physical deterioration of the family member, helplessness, and emotional lability. Forewarning the child that the family member may demonstrate physical changes, such as appearing thinner or losing hair, will help the child to adjust. These warnings combined with simple yet specific explanations of the need for equipment, such as a nasogastric tube for nutrition, an oxygen mask, or a ventilator, will help lessen the child's fear. Children should be honestly informed of what is happening, in language they can understand, allowing them choices, but with parental involvement in decision-making. They should be encouraged, but not forced, to see their ill family member. Parents who are caring for a dying spouse or child may be too emotionally depleted to be able to tend to their healthy child's needs or to continue regular routines. Children of a dying parent may suffer the loss of security and belief in the world as a safe place, and the
surviving parent may be inclined to impose his or her own need for support and comfort onto the child. However, the well parent and caring relatives must keep in mind that children need to be allowed to remain children, with appropriate support and attention. Sudden, unexpected deaths lead to more anxiety and fear because there is no time for preparation, and explanations for the death can cause uncertainty.

**Grief and Bereavement**

**Grief** is a personal, emotional state of bereavement or an anticipated response to loss, such as a death. Common reactions include sadness, anger, guilt, fear, and at times, relief. The normality of these reactions needs to be emphasized. Most bereaved families remain socially connected and expect that life will return to some new, albeit different, sense of normalcy. The pain and suffering imposed by grief should never be automatically deemed “normal” and thus neglected or ignored. In uncomplicated grief reactions, the steadfast concern of the pediatrician can help promote the family's sense of well-being. In more distressing reactions, as seen in traumatic grief of sudden death, the pediatrician may be a major, first-line force in helping children and families address their loss.

Participation in the care of a child with a life-threatening or terminal illness is a profound experience. Parents experience much anxiety and worry during the final stages of their child's life. In one study, 45% of children dying from cancer died in the pediatric intensive care unit, and parents report that 89% of their children suffered “a lot” or “a great deal” during the last month of life. Physicians consistently underreport children's symptoms in comparison to parents' reports. Better ways are needed to provide care for dying children. Providers need to maintain honest and open communication, provide appropriate pain management, and meet the families' wishes as to the preferred location of the child's death, in some cases in their own home. Inclusion of multiple disciplines, such as hospice, clergy, nursing, pain service, child life specialists, and social work, often helps to support families fully during this difficult experience.

The practice of withholding information from children and parents regarding a child's diagnosis and prognosis has generally been abandoned, because physicians have learned that protecting parents and patients from the seriousness of their child's condition does not alleviate concerns and anxieties. Even very
young children may have a real understanding of their illness. Children who have serious diseases and are undergoing aggressive treatment and medication regimens, but who are told by their parents that they are okay, are not reassured. These children understand that something serious is happening to them, and they are often forced to suffer in silence and isolation because the message they have been given by their parents is to not discuss it and to maintain a cheerful demeanor. Children have the right to know their diagnosis and should be informed early in their treatment. The content and depth of the discussion needs to be tailored to the child's personality and developmental level of understanding. Parents have choices as to how to orchestrate the disclosure. Parents may want to be the ones to inform the child themselves, may choose for the pediatric healthcare provider to do so, or may do it in partnership with the pediatrician.

A death, especially the death of a family member, is the most difficult loss for a child. Many changes in normal patterns of functioning may occur, including loss of love and support from the deceased family member, a change in income, the possible need to relocate, less emotional support from surviving family members, altering of routines, and a possible change in status from sibling to only child. Relationships between family members may become strained, and children may blame themselves or other family members for the death of a parent or sibling. Bereaved children may exhibit many of the emotions discussed earlier as a result of the loss, in addition to behaviors of withdrawal into their own world, sleep disturbances, nightmares, and symptoms such as headache, abdominal pains, or possibly similar to those of the family member who has died. Children 3-5 yr of age who have experienced a family bereavement may show regressive behaviors such as bed-wetting and thumb sucking. School-age children may exhibit nonspecific symptoms, such as headache, abdominal pain, chest pain, fatigue, and lack of energy. Children and adolescents may also demonstrate enhanced anxiety if these symptoms resemble those of the family member who died. The presence of secure and stable adults who can meet the child's needs and who permit discussion about the loss is most important in helping a child to grieve. The pediatrician should help the family understand this necessary presence and encourage the protective functioning of the family unit. More frequent visits to the healthcare professional may be necessary to address these symptoms and provide reassurance when appropriate. Suggested availability of clergy or mental health providers can provide additional support and strategies to facilitate the transitions after the death.
Death, separation, and loss as a result of natural catastrophes and human-made disasters have become increasingly common events in children's lives. Exposure to such disasters occurs either directly or indirectly, where the event is experienced through the media. Examples of indirect exposure include televised scenes of earthquakes, hurricanes, tsunamis, tornadoes, and domestic and international terrorist attacks. Children who experience personal loss in disasters tend to watch more television coverage than children who do not. Children without a personal loss watch as a way of participating in the event and may thus experience repetitive exposure to traumatic scenes and stories. The loss and devastation for a child who personally lives through a disaster are significant; the effect of the simultaneous occurrence of disaster and personal loss complicates the bereavement process as grief reactions become interwoven with posttraumatic stress symptoms (see Chapter 38 ). After a death resulting from aggressive or traumatic circumstances, access to expert help may be required. Under conditions of threat and fear, children seek proximity to safe, stable, protective figures.

It is important for parents to grieve with their children. Some parents want to protect their children from their grief, so they put on an outwardly brave front or do not talk about the deceased family member or traumatic event. Instead of the desired protective effect, the child receives the message that demonstrating grief or talking about death is wrong, leading the child to feel isolated, grieve privately, or delay grieving. The child may also conclude that the parents did not really care about the deceased because they seem to have forgotten the person so easily or demonstrate no emotion. The parents' efforts to avoid talking about the death may cause the parents to isolate themselves from their children at a time when the children most need them. Children need to know that their parents love them and will continue to protect them. Children need opportunities to talk about their relative's death and associated memories. A surviving sibling may feel guilty simply because he or she survived, especially if the death was the result of an accident that involved both children. Siblings' grief, especially when compounded by feelings of guilt, may manifest as regressive behavior or anger. Parents should be informed of this possibility and encouraged to discuss it with their children.

Developmental Perspective

Children's responses to death reflect the family's current culture, their past
heritage, their experiences, and the sociopolitical environment. Personal experience with terminal illness and dying may also facilitate children's comprehension of death and familiarity with mourning. Developmental differences exist in children's efforts to make sense of and master the concept and reality of death and profoundly influence their grief reactions.

Children younger than 3 yr have little or no understanding of the concept of death. Despair, separation anxiety, and detachment may occur at the withdrawal of nurturing caretakers. Young children may respond in reaction to observing distress in others, such as a parent or sibling who is crying, withdrawn, or angry. Young children also express signs and symptoms of grief in their emotional states, such as irritability or lethargy, and in severe cases, mutism. If the reaction is severe, failure to thrive may occur.

Preschool children are in the preoperational cognitive stage, in which communication takes place through play and fantasy (see Chapter 24). They do not show well-established cause-and-effect reasoning. They feel that death is reversible, analogous to someone going away. In attempts to master the finality and permanence of death, preschoolers frequently ask unrelenting, repeated questions about when the person who died will be returning. This makes it difficult for parents, who may become frustrated because they do not understand why the child keeps asking and do not like the constant reminders of the person's death. The primary care provider has a very important role in helping families understand the child's struggle to comprehend death. Preschool children typically express magical explanations of death events, sometimes resulting in guilt and self-blame (“He died because I wouldn't play with him”; “She died because I was mad at her”). Some children have these thoughts but do not express them verbally because of embarrassment or guilt. Parents and primary care providers need to be aware of magical thinking and must reassure preschool children that their thoughts had nothing to do with the outcome. Children of this age are often frightened by prolonged, powerful expressions of grief by others. Children conceptualize events in the context of their own experiential reality, and therefore consider death in terms of sleep, separation, and injury. Young children express grief intermittently and show marked affective shifts over brief periods.

Younger school-age children think concretely, recognize that death is irreversible, but believe it will not happen to them or affect them, and begin to understand biologic processes of the human body (“You'll die if your body stops working”). Information gathered from the media, peers, and parents forms lasting impressions. Consequently, they may ask candid questions about death
that adults will have difficulty addressing (“He must have been blown to pieces, huh?”).

**Children approximately 9 yr and older** do understand that death is irreversible and that it may involve them or their families. These children tend to experience more anxiety, overt symptoms of depression, and somatic complaints than do younger children. School-aged children are often left with anger focused on the loved one, those who could not save the deceased, or those presumed responsible for the death. Contact with the pediatrician may provide great reassurance, especially for the child with somatic symptoms, and particularly when the death followed a medical illness. School and learning problems may also occur, often linked to difficulty concentrating or preoccupation with the death. Close collaboration with the child's school may provide important diagnostic information and offer opportunities to mobilize intervention or support.

At **12-14 yr of age**, children begin to use symbolic thinking, reason abstractly, and analyze hypothetical, or “what if,” scenarios systematically. Death and the end of life become concepts rather than events. Teenagers are often ambivalent about dependence and independence and may withdraw emotionally from surviving family members, only to mourn in isolation. Adolescents begin to understand complex physiologic systems in relationship to death. Since they are often egocentric, they may be more concerned about the impact of the death on themselves than about the deceased or other family members. Fascination with dramatic, sensational, or romantic death sometimes occurs and may find expression in *copycat behavior*, such as cluster suicides, as well as *competitive behavior*, to forge emotional links to the deceased person (“He was my best friend”). Somatic expression of grief may revolve around highly complex syndromes such as eating disorders (see Chapter 41) or conversion reactions (Chapter 35), as well as symptoms limited to the more immediate perceptions (stomachaches). *Quality of life* takes on meaning, and the teenager develops a focus on the future. Depression, resentment, mood swings, rage, and risk-taking behaviors can emerge as the adolescent seeks answers to questions of values, safety, evil, and fairness. Alternately, adolescents may seek philosophic or spiritual explanations (“being at peace”) to ease their sense of loss. The death of a peer may be especially traumatic.

Families often struggle with how to inform their children of the death of a family member. The answer depends on the child's developmental level. It is best to avoid misleading euphemisms and metaphor. A child who is told that the
relative who died “went to sleep” may become frightened of falling asleep, resulting in sleep problems or nightmares. Children can be told that the person is “no longer living” or “no longer moving or feeling.” Using examples of pets that have died sometimes can help children gain a more realistic idea of the meaning of death. Parents who have religious beliefs may comfort their children with explanations, such as, “Your sister's soul is in heaven,” or “Grandfather is now with God,” provided those beliefs are honestly held. If these are not religious beliefs that the parents share, children will sense the insincerity and experience anxiety rather than the hoped-for reassurance. Children's books about death can provide an important source of information, and when read together, these books may help the parent to find the right words while addressing the child's needs.

**Role of the Pediatrician in Grief**

The pediatric healthcare provider who has had a longitudinal relationship with the family will be an important source of support in the disclosure of bad news and in critical decision-making, during both the dying process and the bereavement period. The involvement of the healthcare provider may include being present at the time the diagnosis is disclosed, at the hospital or home at the time of death, being available to the family by phone during the bereavement period, sending a sympathy card, attending the funeral, and scheduling a follow-up visit. Attendance at the funeral sends a strong message that the family and their child are important, respected by the healthcare provider, and can also help the pediatric healthcare provider to grieve and reach personal closure about the death. A family meeting 1-3 mo later may be helpful because parents may not be able to formulate their questions at the time of death. This meeting allows the family time to ask questions, share concerns, and review autopsy findings (if one was performed), and allows the healthcare provider to determine how the parents and family are adjusting to the death.

Instead of leaving the family feeling abandoned by a healthcare system that they have counted on, this visit allows them to have continued support. This is even more important when the healthcare provider will be continuing to provide care for surviving siblings. The visit can be used to determine how the mourning process is progressing, detect evidence of marital discord, and evaluate how well surviving siblings are coping. This is also an opportunity to evaluate whether referrals to support groups or mental health providers may be of benefit. Continuing to recognize the child who has died is important. Families appreciate
the receipt of a card on their child's birthday, around holidays, or the anniversary of their child's death.

The healthcare provider needs to be an educator about disease, death, and grief. The pediatrician can offer a safe environment for the family to talk about painful emotions, express fears, and share memories. By giving families permission to talk and modeling how to address children's concerns, the pediatrician demystifies death. Parents often request practical help. The healthcare provider can offer families resources, such as literature (both fiction and nonfiction), referrals to therapeutic services, and tools to help them learn about illness, loss, and grief. In this way the physician reinforces the sense that other people understand what they are going through and helps to normalize their distressing emotions. The pediatrician can also facilitate and demystify the grief process by sharing basic tenets of grief therapy. There is no single right or wrong way to grieve. Everyone grieves differently; mothers may grieve differently than fathers, and children mourn differently than adults. Helping family members to respect these differences and reach out to support each other is critical. Grief is not something to “get over,” but a lifelong process of adapting, readjusting, and reconnecting.

Parents may need help in knowing what constitutes normal grieving. Hearing, seeing, or feeling their child's presence may be a normal response. Vivid memories or dreams may occur. The pediatrician can help parents to learn that, although their pain and sadness may seem intolerable, other parents have survived similar experiences, and their pain will lessen over time.

Pediatricians are often asked whether children should attend the funeral of a parent or sibling. These rituals allow the family to begin their mourning process. Children >4 yr old should be given a choice. If the child chooses to attend, the child should have a designated, trusted adult who is not part of the immediate family and who will stay with the child, offer comfort, and be willing to leave with the child if the experience proves to be overwhelming. If the child chooses not to attend, the child should be offered additional opportunities to share in a ritual, go to the cemetery to view the grave, tell stories about the deceased, or obtain a keepsake object from the deceased family member as a remembrance.

In the era of regionalized tertiary care medicine, the primary care provider and medical home staff may not be informed when one of their patients dies in the hospital. Yet, this communication is critically important. Families assume their pediatrician has been notified and often feel hurt when they do not receive some symbol of condolence. Because of their longitudinal relationship with the family,
primary care providers may offer much needed support. There are practical
issues, such as the need to cancel previously made appointments and to alert
office and nursing staff so that they are prepared should the family return for a
follow-up visit or for ongoing health maintenance care with the surviving
siblings. Even minor illnesses in the surviving siblings may frighten children.
Parents may contribute to this anxiety because their inability to protect the child
who has died may leave them with a sense of guilt or helplessness. They may
seek medical attention sooner or may be hypervigilant in the care of the siblings
because of guilt over the other child's death, concern about their judgment, or the
need for continued reassurance. A visit to the pediatrician can do much to allay
their fears.

Clinicians must remain vigilant for risk factors in each family member and in
the family unit as a whole. Primary care providers, who care for families over
time, know bereft patients' premorbid functioning and can identify those at
current or future risk for physical and psychiatric morbidity. Providers must
focus on symptoms that interfere with a patient's normal activities and
compromise a child's attainment of developmental tasks. Symptom duration,
intensity, and severity, in context with the family's culture, can help identify
complicated grief reactions in need of therapeutic attention. Descriptive words
such as “unrelenting,” “intense,” “intrusive,” or “prolonged” should raise
concern. Total absence of signs of mourning, specifically an inability to discuss
the loss or express sadness, also suggests potential problems.

No specific sign, symptom, or cluster of behaviors identifies the child or
family in need of help. Further assessment is indicated if the following occur: (1)
persistent somatic or psychosomatic complaints of undetermined origin
(headache, stomachache, eating and sleeping disorders, conversion symptoms,
symptoms related to the deceased's condition, hypochondriasis); (2) unusual
circumstances of death or loss (sudden, violent, or traumatic death; inexplicable,
unbelievable, or particularly senseless death; prolonged, complicated illness;
unexpected separation); (3) school or work difficulties (declining grades or
school performance, social withdrawal, aggression); (4) changes in home or
family functioning (multiple family stresses, lack of social support, unavailable
or ineffective functioning of caretakers, multiple disruptions in routines, lack of
safety); and (5) concerning psychologic factors (persistent guilt or blame, desire
to die or talk of suicide, severe separation distress, disturbing hallucinations,
self-abuse, risk-taking behaviors, symptoms of trauma such as hyperarousal or
severe flashbacks, grief from previous or multiple deaths). Children who are
intellectually impaired may require additional support.

Finally, pediatric healthcare providers need to recognize that the loss of a patient will have an impact on them, both as a health professional and as a caring individual. Identifying one's responses to the loss (grief, guilt, anger, sadness) and finding time to process these feelings is important. Providers cope with these experiences in many ways. Strong coping mechanisms foster resilience and allow providers to continue to engage with patients and families in meaningful ways even in the face of grief and loss.

**Treatment**

Suggesting interventions outside the natural support network of family and friends can often prove useful to grieving families. Bereavement counseling should be readily offered if needed or requested by the family. Interventions that enhance or promote attachments and security, as well as give the family a means of expressing and understanding death, help to reduce the likelihood of future or prolonged disturbance, especially in children. Collaboration between pediatric and mental health professionals can help determine the timing and appropriateness of services.

Interventions for children and families who are struggling to cope with a loss in the community include gestures such as sending a card or offering food to the relatives of the deceased and teaching children the etiquette of behaviors and rituals around bereavement and mutual support. Performing community service or joining charitable organizations, such as fund-raising in memory of the deceased, may be useful. In the wake of a disaster, parents and older siblings can give blood or volunteer in search and recovery efforts. When a loss does not involve an actual death (e.g., parental divorce, geographic relocation), empowering the child to join or start a “divorced kids' club” in school or planning a “new kids in town” party may help. Participating in a constructive activity moves the family away from a sense of helplessness and hopelessness and helps them find meaning in their loss.

**Psychotherapeutic services** may benefit the entire family or individual members. Many support or self-help groups focus on specific types of losses (sudden infant death syndrome, suicide, widow/widowers, AIDS) and provide an opportunity to talk with other people who have experienced similar losses. Family, couple, sibling, or individual counseling may be useful, depending on the nature of the residual coping issues. Combinations of approaches may work
well for children or parents with evolving needs. A child may participate in family therapy to deal with the loss of a sibling and use individual treatment to address issues of personal ambivalence and guilt related to the death.

The question of **pharmacologic intervention** for grief reactions often arises. Explaining that medication does not cure grief and often does not reduce the intensity of some symptoms (separation distress) can help. Although medication can blunt reactions, the psychologic work of grieving still must occur. The pediatrician must consider the patient's premorbid psychiatric vulnerability, current level of functioning, other available supports, and the use of additional therapeutic interventions. Medication as a first line of defense rarely proves useful in normal or uncomplicated grief reactions. In certain situations (severe sleep disruption, incapacitating anxiety, intense hyperarousal), an anxiolytic or antidepressant may help to achieve symptom relief and provide the patient with the emotional energy to mourn. Medication used in conjunction with some form of psychotherapy, and in consultation with a psychopharmacologist, has optimal results.

Children who are **refugees** and may have experienced war, violence, or personal torture, while often resilient, may experience posttraumatic stress disorder if exposures were severe or repeated (see **Chapter 14.3**). Sequelae such as depression, anxiety, and grief need to be addressed, and mental health therapy is indicated. Cognitive-behavioral therapy, use of journaling and narratives to bear witness to the experiences, and use of translators may be essential.

## Spiritual Issues

Responding to patients' and families' spiritual beliefs can help in comforting them during family tragedies. Offering to call members of pastoral care teams or their own spiritual leader can provide needed support and can aid in decision-making. Families have found it important to have their beliefs and their need for hope acknowledged in end-of-life care. The majority of patients report welcoming discussions on spirituality, which may help individual patients cope with illness, disease, dying, and death. In addressing spirituality, physicians need to follow certain guidelines, including maintaining respect for the patient's beliefs, following the patient's lead in exploring how spirituality affects the patient's decision-making, acknowledging the limits of their own expertise and role in spirituality, and maintaining their own integrity by not saying or doing anything that violates their own spiritual or religious views. Healthcare providers
should not impose their own religious or nonreligious beliefs on patients, but rather should listen respectfully to their patients. By responding to spiritual needs, physicians may better aid their patients and families in end-of-life care and bereavement and take on the role of healers.

Basics of Sleep and Chronobiology

Sleep, with its counterpart of wakefulness, is a highly complex and intricately regulated neurobiologic system that both influences and is influenced by all physiologic systems in the body, as well as by the environment and sociocultural practices. The concept of sleep regulation is based on what is usually referred to as the “2-process model” because it requires the simultaneous operation of 2 basic, highly coupled processes that govern sleep and wakefulness. The homeostatic process ("Process S"), regulates the length and depth of sleep and is thought to be related to the accumulation of adenosine and other sleep-promoting chemicals ("somnogens"), such as cytokines, during prolonged periods of wakefulness. This sleep pressure appears to build more quickly in infants and young children, thus limiting the duration that wakefulness can be sustained during the day and necessitating periods of daytime sleep (i.e., naps). The endogenous circadian rhythms ("Process C") influence the internal organization of sleep and the timing and duration of daily sleep–wake cycles and govern predictable patterns of alertness throughout the 24 hr day.

The “master circadian clock” that controls sleep–wake patterns, of which melatonin secretion is the principal biomarker, is located in the suprachiasmatic nucleus in the ventral hypothalamus. In addition, “circadian clocks” are present in virtually every cell in the body, which in turn govern the timing of multiple other physiologic systems (e.g., cardiovascular reactivity, hormone levels, renal and pulmonary functions). Because the human circadian clock is slightly longer than 24 hr, intrinsic circadian rhythms must be synchronized or “entrained” to the 24 hr day cycle by environmental cues called zeitgebers. The dark–light cycle is the most powerful of the zeitgebers; light signals are transmitted to the
suprachiasmatic nucleus via the circadian photoreceptor system within the retina (functionally and anatomically separate from the visual system), which switch the pineal gland's production of the hormone melatonin off (light) or on (dark). Circadian rhythms are also synchronized by other external time cues, such as timing of meals and alarm clocks.

Sleep propensity, the relative level of sleepiness or alertness experienced at any given time during a 24 hr period, is partially determined by the homeostatic sleep drive, which in turn depends on the duration and quality of previous sleep and the amount of time awake since the last sleep period. Interacting with this sleep homeostat is the 24 hr cyclic pattern or rhythm characterized by clock-dependent periods of maximum sleepiness (circadian troughs) and maximum alertness (circadian nadirs). There are two periods of maximum sleepiness, one in the late afternoon (approximately 3:00-5:00 PM) and one toward the end of the night (around 3:00-5:00 AM), and two periods of maximum alertness, one in mid-morning and one in the evening just before the onset of natural sleep, the so-called forbidden zone or second-wind phenomenon, which allows for the maintenance of wakefulness in the face of accumulated sleep drive.

There are significant health, safety, and performance consequences of failure to meet basic sleep needs, termed insufficient/inadequate sleep or sleep loss. Sufficient sleep is a biologic imperative, necessary for optimal brain and body functioning. Slow-wave sleep (SWS) (i.e., N3, delta, or deep sleep) appears to be the most restorative form of sleep; it is entered relatively quickly after sleep onset, is preserved in the face of reduced total sleep time, and increases (rebounds) after a night of restricted sleep. These restorative properties of sleep may be linked to the “glymphatic system,” which increases clearance of metabolic waste products, including β-amyloid, produced by neural activity in the awake brain. Rapid eye movement (REM) sleep (stage R or “dream” sleep) appears to be involved in numerous important brain processes, including completion of vital cognitive functions (e.g., consolidation of memory), promoting the plasticity of the central nervous system (CNS), and protecting the brain from injury. Sufficient amounts of these sleep stages are necessary for optimal cognitive functioning and emotional and behavioral self-regulation.

Partial sleep loss (i.e., sleep restriction) on a chronic basis accumulates in a sleep debt and over several days produces deficits equivalent to those seen under conditions of 1 night of total sleep deprivation. If the sleep debt becomes large enough and is not voluntarily repaid by obtaining sufficient recovery sleep, the body may respond by overriding voluntary control of wakefulness. This
results in periods of decreased alertness, dozing off, and unplanned napping, recognized as *excessive daytime sleepiness*. The sleep-restricted individual may also experience very brief (several seconds) repeated daytime microsleeps, of which the individual may be completely unaware, but which nonetheless may result in significant lapses in attention and vigilance. There is also a relationship between the amount of sleep restriction and performance on cognitive tasks, particularly those requiring sustained attention and higher-level cognitive skills (*executive functions* ; see Chapter 48 ), with a decay in performance correlating with declines in sleep amounts.

It has also been increasingly recognized that what may be globally described as “deficient” sleep involves alterations in both amount and *timing* of sleep. Misalignment of intrinsic circadian rhythms with extrinsic societal demands, such as shift work and early school start times, is associated with deficits in cognitive function and self-regulation, increased emotional and behavioral problems and risk-taking behaviors, and negative impacts on health, such as increased risk of cardiovascular disease, obesity, and metabolic dysfunction.

Insufficient quantity of sleep, mistimed sleep, and poor-quality sleep in children and adolescents frequently result in excessive daytime sleepiness and decreased daytime alertness levels. *Sleepiness* in children may be recognizable as drowsiness, yawning, and other classic “sleepy behaviors,” but can also manifest as mood disturbance, including complaints of moodiness, irritability, emotional lability, depression, and anger; fatigue and daytime lethargy, including increased somatic complaints (headaches, muscle aches); cognitive impairment, including problems with memory, attention, concentration, decision-making, and problem solving; daytime behavior problems, including hyperactivity, impulsivity, and noncompliance; and academic problems, including chronic tardiness related to insufficient sleep and school failure resulting from chronic daytime sleepiness.

**Developmental Changes in Sleep**

Sleep disturbances, as well as many characteristics of sleep itself, have some distinctly different features in children from sleep and sleep disorders in adults. Changes in sleep architecture and the evolution of sleep patterns and behaviors reflect the physiologic/chronobiologic, developmental, and social/environmental changes that are occurring across childhood. These trends may be summarized as the gradual assumption of more adult sleep patterns as children mature:
1. Sleep is the primary activity of the brain during early development; for example, by age 2 yr, the average child has spent 9500 hr (approximately 13 mo) asleep vs 8000 hr awake, and between 2 and 5 yr, the time asleep is equal to the time awake.

2. There is a gradual decline in the average 24 hr sleep duration from infancy through adolescence, which involves a decrease in both diurnal and nocturnal sleep amounts. The decline in daytime sleep (scheduled napping) results in termination of naps typically by age 5 yr. There is also a gradual continued decrease in nocturnal sleep amounts into late adolescence; however, the typical adolescent still requires 8-10 hr of sleep per night.

3. There is also a decline in the relative percentage of REM sleep from birth (50% of sleep) through early childhood into adulthood (25–30%), and a similar initial predominance of SWS that peaks in early childhood, drops off abruptly after puberty (40–60% decline), and then further decreases over the life span. This SWS preponderance in early life has clinical significance; for example, the high prevalence of partial arousal parasomnias (sleepwalking and sleep terrors) in preschool and early school-age children is related to the relative increased percentage of SWS in this age-group.

4. The within-sleep ultradian cycle lengthens from about 50 min in the term infant to 90-110 min in the school-age child. This has clinical significance in that typically a brief arousal or awakening occurs during the night at the termination of each ultradian cycle. As the length of the cycles increase, there is a concomitant decrease in the number of these end-of-cycle arousals (night wakings).

5. A gradual shift in the circadian sleep–wake rhythm to a delayed (later) sleep onset and offset time, linked to pubertal stage rather than chronological age, begins with pubertal onset in middle childhood and accelerates in early to mid-adolescence. This biologic phenomenon often coincides with environmental factors, which further delay bedtime and advance wake time and result in insufficient sleep duration, including exposure to electronic “screens” (television, computer) in the evening, social networking, academic and extracurricular demands, and early (before 8:30 AM ) high school start times.

6. Increasing irregularity of sleep–wake patterns is typically observed across childhood into adolescence; this is characterized by increasingly
larger discrepancies between school night and non–school night bedtimes and wake times, and increased “weekend oversleep” in an attempt to compensate for chronic weekday sleep insufficiency. This phenomenon, often referred to as “social jet lag,” not only fails to adequately address performance deficits associated with insufficient sleep on school nights, but further exacerbates the normal adolescent phase delay and results in additional circadian disruption (analogous to that experienced by shift workers).

Table 31.1 lists normal developmental changes in children's sleep.

## Common Sleep Disorders

Childhood sleep problems may be conceptualized as resulting from (1) inadequate duration of sleep for age and sleep needs (insufficient sleep quantity); (2) disruption and fragmentation of sleep (poor sleep quality) as a result of frequent, repetitive, and brief arousals during sleep; and (3) misalignment of sleep–wake timing with circadian rhythms or CNS-mediated hypersomnia (excessive daytime sleepiness and increased sleep needs). Insufficient sleep is usually the result of difficulty initiating (delayed sleep onset) or maintaining sleep (prolonged night wakings), but, especially in older children and adolescents, may also represent a conscious lifestyle decision to sacrifice sleep in favor of competing priorities, such as homework and social activities. The underlying causes of delayed sleep onset/prolonged night wakings or sleep fragmentation may in turn be related to primarily behavioral factors (e.g., bedtime resistance resulting in shortened sleep duration) or medical causes (e.g., obstructive sleep apnea causing frequent, brief arousals).

Certain pediatric populations are relatively more vulnerable to acute or chronic sleep problems. These include children with medical problems, such as chronic illnesses or pain conditions (e.g., cystic fibrosis, asthma, idiopathic juvenile arthritis) and acute illnesses (e.g., otitis media); children taking stimulants (e.g., psychostimulants, caffeine), sleep-disrupting medications (e.g., corticosteroids), or daytime-sedating medications (some anticonvulsants, α-agonists); hospitalized children; and children with a variety of psychiatric disorders, including attention-deficit/hyperactivity disorder (ADHD), depression,
bipolar disorder, and anxiety disorders. Children with neurodevelopmental disorders such as autism, intellectual disability, blindness, and some chromosomal syndromes (e.g., Smith-Magenis, fragile X) have especially high rates of sleep disturbances for a wide variety of reasons. They may have comorbid medical issues or may be taking sleep-disrupting medications, may be more prone to nocturnal seizures, may be less easily entrained by environmental cues and thus more vulnerable to circadian disruption, and are more likely to have psychiatric and behavioral comorbidities that further predispose them to disrupted sleep.

**Insomnia of Childhood**

**Insomnia** is defined as difficulty initiating and/or maintaining sleep that occurs despite age-appropriate time and opportunity for sleep and results in some degree of impairment in daytime functioning for the child and/or family (ranging from fatigue, irritability, lack of energy, and mild cognitive impairment to effects on mood, school performance, and quality of life). Insomnia may be of a short-term and transient nature (usually related to an acute event) or may be characterized as long-term and chronic. Insomnia is a set of symptoms with many possible etiologies (e.g., pain, medication, medical/psychiatric conditions, learned behaviors). As with many behavioral issues in children, insomnia is often primarily defined by parental concerns rather than by objective criteria, and therefore should be viewed in the context of family (maternal depression, stress), child (temperament, developmental level), and environmental (cultural practices, sleeping space) considerations.

While current terminology (*Diagnostic and Statistical Manual of Mental Disorders*, 5th edition, 2015; *International Classification of Sleep Disorders*, 3rd edition, 2014) groups most types of insomnia in both children and adults under a single category of Chronic Insomnia Disorder, the descriptor of Behavioral Insomnia of Childhood and its subtypes (Sleep Onset Association and Limit Setting) remains a useful construct, particularly for young children (0-5 yr) in clinical practice. One of the most common presentations of insomnia found in infants and toddlers is the **sleep-onset association type**. In this situation the child learns to fall asleep only under certain conditions or associations, which typically require parental presence, such as being rocked or fed, and does not develop the ability to self-soothe. During the night, when the child experiences the type of brief arousal that normally occurs at the end of an ultradian sleep
cycle or awakens for other reasons, the child is not able to get back to sleep without those same associations being present. The infant then “signals” the parent by crying (or coming into the parents' bedroom, if the child is ambulatory) until the necessary associations are provided. The presenting complaint is typically one of prolonged night waking requiring caregiver intervention and resulting in insufficient sleep (for both child and parent).

Management of night wakings should include establishment of a set sleep schedule and bedtime routine and implementation of a behavioral program. The treatment approach typically involves a program of rapid withdrawal (extinction) or more gradual withdrawal (graduated extinction) of parental assistance at sleep onset and during the night. Extinction (“cry it out”) involves putting the child to bed at a designated bedtime, “drowsy but awake,” to maximize sleep propensity and then systematically ignoring any protests by the child until a set time the next morning. Although it has considerable empirical support, extinction is often not an acceptable choice for families. Graduated extinction involves gradually weaning the child from dependence on parental presence; typically, the parent leaves the room at “lights out” and then returns or “checks” periodically at fixed or successively longer intervals during the sleep–wake transition to provide brief reassurance until the child falls asleep. The exact interval between checks is generally determined by the parents' tolerance for crying and the child's temperament. The goal is to allow the infant or child to develop skills in self-soothing during the night, as well as at bedtime. In older infants and young children, the introduction of more appropriate sleep associations that will be readily available to the child during the night (transitional objects, such as a blanket or toy), in addition to positive reinforcement (stickers for remaining in bed), is often beneficial. If the child has become habituated to awaken for nighttime feedings (learned hunger), these feedings should be slowly eliminated. Parents must be consistent in applying behavioral programs to avoid inadvertent, intermittent reinforcement of night wakings. They should also be forewarned that crying behavior often temporarily escalates at the beginning of treatment (postextinction burst).

Bedtime problems, including stalling and refusing to go to bed, are more common in preschool-age and older children. This type of insomnia is frequently related to inadequate limit setting and is often the result of parental difficulties in setting limits and managing behavior in general and the inability or unwillingness to set consistent bedtime rules and enforce a regular bedtime. The situation may be exacerbated by the child's oppositional behavior. In some cases
the child's resistance at bedtime is the result of an underlying problem in falling asleep that is caused by other factors (medical conditions such as asthma or medication use; a sleep disorder such as restless legs syndrome; anxiety) or a mismatch between the child's intrinsic circadian rhythm ("night owl") and parental expectations regarding an “appropriate” bedtime.

Successful treatment of limit-setting sleep problems generally involves a combination of parent education regarding appropriate limit setting, decreased parental attention for bedtime-delaying behavior, establishment of bedtime routines, and positive reinforcement (sticker charts) for appropriate behavior at bedtime. Other behavioral management strategies that have empirical support include **bedtime fading**, or temporarily setting the bedtime closer to the actual sleep-onset time and then gradually advancing the bedtime to an earlier target bedtime. Older children may benefit from being taught relaxation techniques to help themselves fall asleep more readily. Following the principles of healthy sleep practices for children is essential (Table 31.2).

**Table 31.2**

**Basic Principles of Healthy Sleep for Children**

1. **Have a set bedtime and bedtime routine** for your child.
2. **Bedtime and wake-up time should be about the same time on school nights and non–school nights.** There should not be more than about 1 hr difference from one day to another.
3. **Make the hour before bed shared quiet time.** Avoid high-energy activities, such as rough play, and stimulating activities, such as watching television or playing computer games, just before bed.
4. **Don't send your child to bed hungry.** A light snack (e.g., milk and cookies) before bed is a good idea. Heavy meals within 1 hr or 2 of bedtime, however, may interfere with sleep.
5. **Avoid products containing caffeine for at least several hours before bedtime.** These include caffeinated sodas, coffee, tea, and chocolate.
6. **Make sure your child spends time outside every day,** whenever possible, and is involved in regular exercise.
7. **Keep your child 's bedroom quiet and dark.** A low-level night light is acceptable for children who find completely dark rooms frightening.
8. **Keep your child 's bedroom at a comfortable temperature** during the night (<24°C [75°F]).
9. **Don't use your child's bedroom for time-out or punishment.**
10. **Keep the television set out of your child's bedroom.** Children can easily develop the bad habit of “needing” the television to fall asleep. It is also much more difficult to control your child's viewing if the set is in the bedroom.

A 3rd type of childhood insomnia is related to a mismatch between parental expectations regarding time in bed and the child's intrinsic sleep needs. If, as illustrated in Fig. 31.1, a child's typical sleep time is 10 hr but the “sleep window” is set for 12 hr (7 PM to 7 AM), the result is likely to be a prolonged sleep onset of 2 hr, an extended period of wakefulness during the night, or early morning waking (or a combination); these periods are usually characterized by “normal” wakefulness in the child that is not accompanied by excessive distress. This situation is important to recognize because the solution—reducing the time in bed to actual sleep time—is typically simple and effective.

![Fig. 31.1 Mismatch between sleep needs/duration and time in bed, resulting in insomnia.](image)

Another form of insomnia that is more common in older children and adolescents is often referred to as *psychophysiologic, primary, or learned* insomnia. **Primary insomnia** occurs mainly in adolescents and is characterized by a combination of learned sleep-preventing associations and heightened physiologic arousal resulting in a complaint of sleeplessness and decreased daytime functioning. A hallmark of primary insomnia is excessive worry about
sleep and an exaggerated concern of the potential daytime consequences. The physiologic arousal can be in the form of cognitive hypervigilance, such as “racing” thoughts; in many individuals with insomnia, an increased baseline level of arousal is further intensified by this secondary anxiety about sleeplessness. Treatment usually involves educating the adolescent about the principles of healthy sleep practices (Table 31.3), institution of a consistent sleep–wake schedule, avoidance of daytime napping, instructions to use the bed for sleep only and to get out of bed if unable to fall asleep (stimulus control), restricting time in bed to the actual time asleep (sleep restriction), addressing maladaptive cognitions about sleep, and teaching relaxation techniques to reduce anxiety.

<table>
<thead>
<tr>
<th>Table 31.3</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Basic Principles of Healthy Sleep for Adolescents</strong></td>
</tr>
</tbody>
</table>

1. **Wake up and go to bed at about the same time** every night. Bedtime and wake-up time should not differ from school to non–school nights by more than approximately 1 hr.
2. **Avoid sleeping in on weekends** to “catch up” on sleep. This makes it more likely that you will have problems falling asleep.
3. If you take **naps**, they should be **short** (no more than 1 hr) and **scheduled in the early to mid-afternoon**. However, if you have a problem with falling asleep at night, napping during the day may make it worse and should be avoided.
4. **Spend time outside** every day. Exposure to sunlight helps to keep your body's internal clock on track.
5. **Exercise regularly.** Exercise may help you fall asleep and sleep more deeply.
6. **Use your bed for sleeping only.** Don't study, read, listen to music, or watch television on your bed.
7. **Make the 30-60 minutes before bedtime a quiet or wind-down time.** Relaxing, calm, enjoyable activities, such as reading a book or listening to calm music, help your body and mind slow down enough to let you get to sleep. Don't study, watch exciting/scary movies, exercise, or get involved in “energizing” activities just before bed.
8. Eat regular meals, and **don't go to bed hungry**. A light snack before bed
is a good idea; eating a full meal within 1 hr before bed is not.

9. **Avoid** eating or drinking products containing **caffeine** from dinnertime to bedtime. These include caffeinated sodas, coffee, tea, and chocolate.

10. **Do not use alcohol.** Alcohol disrupts sleep and may cause you to awaken throughout the night.

11. Smoking (e.g., cigarettes) disturbs sleep. Although you should not smoke at all, if you do, **do not smoke at least 2 hr before bed**.

12. **Do not use sleeping pills, melatonin, or other nonprescription sleep aids** to help you sleep unless specifically recommended by your doctor. These can be dangerous, and the sleep problems often return when you stop taking the medicine.

Behavioral treatments for insomnia, even in young children, appear to be highly effective and well tolerated. Several studies have failed to demonstrate long-term negative effects of behavioral strategies such as “sleep training” on parent–child relationships and attachment, psychosocial-emotional functioning, and chronic stress. In general, hypnotic medications or supplements such as melatonin are infrequently needed as an adjunct to behavioral therapy to treat insomnia in typically developing and healthy children.

### Obstructive Sleep Apnea Syndrome

**Sleep-related breathing disorder (SRBD)** in children encompasses a broad spectrum of respiratory disorders that occur exclusively in sleep or that are exacerbated by sleep, including primary snoring and upper airway resistance syndrome, as well as apnea of prematurity (see Chapter 122.2) and central apnea (see Chapter 446.2). **Obstructive sleep apnea syndrome (OSAS)**, the most important clinical entity within the SRBD spectrum, is characterized by repeated episodes of prolonged upper airway obstruction during sleep despite continued or increased respiratory effort, resulting in complete (apnea) or partial (hypopnea; ≥30% reduction in airflow accompanied by ≥3% O₂ desaturation and/or arousal) cessation of airflow at the nose and/or mouth, as well as in disrupted sleep. Both intermittent hypoxia and the multiple arousals resulting from these obstructive events likely contribute to significant metabolic, cardiovascular, and neurocognitive-neurobehavioral morbidity.

**Primary snoring** is defined as snoring without associated ventilatory abnormalities on overnight polysomnogram (e.g., apneas or hypopneas,
hypoxemia, hypercapnia) or respiratory-related arousals and is a manifestation of the vibrations of the oropharyngeal soft tissue walls that occur when an individual attempts to breathe against increased upper airway resistance during sleep. Although generally considered nonpathologic, primary snoring in children may still be associated with subtle breathing abnormalities during sleep, including evidence of increased respiratory effort, which in turn may be associated with adverse neurodevelopmental outcomes.

**Etiology**

OSAS results from an anatomically or functionally narrowed upper airway; this typically involves some combination of decreased upper airway patency (upper airway obstruction and/or decreased upper airway diameter), increased upper airway collapsibility (reduced pharyngeal muscle tone), and decreased drive to breathe in the face of reduced upper airway patency (reduced central ventilatory drive) (Table 31.4). Upper airway obstruction varies in degree and level (i.e., nose, nasopharynx/oropharynx, hypopharynx) and is most frequently caused by adenotonsillar hypertrophy, although tonsillar size does not necessarily correlate with degree of obstruction, especially in older children. Other causes of airway obstruction include allergies associated with chronic rhinitis or nasal obstruction; craniofacial abnormalities, including hypoplasia or displacement of the maxilla and mandible; gastroesophageal reflux with resulting pharyngeal reactive edema (see Chapter 349); nasal septal deviation (Chapter 404); and velopharyngeal flap cleft palate repair. Reduced upper airway tone may result from neuromuscular diseases, including hypotonic cerebral palsy and muscular dystrophies (see Chapter 627), or hypothyroidism (Chapter 581). Reduced central ventilatory drive may be present in some children with Arnold-Chiari malformation (see Chapter 446); rapid-onset obesity with hypothalamic dysfunction, hypoventilation, and autonomic dysregulation (Chapter 60.1); and meningomyelocele (Chapter 609.4). In other situations the etiology is mixed; individuals with Down syndrome (see Chapter 98.2), because of their facial anatomy, hypotonia, macroglossia, and central adiposity, as well as the increased incidence of hypothyroidism, are at particularly high risk for OSAS, with some estimates of prevalence as high as 70%.

**Table 31.4**

| Anatomic Factors That Predispose to |
Obstructive Sleep Apnea Syndrome and Hypoventilation in Children

Nose

- Anterior nasal stenosis
- Choanal stenosis/atresia
- Deviated nasal septum
- Seasonal or perennial rhinitis
- Nasal polyps, foreign body, hematoma, mass lesion

Nasopharyngeal and Oropharyngeal

- Adenotonsillar hypertrophy
- Macroglossia
- Cystic hygroma
- Veloopharyngeal flap repair
- Cleft palate repair
- Pharyngeal mass lesion

Craniofacial

- Micrognathia/retrognathia
- Midface hypoplasia (e.g., trisomy 21, Crouzon disease, Apert syndrome)
- Mandibular hypoplasia (Pierre Robin, Treacher Collins, Cornelia de Lange syndromes)
- Craniofacial trauma
- Skeletal and storage diseases
- Achondroplasia
- Storage diseases (e.g., glycogen; Hunter, Hurler syndromes)

Although many children with OSAS are of normal weight, an increasingly large percentage are overweight or obese, and many of these children are school-age or younger (see Chapter 60). There is a significant correlation between weight and SRBD (e.g., habitual snoring, OSAS, sleep-related hypoventilation).
Although adenotonsillar hypertrophy also plays an important etiologic role in overweight/obese children with OSAS, mechanical factors related to an increase in the amount of adipose tissue in the throat (pharyngeal fat pads), neck (increased neck circumference), and chest wall and abdomen can increase upper airway resistance, worsen gas exchange, and increase the work of breathing, particularly in the supine position and during REM sleep. A component of blunted central ventilatory drive in response to hypoxia/hypercapnia and hypoventilation may occur as well (see Chapter 446.3), particularly in children with morbid or syndrome-based (e.g., Prader-Willi) obesity. Overweight and obese children and adolescents are at particularly high risk for metabolic and cardiovascular complications of SRBD, such as insulin resistance and systemic hypertension. Morbidly obese children are also at increased risk for postoperative complications as well as residual OSAS after adenotonsillectomy.

**Epidemiology**

Overall prevalence of parent-reported snoring in the pediatric population is approximately 8%; “always” snoring is reported in 1.5–6%, and “often” snoring in 3–15%. When defined by parent-reported symptoms, the prevalence of OSAS is 4–11%. The prevalence of pediatric OSAS as documented by overnight sleep studies using ventilatory monitoring procedures (e.g., in-lab polysomnography, home studies) is 1–4% overall, with a reported range of 0.1–13%. Prevalence is also affected by the demographic characteristics such as age (increased prevalence between 2 and 8 yr), gender (more common in boys, especially after puberty), race/ethnicity (increased prevalence in African American and Asian children), history of prematurity, and family history of OSAS.

**Pathogenesis**

The upregulation of inflammatory pathways, as indicated by an increase in peripheral markers of inflammation (e.g., C-reactive protein, interleukins), appears to be linked to metabolic dysfunction (e.g., insulin resistance, dyslipidemia, alterations in neurohormone levels such as leptin) in both obese and nonobese children with OSAS. Systemic inflammation and arousal-mediated increases in sympathetic autonomic nervous system activity with altered vasomotor tone may be key contributors to increased cardiovascular risk due to alterations in vascular endothelium in both adults and children with OSA. Other potential mechanisms that may mediate cardiovascular sequelae in adults and
children with OSA include elevated systemic blood pressure and ventricular dysfunction. Mechanical stress on the upper airway induced by chronic snoring may also result in both local mucosal inflammation of adenotonsillar tissues and subsequent upregulation of inflammatory molecules, most notably leukotrienes.

One of the primary mechanisms by which OSAS is believed to exert negative influences on cognitive function appears to involve repeated episodic arousals from sleep leading to sleep fragmentation and sleepiness. Equally important, intermittent hypoxia may lead directly to systemic inflammatory vascular changes in the brain. Levels of inflammatory markers such as C-reactive protein and interleukin-6 are elevated in children with OSAS and are also associated with cognitive dysfunction.

**Clinical Manifestations**

The clinical manifestations of OSAS may be divided into sleep-related and daytime symptoms. The most common nocturnal manifestations of OSAS in children and adolescents are loud, frequent, and disruptive snoring; breathing pauses; choking or gasping arousals; restless sleep; and nocturnal diaphoresis. Many children who snore do not have OSAS, but few children with OSAS do not snore (caregivers may not be aware of snoring in older children and adolescents). Children, like adults, tend to have more frequent and more severe obstructive events in REM sleep and when sleeping in the supine position. Children with OSAS may adopt unusual sleeping positions, keeping their necks hyperextended to maintain airway patency. Frequent arousals associated with obstruction may result in nocturnal awakenings but are more likely to cause fragmented sleep.

Daytime symptoms of OSAS include mouth breathing and dry mouth, chronic nasal congestion or rhinorrhea, hyponasal speech, morning headaches, difficulty swallowing, and poor appetite. Children with OSAS may have secondary enuresis, postulated to result from the disruption of the normal nocturnal pattern of atrial natriuretic peptide secretion by changes in intrathoracic pressure associated with OSAS. Partial arousal parasomnias (sleepwalking and sleep terrors) may occur more frequently in children with OSAS, related to the frequent associated arousals and an increased percentage of SWS.

One of the most important but frequently overlooked sequelae of OSAS in children is the effect on mood, behavior, learning, and academic functioning. The neurobehavioral consequences of OSAS in children include daytime sleepiness with drowsiness, difficulty in morning waking, and unplanned
napping or dozing off during activities, although evidence of frank hypersomnolence tends to be less common in children compared to adults with OSA (except in very obese children or those with severe disease). Mood changes include increased irritability, mood instability and emotional dysregulation, low frustration tolerance, and depression or anxiety. Behavioral issues include both “internalizing” (i.e., increased somatic complaints and social withdrawal) and “externalizing” behaviors, including aggression, impulsivity, hyperactivity, oppositional behavior, and conduct problems. There is substantial overlap between the clinical impairments associated with OSAS and the diagnostic criteria for ADHD, including inattention, poor concentration, and distractibility (see Chapter 49).

Many of the studies that have looked at changes in behavior and neuropsychologic functioning in children after treatment (usually adenotonsillectomy) for OSAS have largely documented significant improvement in outcomes, both short term and long term, including daytime sleepiness, mood, behavior, academics, and quality of life. However, most studies failed to find a dose-dependent relationship between OSAS in children and specific neurobehavioral-neurocognitive deficits, suggesting that other factors may influence neurocognitive outcomes, including individual genetic susceptibility, racial/ethnic background, environmental influences (e.g., passive smoking exposure), and comorbid conditions, such as obesity, shortened sleep duration, and other sleep disorders.

**Diagnosis**

The 2012 revised American Academy of Pediatrics clinical practice guidelines provide excellent information for the evaluation and management of uncomplicated childhood OSAS (Table 31.5). No physical examination findings are truly pathognomonic for OSAS, and most healthy children with OSAS appear normal; however, certain physical examination findings may suggest OSAS. Growth parameters may be abnormal (obesity, or less frequently, failure to thrive), and there may be evidence of chronic nasal obstruction (hyponasal speech, mouth breathing, septal deviation, “adenoidal facies”) as well as signs of atopic disease (i.e., “allergic shiners”). Oropharyngeal examination may reveal enlarged tonsils, excess soft tissue in the posterior pharynx, and a narrowed posterior pharyngeal space, as well as dental features consistent with obstruction (e.g., teeth crowding, narrow palate, short frenulum). Any abnormalities of head position, such as forward head posture, and facial structure, such as retrognathia,
micrognathia, and midfacial hypoplasia, best appreciated by inspection of the lateral facial profile, increase the likelihood of OSAS and should be noted. In severe cases the child may have evidence of pulmonary hypertension, right-sided heart failure, and cor pulmonale; systemic hypertension may occur, especially in obese children.

Table 31.5

American Academy of Pediatrics Clinical Practice Guideline: Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (OSAS)

Key Action Statement 1: Screening for OSAS

As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS, clinicians should perform a more focused evaluation. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)

Key Action Statement 2A: Polysomnography

If a child or adolescent snores on a regular basis and has any of the complaints or findings of OSAS, clinicians should either (1) obtain a polysomnogram (Evidence Quality: Grade A; Recommendation Strength: Recommendation) or (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence Quality: Grade D; Recommendation Strength: Option.)

Key Action Statement 2B: Alternative Testing

If polysomnography is not available, clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C; Recommendation Strength: Option.)
Key Action Statement 3: Adenotonsillectomy

If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery, the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6 ). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)

Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy

Clinicians should monitor high-risk patients undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)

Key Action Statement 5: Reevaluation

Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)

Key Action Statement 5B: Reevaluation of High-Risk Patients

Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2 ), or refer such patients to a sleep specialist. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)
Key Action Statement 6: Continuous Positive Airway Pressure (CPAP)

Clinicians should refer patients for CPAP management if symptoms/signs or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B; Recommendation Strength: Recommendation.)

Key Action Statement 7: Weight Loss

Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C; Recommendation Strength: Recommendation.)

Key Action Statement 8: Intranasal Corticosteroids

Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B; Recommendation Strength: Option.)

Because no combination of clinical history and physical findings can accurately predict which children with snoring have OSAS, the gold standard for diagnosing OSAS remains an in-lab overnight polysomnogram (PSG). Overnight PSG is a technician-supervised, monitored study that documents physiologic variables during sleep; sleep staging, arousal measurement, cardiovascular parameters, and body movements (electroencephalography, electrooculography, chin and leg electromyography, electrocardiogram, body position sensors, and video recording), and a combination of breathing monitors (oronasal thermal sensor and nasal air pressure transducer for airflow), chest/abdominal monitors (e.g., inductance plethysmography for respiratory effort, pulse oximeter for O$_2$ saturation, end-tidal or transcutaneous CO$_2$ for CO$_2$ retention, snore microphone). The PSG parameter most often used in evaluating
for sleep-disordered breathing is the **apnea-hypopnea index (AHI)**, which indicates the number of apneic and hypopneic (both obstructive and central) events per hour of sleep. Currently, there are no universally accepted PSG normal reference values or parameters for diagnosing OSAS in children, and it is still unclear which parameters best predict morbidity. Normal preschool and school-age children generally have a total AHI <1.5 (obstructive AHI <1), and this is the most widely used cutoff value for OSA in children ≤12 yr old; in older adolescents the adult cutoff of an AHI ≥5 is generally used. When AHI is between 1 and 5 obstructive events per hour, assessment of additional PSG parameters (e.g., elevated CO$_2$ indicating obstructive hypoventilation, O$_2$ desaturation, respiratory-related arousals), clinical judgment regarding risk factors for SRBD, presence and severity of clinical symptoms, and evidence of daytime sequelae should determine further management.

**Treatment**

At present, no universally accepted guidelines exist regarding the indications for treatment of pediatric SRBD, including primary snoring and OSAS. Current recommendations largely emphasize weighing what is known about the potential cardiovascular, metabolic, and neurocognitive sequelae of SRBD in children in combination with the individual healthcare professional's clinical judgment. The decision of whether and how to treat OSAS specifically in children depends on several parameters, including severity (nocturnal symptoms, daytime sequelae, sleep study results), duration of disease, and individual patient variables such as age, comorbid conditions, and underlying etiologic factors. In the case of moderate (AHI 5-10) to severe (AHI >10) disease, the decision to treat is usually straightforward, and most pediatric sleep experts recommend that any child with AHI >5 should be treated. However, a large randomized trial of early adenotonsillectomy vs watchful waiting with supportive care demonstrated that 46% of the control group children normalized on PSG (vs 79% of early adenotonsillectomy group) during the 7 mo observation period.

In the majority of cases of pediatric OSAS, adenotonsillectomy is the first-line treatment in any child with significant adenotonsillar hypertrophy, even in the presence of additional risk factors such as obesity. Adenotonsillectomy in uncomplicated cases generally (70–90% of children) results in complete resolution of symptoms; regrowth of adenoidal tissue after surgical removal occurs in some cases. Groups considered at high risk include young children (<3 yr) as well as those with severe OSAS documented by PSG, significant clinical
sequelae of OSAS (e.g., failure to thrive), or associated medical conditions, such as craniofacial syndromes, morbid obesity, and hypotonia. All patients should be reevaluated postoperatively to determine whether additional evaluation, a repeat PSG, and treatment are required. The American Academy of Sleep Medicine recommends that in high-risk groups (children with obesity, craniofacial anomalies, Down syndrome, or moderate-severe OSAS) or in children with continued symptoms of OSAS, a follow-up sleep study about 6 wk after adenotonsillectomy is indicated. Also, a number of studies have suggested that children who are underweight, normal weight, or overweight/obese at baseline all tend to gain weight after AT, and thus clinical vigilance is required during follow-up.

Additional treatment measures that may be appropriate include weight loss, positional therapy (attaching a firm object, such as a tennis ball, to the back of a sleep garment to prevent the child from sleeping in the supine position) and aggressive treatment of additional risk factors when present, such as asthma, seasonal allergies, and gastroesophageal reflux. Evidence suggests that intranasal corticosteroids and leukotriene inhibitors may be helpful in reducing upper airway inflammation in mild OSAS. Other surgical procedures (e.g., uvulopharyngopalatoplasty) and maxillofacial surgery (e.g., mandibular distraction osteogenesis) are seldom performed in children. Oral appliances, such as mandibular advancing devices and palatal expanders, may be considered in select cases; consultation with a pediatric dentist or orthodontist is recommended. Neuromuscular reeducation or repatterning of the oral and facial muscles with exercises to address abnormal tongue position and low upper airway tone (i.e., myofunctional therapy) have been shown to be beneficial in addressing pediatric OSAS as well as alleviating chewing and swallowing problems in children able to cooperate with the behavioral program.

Continuous or bilevel positive airway pressure (CPAP or BiPAP) is the most common treatment for OSAS in adults and can be used successfully in children and adolescents. Positive airway pressure (PAP) may be recommended if removing the adenoids and tonsils is not indicated, if there is residual disease following adenotonsillectomy, or if there are major risk factors not amenable to surgery (obesity, hypotonia). PAP delivers humidified, warmed air through an interface (mask, nasal pillows) that, under pressure, effectively “splints” the upper airway open. Optimal pressure settings (that abolish or significantly reduce respiratory events without increasing arousals or central apneas) are determined in the sleep lab during a full-night PAP titration. Careful attention
should be paid to education of the child and family, and desensitization protocols should usually be implemented to increase the likelihood of adherence. Efficacy studies at the current pressure and retitrations should be conducted periodically with long-term use (at least annually) or in association with significant weight changes or resurgence of SRBD symptoms.

Parasomnias

Parasomnias are episodic nocturnal behaviors that often involve cognitive disorientation and autonomic and skeletal muscle disturbance. Parasomnias may be further characterized as occurring primarily during non-REM sleep (partial arousal parasomnias) or in association with REM sleep, including nightmares, hypnogogic hallucinations, and sleep paralysis; other common parasomnias include sleep-talking and hypnic jerks or “sleep starts.”

Etiology

**Partial arousal parasomnias** represent a dissociated sleep–wake state, the neurobiology of which remains unclear, although genetic factors and an intrinsic oscillation of subcortical-cortical arousal with sleep have been proposed. These episodic events, which include sleepwalking, sleep terrors, and confusional arousals, are more common in preschool and school-age children because of the relatively higher percentage of SWS in younger children. Partial arousal parasomnias typically occur when SWS predominates, in the 1st third of the night. In contrast, **nightmares**, which are much more common than partial arousal parasomnias but are often confused with them, tend to be concentrated in the last third of the night, when REM sleep is most prominent. Any factor associated with an increase in the relative percentage of SWS (certain medications, previous sleep restriction) may increase the frequency of events in a predisposed child. There appears to be a genetic predisposition for both sleepwalking and night terrors. Partial arousal parasomnias may also be difficult to distinguish from nocturnal seizures. Table 31.6 summarizes similarities and differences among these nocturnal arousal events.

CNS, Central nervous system; EEG, electroencephalogram; REM, rapid eye movement; SWA, slow-wave arousal.

**Epidemiology**

Many children sleepwalk on at least one occasion; the lifetime prevalence by age 10 yr is 13%. **Sleepwalking** (somnambulism) may persist into adulthood, with the prevalence in adults of approximately 4%. The prevalence is approximately 10 times greater in children with a family history of sleepwalking. The peak prevalence of **sleep terrors** is 34% at age 1-5 yr, decreasing to 10% by age 7; the age at onset is usually between 4 and 12 yr. Because of the common genetic predisposition, the likelihood of developing sleepwalking after age 5 is almost 2-fold higher in children with a history of sleep terrors. Although sleep terrors can occur at any age from infancy through adulthood, most individuals outgrow sleep terrors by adolescence. **Confusional arousals** (sleep drunkenness, sleep inertia) usually occur with sleepwalking and sleep terrors; prevalence rates have been estimated at >15% in children age 3-13 yr.

**Clinical Manifestations**

The partial arousal parasomnias have several features in common. Because they typically occur at the transition out of “deep” sleep or SWS, partial arousal
parasomnias have clinical features of both the awake (ambulation, vocalizations) and the sleeping (high arousal threshold, unresponsiveness to environment) states, usually with amnesia for the events. External (noise) or internal (obstruction) factors may trigger events in some individuals. The duration is typically a few minutes (sleep terrors) up to 30-40 min (confusional arousals). Sleep terrors are sudden in onset and characteristically involve a high degree of autonomic arousal (tachycardia, dilated pupils). Confusional arousals typically arise more gradually from sleep, may involve thrashing around but usually not displacement from bed, and are often accompanied by slow mentation, disorientation, and confusion on forced arousal from SWS or on waking in the morning. Sleepwalking may be associated with safety concerns (e.g., falling out of windows, wandering outside). The child's avoidance of, or increased agitation with, comforting by parents or attempts at awakening is also common to all partial arousal parasomnias.

**Treatment**

Management of partial arousal parasomnias involves some combination of parental education and reassurance, healthy sleep practices, and avoidance of exacerbating factors such as sleep restriction and caffeine. Particularly in the case of sleepwalking, it is important to institute safety precautions such as use of gates in doorways and at the top of staircases, locking of outside doors and windows, and installation of parent notification systems such as bedroom door alarms. **Scheduled awakenings** is a behavioral intervention that involves having the parent wake the child 15-30 min before the time of night that the 1st parasomnia episode occurs and is most likely to be successful in situations where partial arousal episodes occur on a nightly basis. Pharmacotherapy is rarely necessary but may be indicated in cases of frequent or severe episodes, high risk of injury, violent behavior, or serious disruption to the family. The primary pharmacologic agents used are potent SWS suppressants, primarily benzodiazepines and tricyclic antidepressants.

**Sleep-Related Movement Disorders: Restless Legs Syndrome/Periodic Limb Movement Disorder and Rhythmic Movements**

Restless legs syndrome (RLS), also termed Willis-Ekbom disease, is a chronic
neurologic disorder characterized by an almost irresistible urge to move the legs, often accompanied by uncomfortable sensations in the lower extremities. Both the urge to move and the sensations are usually worse at rest and in the evening and are at least partially relieved by movement, including walking, stretching, and rubbing, but only if the motion continues. RLS is a clinical diagnosis that is based on the presence of these key symptoms (Table 31.7).

**Table 31.7**

**Diagnostic Criteria for Restless Legs Syndrome**

A. An urge to move legs, usually accompanied by or in response to uncomfortable and unpleasant sensations in the legs, characterized by the following:
   1. The urge to move the legs begins or worsens during periods of rest or inactivity.
   2. The urge to move the legs is partially or totally relieved by movement.
   3. The urge to move the legs is worse in the evening or at night than during the day, or occurs only in the evening or at night.

B. The symptoms in Criterion A occur at least three times per week and have persisted for at least 3 months.

C. The symptoms in Criterion A are accompanied by significant distress or impairment in social, occupational, educational, academic, behavioral, or other important areas of functioning.

D. The symptoms in Criterion A are not attributable to another mental disorder or medical condition (e.g., arthritis, leg edema, peripheral ischemia, leg cramps) and are not better explained by a behavioral condition (e.g., positional discomfort, habitual foot tapping).

E. The symptoms are not attributable to the physiological effects of a drug or abuse or medication (e.g., akathisia).

Periodic limb movement disorder (PLMD) is characterized by periodic, repetitive, brief (0.5-10 sec), and highly stereotyped limb jerks typically occurring at 20-40 sec intervals. These movements occur primarily during sleep, usually occur in the legs, and frequently consist of rhythmic extension of the big toe and dorsiflexion at the ankle. The diagnosis of periodic limb movements (PLMs) requires overnight PSG to document the characteristic limb movements with anterior tibialis electromyography leads.

**Etiology**

“Early-onset” RLS (onset of symptoms before 35-40 yr of age), often termed primary RLS, appears to have a particularly strong genetic component, with a 6-7–fold increase in prevalence in first-degree relatives of RLS patients. The mode of inheritance is complex, and several genetic loci have been identified (MEIS1, BTBD9, MAP2K5). Low serum iron levels (even without anemia) in both adults and children may be an important etiologic factor for the presence and severity of both RLS symptoms and PLMs. As a marker of decreased iron stores, serum ferritin levels in both children and adults with RLS are frequently low; (<50 µg/mL). The postulated underlying mechanism is related to the role of iron as a cofactor in tyrosine hydroxylation, a rate-limiting step in dopamine synthesis; in turn, dopaminergic dysfunction has been implicated, particularly in the genesis of the sensory component of RLS, as well as in PLMD. Certain medical conditions, including diabetes mellitus, end-stage renal disease, cancer, idiopathic juvenile arthritis, hypothyroidism, and pregnancy, may also be associated with RLS/PLMD, as are specific medications (e.g., antihistamines such as diphenhydramine, antidepressants, H₂ blockers such as cimetidine) and substances (notably, caffeine).

**Epidemiology**

Previous studies found prevalence rates of RLS in the pediatric population ranging from 1–6%; approximately 2% of 8-17 yr olds meet the criteria for “definite” RLS. Prevalence rates of PLMs >5 per hour in clinical populations of children referred for sleep studies range from 5–27%; in survey studies of PLM symptoms, rates are 8–12%. About 40% of adults with RLS have symptoms before age 20 yr; 20% report symptoms before age 10. Familial cases usually have a younger age of onset. Several studies in referral populations have found that PLMs occur in as many as 25% of children diagnosed with ADHD.
Clinical Manifestations

In addition to the urge to move the legs and the sensory component (paresthesia-like, tingling, burning, itching, crawling), most RLS episodes are initiated or exacerbated by rest or inactivity, such as lying in bed to fall asleep or riding in a car for prolonged periods. A unique feature of RLS is that the timing of symptoms also appears to have a circadian component, in that they often peak in the evening hours. Some children may complain of “growing pains,” although this is considered a nonspecific feature. Because RLS symptoms are usually worse in the evening, bedtime struggles and difficulty falling asleep are two of the most common presenting complaints. In contrast to patients with RLS, individuals with PLMs are usually unaware of these movements, but children may complain of morning muscle pain or fatigue; these movements may result in arousals during sleep and consequent significant sleep disruption. Parents of children with RLS/PLMD may report that their child is a restless sleeper, moves around, or even falls out of bed during the night.

The differential diagnosis includes growing pains, leg cramps, neuropathy, arthritis, myalgias, nerve compression (“leg fell asleep”), and dopamine antagonist–associated akathisia.

Treatment

The decision of whether and how to treat RLS depends on the level of severity (intensity, frequency, and periodicity) of sensory symptoms, the degree of interference with sleep, and the impact of daytime sequelae in a particular child or adolescent. With PLMs, for an index (PLMs/hr) <5, usually no treatment is recommended; for an index >5, the decision to specifically treat PLMs should be based on the presence or absence of nocturnal symptoms (restless or nonrestorative sleep) and daytime clinical sequelae.

The acronym AIMS represents a comprehensive approach to the treatment of RLS: avoidance of exacerbating factors, such as caffeine and drugs, that increase symptoms; iron supplementation when appropriate; muscle activity, with increased physical activity, muscle relaxation, and application of heat/cold compresses; and sleep, with a regular sleep schedule and sufficient sleep for age. Iron supplements should be instituted if serum ferritin levels are <50 µg/L; it should be kept in mind that ferritin is an acute-phase reactant and thus may be falsely elevated (i.e., normal) in the setting of a concomitant illness. The recommended dose of oral ferrous sulfate is typically 3-6 mg/kg/day for 3 mo. If
there is no response to oral iron, intravenous iron compounds may be needed. Medications that increase dopamine levels in the CNS, such as ropinirole and pramipexole, are effective in relieving RLS/PLMD symptoms in adults; data in children are extremely limited. Dopaminergic therapy may lead to a loss of therapeutic response. Some recommend gabapentin enacarbil or other related alpha-2 delta ligands that bind to the alpha-2 delta subunit of the voltage-activated calcium channel.

Sleep-related rhythmic movements, including head banging, body rocking, and head rolling, are characterized by repetitive, stereotyped, and rhythmic movements or behaviors that involve large muscle groups. These behaviors typically occur with the transition to sleep at bedtime, but also at nap times and after nighttime arousals. Children typically engage in these behaviors as a means of soothing themselves to (or back to) sleep; these are much more common in the 1st yr of life and usually disappear by preschool age. In most cases, rhythmic movement behaviors are benign, because sleep is not significantly disrupted, and associated significant injury is rare. These behaviors typically occur in normally developing children and in the majority of cases do not indicate some underlying neurologic or psychologic problem. Usually, the most important aspect in management of sleep-related rhythmic movements is reassurance to the family that this behavior is normal, common, benign, and self-limited.

Narcolepsy

Hypersomnia is a clinical term that is used to describe a group of disorders characterized by recurrent episodes of excessive daytime sleepiness (EDS), reduced baseline alertness, and/or prolonged nighttime sleep periods that interfere with normal daily functioning (Table 31.8). The many potential causes of EDS can be broadly grouped as “extrinsic” (e.g., secondary to insufficient and/or fragmented sleep) or “intrinsic” (e.g., resulting from an increased need for sleep). Narcolepsy is a chronic, lifelong CNS disorder, typically presenting in adolescence and early adulthood, characterized by profound daytime sleepiness resulting in significant functional impairment. More than half of patients with narcolepsy also present with cataplexy (type 1), defined as the sudden, brief, partial or complete loss of skeletal muscle tone, typically triggered by strong emotion (e.g., laughter, surprise, anger), with retained consciousness. Other symptoms frequently associated with narcolepsy, including hypnogogic/hypnopompic (immediately before falling asleep/awakening)
typically visual hallucinations and sleep paralysis, may be conceptualized as representing the “intrusion” of REM sleep features into the waking state. Other REM-related features include observance of eye movements and twitches at sleep onset and vivid dreams. Rapid weight gain, especially near symptom onset, is frequently observed, and young children with narcolepsy have been reported to develop precocious puberty.

### Table 31.8

**Diagnostic Criteria for Narcolepsy**

<table>
<thead>
<tr>
<th>A. Recurrent periods of an irrepressible need to sleep, lapsing into sleep, or napping occurring within the same day. These must have been occurring at least three times per week over the past 3 months.</th>

<tr>
<td>B. The presence of at least one of the following:</td>
</tr>
<tr>
<td>1. Episodes of cataplexy, defined as either (a) or (b), occurring at least a few time per month:</td>
</tr>
<tr>
<td>a. In individuals with long-standing disease, brief (seconds to minutes) episodes of sudden bilateral loss of muscle tone with maintained consciousness that are precipitated by laughter or joking.</td>
</tr>
<tr>
<td>b. In children or individuals within 6 months of onset, spontaneous grimaces or jaw-opening episodes with tongue thrusting or a global hypotonia, without any obvious emotional triggers.</td>
</tr>
<tr>
<td>2. Hypocretin deficiency, as measured using cerebrospinal fluid (CSF) hypocretin-1 immunoreactivity values (less than or equal to one-third of values obtained in healthy subjects tested using the same assay, or less than or equal to 110 pg/mL). Low CSF levels of hypocretin-1 must not be observed in the context of acute brain injury, inflammation, or infection.</td>
</tr>
<tr>
<td>3. Nocturnal sleep polysomnography showing rapid eye movement (REM) sleep latency less than or equal to 15 minutes, or a multiple sleep latency test showing a mean sleep latency less than or equal to 8 minutes and two or more sleep-onset REM periods.</td>
</tr>
</tbody>
</table>

*Specify whether:*
**Narcolepsy without cataplexy but with hypocretin deficiency:** Criterion B requirements of low CSF hypocretin-1 levels and positive polysomnography/multiple sleep latency test are met, but no cataplexy is present (Criterion B1 not met).

**Narcolepsy with cataplexy but without hypocretin deficiency:** In this rare sub-type (less than 5% of narcolepsy cases), Criterion B requirements of cataplexy and positive polysomnography/multiple sleep latency test are met, but CSF hypocretin-1 levels are normal (Criterion B2 not met).

**Autosomal dominant cerebellar ataxia, deafness, and narcolepsy:** This sub-type is caused by exon 21 DNA (cytosine-5)-methyltransferase-1 mutations and is characterized by late-onset (age 30-40 years) narcolepsy (with low or intermediate CSF hypocretin-1 levels), deafness, cerebellar ataxia, and eventually dementia.

**Autosomal dominant narcolepsy, obesity, and type 2 diabetes:** Narcolepsy, obesity, and type 2 diabetes are low CSF hypocretin-1 levels have been described in rare cases and are associated with a mutation in the myelin oligodendrocyte glycoprotein gene.

**Narcolepsy without cataplexy but with hypocretin deficiency:** This sub-type is for narcolepsy that develops secondary to medical conditions that cause infectious (e.g., Whipple's disease, sarcoidosis), traumatic, or tumoral destruction of hypocretin neurons.

**Severity:**

**Mild:** Infrequent cataplexy (less than once per week), need for naps only once or twice per day, and less disturbed nocturnal sleep.

**Moderate:** Cataplexy once daily or every few days, disturbed nocturnal sleep and need for multiple naps daily.

**Severe:** Drug-resistant cataplexy with multiple attacks daily, nearly constant sleepiness, and disturbed nocturnal sleep (i.e., movements, insomnia, and vivid dreaming).

Etiology

The genesis of narcolepsy with cataplexy (type 1) is thought to be related to a specific deficit in the hypothalamic orexin/hypocretin neurotransmitter system involving the selective loss of cells that secrete hypocretin/orexin in the lateral hypothalamus. Hypocretin neurons stimulate a range of wake-promoting neurons in the brainstem, hypothalamus, and cortex and basal forebrain that produce neurochemicals to sustain the wake state and prevent lapses into sleep.

The development of narcolepsy most likely involves autoimmune mechanisms, possibly triggered by streptococcal, influenza virus, H1N1, and other viral infections, likely in combination with a genetic predisposition and environmental factors. A 12-13–fold increase in narcolepsy type 1 cases, especially in children, was reported in parts of Europe in 2009–2010 following immunization with the AS03 adjuvanted H1N1 influenza vaccine. Human leukocyte antigen testing also shows a strong association with narcolepsy; the majority of individuals with this antigen do not have narcolepsy, but most (>90%) patients with narcolepsy with cataplexy are HLA-DQB1*0602–positive. Patients with narcolepsy without cataplexy (type 2) are increasingly thought to have a significantly different pathophysiology; they are much less likely to be HLA-DQB1*0602–positive (4–50%), and cerebrospinal fluid (CSF) hypocretin levels are normal in most patients.

Although the majority of cases of narcolepsy are considered idiopathic (autoimmune), secondary narcolepsy can be caused by lesions to the posterior hypothalamus induced by traumatic brain injury, tumor, stroke, and neuroinflammatory processes such as post-streptococcal PANDAS (see Chapter 210), as well as by neurogenetic diseases such as Prader-Willi syndrome (Chapter 98.8), Niemann-Pick type C (Chapter 104.4), myotonic dystrophy (Chapter 627.6), and Norrie disease.

Epidemiology

Narcolepsy is a rare disorder with a prevalence of approximately 0.025–0.05%. The risk of developing narcolepsy with cataplexy in a first-degree relative of a narcoleptic patient is estimated at 1–2%. This represents an increase of 10-40–fold compared to the general population, but the risk remains very low, reinforcing the likely role for other etiologic factors.

Clinical Manifestations and Diagnosis
The typical onset of symptoms of narcolepsy is in adolescence and early adulthood, although symptoms may initially present in school-age and even younger children. The early manifestations of narcolepsy are often ignored, misinterpreted, or misdiagnosed as other medical, neurologic, or psychiatric conditions, and the appropriate diagnosis is frequently delayed for years. The onset may be abrupt or slowly progressive.

The most prominent clinical manifestation of narcolepsy is profound daytime sleepiness, characterized by both an increased baseline level of daytime drowsiness and the repeated occurrence of sudden and unpredictable sleep episodes. These “sleep attacks” are often described as “irresistible,” in that the child or adolescent is unable to stay awake despite considerable effort, and occur even in the context of normally stimulating activities (e.g., during meals, in conversation). Very brief (several seconds) sleep attacks may also occur in which the individual may “stare off,” appear unresponsive, or continue to engage in an ongoing activity (automatic behavior ). EDS may also be manifested by increased nighttime sleep needs and extreme difficulty waking in the morning or after a nap.

Cataplexy is considered virtually pathognomonic for narcolepsy but can develop several years after the onset of EDS. Manifestations are triggered by strong positive (laughing, joy) or negative (fright, anger, frustration) emotions and predominantly include facial slackening, head nodding, jaw dropping, and less often, knees buckling or complete collapse with falling to the ground. The cataplectic attacks are typically brief (seconds to minutes), the patient is awake and aware, and episodes are fully reversible, with complete recovery of normal tone when the episode ends. A form of cataplexy unique to children known as cataplectic facies is characterized by prolonged tongue protrusion, ptosis, slack jaw, slurred speech, grimacing, and gait instability. Additionally, children may have positive motor phenomenon similar to dyskinesias or motor tics, with repetitive grimacing and tongue thrusting. The cataplectic attacks are typically brief (seconds to minutes) but in children may last for hours or days (status cataplecticus ).

Hypnogogic/hypnopompic hallucinations usually involve vivid visual but also auditory and sometimes tactile sensory experiences during transitions between sleep and wakefulness, either at sleep offset (hypnopompic) or sleep onset (hypnogogic). Sleep paralysis is the inability to move or speak for a few seconds or minutes at sleep onset or offset and often accompanies the hallucinations. Other symptoms associated with narcolepsy include disrupted
nocturnal sleep, impaired cognition, inattention and ADHD-like symptoms, and behavioral and mood dysregulation.

Several pediatric screening questionnaires for EDS, including the modified Epworth Sleepiness Scale, help to guide the need for further evaluation in clinical practice when faced with the presenting complaint of daytime sleepiness. Physical examination should include a detailed neurologic assessment. Overnight PSG and a multiple sleep latency test (MSLT) are strongly recommended components in the evaluation of a patient with profound unexplained daytime sleepiness or suspected narcolepsy. The purpose of the overnight PSG is to evaluate for primary sleep disorders (e.g., OSAS) that may cause EDS. The MSLT involves a series of 5 opportunities to nap (20 min long), during which patients with narcolepsy demonstrate a pathologically shortened mean sleep-onset latency ($\leq 8$ min, typically $< 5$ min) as well as at least 2 periods of REM sleep occurring immediately after sleep onset. Alternatively, a diagnosis can be made by findings of low CSF hypocretin-1 concentration (typically $\leq 110$ pg/mL) with a standardized assay.

**Treatment**

An individualized narcolepsy treatment plan usually involves education, good sleep hygiene, behavioral changes, and medication. Scheduled naps during the day are often helpful. Wake-promoting medications such as modafinil or armodafinil may be prescribed to control the EDS, although these are not approved for use in children by the U.S. Food and Drug Administration (FDA), and potential side effects include rare reports of Stevens-Johnson syndrome and reduced efficacy of hormone-based contraceptives. Psychostimulants are approved for ADHD in children and can be used for EDS; side effects include appetite suppression, mood lability, and cardiovascular effects. Antidepressants (serotonin reuptake inhibitors, venlafaxine) may be used to reduce cataplexy. Sodium oxybate, also not currently FDA-approved for use in children, is a unique drug that appears to have a positive impact on daytime sleepiness, cataplexy, and nocturnal sleep disruption; reported side effects include dizziness, weight loss, enuresis, exacerbation of OSAS, depression, and risk of respiratory depression, especially when combined with CNS depressants, including alcohol. Pitolisant, a histamine (H$_3$) receptor agonist, has been shown to improve cataplexy and EDS in adult patients with narcolepsy. The goal for the child should be to allow the fullest possible return of normal functioning in school, at home, and in social situations.
Delayed Sleep–Wake Phase Disorder

Delayed sleep–wake phase disorder (DSWPD), a circadian rhythm disorder, involves a significant, persistent, and intractable phase shift in sleep–wake schedule (later sleep onset and wake time) that conflicts with the individual's normal school, work, and lifestyle demands. DSWPD may occur at any age but is most common in adolescents and young adults.

Etiology

Individuals with DSPD may start out as “night owls”; that is, they have an underlying predisposition or circadian “eveningness” preference for staying up late at night and sleeping late in the morning, especially on weekends, holidays, and summer vacations. The underlying pathophysiology of DSWPD is still unknown, although some theorize that it involves an intrinsic abnormality in the circadian oscillators that govern the timing of the sleep period.

Epidemiology

Studies indicate that the prevalence of DSWPD may be as high as 7–16% in adolescents and young adults.

Clinical Manifestations

The most common clinical presentation is sleep-initiation insomnia when the individual attempts to fall asleep at a “socially acceptable” desired bedtime and experiences very delayed sleep onset (often after 1-2 AM), accompanied by daytime sleepiness. Patients may have extreme difficulty arising in the morning even for desired activities, with pronounced confusion on waking (sleep inertia). Sleep maintenance is generally not problematic, and no sleep-onset insomnia is experienced if bedtime coincides with the preferred sleep-onset time (e.g., on weekends, school vacations). School tardiness and frequent absenteeism with a decline in academic performance often occur. Patients may also develop “secondary” psychophysiologic insomnia as a result of spending prolonged time in bed attempting to fall asleep at bedtime.

Treatment

The treatment of DSWPD usually has three components, all directed toward the goals of shifting the sleep–wake schedule to an earlier, more desirable time and
maintaining the new schedule. The initial step involves shifting the sleep–wake schedule to the desired earlier times, usually with gradual (i.e., in 15-30 min increments every few days) advancement of bedtime in the evening and rise time in the morning. More significant phase delays (i.e., larger difference between current sleep onset and desired bedtime) may require chronotherapy, which involves delaying bedtime and wake time by 2-3 hr every 24 hr “forward around the clock” until the target bedtime is reached. Because melatonin secretion is highly sensitive to light, exposure to light in the morning (either natural light or a “light box,” which typically produces light at around 10,000 lux) and avoidance of evening light exposure (especially from screens emitting predominantly blue light, such as computers and laptops) are often beneficial. Exogenous oral melatonin supplementation may also be used; larger, mildly sedating doses (5 mg) are typically given at bedtime, but some studies have suggested that physiologic doses of oral melatonin (0.3-0.5 mg) administered in the afternoon or early evening (5-7 hr before the habitual sleep-onset time) may be more effective in advancing the sleep phase.

**Health Supervision**

It is especially important for pediatricians to screen for and recognize sleep disorders in children and adolescents during healthcare encounters. The well-child visit is an opportunity to educate parents about normal sleep in children and to teach strategies to prevent sleep problems from developing (primary prevention) or becoming chronic, if problems already exist (secondary prevention). Developmentally appropriate screening for sleep disturbances should take place in the context of every well-child visit and should include a range of potential sleep problems; Table 31.9 outlines a simple sleep screening algorithm, the “BEARS.” Because parents may not always be aware of sleep problems, especially in older children and adolescents, it is also important to question the child directly about sleep concerns. The recognition and evaluation of sleep problems in children require both an understanding of the association between sleep disturbances and daytime consequences (e.g., irritability, inattention, poor impulse control) and familiarity with the developmentally appropriate differential diagnoses of common presenting sleep complaints (difficulty initiating and maintaining sleep, episodic nocturnal events). An assessment of sleep patterns and possible sleep problems should be part of the initial evaluation of every child presenting with behavioral or academic
problems, especially ADHD.

Table 31.9
BEARS Sleep Screening Algorithm

C, Child; P, parent.

Effective preventive measures include educating parents of newborns about normal sleep amounts and patterns. The ability to regulate sleep, or control internal states of arousal to fall asleep at bedtime and to fall back asleep during the night, begins to develop in the 1st 8-12 wk of life. Thus it is important to recommend that parents put their 2-4 mo old infants to bed “drowsy but awake” if they want to avoid dependence on parental presence at sleep onset and foster the infant's ability to self-soothe. Other important sleep issues include discussing the importance of regular bedtimes, bedtime routines, and transitional objects for
toddlers, and providing parents and children with basic information about healthy sleep practices, recommended sleep amounts at different ages, and signs that a child is not getting sufficient sleep (wakes with difficulty at required time in morning, sleeps longer given opportunity on weekends and vacation days).

The cultural and family context within which sleep problems in children occur should be considered. For example, bed-sharing of infants and parents is a common and accepted practice in many racial/ethnic groups, and these families may not share the goal of independent self-soothing in young infants. Anticipatory guidance needs to balance cultural awareness with the critical importance of “safe sleep” conditions in sudden infant death syndrome prevention (i.e., sleeping in the supine position, avoidance of bed-sharing but encouragement of room-sharing in the 1st yr of life) (see Chapter 402 ). On the other hand, the institution of cosleeping by parents as an attempt to address a child's underlying sleep problem (so-called reactive cosleeping), rather than as a conscious family decision, is likely to yield only a temporary respite from the problem and may set the stage for more significant sleep issues.

**Evaluation of Pediatric Sleep Problems**

The clinical evaluation of a child presenting with a sleep problem involves obtaining a careful medical history to assess for potential medical causes of sleep disturbances, such as allergies, concomitant medications, and acute or chronic pain conditions. A developmental history is important because of the increased risk of sleep problems in children with neurodevelopmental disorders. Assessment of the child's current level of functioning (school, home) is a key part of evaluating possible mood, behavioral, and neurocognitive sequelae of sleep problems. Current sleep patterns, including the usual sleep duration and sleep–wake schedule, are often best assessed with a sleep diary, in which a parent (or adolescent) records daily sleep behaviors for an extended period (1-2 wk). A review of sleep habits, such as bedtime routines, daily caffeine intake, and the sleeping environment (e.g., temperature, noise level), may reveal environmental factors that contribute to the sleep problems. Nocturnal symptoms that may be indicative of a medically based sleep disorder, such as OSAS (loud snoring, choking or gasping, sweating) or PLMs (restless sleep, repetitive kicking movements), should be elicited. Home video recording may be helpful in the evaluation of potential parasomnia episodes and the assessment of snoring and increased work of breathing in children with OSAS. An overnight sleep
study (PSG) is not routinely warranted in the evaluation of a child with sleep problems unless there are symptoms suggestive of OSAS or PLMs, unusual features of episodic nocturnal events, or unexplained daytime sleepiness.

Chapter 43 Tantrums and Breath-Holding Spells
Chapter 44 Lying, Stealing, and Truancy
Chapter 45 Aggression
Chapter 46 Self-Injurious Behavior
Chapter 47 Childhood Psychoses
It is estimated that 20% of children living in the United States experience a mental illness in a given year, at a cost of almost $14 billion. In children, mental illness is more prevalent than leukemia, diabetes, and AIDS combined; more money is spent on mental disorders than on any other childhood illness, including asthma, trauma, and infectious diseases. Although nearly 1 in 5 youths suffers from a psychiatric disorder, 75–85% do not receive specialty mental health services. Those who do, primarily receive services in nonspecialty sectors (primary care, schools, child welfare, juvenile justice), where mental health expertise may be limited. Untreated or inadequately treated psychiatric disorders persist over decades, become increasingly intractable to treatment, impair adherence to medical treatment regimens, and incur progressively greater social, educational, and economic consequences over time.

Aims of Assessment

A psychosocial assessment in the pediatric setting should determine whether there are signs and symptoms of cognitive, developmental, emotional, behavioral, or social difficulties and characterize these signs and symptoms sufficiently to determine their appropriate management. The focus of the assessment varies with the nature of the presenting problem and the clinical setting. Under emergency circumstances, the focus may be limited to an assessment of “dangerousness to self or others” for the purpose of determining the safest level of care. In routine circumstances (well-child visits), the focus may be broader, involving a screen for symptoms and functional impairment in
the major psychosocial domains. The challenge for the pediatric practitioner will be to determine as accurately as possible whether the presenting signs and symptoms are likely to meet criteria for a psychiatric disorder and whether the severity and complexity of the disorder suggest referral to a mental health specialist or management in the pediatric setting.

**Presenting Problems**

**Infants** may come to clinical attention because of problems with eating and/or sleep regulation, concerns about failure to gain weight and length, poor social responsiveness, limited vocalization, apathy or disinterest, and response to strangers that is excessively fearful or overly familiar. Psychiatric disorders most commonly diagnosed during this period are rumination and reactive attachment disorders.

**Toddlers** are assessed for concerns about sleep problems, language delay, motor hyperactivity, extreme misbehavior, extreme shyness, inflexible adherence to routines, difficulty separating from parents, struggles over toilet training, dietary issues, and testing limits. Developmental delays and more subtle physiologic, sensory, and motor processing problems can be presented as concerns. Problems with “goodness of fit” between the child's temperament and the parents' expectations can create relationship difficulties that also require assessment (see Chapter 19). Psychiatric disorders most commonly diagnosed during this period are autism spectrum disorder (ASD) and reactive attachment disorders.

Presenting problems in **preschoolers** include elimination difficulties, sibling jealousy, lack of friends, self-destructive impulsiveness, multiple fears, nightmares, refusal to follow directions, somatization, speech that is difficult to understand, and temper tantrums. Psychiatric disorders most commonly diagnosed in this period are ASD communication, oppositional, attention-deficit/hyperactivity disorder (ADHD), anxiety (separation, selective mutism), reactive attachment, gender dysphoria, and sleep disorders.

**Older children** are brought to clinical attention because of concerns about angry or sad mood, bedwetting, overactivity, impulsiveness, distractibility, learning problems, arguing, defiance, nightmares, school refusal, bullying or being bullied, worries and fears, somatization, communication problems, tics, and withdrawal or isolation. Psychiatric disorders most commonly diagnosed during this period are ADHD, oppositional, anxiety (generalized, phobias),
elimination, somatic symptom, specific learning, and tic disorders. 

Adolescents are assessed for concerns about the family situation, experimentation with sexuality and drugs, delinquency and gang involvement, friendship patterns, issues of independence, identity formation, self-esteem, and morality. Psychiatric disorders most often diagnosed during this period are anxiety (panic, social anxiety), depressive, bipolar, psychotic, obsessive-compulsive, impulse control, conduct, substance-related, and eating disorders.

General Principles of the Psychosocial Interview

Psychosocial interviewing in the context of a routine pediatric visit requires adequate time and privacy. The purpose of this line of inquiry should be explained to the child and parents (“to make sure things are going OK at home, at school, and with friends”), along with the limits of confidentiality. Thereafter, the first goal of the interview is to build rapport with both the child and the parents (see Chapters 17 and 34 for further discussion of strategies for engaging families).

With the parents, this rapport is grounded in respect for the parents' knowledge of their child, their role as the central influence in their child's life, and their desire to make a better life for their child. Parents often feel anxious or guilty because they believe that problems in a child imply that their parenting skills are inadequate. Parents' experiences of their own childhood influence the meaning a parent places on a child's feelings and behavior. A good working alliance allows mutual discovery of the past as it is active in the present and permits potential distortions to be modified more readily. Developmentally appropriate overtures can facilitate rapport with the child. Examples include playing peek-a-boo with an infant, racing toy cars with a preschooler, commenting on sports with a child who is wearing a baseball cap, and discussing music with a teenager who is wearing a rock band T-shirt.

After an overture with the child, it is helpful to begin with family-centered interviewing, in which the parent is invited to present any psychosocial concerns (learning, feelings, behavior, peer relationships) about the child. With adolescent patients, it is important to conduct a separate interview to give the adolescent an opportunity to confirm or refute the parent's presentation and to present the problem from his or her perspective. Following the family's
undirected presentation of the primary problem, it is important to shift to direct questioning to clarify the duration, frequency, and severity of symptoms, associated distress or functional impairment, and the developmental and environmental context in which the symptoms occur.

Because of the high degree of comorbidity of psychosocial problems in children, after eliciting the presenting problem, the pediatric practitioner should then briefly screen for problems in all the major developmentally appropriate categories of cognitive, developmental, emotional, behavioral, and social disturbance, including problems with mood, anxiety, attention, behavior, thinking and perception, substance use, social relatedness, eating, elimination, development, language, and learning. This can be preceded by a transition statement such as, “Now I'd like to ask about some other issues that I ask all parents and kids about.”

A useful guide for this area of inquiry is provided by the 11 Action Signs (Table 32.1), designed to give frontline clinicians the tools needed to recognize early symptoms of mental disorders. Functional impairment can be assessed by inquiring about symptoms and function in the major life domains, including home and family, school, peers, and community. These domains are included in the HEADSS (Home, Education, Activities, Drugs, Sexuality, Suicide/Depression) Interview Guide, often used in the screening of adolescents (Table 32.2).

Table 32.1

Mental Health Action Signs

- Feeling very sad or withdrawn for more than 2 weeks
- Seriously trying to harm or kill yourself, or making plans to do so
- Sudden overwhelming fear for no reason, sometimes with a racing heart or fast breathing
- Involvement in many fights, using a weapon, or wanting to badly hurt others
- Severe out-of-control behavior that can hurt yourself or others
- Not eating, throwing up, or using laxatives to make yourself lose weight
- Intense worries or fears that get in the way of your daily activities
- Extreme difficulty in concentrating or staying still that puts you in physical danger or causes school failure
- Repeated use of drugs or alcohol
• Severe mood swings that cause problems in relationships
• Drastic changes in your behavior or personality

From The Action Signs Project, Center for the Advancement of Children's Mental Health at Columbia University.

Table 32.2
HEADSS* Screening Interview for Taking a Rapid Psychosocial History

Parent Interview

Home

• How well does the family get along with each other?

Education

• How well does your child do in school?

Activities

• What does your child like to do?
• Does your child do anything that has you really concerned?
• How does your child get along with peers?

Drugs

• Has your child used drugs or alcohol?

Sexuality

• Are there any issues regarding sexuality or sexual activity that are of concern to you?
Suicide/Depression

• Has your child ever been treated for an emotional problem?
• Has your child ever intentionally tried to hurt him/herself or made threats to others?

Adolescent Interview

Home

• How do you get along with your parents?

Education

• How do you like school and your teachers?
• How well do you do in school?

Activities

• Do you have a best friend or group of good friends?
• What do you like to do?

Drugs

• Have you used drugs or alcohol?

Sexuality

• Are there any issues regarding sexuality or sexual activity that are of concern to you?

Suicide/Depression

• Everyone feels sad or angry some of the time. How about you?
• Did you ever feel so upset that you wished you were not alive or so angry
you wanted to hurt someone else badly?

* HEADSS, Home, Education, Activities, Drugs, Sexuality, Suicide/Depression.

The nature and severity of the presenting problem(s) can be further characterized through a standardized self-, parent-, or teacher-informant symptom rating scale; Table 32.3 lists selected scales in the public domain. A *rating scale* is a type of measure that provides a relatively rapid assessment of a specific construct with an easily derived numerical score that is readily interpreted. The use of symptom rating scales can ensure efficient, systematic coverage of relevant symptoms, quantify symptom severity, and document a baseline against which treatment effects can be measured. Functional impairment also can be assessed with self- and other-reported rating scales.

Clinical experience and methodological studies suggest that parents and teachers are more likely than the child to report externalizing problems (disruptive, impulsive, overactive, or antisocial behavior). Children may be more likely to report anxious or depressive feelings, including suicidal thoughts and acts, of which the parents may be unaware. Discrepancies across informants are common and can shed light on whether the symptoms are pervasive or contextual. Although concerns have been raised about children's competence as self-reporters (because of limitations in linguistic skills; self-reflection; emotional awareness; ability to monitor behavior, thoughts, and feelings; tendency toward social desirability), children and adolescents can be reliable and valid self-reporters.

Clinicians are encouraged to become familiar with the psychometric characteristics and appropriate use of at least 1 broad-band symptom rating scale, such as the Strengths and Difficulties Questionnaire (SDQ),* the Pediatric Symptom Checklist (PSC), † or the Swanson, Nolan, and Pelham–IV (SNAP-IV). ‡ These measures are available in multiple languages. If the clinical interview or
broad-band rating scale suggests difficulties in one or more specific symptom areas, the clinician can follow with a psychometrically sound, relevant narrow-band instrument, such as the Vanderbilt ADHD Diagnostic Rating Scale for attention, behavior, and learning problems; the Center for Epidemiological Studies Depression Scale for Children (CES-DC), Mood and Feelings Questionnaire (MFQ), or Patient Health Questionnaire-9 (PHQ-9) for depression; or the Screen for Child Anxiety Related Emotional Disorders (SCARED) for anxiety.

Children and adolescents scoring above standardized rating scale cutpoints in most cases should be referred to a qualified mental health professional for assessment and treatment, because scores above cutpoint are highly correlated with clinically significant psychiatric disorders. Youths scoring just below or only slightly above cutpoints (e.g., subsyndromal or mild mood, anxiety, or disruptive behavior disorders) may be appropriate for management in the pediatric primary care or subspecialty settings, as may youths scoring well above cutpoints for certain neurodevelopmental disorders (ADHD, autism spectrum, tic).

The safety of the child in the context of the home and community is of paramount importance. The interview should sensitively assess whether the child has been exposed to any frightening events, including abuse, neglect, bullying, marital discord, or domestic or community violence; whether the child shows any indication of dangerousness to self or others or a severely altered mental status (psychosis, intoxication, delirium, rage, hopelessness); or whether the child (if age appropriate) has been involved in any risky behavior, including running away, staying out without permission, truancy, gang involvement, experimentation with substances, and unprotected sexual encounters. The interview also should assess the capacity of the parents to adequately provide for the child's physical, emotional, and social needs or whether parental capacity has been diminished by psychiatric disorder, family dysfunction, or the sequelae of disadvantaged socioeconomic status. Any indications of threats to the child's safety should be immediately followed by thorough assessment and protective action.

**Indications for Referral**

There is variability in the level of confidence pediatric practitioners perceive in diagnosing psychosocial problems in children and adolescents. Pediatric
practitioners who have familiarity with psychiatric diagnostic criteria may feel confident diagnosing certain disorders, particularly the neurodevelopmental and other biologically based disorders (ADHD, ASD, tic disorders, enuresis, encopresis, insomnia, anorexia). The disorders about which some pediatric practitioners might have less diagnostic confidence include the disruptive/impulse control/conduct, depressive, bipolar, anxiety, psychotic, obsessive-compulsive, trauma-related, somatic symptom, and substance-related disorders. Pediatric practitioners should refer to a mental health practitioner whenever they experience diagnostic uncertainty with a child who has distressing or functionally impairing psychosocial symptoms. Children found to have indicators of dangerousness on initial assessment always should be immediately referred to a mental health professional.

Psychiatric Diagnostic Evaluation

The objectives of the psychiatric diagnostic evaluation of the child and adolescent are to determine whether psychopathology or developmental risk is present and if so, to establish an explanatory formulation and a differential diagnosis, and to determine whether treatment is indicated and if so, to develop a treatment plan and facilitate the parents' and child's involvement in the plan. The aims of the diagnostic evaluation are to clarify the reasons for the referral; to obtain an accurate accounting of the child's developmental functioning and the nature and extent of the child's psychosocial difficulties, functional impairment, and subjective distress; and to identify potential individual, family, or environmental factors that might account for, influence, or ameliorate these difficulties. The issues relevant to diagnosis and treatment planning can span genetic, constitutional, and temperamental factors; individual psychodynamics; cognitive, language, and social skills; family patterns of interaction and child-rearing practices; and community, school, and socioeconomic influences.

The focus of the evaluation is developmental; it seeks to describe the child's functioning in various realms and to assess the child's adaptation in these areas relative to that expected for the child's age and phase of development. The developmental perspective extends beyond current difficulties to vulnerabilities that can affect future development and as such are important targets for preventive intervention. Vulnerabilities may include subthreshold or subsyndromal difficulties that, especially when manifold, often are accompanied by significant distress or impairment and as such are important as potential
harbingers of future problems.

Throughout the assessment, the clinician focuses on identifying a realistic balance of vulnerabilities and strengths in the child, in the parents, and in the parent–child interactions. From this strength-based approach, over time a hopeful family narrative is co-constructed to frame the child's current developmental progress and predict the child's ongoing progress within the scope of current risk and protective factors.

Although the scope of the evaluation will vary with the clinical circumstance, the comprehensive psychiatric diagnostic evaluation has 12 major components: the presenting problem(s) and the context in which they occur; a review of psychiatric symptoms; a history of psychiatric treatment; a medical history, a developmental history; an educational history; a family history; a mental status examination; a biopsychosocial clinical formulation; a *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) diagnosis; a risk assessment; and a treatment plan. For infants and young children, the presenting problem and historical information is derived from parents and other informants. As children mature, they become increasingly important contributors to the information base, and they become the primary source of information in later adolescence. Information relevant to formulation and differential diagnosis is derived in multiple ways, including directive and nondirective questioning, interactive play, and observation of the child alone and together with the caregiver(s).

The explication of the **presenting problem(s)** includes information about onset, duration, frequency, setting, and severity of symptoms; associated distress and/or functional impairment; and predisposing, precipitating, perpetuating, and ameliorating contextual factors. The **symptom review** assesses potential comorbidity in the major domains of child and adolescent psychopathology, including problems with intellectual, communication, motor, learning, and developmental capabilities; attention deficits; angry, sad, or elated mood; anxiety; obsessions or compulsions; trauma or stress reactions; somatic symptoms; eating, elimination, sleep, or gender disturbances; disruptive, impulse-control, or conduct problems; psychosis; or substance abuse or addiction. The **history of psychiatric treatment** includes gathering information about prior emergency mental health assessments, psychiatric hospitalizations, day treatment, psychotherapy, pharmacotherapy, and nontraditional treatments.

The **medical history** includes information about the source of primary care, the frequency of health supervision, past and current medical illnesses and
treatments, and the youth and family's history of adherence to medical treatment. A systematic review of organ or functional systems facilitates the identification of abnormalities that require investigation or monitoring by the pediatric practitioner, as well as the identification of cautionary factors related to the prescription of psychotropic medication. The developmental history includes information about the circumstances of conception, pregnancy, or adoption; pre-, peri-, or postnatal insults; attachment and temperament; cognitive, motor, linguistic, emotional, social, and moral development; health habits, sexuality, and substance use (as age appropriate), coping and defensive structure, future orientation, and perceived strengths. The educational history includes schools attended; typical grades, attendance, and behavior; classroom accommodations; special education services; disciplinary actions; social relationships; extracurricular activities; and barriers to learning. The family history assesses family composition; sociodemographic and neighborhood characteristics; domiciliary arrangements; parenting capacities; family function; medical/psychiatric histories of family members; and cultural/religious affiliations.

Orientation is tested by the ability to correctly identify time (date, month, year, season), place (hospital, clinic, city, state, country), and name, as well as remember (recall) 3 objects. Attention/calculation testing is age dependent and includes counting forward by 3s, or more classically, counting backward from 100 by 7 (“serial 7s”) or 5. Language is tested by pointing to familiar objects (clock, pen) and asking the patient to name them, as well as having the patient follow a 3-step command. Language is also tested by having the patient write a sentence, as well as having the patient read another sentence and perform the command in that sentence.

The mental status examination assesses appearance, relatedness, cognition, communication, mood, affective expression, behavior, memory, orientation, and perception.

The evaluation culminates in a biopsychosocial formulation, diagnosis, and risk assessment. The biopsychosocial formulation is derived from an assessment of vulnerabilities and strengths in the biologic, psychological, and social domains and serves to identify targets for intervention and treatment. In the biologic domain, major vulnerabilities include a family history of psychiatric disorder and personality or behavior problems, as well as a personal history of pre-, peri-, or postnatal insults; cognitive or linguistic impairments; chronic physical illness; and a difficult temperament. In the psychological domain, major
vulnerabilities include failure to achieve developmental tasks, unresolved unconscious conflicts, and maladaptive coping and defensive styles. In the social domain, major vulnerabilities include parental incapacity; unskilled parenting; family dysfunction; social isolation; unfavorable school setting; unsupportive community structures; and sociodemographic disadvantage. Major strengths include cognitive and linguistic capability; physical health and attractiveness; stable, moderate temperamental characteristics; and stable supportive parenting, family, peer, and community structures. The biopsychosocial formulation can be organized to reflect predisposing, precipitating, perpetuating, and protective (ameliorating) factors (the “4 Ps”) influencing the development of the observed psychopathology.

The diagnosis must be made in accordance with the nomenclature in DSM-5. This nomenclature categorizes cross-sectional phenomenology into discrete clinical syndromes and seeks to improve diagnostic accuracy at the expense of theories of causation and dimensional presentations. By DSM-5 convention, if diagnostic criteria are met, the diagnosis is given (except where hierarchical rules apply); consequently, psychiatric comorbidity is a common occurrence. The risk assessment includes a careful assessment of risk status, including suicidality, homicidality, assaultiveness, self-injuriousness, and involvement in risky behavior or situations.

The psychiatric diagnostic evaluation culminates in a treatment plan that brings the broad array of targeted psychosocial interventions to the service of the child. Diagnoses drive the choice of evidence-based psychotherapeutic and psychopharmacologic treatments. The formulation drives the selection of interventions targeted at biologic, psychological, and social vulnerabilities and strengths. Many of these treatments and interventions are described in the succeeding chapters.

Special Considerations in the Diagnostic Evaluation of Infants and Young Children

Psychiatric evaluation of infants and young children includes the domains of physiology, temperament, language and motor development, affective behavior, social behavior, and communication. Although much of the information in these domains will be derived from parent report, much also can be gleaned from nonverbal behavior and observation of the parent–child interaction. Observations
should include predominant affective tone of parent and child (positive, negative, apathetic); involvement in the situation (curiosity, disinterest); social responsiveness (mutuality of gaze, auditory responsiveness); and reactions to transitions (including separation).

A screen for maternal depression* is critical at this stage, as is an assessment of the mother's (or other caregiver's) ability to respond rapidly on a contingent basis to the child's expressed needs, regulate the child's rapid shifts of emotion and behavior, and provide a stimulus shelter to prevent the child from being overwhelmed.

Standardized screening instruments—*Ages and Stages Questionnaires, Brief Infant-Toddler Social & Emotional Assessment, Early Childhood Screening Assessment, Modified Checklist for Autism in Toddlers, Parents' Evaluation of Developmental Status, and Survey of Well-being of Young Children*—designed for this age-group can be helpful in systematizing the evaluation. In addition, the *Infant, Toddler and Preschool Mental Status Exam (ITP-MSE)* is a reference tool that describes how traditional categories of the mental status examination can be adapted to observations of young children. Additional categories, including sensory and state regulation, have been added that reflect important areas of development in young children.

Diagnostic systems that are more age appropriate than DSM-5 have been developed for infants and young children. These systems include the *Research Diagnostic Criteria–Preschool Age (RDC-PA)* and *Zero to Three Diagnostic Classification of Mental Health and Developmental Disorders of Infancy and Early Childhood-Revised (DC: 0-3R)*. The DC: 0-3R includes a relationship classification that assesses the range of interactional adaptation in each parent–child relationship and regulation disorders of sensory processing that identify a range of constitutionally and maturationally based sensory reactivity patterns, motor patterns, and behavior patterns that together can dysregulate a child internally and impact the child's interactions with caregivers.

Psychopharmacology is the first-line treatment for several child and adolescent psychiatric disorders (e.g., ADHD, schizophrenia, bipolar) and is used adjunctively with psychosocial treatments for other disorders (or coexisting conditions), including anxiety, depression, autism spectrum, tic, trauma-related, and obsessive-compulsive disorders. Although pediatric primary care practitioners (PCPs) may routinely manage medications for attention-deficit/hyperactivity disorder (ADHD), anxiety, and depression, they may be called on to manage psychotropic medications with which they have had less experience. As such, it is useful for PCPs to be familiar with basic information about child and adolescent psychopharmacology. Before prescribing a psychotropic medication, PCPs should review full prescribing information for each medication (in package inserts or at reliable websites such as the National Institutes of Health DailyMed *) to obtain complete and up-to-date information about indications, contraindications, warnings, interactions, and precautions.

Pediatric prescribers should be aware of “best practice” principles that underlie medication assessment and management by child and adolescent psychiatrists (Table 33.1), so as to consider extrapolation of these principles to prescribing in the primary care setting. The use of medication involves a series of interconnected steps, including performing an assessment, constructing working diagnoses and an explanatory formulation, deciding on treatment and a monitoring plan, obtaining treatment assent/consent, and implementing treatment.

**Table 33.1**

**Best Principles for Use of Psychotropic Medications With Children and Adolescents**
1. Before initiating pharmacotherapy, a psychiatric evaluation is completed.
2. Before initiating pharmacotherapy, a medical history is obtained, and a medical evaluation is considered when appropriate.
3. The prescriber communicates with other professionals to obtain collateral history and collaborate in the monitoring of outcome and side effects during the medication trial.
4. The prescriber develops a psychosocial and psychopharmacologic treatment plan based on the best available evidence.
5. The prescriber develops a plan to monitor the patient during the medication trial.
6. The prescriber is cautious when the medication trial cannot be appropriately monitored.
7. The prescriber educates the patient and family about the patient's diagnosis and treatment plan.
8. The prescriber obtains and documents informed consent before initiating the medication trial and at appropriate intervals during the trial.
9. The informed-consent process focuses on the risks and benefits of the proposed and alternative treatments.
10. The medication trial should involve an adequate dose of medication for an adequate duration.
11. The prescriber reassesses the patient if the patient fails to respond to the medication trial as expected.
12. The prescriber has a clear rationale for using medication combinations.
13. The prescriber has a specific plan for medication discontinuation.

Questions remain about the quality of the evidence supporting the use of many psychotropic medications in children and adolescents. Therefore, cognitive, emotional, and behavioral symptoms are targets for medication treatment when (1) there is no or insufficient response to available evidence-based psychosocial interventions, (2) the patient's symptoms convey significant risk of harm, or (3) the patient is experiencing significant distress or functional impairment. Common target symptoms include agitation, aggression, anxiety, depression, hyperactivity, inattention, impulsivity, mania, obsessions, compulsions, and
psychosis (Table 33.2). All these can be quantitatively measured with standardized symptom rating scales to establish baseline symptom severity and facilitate “treating to target.”

**Stimulants and Other ADHD Medications**

Stimulants are sympathomimetic drugs that act both in the central nervous system (CNS) and peripherally by enhancing dopaminergic and noradrenergic transmission (Table 33.3). Strong evidence exists for the effectiveness of these medications for the treatment of ADHD and aggression, as well as moderate evidence for the treatment of hyperactivity in autism spectrum disorder (ASD). In some cases, stimulants are used adjunctively with antidepressants in the treatment of depression and as monotherapy for fatigue or malaise associated with chronic physical illnesses.

* Doses shown in table may exceed maximum recommended dose for some children.
† Capsule contents may be sprinkled on soft food.

FDA, U.S. Food and Drug Administration; CV, cardiovascular; Ht, height; Wt, weight; BP, blood pressure; P, pulse; GI, gastrointestinal.

No major differences in efficacy or tolerability have been found between different classes of stimulants, and no consistent patient profile identifies those who will respond preferentially to one class over another. The most common (generally dose-dependent) side effects of stimulants include headache, stomachache, appetite suppression, weight loss, blood pressure (BP) and heart rate increases, and delayed sleep onset. Less common side effects include irritability (particularly prominent in younger children), aggression, social withdrawal, and hallucinations (visual or tactile). Amphetamine preparations prescribed concurrently with serotonergic antidepressants can be associated with the development of serotonin syndrome.

Stimulants have been associated with elevations in mean BP (<5 mm Hg) and pulse (<10 beats/min); a subset of individuals (5–10%) may have greater increases. The rate of sudden death in pediatric patients taking stimulants is comparable to children in the general population; the hazard ratio for serious cardiovascular (CV) events is 0.75 (although up to a 2-fold increase in risk could not be ruled out). Moreover, a case series analysis of children with a CV incident and treatment with methylphenidate demonstrated an increased risk of arrhythmia (incidence rate ratio, 1.61) that was highest in the presence of congenital heart disease. The U.S. Food and Drug Administration (FDA)
recommends that stimulants should be avoided in the presence of structural cardiac abnormalities (e.g., postoperative tetralogy of Fallot, coronary artery abnormalities, subaortic stenosis, hypertrophic cardiomyopathy) and patient symptoms (syncope, palpitations, arrhythmias) or family history (e.g., unexplained sudden death) suggestive of CV disease. In these circumstances, cardiology consultation is recommended before prescribing. Routine electrocardiograms (ECGs) are not recommended in the absence of cardiac risk factors.

**Atomoxetine** is a selective inhibitor of presynaptic norepinephrine reuptake; it increases dopamine and norepinephrine in the prefrontal cortex. It is less effective for the treatment of ADHD and aggression than stimulants, but atomoxetine has a longer duration of action (approximately 24 hr). Atomoxetine can have an onset of action within 1-2 wk of starting treatment, but there is an incrementally increasing response for up to 24 wk or longer. Common side effects include nausea, headache, abdominal pain, insomnia, somnolence, erectile dysfunction, irritability, fatigue, decreased appetite, weight loss, and dizziness, along with nonclinical increases in heart rate and BP. Potential serious neuropsychiatric reactions include psychosis, mania, panic attacks, aggressive behavior, depression, seizures, and suicidal thinking. Atomoxetine carries an FDA warning regarding the risk of suicidal thinking and the need to monitor this closely. Atomoxetine also has been associated with hepatotoxicity and should be discontinued in patients with jaundice or laboratory evidence of liver injury, and should not be restarted. Because of the risk of sudden death, atomoxetine generally should be avoided in youth with known serious structural cardiac abnormalities, cardiomyopathy, heart rhythm abnormalities, or other serious cardiac problems.

The α-adrenergic agents **clonidine** and **guanfacine**, along with the longer-acting preparation of each, are presynaptic adrenergic agonists that appear to stimulate inhibitory presynaptic autoreceptors in the CNS. The extended-release formulation of guanfacine has moderate to strong evidence for the monotherapy of ADHD and weaker evidence as adjunctive therapy to stimulant medication. Combination stimulant/α-agonist therapy is superior to monotherapy with either and to placebo for improving inattention and working memory. Extended-release guanfacine also has moderate evidence for effective treatment of ADHD with comorbid oppositional defiant disorder (ODD), favorably affecting both symptom clusters, as well as for the treatment of agitation in autism.
Sedation, somnolence, headache, abdominal pain, hypotension, bradycardia, cardiac conduction abnormalities, dry mouth, depression, and confusion are potential side effects of clonidine and guanfacine. Abrupt withdrawal can result in rebound hypertension; overdose can result in death.

### Antidepressants

Antidepressant drugs act on pre- and postsynaptic receptors affecting the release and reuptake of brain neurotransmitters, including norepinephrine, serotonin, and dopamine (Table 33.4). There is strong evidence for the effectiveness of antidepressant medications in the treatment of anxiety and obsessive-compulsive disorders and weaker evidence for the treatment of depressive disorders. Suicidal thoughts have been reported during treatment with all antidepressants. The overall risk difference of suicidal ideation/attempts across all randomized controlled trials (RCTs) of antidepressants and indications has been reported as 0.7%, corresponding to a number needed to harm of 143. All antidepressants carry an FDA warning for suicidality; careful monitoring is recommended during the initial stages of treatment and following dose adjustments.

| Hydroxyzine (Atarax, Vistaril) | Anxiety | Anxiety | 50 mg | Age <6: 50 mg | Age >6: 50-100 mg | QT prolongation |

* Doses shown in table may exceed maximum recommended dose for some children.

OCD, Obsessive-compulsive disorder; BP, blood pressure; P, pulse; ECG, electrocardiogram; SS, serotonin syndrome; DS, discontinuation syndrome.

The **selective serotonin reuptake inhibitor (SSRI)** fluoxetine outperforms all other antidepressants (both SSRI and non-SSRI) studied and is the only SSRI separating from placebo in studies of depressed *preadolescents*. SSRIs have a large margin of safety. Side effects to SSRIs generally manifest in the first few weeks of treatment, and many will resolve with time. More common side effects include nausea, irritability, insomnia, appetite changes, weight loss/gain, headaches, dry mouth, dizziness, bruxism, diaphoresis, tremors, akathisia, restlessness, and behavioral activation. Approximately 5% of youth taking SSRIs, particularly children, develop **behavioral activation** (increased impulsivity, agitation, and irritability) that can be confused with mania, but the activation symptoms typically resolve when the dose is decreased or the medication discontinued. Sexual side effects are common, including decreased libido, anorgasmia, and erectile dysfunction. There is an increased risk of bleeding, especially when used with aspirin or nonsteroidal antiinflammatory drugs (NSAIDs).

SSRIs can be associated with abnormal heart rhythms, and citalopram causes dose-dependent QT-interval prolongation, contraindicating doses >40 mg/day. Patients with diabetes may experience hypoglycemia during SSRI treatment and hyperglycemia on discontinuation. **Discontinuation symptoms** (e.g., dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania) are common with short-acting SSRIs (sertraline, citalopram, escitalopram), leading to a recommendation for divided doses if these medications are used at higher doses and graduated reduction if discontinued.

The **serotonin syndrome** is characterized by the triad of mental status changes (e.g., agitation, hallucinations, delirium, coma), autonomic instability (e.g., tachycardia, labile BP, dizziness, diaphoresis, flushing, hyperthermia), and neuromuscular symptoms (e.g., tremor, rigidity, myoclonus, hyperreflexia,
incoordination). Serotonin syndrome results from excessive agonism of the CNS and peripheral nervous system serotonergic receptors and can be caused by a range of drugs, including SSRIs, valproate, and lithium. Interactions that can cause serotonin syndrome include SSRIs with linezolid (antibiotic with monoamine oxidase inhibitor properties) and with antimigraine preparations, as well as with amphetamine preparations, trazodone, buspirone, and venlafaxine. Serotonin syndrome is generally self-limited and can resolve spontaneously after the serotonergic agents are discontinued. Patients with severe disease require the control of agitation, autonomic instability, and hyperthermia as well as administration of 5-hydroxytryptamine (5-HT$_{2A}$, serotonin) antagonists (e.g., cyproheptadine).

The non-SSRI antidepressants include bupropion, duloxetine, venlafaxine, and mirtazapine (Table 33.4). These medications all lack rigorous evidence to support their effectiveness in children and adolescents, and as such should not be considered first-line options. Bupropion, a norepinephrine-dopamine reuptake inhibitor (NDRI), appears to have an indirect mixed-agonist effect on dopamine and norepinephrine transmission. No rigorous studies of bupropion for anxiety or depression have been conducted with children or adolescents, although some evidence suggests that bupropion may be effective for smoking cessation and ADHD in youth. Common side effects include irritability, nausea, anorexia, headache, and insomnia. Dose-related seizures (0.1% risk at 300 mg/day and 0.4% risk at 400 mg/day) have occurred with bupropion, so it is contraindicated in those with epilepsy, eating disorders, or at risk for seizures.

Duloxetine and venlafaxine are serotonin-norepinephrine reuptake inhibitors (SNRIs). Duloxetine has FDA approval for treatment of generalized anxiety disorder in children and adolescents, but studies of duloxetine for depression in youth have been negative. There is some evidence in adults that duloxetine can be useful for fibromyalgia and chronic musculoskeletal pain, an effect that has also been observed in children and adolescents. Common side effects of duloxetine include nausea, diarrhea, decreased weight, and dizziness. Increases in heart rate and BP have been noted, and BP should be monitored at each visit and with each dosage change. In addition, there have been reports of hepatic failure, sometimes fatal; duloxetine should be discontinued and not resumed in patients who develop jaundice or other evidence of liver dysfunction. Duloxetine also has been associated with severe skin reactions (erythema multiforme and Stevens-Johnson syndrome).

Venlafaxine has only negative trials for the treatment of depression in children
and adolescents, but does have favorable evidence for the treatment of anxiety. Side effects are similar to SSRIs, including hypertension, irritability, insomnia, headaches, anorexia, nervousness, and dizziness, and dropout rates are high in clinical trials of venlafaxine. BP should be monitored at each visit and with each dosage change. Discontinuation symptoms (e.g., dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, seizures) are more pronounced with venlafaxine than the other non-SSRI antidepressants. In addition, suicidal thinking and agitation may be more common with venlafaxine than with other antidepressants, requiring close monitoring. In light of the substantial adverse effects, venlafaxine likely should be considered to be a third-line medication.

*Mirtazapine* is both a noradrenergic and a specific serotonergic antidepressant. Mirtazapine has only negative trials for the treatment of depression in youth and has no rigorous evidence of effectiveness for any other child or adolescent psychiatric disorder. Mirtazapine is associated with a risk for substantial weight gain and more rarely, hypotension, elevated liver enzymes, agranulocytosis, and QT prolongation. While its sedating properties have led to its adjunctive use for insomnia in adults with depressive/anxiety disorders, there is no evidence for use of mirtazapine in childhood sleep disorders.

The **tricyclic antidepressants (TCAs)** have mixed mechanisms of action; for example, clomipramine is primarily serotonergic, and imipramine is both noradrenergic and serotonergic. With the advent of the SSRIs, the lack of efficacy studies, particularly in depression, and more serious side effects, the use of TCAs in children has declined. *Clomipramine* is used in the treatment of obsessive-compulsive disorder (*Table 33.4*). Unlike the SSRIs, the TCAs may be helpful in pain disorders. They have a narrow therapeutic index, with overdoses being potentially fatal. Anticholinergic symptoms (e.g., dry mouth, blurred vision, constipation) are the most common side effects. TCAs can have cardiac conduction effects in doses >3.5 mg/kg. BP and ECG monitoring is indicated at doses above this level.

**Anxiolytic agents**, including lorazepam, clonazepam, and hydroxyzine, have been effectively used for the short-term relief of the symptoms of acute anxiety (*Table 33.4*). They are less effective as chronic (>4 mo) anxiolytic medications, particularly when one is used as monotherapy. Chronic use carries a significant risk of physical and psychological dependence.
Antipsychotics

Based on their mechanism of action, antipsychotic medications can be divided into first-generation (blocking dopamine D₂ receptors) and second-generation (mixed dopaminergic and serotonergic antagonists) agents (Table 33.5).

</tbody>
</table>
The second-generation (or atypical) antipsychotics (SGAs) have relatively strong antagonistic interactions with 5-HT₂ receptors and perhaps more variable activity at central adrenergic, cholinergic, and histaminic sites, which might account for the varying side effects, particularly metabolic, noted among these agents. The SGAs have moderate evidence for the treatment of agitation in autism and for the treatment of schizophrenia, bipolar disorder, and aggression. Haloperidol is a high-potency antipsychotic that is the first-generation (or typical) antipsychotic most commonly used in treatment of agitation and schizophrenia.

The SGAs have significant side effects, including sedation, extrapyramidal
symptoms, weight gain, metabolic syndrome, diabetes, hyperlipidemia, hyperprolactinemia, hematologic effects (e.g., leukopenia, neutropenia), elevated liver transaminases, seizures, and CV effects (Table 33.6). They have an FDA warning for increased risk of diabetes. Youth appear to be more sensitive to sedation, extrapyramidal side effects (except akathisia), withdrawal dyskinesia, prolactin abnormalities, weight gain, hepatotoxicity, and metabolic abnormalities. The development of diabetes or tardive dyskinesia appears less prevalent than in adults, although this may be a function of short follow-up periods because these side effects may not emerge until adulthood.

The management of adverse effects should be proactive with baseline assessment and ongoing monitoring (Table 33.7). Abnormal movements (dystonia, akathisia, tardive dyskinesia) need periodic assessment using a standardized instrument such as the Abnormal Involuntary Movement Scale (AIMS). Valbenazine is FDA approved for the treatment of tardive dyskinesia in adults. The need for antiparkinsonian agents may be a consideration, particularly
for patients at risk for acute dystonia or who have a previous history of dystonic reactions. CV effects of SGAs include prolongation of the QTc interval, tachycardia, orthostatic hypertension, and pericarditis. In patients with a personal or family history of cardiac abnormalities, including syncope, palpitations, arrhythmias, or sudden unexplained death, a baseline ECG with subsequent monitoring should be considered, along with cardiology consultation before prescribing. Alternative pharmacology should be considered if the resting heart rate exceeds 130 beats/min, or the PR, QRS, and QTc exceed 200, 120, and 460 milliseconds (msec), respectively.

* Personal and family history of obesity, hypertension, and cardiovascular disease.

BMI, Body mass index; Hb, hemoglobin.

The cytochrome P450 (CYP) enzymes metabolize the antipsychotics and as such necessitate that the PCP and psychiatrist are alert for potential drug-drug interactions that may impact the serum levels of all patient medications. CYP3A4 is mainly relevant to lurasidone, quetiapine, olanzapine, and haloperidol, whereas CYP2D6 predominately clears aripiprazole and risperidone. Asenapine is metabolized by CYP1A2 as well as direct glucuronidation by UGT1A4. Because <10% of paliperidone undergoes CYP first-pass metabolism, there is a lower likelihood of drug-drug interactions.

Primary prevention strategies to manage weight and metabolic dysfunction include educating the youth and family about healthy lifestyle behaviors and
selecting an agent that has the lowest likelihood of impacting metabolic status. Secondary strategies would include intensifying healthy lifestyle instructions, consideration of switching agents, and a weight loss treatment program. Consideration of weight management interventions and increased monitoring of blood glucose and lipid levels should be implemented if weight gain exceeds the 90th percentile of body mass index (BMI) for age, or a change of 5 BMI units in youth who were obese at the initiation of treatment. Tertiary strategies, where diabetes, hypertension, obesity, or another metabolic abnormality has occurred, require more intensive weight reduction interventions, changing medication, and consultation with a medical subspecialist. Metformin has been used to treat severe weight gain associated with antipsychotic medication. Extrapyramidal adverse effects are generally dose and titration rate dependent and may respond to dose or titration rate reductions. More disabling effects may benefit from adjunctive treatment (e.g., anticholinergics, antihistamines).

**Neuroleptic malignant syndrome** is a rare, potentially fatal reaction that can occur during antipsychotic therapy. The syndrome generally manifests with fever, muscle rigidity, autonomic instability, and delirium. It is associated with elevated serum creatine phosphokinase levels, a metabolic acidosis, and high end-tidal CO$_2$ excretion. It has been estimated to occur in 0.2–1% of patients treated with dopamine-blocking agents. Malnutrition and dehydration in the context of an organic brain syndrome and simultaneous treatment with lithium and antipsychotic agents (particularly haloperidol) can increase the risk. Mortality rates may be as high as 20–30% as a result of dehydration, aspiration, kidney failure, and respiratory collapse. Differential diagnosis of neuroleptic malignant syndrome includes infections, heat stroke, malignant hyperthermia, lethal catatonia, agitated delirium, thyrotoxicosis, serotonin syndrome, drug withdrawal, and anticholinergic or amphetamine, ecstasy, and salicylate toxicity.

**Mood Stabilizers**

Because of their limited evidence of effectiveness and concerns about safety, mood-stabilizing medications (see Table 33.5) have limited use in the treatment of child and adolescent psychiatric disorders. For the treatment of bipolar mania in adolescents, atypical antipsychotics are considered first-line therapy. Of the mood stabilizers, lithium alone has rigorous support for the treatment of bipolar mania. Lithium's mechanism of action is not well understood;
proposed theories relate to neurotransmission, endocrine effects, circadian rhythm, and cellular processes. Common side effects include polyuria and polydipsia, hypothyroidism, hyperparathyroidism, weight gain, nausea, abdominal pain, diarrhea, acne, and CNS symptoms (sedation, tremor, somnolence, memory impairment). Periodic monitoring of lithium levels along with thyroid and renal function is needed. Lithium serum levels of 0.8-1.2 mEq/L are targeted for acute episodes and 0.6-0.9 mEq/L are targeted for maintenance therapy. Acute overdose (level > 1.5 mEq/L) manifests with neurologic symptoms (e.g., tremor, ataxia, nystagmus, hyperreflexia, myoclonus, slurred speech, delirium, coma, seizures), and altered renal function. Toxicity is enhanced when dehydrated or with drugs that affect renal function, such as NSAIDs or angiotensin-converting enzyme (ACE) inhibitors. Neuroleptic malignant syndrome has been reported in patients concurrently taking antipsychotic drugs and lithium.

**Medication Use in Physical Illness**

There are special considerations in the use of psychotropic medications with physically ill children. Between 80% and 95% of most psychotropic medications are protein bound, the exceptions being lithium (0%), methylphenidate (10–30%), and venlafaxine (25–30%). As a result, psychotropic levels may be directly affected because albumin binding is reduced in many physical illnesses. Metabolism is primarily through the liver and gastrointestinal (GI) tract, with excretion via the kidney. Therefore, dosages may need to be adjusted in children with hepatic or renal impairment.

**Hepatic Disease**

Lower doses of medications may be required in patients with hepatic disease. Initial dosing of medications should be reduced, and titration should proceed slowly. In steady-state situations, changes in protein binding can result in elevated unbound medication, resulting in increased drug action even in the presence of normal serum drug concentrations. Because it is often difficult to predict changes in protein binding, it is important to maintain attention to the clinical effects of psychotropic medications and not rely exclusively on serum drug concentrations.

In acute hepatitis, there is generally no need to modify dosing because
metabolism is only minimally altered. In chronic hepatitis and cirrhosis, hepatocytes are destroyed, and doses may need to be modified.

Medications with high baseline rates of liver clearance (e.g., haloperidol, sertraline, venlafaxine, TCAs) are significantly affected by hepatic disease. For drugs that have significant hepatic metabolism, intravenous administration may be preferred because parenteral administration avoids first-pass liver metabolic effects, and the dosing and action of parenteral medications are similar to those in patients with normal hepatic function. Valproic acid can impair the metabolism of the hepatocyte disproportionate to the degree of hepatocellular damage. In patients with valproate-induced liver injury, low albumin, high prothrombin, and high ammonia levels may be seen without significant elevation in liver transaminases.

**Gastrointestinal Disease**

Medications with anticholinergic side effects can slow GI motility, affecting absorption and causing constipation. SSRIs increase gastric motility and can cause diarrhea. SSRIs can increase the risk of GI bleeding, especially when administered with NSAIDs. Extended-release or controlled-release preparations of medications can reduce GI side effects, particularly where gastric distress is related to rapid increases in plasma drug concentrations.

**Renal Disease**

With the exceptions of lithium and gabapentin, psychotropic medications do not generally require significant dosing adjustments in kidney failure. It is important to monitor serum concentrations in renal insufficiency, particularly for medications with a narrow therapeutic index; cyclosporine can elevate serum lithium levels by decreasing lithium excretion. Patients with kidney failure and those on dialysis appear to be more sensitive to TCA side effects, possibly because of the accumulation of hydroxylated tricyclic metabolites.

Because most psychotropic medications are highly protein bound, they are not significantly cleared by dialysis. Lithium is essentially completely removed by dialysis, and the common practice is to administer lithium after dialysis. Patients on dialysis often have significant fluid shifts and are at risk for dehydration, with neuroleptic malignant syndrome more likely in these situations.
Cardiac Disease

Antipsychotics, TCAs, and citalopram (>40 mg/day) can lead to prolongation of the QTc interval, with increased risk of ventricular tachycardia and ventricular fibrillation, particularly in patients with structural heart disease. Patients with a baseline QTc interval of >440 msec should be particularly considered at risk. The normal QTc value in children is 400 msec (±25-30 msec). A QTc value that exceeds 2 SD (>450-460 msec) is considered too long and may be associated with increased mortality. An increase in the QTc from baseline of >60 msec is also associated with increased mortality.

There is increased risk of morbidity and mortality in patients with preexisting cardiac conduction problems. Some of the calcium channel–blocking agents (e.g., verapamil) can slow atrioventricular conduction and can theoretically interact with TCAs. Patients with Wolff-Parkinson-White syndrome who have a short PR interval (<0.12 sec) and widened QRS interval associated with paroxysmal tachycardia are at high risk for life-threatening ventricular tachycardia that may be exacerbated by the use of antipsychotics, TCAs, and citalopram.

Respiratory Disease

Anxiolytic agents can increase the risk of respiratory suppression in patients with pulmonary disease. In these situations, SSRIs and buspirone are good alternative medications to consider in treating disabling anxiety. Possible airway compromise caused by acute laryngospasm should be considered when dopamine-blocking antipsychotic agents are used.

Neurologic Disease

Psychotropic medications can be used safely with epilepsy following consideration of potential interactions among the medication, the seizure disorder, and the anticonvulsant. Any behavioral toxicity of anticonvulsants used either alone or in combination should be considered before proceeding with psychotropic treatment. Simplification of combination anticonvulsant therapy or a change to another agent can result in a reduction of behavioral or emotional symptoms and obviate the need for psychotropic intervention. Clomipramine and bupropion possess significant seizure-inducing properties and should be avoided when the risk of seizures is present.
Principles for Psychotropic Prescribing in Primary Care

Because nonpsychiatrist physicians (predominantly pediatricians) provide three quarters and two thirds, respectively, of all child and adolescent mental health visits in which new psychotropic medications are initiated, it can be helpful for PCPs to develop consultative relationships with child and adolescent psychiatrists who can advise about safe and effective psychotropic prescribing. If such consultation is not readily available, PCPs may benefit from following a standardized approach to prescribing that is feasible in the primary care setting (Table 33.8). This approach emphasizes baseline assessment with standardized rating scales to identify target symptoms and their level of severity; selection of FDA-approved medications for the target symptom and patient age range; adherence to recommendations regarding therapeutic dosage ranges; follow-up rating scale assessment to monitor medication response; sufficient duration of the medication trial; and switching to an alternative FDA-approved medication if the first medication trial is ineffective. Generally, consultation with a physician experienced in managing the child's disorder should occur if one is considering using multiple psychotropic medications, doses outside of therapeutic range, or non-FDA-approved medications.

Table 33.8

Principles for Psychotropic Prescribing in Primary Care

1. Identify potential target symptoms through the systematic use (e.g., at all well-child visits) of broad-band mental health screening instruments, such as the Pediatric Symptom Checklist or the Strengths and Difficulties Questionnaire.

2. Establish the baseline severity of identified target symptom(s) through the use of narrow-band symptom rating scales, such as the following (selected from instruments in the public domain):
   a. Depression
      • Mood and Feelings Questionnaire
      • Centers for Epidemiologic Studies Depression Scale
      • Patient Health Questionnaire-9
b. Anxiety
   • Screen for Child Anxiety Related Disorders
c. ADHD, Behavior Problems
   • Vanderbilt ADHD Diagnostic Rating Scale
   • SNAP-IV 19
d. Aggression
   • Outburst Monitoring Scale

3. Select a medication that is FDA approved for the target symptom and age range; titrate as tolerated from starting dose to therapeutic dosage range.

4. Treat to target: Readminister baseline symptom rating scale at regular intervals (at least monthly) to assess treatment response (reduction in rating scale score), with the goal of remission (rating scale score below clinical cutpoint).

5. If medication trial is unsuccessful after adherence to therapeutic dose for adequate duration (typically 1-2 mo), consider 2nd trial of alternative medication with FDA approval for target symptom and age range, following same principles as for 1st trial.

6. If 2nd medication trial is unsuccessful, consultation with a child and adolescent psychiatrist is recommended before resorting to medication doses outside therapeutic range, polypharmacy, or non-FDA-approved medications.

ADHD, Attention-deficit/hyperactivity disorder; FDA, U.S. Food and Drug Administration.

Psychotherapy and Psychiatric Hospitalization

Heather J. Walter, David R. DeMaso

Psychotherapy

Psychotherapy is the first-line treatment for most child and adolescent psychiatric disorders, because this type of treatment generally produces outcomes similar to pharmacotherapy, with less risk of harm. Even with disorders such as schizophrenia, bipolar disorder, and attention-deficit/hyperactivity disorder (ADHD) for which medication is the first-line treatment, adjunctive psychotherapy can convey considerable additional benefit. Because pediatric primary care practitioners (PCPs) likely will be referring youth with psychiatric disorders for psychotherapy, they should be familiar with basic information about child and adolescent psychotherapy.

Overall, psychotherapy is moderately effective in reducing psychiatric symptomatology and achieving remission of illness. In a 2017 multilevel meta-analysis of almost 500 randomized trials over 5 decades, there was a 63% probability that a youth receiving psychotherapy fared better than a youth in a control condition. Effects varied across multiple moderators, including the problem targeted in treatment. Thus, the mean posttreatment and follow-up effect sizes were highest for anxiety, followed by behavior/conduct, ADHD, and depression, and lowest for multiple concurrent comorbidities. Effect sizes varied according to outcome measure informant, with youth and parents generally reporting larger effects than teachers. Ethnicity moderator tests showed no significant differences in treatment benefit between majority Caucasian samples and majority non-Caucasian samples.

A variety of psychotherapeutic programs have been developed, with varying levels of effectiveness (Table 34.1). Differences between therapeutic approaches
may be less pronounced in practice than in theory. The quality of the therapist–patient alliance is consistently an important predictor of treatment outcome. A positive working relationship, expecting change to occur, facing problems assertively, increasing mastery, and attributing change to the participation in the therapy have all been connected to effective therapy.

* Two or more consistent randomized controlled trials demonstrating superiority of treatment over control groups; conducted by independent investigators working at different research settings.

† Same as above, but lacking independent investigator criterion.

ADHD, Attention-deficit/hyperactivity disorder CBT, cognitive-behavioral therapy; ABA, applied behavioral analysis; DSP, developmental social-pragmatic; ODD, oppositional defiant disorder; CD, conduct disorder; OCD, obsessive-compulsive disorder; PTSD, posttraumatic stress disorder.

All psychotherapy interventions involve a series of interconnected steps, including performing an assessment, constructing working diagnoses and an explanatory formulation, deciding on treatment and a monitoring plan, obtaining treatment assent/consent, and implementing treatment. Psychotherapists ideally develop a treatment plan by combining known evidence-based therapies with clinical judgment and patient/family preference to arrive at a specific intervention plan for the individual patient.

**Behavior Therapy**

Behavior therapy is based on both classic (Pavlovian) and operant (Skinnerian) conditioning. Both approaches do not concern themselves with the inner motives of the individual, but instead address the antecedent stimuli and consequent responses. The treatment begins with a behavioral assessment with interview, observation, diary, and rating scale components, along with a functional analysis of the setting context, immediately preceding external events, and real-world consequences of the behavior. A treatment plan is developed to modify the maladaptive functions of the behavior, using tools such as positive and negative reinforcement, social and tangible rewards, shaping, modeling, and prompting to increase positive behavior, and extinction, stimulus control, punishment, response cost, overcorrection, differential reinforcement of incompatible behavior, graded exposure/systematic desensitization, flooding, modeling, and role-playing to decrease negative behavior.

Behavior therapy has shown applicability to anxiety disorders, obsessive-compulsive and related disorders, behavior disorders, ADHD, and autism spectrum disorder.
Cognitive-Behavioral Therapy

Cognitive-behavioral therapy (CBT) is based on social and cognitive learning theories and extends behavior therapy to address the influence of cognitive processes on behavior. CBT is a problem-oriented treatment centered on correcting problematic patterns in thinking and behavior that lead to emotional difficulties and functional impairments. The CBT therapist seeks to identify and change cognitive distortions (e.g., learned helplessness, irrational fears), identify and avoid distressing situations, and identify and practice distress-reducing behavior. Self-monitoring (daily thought records), self-instruction (brief sentences asserting thoughts that are comforting and adaptive), and self-reinforcement (rewarding oneself) are key tools used to facilitate achievement of the CBT goals. Table 34.2 outlines the key descriptive features of CBT that can be used by PCPs when describing CBT to patients and their family members.

**Table 34.2**

Core Components and Characteristics of Cognitive-Behavioral Therapy

- One 60- to 90-minute session each week, typically for 6-12 weeks
- Symptom measures typically are collected frequently.
- Treatment is goal-oriented and collaborative with patient as an active participant.
- Treatment is focused on changing current problematic thoughts or behaviors.
- Weekly homework typically is assigned.

CBT has good-quality evidence for the treatment of depression, anxiety, obsessive-compulsive disorders (OCDs), behavior disorders, substance abuse, and insomnia (see Table 34.1). For many childhood psychiatric disorders, CBT alone provides outcomes comparable to psychotropic medication alone, and the combination of both may convey additional benefit in symptom and harm
Modified versions of CBT have shown applicability to the treatment of other disorders. **Trauma-focused cognitive-behavioral therapy (TF-CBT)** involves a combination of psychoeducation; teaching effective relaxation, affective modulation, and cognitive coping and processing skills; engaging in a trauma narrative; mastering trauma reminders; and enhancing future safety and development. TF-CBT is considered the first-line treatment for posttraumatic stress disorder (PTSD).

**Dialectical behavioral therapy (DBT)** is a CBT approach targeted at emotional and behavioral dysregulation by synthesizing or integrating the seemingly opposite strategies of acceptance and change. Dialectic conflicts (wanting to die vs wanting to live) often exist in the same patient and are important to address. The 4 skills modules—**mindfulness** (the practice of being fully aware and present in the moment), **distress tolerance** (how to tolerate emotional pain), **interpersonal effectiveness** (how to maintain self-respect and effective communication in relationships with others), and **emotion regulation** (how to manage complex emotions)—are balanced in terms of acceptance and change. Patients who receive DBT typically have multiple problems; the treatment targets, in order of priority within a given session, are **life-threatening** behaviors, such as suicidal and self-injurious behaviors or communications; **therapy-interfering** behaviors, such as coming late to sessions, cancelling appointments, and being noncollaborative in working toward treatment goals; **quality-of-life** behaviors, including relationship and occupational problems and financial crises; and skills acquisition to help patients achieve their goals. DBT has shown promise for the treatment of personality disorders, suicidal behavior, bipolar disorder, and other manifestations of emotional-behavioral dysregulation.

**Interpersonal Psychotherapy**

Interpersonal psychotherapy (IPT) focuses on interpersonal issues that lead to psychological distress. Patients are viewed to having biopsychosocial strengths and vulnerabilities that determine the manner in which they cope or respond to an interpersonal crisis (**stressor**). Symptom resolution, improved interpersonal functioning, and increased social support are the IPT targets. IPT has proved to be a well-established treatment for adolescent depression.

**Psychodynamic Psychotherapy**
At the core of psychodynamic psychotherapy lies a *dynamic* interaction between different dimensions of the mind. This approach is based on the belief that much of one's mental activity occurs outside one's awareness. The patient is often unaware of internal conflicts because threatening or painful emotions, impulses, and memories are repressed. Behavior is then controlled by what the patient does not know about himself or herself. Therapy objectives are to increase self-understanding, increase acceptance of feelings, and develop realistic relationships between self and others. This therapy is nondirective to allow a patient's characteristic patterns to emerge, so that self-understanding and a corrective emotional experience can then be fostered.

Psychodynamic psychotherapy has shown applicability for the treatment of anxiety and depression as well as maladaptive aspects of personality. Brief, time-limited psychodynamic psychotherapy can be appropriate for youth who are in acute situational distress. Long-term therapy can be appropriate when the biologic or social factors destabilizing the child's adaptation and development are chronic, or the psychological difficulties caused by comorbidities are complex, or if entrenched conflicts and developmental interferences are present.

**Supportive Psychotherapy**

Supportive psychotherapy aims to minimize levels of emotional distress through the provision of individual and contextual support. The goal is to reduce symptoms, and treatment is focused on the “here and now.” The therapist is active and helpful in providing the patient with symptomatic relief by helping the patient to contain and manage anxiety, sadness, and anger. The therapist provides support and encouragement to bolster a patient's existing coping mechanisms, facilitates problem-solving, and provides social and instrumental support for ameliorating or lessening contextual precipitants. CBT-informed techniques are often combined with supportive psychotherapy. Probably the most common psychotherapy employed by therapists, supportive psychotherapy has shown comparable results to CBT in a number of research studies.

**Family Therapy**

The core premise in family therapy is that dysfunctional family interaction patterns precipitate and/or perpetuate an individual's emotional or behavioral difficulties. Family dysfunction can take a variety of forms, including
enmeshment, disengagement, role-reversal or confusion, and maladaptive communication patterns. Family therapy begins with an assessment of the family system, including observing patterns of interaction, assessing family beliefs and the meanings attached to behaviors, defining social and cultural contexts, exploring the presenting problem in the context of individual and family development, assessing the family's style of dealing with problems, and identifying family strengths and weaknesses.

Family therapy techniques are drawn from 2 major theoretical models: structural and behavioral. *Structural* family therapy develops structures believed to foster well-functioning families, including clear and flexible boundaries between individuals, well-defined roles, and an appropriate balance between closeness and independence. *Behavioral* family therapy focuses on behavioral sequences that occur in daily life and attempts to interrupt unhelpful patterns and strengthen positive patterns through effective communication and problem solving.

Family therapy has shown established applicability in anorexia nervosa and substance use and may be a promising treatment for depression.

**Parenting Interventions**
(See Chapter 19 for more details)

Parenting interventions seek to improve both the parent–child relationship and parenting skills using the principles of behavior therapy previously described. They can be provided in individual or group therapy formats. Core relationship recommendations include spending quality time with the child, increasing verbal interaction, showing physical affection, providing contingent praise, and engaging in child-directed play. Core parenting skills include increasing reinforcement of positive behaviors, decreasing reinforcement of negative behaviors, ignoring merely annoying behaviors, applying consequences for dangerous/destructive behaviors, and making parental responses predictable, contingent, and immediate. Parenting interventions have shown applicability for behavior disorders and ADHD.

**Common Elements of Evidence-Based Psychotherapies**

A major challenge for the practitioner is selecting the “right intervention” for the
“right person” in the “right setting,” and delivering the intervention in the “right way” (to meet the needs of patients and families). This challenge has led to interest in identifying common **practice elements** across efficacious evidence-based therapies that could be “matched” in a flexible way to patients of a certain age, gender, and race/ethnicity who have certain psychiatric disorders. Table 34.3 provides the major practice elements for 3 of the most common child and adolescent psychiatric disorders: anxiety, depression, and disruptive behaviors. These practice elements, when made available to patients with psychiatric disorders in a system of care, are estimated to be relevant to approximately two thirds of the patients. Six of the practice elements—problem-solving skills, psychoeducation of the parent, relaxation skills, self-monitoring, cognitive/coping skills, and psychoeducation of the child—are applicable to all 3 disorders and as such could be considered “core skills” for the child and adolescent psychotherapist.

</tbody>
</table>
Psychoeducation is the education of the parent and child about the cause, course, prognosis, and treatment of the disorder. Problem solving is techniques, discussions, or activities designed to bring about solutions to targeted problems, with the intention of imparting a skill for how to approach and solve future problems in a similar manner. Relaxation is techniques designed to create and maintain the physiologic relaxation response. Self-monitoring is the repeated measurement of a target metric by the child. Cognitive/coping skills consist of techniques designed to alter interpretations of events through examination of the child's reported thoughts, accompanied by exercises designed to test the validity of the reported thoughts. PCPs can incorporate some of these elements into their anticipatory guidance work with pediatric patients.

Modular Therapy Packages

Of considerable importance to day-to-day clinical work is the manner in which common therapy practice elements are selected, sequenced, repeated, or selectively applied. This coordination of psychotherapeutic elements is particularly relevant for patients presenting with multiple concurrent psychiatric disorders. The Modular Approach to Therapy for Children (MATCH) is a multidisorder intervention system that incorporates treatment procedures (practice elements) and treatment logic (coordination) corresponding to efficacious interventions for childhood anxiety, depression, and behavior problems, with modifications to allow the system to operate as a single protocol. Compared with standard manualized treatments for individual disorders and with usual care, the modular package outperformed both comparators on multiple clinical and service outcome measures when assessed over a 2-yr period, although additional, independently derived evidence is needed to categorize this treatment approach as well established.

Common Elements of Treatment Engagement Interventions

Treatment engagement is conceptualized as a multidimensional construct
targeting cognitive, attendance, and adherence domains. Research has identified several key factors addressing these domains that are associated with treatment engagement: accessibility promotion, psychoeducation about services, appointment reminders, assessment of treatment barriers, patient assessment, expectation setting, modeling, and homework assignments (Table 34.4). To promote treatment engagement, the first 7 of these factors can be addressed by the PCP and the medical home team as soon as a mental health problem is identified that would benefit from treatment (see Chapter 17 for further discussion).

Table 34.4
Select Psychotherapy Engagement Elements

<table>
<thead>
<tr>
<th>ELEMENT</th>
<th>DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessibility promotion</td>
<td>Any strategy used to make services convenient and accessible in order to proactively encourage and increase participation in treatment; e.g., hiring a co-located therapist or referring to a local community-based therapist with whom the practice has an ongoing collaborative relationship</td>
</tr>
<tr>
<td>Psychoeducation about services</td>
<td>Provision of information about services or the service delivery system; e.g., type of therapy being recommended, information about the therapist, session frequency and duration</td>
</tr>
<tr>
<td>Appointment reminders</td>
<td>Providing information about the day, time, and location of the therapy office for the initial appointment via mail, text, phone, email, etc., to increase session attendance</td>
</tr>
<tr>
<td>Assessment of treatment barriers</td>
<td>Discussion to elicit and identify barriers that hinder participation in treatment; e.g., transportation, scheduling, childcare, previous experiences with therapy, stigma</td>
</tr>
<tr>
<td>Assessment</td>
<td>Measurement of the patient's strengths/needs through a variety of methods; e.g., mental health screening instruments, interviews, recorded reviews during which the referring practitioner can motivate treatment engagement</td>
</tr>
<tr>
<td>Modeling</td>
<td>Vehicle to convey information about specific roles of the therapist; e.g., introductory video or brochure</td>
</tr>
<tr>
<td>Expectation setting</td>
<td>Instillation of hope regarding the efficacy of therapy and the patient's ability to participate successfully in treatment</td>
</tr>
<tr>
<td>Homework assignment</td>
<td>Therapeutic tasks given to the patient to complete outside the therapy session to reinforce or facilitate knowledge or skills that are consistent with the treatment plan</td>
</tr>

</table>

Psychotherapy in the Medical Home

Recognizing that up to one half of visits to PCPs involve a mental health problem, and that an estimated one fifth of pediatric patients have a functionally impairing psychiatric disorder, in the context of limited access to specialty
mental health services in community or hospital settings, a number of models have been developed to deliver psychotherapy in primary care. Two prominent models, both originally developed for adult populations, are collaborative care and primary care behavioral health.

**Collaborative care** integrates physical and mental healthcare for patients who have a psychiatric disorder in a treatment model that provides both psychotropic medication and psychotherapy delivered by an interdisciplinary care team of PCPs, social workers, and care managers supported by a consulting psychiatrist. The role of the consulting psychiatrist is to advise the PCPs about psychotropic medication management and the therapists about brief psychotherapeutic interventions. The 4 critical elements of collaborative care are team-driven, population-focused, measurement-guided, and evidence-based. These elements guide a treatment approach in which evidence-based, measurement-guided (e.g., symptom rating scale scores as treatment targets) mental healthcare is delivered by the multidisciplinary team to the entire patient population as indicated, such that the patient perceives a seamless integration of medical and mental healthcare.

In children and adolescents, randomized controlled trials (RCT) have shown that collaborative care for behavior problems, adolescent depression, and adolescent substance use is associated with more favorable treatment adherence, symptom reduction, disorder remission, and consumer satisfaction outcomes than usual care, with or without specialty referral. In a meta-analysis and systematic review, overall integrated medical-mental healthcare for children and adolescents led to improved mental health outcomes compared with usual care. Larger effects were observed for treatment trials targeting diagnoses and elevated symptoms relative to prevention trials, as well as for collaborative care models relative to other integrated mental healthcare.

**Primary care behavioral health** employs an on-site mental health professional (psychologist, social worker, mental health counselor) to provide focused assessment of patients with mental health, health behavior, and substance use problems and short-term therapy as well as health/mental health promotion and prevention interventions. Mental health clinicians typically collaborate with primary care physicians to develop treatment plans, monitor patient progress, and flexibly provide care to meet patients' changing needs. The model uses a “wide net” approach aimed at serving the entire primary care population, with emphasis on brief, focused interventions. Key features of the model include “warm handoffs,” in which the physician introduces the mental
health clinician directly to the patient, and “curbside consultations,” in which the physician and mental health clinician have frequent informal interactions to discuss patients.

A limited evidence base supports the primary care behavioral health model, but the research literature on brief intervention is increasing and encouraging. Brief interventions lasting only 1 session are effective for multiple child psychiatric disorders, particularly anxiety and behavior problems and among children (vs adolescents), and are most effective for CBT approaches. Psychosocial interventions delivered by PCPs (rather than behavioral health clinicians) have not been found to be effective in a Cochrane review.

**Psychiatric Hospitalization**

Youth with severe psychiatric disorders require initial evaluation, treatment planning, and stabilization by child-trained behavioral health clinicians. Psychiatric hospital programs address the serious risks and severe impairments caused by the most acute and complex forms of psychiatric disorder that cannot be managed effectively at any other level of care. The goal is to produce rapid clinical stabilization that allows an expeditious, safe, and appropriate treatment transition to a less intensive level of mental healthcare outside the hospital.

High levels of illness severity combined with significant functional impairment signal a need for hospitalization. Admission criteria must include significant signs and symptoms of active psychiatric disorder. Functional admission indicators generally include a significant risk of self-harm or harm to others, although in some cases the patient is unable to meet basic self-care or healthcare needs, jeopardizing well-being. Serious emotional disturbances that prevent participation in family, school, or community life can also rise to a level of global impairment that can only be addressed on an inpatient basis.

*Discharge planning* begins at admission, when efforts are made to coordinate care with services and resources that are already in place for the child or adolescent in the community. Step-down care might be needed in partial hospital or residential settings if integrated services in a single location are still indicated after sufficient clinical stabilization has occurred in the hospital setting. Transition from the hospital entails active collaboration and communication with PCPs in the child's medical home. In some cases the PCP resumes the pharmacologic treatment of these youth once stabilized.

Chorpita BF, Weisz JR. *MATCH-ADTC: Modular approach to therapy for children with anxiety, depression, trauma, or conduct problems*. PracticeWise: Satellite Beach, FL; 2009.

Pediatric psychosomatic medicine deals with the relation between physical and psychological factors in the causation or maintenance of disease states. The process whereby distress is experienced and expressed in physical symptoms is referred to as somatization or psychosomatic illness. Even though present in virtually every psychiatric disorder, physical symptoms are most prominent in the various somatic symptom and related disorders.

In the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), illnesses previously referred to as “somatoform disorders” are classified as somatic symptom and related disorders (SSRDs). In children and adolescents, the SSRDs include somatic symptom disorder (Table 35.1), conversion disorder (Table 35.2), factitious disorders (Table 35.3), illness anxiety disorder (Table 35.4), and other specified/unspecified somatic symptom disorders (Table 35.5), as well as psychological factors affecting other medical conditions (Table 35.6).

**Table 35.1**

**DSM-5 Diagnostic Criteria for Somatic Symptom Disorder**

A. One or more somatic symptoms that are distressing or result in significant disruption of daily life.

B. Excessive thoughts, feelings, or behaviors related to the somatic symptoms or associated health concerns, as manifested by at least one of the following:
1. Disproportionate and persistent thoughts about the seriousness of one's symptoms.
2. Persistent high level of anxiety about health and symptoms.
3. Excessive time and energy devoted to these symptoms or health concerns.

C. Although any one somatic symptom may not be continuously present, the state of being symptomatic is persistent (typically >6 mo).

Specify if:

**With predominant pain** (previously known as “pain disorder” in DSM IV-TR): for individuals whose somatic symptoms predominantly involve pain.

**Persistent:** A persistent course is characterized by severe symptoms, marked impairment, and long duration (>6 mo).

---

Adapted from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 311.

**Table 35.2**

**DSM-5 Diagnostic Criteria for Conversion Disorder or Functional Neurologic Symptom Disorder**

| A. One or more symptoms of altered voluntary motor or sensory function. |
| B. Clinical findings provide evidence of incompatibility between the symptom and recognized neurologic or medical conditions. |
| C. The symptom is not better explained by another medical or mental disorder. |
| D. The symptom causes clinically significant distress or impairment in social, occupational, or other important areas of functioning or warrants medical evaluation. |

Specify symptom type: weakness or paralysis, abnormal movements, swallowing symptoms, speech symptom, attacks/seizures, anesthesia/sensory loss, special sensory symptom (e.g., visual, olfactory, hearing), or mixed symptoms.
### Table 35.3

**DSM-5 Diagnostic Criteria for Factitious Disorders**

#### Factitious Disorder Imposed on Self

- **A.** Falsification of physical or psychological signs or symptoms, or induction of injury or disease, associated with identified deception.
- **B.** The individual presents himself or herself to others as ill, impaired, or injured.
- **C.** The deceptive behavior is evident even in the absence of obvious external rewards.
- **D.** The behavior is not better explained by another mental disorder, such as delusional disorder or another psychotic disorder.

Specify if: single episode or recurrent episodes.

#### Factitious Disorder Imposed on Another (Previously “Factitious Disorder by Proxy”)

- **A.** Falsification of physical or psychological signs or symptoms, or induction of injury or disease, in another, associated with identified deception.
- **B.** The individual presents another individual (victim) to others as ill, impaired, or injured.
- **C.** The deceptive behavior is evident even in the absence of obvious external rewards.
- **D.** The behavior is not better explained by another mental disorder, such as delusional disorder or another psychotic disorder.

*Note:* The perpetrator, not the victim, receives this diagnosis.

Specify if: single episode or recurrent episodes.
Table 35.4

DSM-5 Diagnostic Criteria for Illness Anxiety Disorder

A. Preoccupation with having or acquiring a serious illness.
B. Somatic symptoms are not present, or, if present, are only mild in intensity. If another medical condition is present or there is a high risk for developing a medical condition (e.g., strong family history is present), the preoccupation is clearly excessive or disproportionate.
C. There is a high level of anxiety about health, and the individual is easily alarmed about personal health status.
D. The individual performs excessive health-related behaviors (e.g., repeatedly checks his or her body for signs of illness) or exhibits maladaptive avoidance (e.g., avoids doctor appointments and hospitals).
E. Illness preoccupation has been present for at least 6 mo, but the specific illness that is feared may change over that time.
F. The illness-related preoccupation is not better explained by another mental disorder.

Specify whether: care-seeking type or care-avoidant type.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p 315.

Table 35.5

DSM-5 Diagnostic Criteria for Other Specified/Unspecified Somatic Symptom and Related Disorders

Other Specified

This category applies to presentations in which symptoms characteristic of a somatic symptom and related disorder that cause clinically significant distress or impairment in social, occupational, or other important areas of functioning predominate but do not meet full criteria for any of the
disorders in the somatic symptom and related disorders diagnostic class. Examples of presentations that can be specified using the “other specified” designation include the following:

1. Brief somatic symptom disorder: duration of symptoms is <6 mo.
2. Brief illness anxiety disorder: duration of symptoms is <6 mo.
3. Illness anxiety disorder without excessive health-related behaviors: Criterion D for illness anxiety disorder is not met (see Table 35.4).
4. Pseudocyesis: a false belief of being pregnant that is associated with objective signs and reported symptoms of pregnancy.

Unspecified

This category applies to presentations in which symptoms characteristic of a somatic symptom and related disorder that cause clinically significant distress or impairment in functioning predominate but do not meet criteria for any of the other disorders in the somatic symptom and related disorders diagnostic class.

Adapted from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (Copyright 2013). American Psychiatric Association, p 327.

Table 35.6

DSM-5 Diagnostic Criteria for Psychological Factors Affecting Other Medical Conditions

A. A medical symptom or condition (other than a mental disorder) is present.
B. Psychological or behavioral factors adversely affect the medical condition in one of the following ways:
   1. The factors have influenced the course of the medical condition, as shown by a close temporal association between the psychological factors and the development or exacerbation of, or delayed recovery from, the medical condition.
   2. The factors interfere with the treatment of the medical condition (e.g., poor adherence).
3. The factors constitute additional well-established health risks for the individual.
4. The factors influence the underlying pathophysiology, precipitating or exacerbating symptoms or necessitating medical attention.

C. The psychological and behavioral factors in Criterion B are not better explained by another mental disorder (e.g., panic disorder, major depressive disorder, posttraumatic stress disorder).

Specify if: mild, moderate, severe, or extreme.

Adapted from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 322.

With the exception of illness anxiety disorder, in which there is a high level of anxiety about health in the absence of significant somatic symptoms, and psychological factors affecting other medical conditions, in which psychological and/or behavioral factors adversely affect a medical condition, SSRDs are classified on the basis of physical symptoms associated with significant distress and impairment, with or without the presence of a diagnosed medical condition. The symptoms form a continuum that can range from pain to disabling neurologic symptoms and generally interfere with school/home life and peer relationships.

Most patients with SSRDs are seen by primary care practitioners or by pediatric subspecialists, who may make specialty-specific diagnoses such as visceral hyperalgesia, chronic fatigue syndrome, psychogenic syncope, or noncardiac chest pain. Even within psychiatry, SSRDs are variously referred to as **functional** or **psychosomatic disorders** or as **medically unexplained symptoms**. The nosologic heterogeneity across the pediatric subspecialties contributes to the varying diagnostic labels. There is a significant overlap in the symptoms and presentation of patients with somatic symptoms who have received different diagnoses from different specialties. Moreover, SSRDs share similarities in etiology, pathophysiology, neurobiology, psychological mechanisms, patient characteristics, and management and treatment response, which is indicative of a single spectrum of somatic disorders.

It is helpful for healthcare providers to avoid the dichotomy of approaching illness using a medical model in which diseases are considered physically or
psychologically based. In contrast, a *biobehavioral continuum* of disease better characterizes illness as occurring across a spectrum ranging from a predominantly biologic to a predominantly psychosocial etiology.

**Epidemiology**

Between 10% and 30% of children worldwide experience physical symptoms that are seemingly unexplained by a physical illness. Estimated prevalence varies greatly between studies based on the type of symptoms and the study methodology. The frequency and heterogeneity of complaints increase with age, with symptoms occurring more frequently in girls than boys.

Many children with persistent complaints of abdominal pain meet criteria for somatic symptom disorder with predominant pain in DSM-5. Headaches and back, limb, and chest pain are also frequently occurring pain symptoms in adolescents. Prevalence rates of conversion disorder in adolescents are 0.3–10%. Nonepileptic seizures, loss of consciousness, and motor symptoms are common conversion symptoms across cultures.

**Risk Factors**

**Individual**

**Temperament/Coping Styles**

Somatic symptoms have been found to be more common in children who are conscientious, sensitive, insecure, internalizers, and anxious, and in those who strive for high academic achievement. Somatization may also occur in children who are unable to verbalize emotional distress. Somatic symptoms are often seen as a form of psychological defense against intrapsychic distress that allows the child to avoid confronting anxieties or conflicts, a process referred to as “primary gain.” The symptoms may also lead to what is described as “secondary gain” if the symptom results in the child being allowed to avoid unwanted responsibilities or consequences.

**Learned Behavior**

Somatic complaints may be reinforced through a decrease in responsibilities or expectations by others and through receiving attention and sympathy. Many
children may have an antecedent underlying general medical condition that may then be reinforced by parental and peer attention as well as additional medical attention in the form of unnecessary tests and investigations.

**Psychiatric Comorbidity**
There is an association between somatization and other psychiatric illness, in particular depressive and anxiety disorders. A familial link exists between SSRDs and other psychiatric disorders (e.g., higher rates of anxiety and depression in family members).

**Childhood Physical Illness**
There appears to be a connection between childhood physical illness and the later development of somatization. Many children with an SSRD have other medical conditions. An antecedent history (e.g., accident, viral illness) may trigger onset of symptoms and lead to prolonged recovery or recurrence of symptoms after illness should have subsided. Children who tend to somatize may have a tendency to experience normal somatic sensations as “intense, noxious, and disturbing,” referred to as somatosensory amplification.

**Family and Environmental Symptom Modeling**
Multiple studies have found evidence that a significant proportion of patients with SSRD had recently encountered similar symptoms in their local environment or live with family members who complain of similar physical symptoms (e.g., child with nonepileptic seizures who has parent or sibling with seizure disorder).

**Parental Responses**
Parent beliefs about the significance of symptoms influence the extent of symptoms the child reports. Having a somatic complaint may be more acceptable or noticed in some households than the expression of strong emotions (e.g., anxiety, fear, anger). In such an environment, a child may garner minimal attention for emotional distress, but obtain more attention and sympathy for physical symptoms. Multiple studies have shown that parental protectiveness predicts child functional disability and parental responses (e.g., discouraging
activity, expressing concern, providing comfort) may serve inadvertently to reinforce and maintain illness behaviors.

**School and Family Stressors**

External environmental factors (e.g., school stress, change in family situation) are common in children presenting with an SSRD. Common school stressors include bullying, beginning the school year, fear of academic failure, or participation in extracurricular school activities. Dysfunction and less support within the family system are common. Transitions within the family system, including death of a family member, birth of a sibling, parental divorce, physical punishment by parents, and increased arguments between parents, have all been linked to somatic symptoms. Nevertheless, a significant minority of patients with SSRD do not appear to have obvious psychosocial precipitants for their symptoms. It is unclear whether recorded stressful events are absent in these patients because they were unwilling or unable to report relevant stressors or because the stressors were simply absent.

**Trauma**

Elevated rates of childhood trauma (e.g., sexual, physical, or emotional abuse) have been found in patients with SSRD, although the trauma prevalence rates in studies vary widely.

**Genetic and Biologic Vulnerabilities**

Genetic and biologic vulnerabilities (e.g., increased pain sensitivity) are thought to contribute to SSRDs. Research has suggested some unifying mechanisms, including aberrant functions of efferent neural pathways, such as the autonomic nervous system and hypothalamic-pituitary axis, and alterations in central processing of sensory input. Hyperactivity of the anterior cingulate cortex has been found in patients with conversion disorder, along with impaired activity of the dorsolateral prefrontal cortex. In chronic pain studies, including migraine and tension-type headaches, there appears to be progressive loss of gray matter density in brain structures involved in registering pain, such as the somatosensory cortex, anterior cingulate cortex, and insula. Additionally, when there is a strong expectation of pain, the anterior insular cortex is activated in proportion to this expectation.
**Assessment**

The majority of patients with SSRD present in the pediatric setting rather than the mental health setting. It is important for pediatric practitioners to make their diagnosis based on positive symptoms and signs (distressing somatic symptoms plus abnormal thoughts, feelings, and behaviors in response to these symptoms) rather than the absence of a medical explanation. As such, the evaluation of suspected disorders should include an assessment of biologic, psychological, social, and developmental realms, both separately and in relation to each other. An integrated approach in which both pediatric and mental health clinicians are involved in the assessment, management, and treatment is indicated.

**Medical**

The presence of a physical illness does not exclude the possibility of somatization playing an important role in the child's presentation. Somatic symptoms early in a disease course that can be directly attributed to a specific physical illness (e.g., acute respiratory illness) may evolve into psychologically based symptoms, particularly in situations where the child may experience benefit from adopting the sick role. Somatic symptoms may also occur in excess of what would be expected of the symptoms experienced in an existing physical illness. Physical findings may occur secondary to the effects of the somatic symptom disorder, especially when chronic or severe (e.g., deconditioning, disuse atrophy and contractures from prolonged immobilization, nutritional deficiency, gastroparesis and constipation from chronic poor oral intake).

A comprehensive medical workup to rule out serious physical illness must be carefully balanced with efforts to avoid unnecessary and potentially harmful tests and procedures. The physical examination will find that the child's symptoms may fluctuate in different contexts, may be anatomically inconsistent, or may be in excess of what would be expected from the physical findings.

**Psychosocial**

If somatization is suspected, mental health consultation should be included early in the diagnostic workup. The reason for consultation should be carefully explained to the family to help avoid the perception that their child's symptoms are not being taken seriously by the pediatric team (i.e., “it's in her head”). It
should be explained that a complete workup involves a thorough assessment of the physical and psychological domains of the child, and that the psychiatric consultation can provide further understanding of the origins of the child's distress, what perpetuates it, and which treatments are likely to be most effective.

The mental health evaluation should include a careful assessment of the psychological and social stressors and risk factors, including a thorough family psychiatric and medical history. The nature of current physical symptoms and any history of prior episodes of somatic symptoms should be included in the assessment, in addition to the child's emotional, social, and academic functioning; coping strategies; and family functioning. The evaluation should provide the clinical team with a biopsychosocial explanation of the child's symptoms, which will inform the treatment plan.

**Differential Diagnoses**

The primary differential diagnosis is between an SSRD and a physical illness. Importantly, however, these disorders are not mutually exclusive and often coexist. Mood and anxiety disorders frequently include the presence of physical symptoms, which tend to remit with treatment of the primary mood or anxiety symptoms, and which appear distinct from physical complaints seen in SSRDs. Chronic pain syndromes may be caused by fibromyalgia and small fiber autonomic neuropathy.

**Management**

With the completion of medical and psychological assessments, a multidisciplinary team meeting of pediatric and mental health clinicians should be arranged to review all the specialty evaluations and tests and discuss diagnostic impressions and treatment recommendations. This should occur to ensure consensus on the diagnosis and treatment plan and facilitate adequate and consistent communication among all providers.

An informing meeting or conference with the family should be facilitated after the team meeting to convey the multidisciplinary team's diagnostic impressions and treatment recommendations to the patient and family. Pediatric and mental health clinicians together should communicate the diagnosis (or diagnoses) in a way that families can understand using a comprehensive biopsychosocial formulation. Medical and psychosocial findings should be acknowledged and
Patients and families with SSRD often present with the belief that there is primarily a medical cause for their problem, and psychosocial contributors are often resisted. After exhaustive medical investigations yield no unifying results, labeling the symptoms as “psychiatric” can effectively shift the search for the cause onto family functioning, resulting in children and parents feeling blamed for the symptoms. The team should help the family move toward an understanding of the mind–body connection and shift their approach from searching for the cause of the symptoms to increasing family functioning. Providing education about the benefits of treatment and risks of no treatment is helpful to move the family through the treatment steps.

**Treatment**

An integrated multidisciplinary rehabilitation model provides a useful framework for treatment that shifts the focus away from finding a cure for symptoms, and instead emphasizes a return to normal adaptive functioning. This includes increased activities of daily living, improved nutrition, enhanced mobility, return to school and socialization with peers.

*Cognitive behavioral therapy (CBT) is the evidence-based intervention of choice.* CBT interventions modify symptom experience (including pain perception) and restore central nervous system abnormalities associated with functional impairment. CBT techniques (e.g., relaxation training, biofeedback, hypnosis) can be used to teach patients the control they can have over certain physiologic processes, such as autonomic system activity. Cognitive restructuring is effective in addressing and altering dysfunctional thoughts regarding symptoms and their implications for functioning. Treatments that encourage active coping strategies and emotional expression and modulation, and that limit patient reliance on emotional support provided by parents, are helpful in reducing symptoms and improving functioning. Modifying parental response patterns that are overprotective and potentially reinforcing (e.g., allowing the child to sleep late or to stay home from school in response to symptoms) help to decrease disability.

Psychopharmacologic treatment may be considered when psychiatric comorbidities are present, specifically, depressive and anxiety disorders. A combination of pharmacotherapy, physical therapy, and psychological interventions in multicomponent management programs has been shown to be
The majority of patients can be managed in the outpatient setting with appropriate mental health follow-up. Scheduled follow-up visits with the primary care provider are important to maintain alliance and investment in treatment, prevent “doctor shopping,” and avoid unnecessary invasive tests and procedures.

Because of the nature of their symptoms, most patients with SSRD do not present in mental health settings for their physical complaints, and only patients who display prominent emotional symptoms or who have a concurrent mental disorder are referred to mental health services. Pediatric specialists treat “their own” specialty somatic syndromes within their service, as a natural consequence of the large number of patients with these disorders presenting at their clinics. The management in these clinics is often monodisciplinary and comprises primarily medically based treatments and interventions. The existence of various syndrome-specific clinics perpetuates the separate, specialty-dominated approach to SSRDs and can perpetuate fragmented care rather than moving toward a more integrated model. Although specialized clinics play an important role in providing the expertise needed in the evaluation of these patients, these clinics are often not prepared to manage patients who have symptoms involving multiorgan systems. These patients may attend several clinics simultaneously and receive several parallel, uncoordinated treatments.

A medical home model with mental health clinicians working in collaboration with pediatric practitioners and/or different pediatric specialists may prove to be the most suitable approach for patients with SSRD. Integrated pediatric and mental health services improve communication, decrease fragmentation of services, and decrease the stigma and resistance some families may have with attending mental health clinics. A treatment program with comprehensive multidisciplinary services and CBT showed immediate, clinically relevant benefits that were sustained at the 1 yr follow-up in a randomized controlled trial.

Patients with profound and pervasive functional impairment likely will need more intensive psychiatric treatment (e.g., medical-psychiatric partial hospital program or inpatient unit). Multidisciplinary inpatient rehabilitation programs have much to offer these patients because they are designed to support both
physical and psychological recovery. Families feel reassured that multidisciplinary staff can continue to monitor symptoms, thus ensuring that any missed diagnoses will be recognized quickly.

Children with a high level of impairment often miss a significant amount of school; communication with the school is often crucial in helping a successful transition back and improving overall functioning. In addition to discussions with the school guidance counselor and nurse, a letter for the school providing education and recommended approaches for the patient's symptoms is often beneficial. These interventions can be formalized by having the school work with the family and medical team to develop either a 504 plan for accommodations needed in regular education settings, or an individualized educational plan (IEP) if the child needs special education services. Ongoing communication between the school and the primary care provider for monitoring of further symptoms is recommended.

Bibliography

36.1 Rumination Disorder

*Rumination disorder* is the repeated regurgitation of food, where the regurgitated food may be rechewed, reswallowed, or spit out, for a period of at least 1 mo following a period of normal functioning. Regurgitation is typically frequent and daily; it does not occur during sleep. It is not caused by an associated gastrointestinal illness or other medical conditions (e.g., gastroesophageal reflux, pyloric stenosis). It does not occur exclusively during the course of anorexia nervosa, bulimia nervosa, binge-eating disorder, or avoidant/restrictive food intake disorder. If the symptoms occur in the context of an intellectual developmental disorder or another neurodevelopmental disorder, the symptoms must be sufficiently severe to warrant additional clinical attention.

Weight loss and failure to make expected weight are common features in infants with rumination disorder. Infants may display a characteristic position of straining and arching the back with the head held back, making sucking movements with their tongue. In infants and older individuals with intellectual disability, the rumination behavior may appear to have a self-soothing or self-stimulating function. Malnutrition may occur in older children and adults, particularly when the regurgitation is associated with restricted food intake (which may be designed to avoid regurgitation in front of others). They may attempt to hide the regurgitation behavior or avoid eating among others.
Epidemiology

Originally thought of as a disorder predominantly seen in infants and those with intellectual disability, rumination disorder has also been recognized in healthy individuals across the life span and can be overlooked in adolescents. In otherwise healthy children, rumination disorder typically appears in the 1st year of life, generally between ages 3 and 12 mo. The disorder can have an episodic course or can occur continuously until treatment is initiated. In infants the disorder frequently remits spontaneously but can be protracted with problematic and even life-threatening malnutrition. Additional complications related to the secondary effects of malnutrition include growth delay and negative effects on development and learning potential.

Etiology and Differential Diagnosis

Risk factors for rumination disorder in infants and young children include a disturbed relationship with primary caregivers, lack of an appropriately stimulating environment, neglect, stressful life situations, learned behavior reinforced by pleasurable sensations, distraction from negative emotions, and inadvertent reinforcement (attention) from primary caregivers. Risk factors for rumination disorder in adolescents include similar early childhood factors along with female gender and comorbid anxiety and depression. The differential diagnosis includes congenital gastrointestinal system anomalies, pyloric stenosis, Sandifer syndrome, gastroparesis, hiatal hernia, increased intracranial pressure, diencephalic tumors, adrenal insufficiency, and inborn errors of metabolism. Older children and adults with anorexia nervosa or bulimia nervosa may also engage in regurgitation because of concerns about weight gain. The diagnosis of rumination disorder is appropriate only when the severity of the disturbance exceeds that routinely associated with a concurrent physical illness or mental disorder.

Treatment

The 1st step in treatment begins with a behavioral analysis to determine if the disorder serves as a self-stimulation purpose and/or is socially motivated. The behavior may begin as self-stimulation, but it subsequently becomes reinforced
and maintained by the social attention given to the behavior. The central focus of behavioral treatment is to reinforce correct eating behavior while minimizing attention to rumination. Diaphragmatic breathing and postprandial gum chewing, when used as a competing response, have been shown to be helpful. Aversive conditioning techniques (e.g., withdrawal of positive attention, introducing bitter/sour flavors when regurgitating) are considered when a child's health is jeopardized but can be more reasonable and useful in adolescents. Additional techniques shown to be useful in adolescents include reswallowing all regurgitation, use of paradoxical intention, and guided progressive food trials.

Successful behavioral treatment requires the child's primary caregivers to be involved in the intervention. The caretakers need education and counseling on responding adaptively to the child's behavior as well as altering any maladaptive responses. No current evidence supports a psychopharmacologic intervention for rumination disorder. In more severe or intractable cases (e.g., severe dehydration, malnutrition), an intensive integrated medical-behavioral treatment program on a medical or medical-psychiatric unit may be necessary.

**Bibliography**

Pica involves the persistent eating of nonnutritive, nonfood substances (e.g., paper, soap, plaster, charcoal, clay, wool, ashes, paint, earth) over a period of at least 1 mo. The eating behavior is inappropriate to the developmental level (e.g., the normal mouthing and tasting of objects in infants and toddlers), and therefore a minimum age of 2 yr is suggested. The eating behavior is not part of a culturally supported or socially normative practice. A diagnosis of pica may be assigned in the presence of any other feeding and eating disorder.

Epidemiology

Pica can occur throughout life but occurs most frequently in childhood. It appears to be more common in those with intellectual disability and autism spectrum disorders, and to a lesser degree in obsessive-compulsive and schizophrenic disorders. The prevalence of pica is unclear, although it appears to increase with the severity of an intellectual disability. It usually remits in childhood but can continue into adolescence and adulthood. Geophagia (eating earth) is associated with pregnancy and is not seen as abnormal in some cultures (e.g., rural or preindustrial societies in parts of Africa and India). Children with pica are at increased risk for lead poisoning, iron-deficiency anemia, mechanical bowel problems, intestinal obstruction, intestinal perforations, dental injury, and parasitic infections. Pica can be fatal based on substances ingested.

Etiology and Differential Diagnosis

Numerous etiologies have been proposed but not proved, ranging from psychosocial causes to physical ones. They include nutritional deficiencies (e.g., iron, zinc, calcium), low socioeconomic factors (e.g., lead paint exposure), child
abuse and neglect, family disorganization (e.g., poor supervision), mental disorder, learned behavior, underlying (but undetermined) biochemical disorder, and cultural and familial factors. The differential diagnosis includes anorexia nervosa, factitious disorder, and nonsuicidal self-injury in personality disorders. A separate diagnosis of pica should be made only if the eating behavior is sufficiently severe enough to warrant additional clinical attention.

**Treatment**

Combined behavioral, social, and medical approaches are generally indicated for pica. Assessment for neglect and family supervision combined with psychiatric assessment for concurrent mental disorders and developmental delay are important in developing an effective intervention strategy for pica. Behavioral interventions, particularly applied behavioral analysis in patients with intellectual disability or autism spectrum disorders, are increasingly found to be helpful. The sequelae related to an ingested item can require specific treatment (e.g., lead toxicity, iron-deficiency anemia, parasitic infestation). Ingestion of hair can require medical or surgical intervention for a gastric bezoar.

**Bibliography**

CHAPTER 37

Motor Disorders and Habits

Colleen A. Ryan, Heather J. Walter, David R. DeMaso

Motor disorders are interrelated sets of psychiatric symptoms characterized by abnormal motor movements and associated phenomena. In the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), motor disorders include tic, stereotypic movement, and developmental coordination disorders. Tic disorders (Tourette, persistent motor or vocal tic, provisional tic, other specified/unspecified tic) and stereotypic movement disorder are addressed in this chapter, along with habits. Although not DSM-5 motor disorders, habits present as repetitive and often problematic motor behaviors (e.g., thumb sucking, teeth grinding).

37.1

Tic Disorders

Colleen A. Ryan, Heather J. Walter, David R. DeMaso

Tourette disorder (TD), persistent (chronic) motor or vocal tic disorder (PTD), and provisional tic disorders are characterized by involuntary, rapid, repetitive, single or multiple motor and/or vocal/phonic tics that wax and wane in frequency but have persisted for >1 yr since first tic onset (<1 yr for provisional tic disorder) (Table 37.1). PTD is differentiated from TD in that PTD is limited to either motor or vocal tics (not both), whereas TD has both
motor and vocal tics at some point in the illness (although not necessarily concurrently). The tic disorders are hierarchical in order (i.e., TD followed by PTD followed by provisional tic disorder), such that once a tic disorder at one level of the hierarchy is diagnosed, a lower-hierarchy diagnosis cannot be made. **Other specified/unspecified tic disorders** are presentations in which symptoms characteristic of a tic disorder that cause significant distress or impairment predominate but do not meet the full criteria for a tic or other neurodevelopmental disorder.

**Table 37.1**

**DSM-5 Diagnostic Criteria for Tic Disorders**

| Note: A tic is a sudden, rapid, recurrent, nonrhythmic motor movement or vocalization. |

**Tourette Disorder**

A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.

B. The tics may wax and wane in frequency but have persisted for >1 yr since first tic onset.

C. Onset is before age 18 yr.

D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).

**Persistent (Chronic) Motor or Vocal Tic Disorder**

A. Single or multiple motor or vocal tics have been present during the illness, but not both motor and vocal.

B. The tics may wax and wane in frequency but have persisted for >1 yr since first tic onset.

C. Onset is before age 18 yr.

D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease,
postviral encephalitis).
E. Criteria have never been met for Tourette disorder.
   Specify if:
   **With motor tics only**
   **With vocal tics only**

**Provisional Tic Disorder**

A. Single or multiple motor and/or vocal tics.
B. The tics have been present for <1 yr since first tic onset.
C. Onset is before age 18 yr.
D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).
E. Criteria have never been met for Tourette disorder or persistent (chronic) motor or vocal tic disorder.

Adapted from the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p. 81.

**Description**

**Tics** are sudden, rapid, recurrent, nonrhythmic motor movements or vocalizations. *Simple motor tics* (e.g., eye blinking, neck jerking, shoulder shrugging, extension of the extremities) are fast, brief movements involving one or a few muscle groups. *Complex motor tics* involve sequentially and/or simultaneously produced, relatively coordinated movements that can seem purposeful (e.g., brushing back one's hair bangs, tapping the foot, imitating someone else's movement [*echopraxia*], or making a sexual or obscene gesture [*copropraxia*]). *Simple vocal tics* (e.g., throat clearing, sniffing, coughing) are solitary, meaningless sounds and noises. *Complex vocal tics* involve recognizable word or utterances (e.g., partial words [syllables], words out of context, coprolalia [obscenities or slurs], palilalia [repeating one's own sounds or words], or *echolalia* [repeating the last heard word or phrase]).

Sensory phenomena (premonitory urges) that precede and trigger the urge to
tic have been described. Individuals with tics can suppress them for varying periods of time, particularly when external demands exert their influence, when deeply engaged in a focused task or activity, or during sleep. Tics are often suggestible and are worsened by anxiety, excitement, or exhaustion. Parents have described increasing frequency of tics at the end of the day. Research has not supported volitional suppressing of tics leading to tic rebound.

**Clinical Course**

Onset of tics is typically between ages 4 and 6 yr. The frequency of tics tends to wax and wane with peak tic severity between ages 10 and 12 yr and marked attenuation of tic severity in most individuals (65%) by age 18-20 yr. A small percentage will have worsening tics into adulthood. New onset of tics in adulthood is very rare and most often is associated with exposure to drugs or insults to the central nervous system. Tics manifest similarly in all age-groups and changes in affected muscle groups and vocalizations occur over time. Some individuals may have tic-free periods of weeks to months.

**Epidemiology**

Prevalence rates for all tics range from 6–18% for boys and 3–11% for girls, with the rate of TD alone estimated as 0.8%. In general, PTD/TD has a male preponderance with a gender ratio varying from 2 : 1 to 4 : 1. Evidence supports higher rates in white youth than black or Hispanic youth.

**Differential Diagnosis**

The differential diagnosis includes the repetitive movements of childhood (Table 37.2). Tics may be difficult to differentiate from stereotypies. Although stereotypies may resemble tics, stereotypies are typically rhythmic movements and do not demonstrate the change in body location or movement type over time that is typical of tics. Compulsions may be difficult to differentiate from tics when tics have premonitory urges. Tics should be differentiated from a variety of developmental and benign movement disorders (e.g., benign paroxysmal torticollis, Sandifer syndrome, benign jitteriness of newborns, shuddering attacks). Tics may present in various neurologic illnesses (e.g., Wilson disease,
neuroacanthocytosis, Huntington syndrome, various frontal-subcortical brain lesions), but it is rare for tics to be the only manifestation of these disorders.

### Table 37.2

**Repetitive Movements of Childhood**

<table>
<thead>
<tr>
<th>MOVEMENT</th>
<th>DESCRIPTION</th>
<th>TYPICAL DISORDERS WHERE PRESENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tics</td>
<td>Sudden rapid, recurrent, nonrhythmic, stereotyped, vocalization or motor movement</td>
<td>Transient tics, Tourette disorder, persistent tic disorder</td>
</tr>
<tr>
<td>Dystonia</td>
<td>Involuntary, sustained, or intermittent muscle contractions that cause twisting and repetitive movements, abnormal postures, or both</td>
<td>DYT1 gene, Wilson disease, myoclonic dystonia, extrapyramidal symptoms caused by dopamine-blocking agents</td>
</tr>
<tr>
<td>Chorea</td>
<td>Involuntary, random, quick, jerking movements, most often of the proximal extremities, that flow from joint to joint. Movements are abrupt, nonrepetitive, and arrhythmic and have variable frequency and intensity</td>
<td>Sydenham chorea, Huntington chorea</td>
</tr>
<tr>
<td>Stereotypies</td>
<td>Stereotyped, rhythmic, repetitive movements or patterns of speech, with lack of variation over time</td>
<td>Autism, stereotypic movement disorder, intellectual disability</td>
</tr>
<tr>
<td>Compulsions</td>
<td>A repetitive, excessive, meaningless activity or mental exercise that a person performs in an attempt to avoid distress or worry</td>
<td>Obsessive-compulsive disorder, anorexia, body dysmorphic disorder, trichotillomania, excoriation disorder</td>
</tr>
<tr>
<td>Myoclonus</td>
<td>Shock-like involuntary muscle jerk that may affect a single body region, one side of the body, or the entire body; may occur as a single jerk or repetitive jerks</td>
<td>Hiccups, hypnic jerks, Lennox-Gastaut syndrome, juvenile myoclonic epilepsy, mitochondrial encephalopathies, metabolic disorders</td>
</tr>
<tr>
<td>Akathisia</td>
<td>Unpleasant sensations of “inner” restlessness, often prompting movements in an effort to reduce the sensations</td>
<td>Extrapyramidal adverse effects from dopamine-blocking agents; anxiety</td>
</tr>
<tr>
<td>Volitional behaviors</td>
<td>Behavior that may be impulsive or caused by boredom, such as tapping peers or making sounds (animal noises)</td>
<td>Attention-deficit/hyperactivity disorder, oppositional defiant disorder, sensory integration disorders</td>
</tr>

</table>

Individuals presenting with tics in the context of declining motor or cognitive function should be referred for neurologic assessment. Substances/medications that are reported to worsen tics include selective serotonin reuptake inhibitors (SSRIs), lamotrigine, and cocaine. If tics develop in close temporal relationship to the use of a substance or medication and then remit when use of the substance is discontinued, a causal relationship is possible. Although a long-standing clinical concern, controlled studies show no evidence that stimulants commonly increase tics.
Comorbidities

Comorbid psychiatric disorders are common, often with both patient and family viewing the accompanying condition as more problematic than the tics. There is a bidirectional association between PTD/TD (especially TD) and obsessive-compulsive disorder (OCD), with 20–60% of TD patients meeting OCD criteria and 20–40% of OCD patients reporting tics (Fig. 37.1). Attention-deficit/hyperactivity disorder (ADHD) occurs in approximately 50% of all childhood PTD/TD, but estimates in clinically referred patients suggest much higher rates (60–80%). PTD/TD is often accompanied by behavior problems, including poor frustration tolerance, temper outbursts, and oppositionality. Learning disabilities have been found in >20% of these patients. Concurrent anxiety and depression have also been observed. Some patients with PTD/TD will display symptoms of autism spectrum disorder (ASD); careful assessment is required to determine which disorder is primary.

**FIG. 37.1** Schematic representation of the behavioral spectrum in Tourette's syndrome. The size of each area is proportional to the estimated prevalence of the symptoms; the background color intensity is proportional to the complexity of the
Etiology

Tics are proposed to be the result of dysfunctional corticostriatal-thalamocortical motor pathways in the basal ganglia, striatum, and frontal lobes associated with abnormalities in the dopamine, serotonin, and norepinephrine neurotransmitter systems. Male predominance in PTD/TD may be attributable to influences of sex hormones on the neurodevelopment of these motor pathways, as reflected by the effects of antiandrogens in the treatment of TD.

Family studies suggest a 10-100-fold increased risk of PTD/TD among first-degree relatives compared to rates in the general population. Twin studies also support a genetic link, with approximately 80% of monozygotic twins and 30% of dizygotic twins showing concordance for PTD/TD. Candidate-gene association and nonparametric linkage studies have not identified specific susceptibility genes for PTD/TD.

Autoimmune-mediated mechanisms have been hypothesized as having a potential etiologic role in some tic disorders. The pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS) designation has been used to describe cases of acute childhood onset of OCD and/or tics following a streptococcal infection. Pediatric acute-onset neuropsychiatric syndrome (PANS) has been used to describe a subtype of acute childhood-onset OCD (tics are not a required feature) in which a link to a prior streptococcal infection is not evident, suggesting that other infectious agents may also be responsible. In addition to a diagnosis of OCD and tics, children with PANS/PANDAS have been reported with symptoms of separation anxiety, nightmares, personality change, oppositional behaviors, and deterioration in math skills and handwriting. Although some studies suggest a prior history of infections may increase the risk for developing tic disorder, this remains controversial.

Premorbid stress has been hypothesized to act as a sensitizing agent in the pathogenesis of TD among susceptible individuals by affecting stress-responsive biologic systems such as the hypothalamic-pituitary-adrenal axis.
Sequelae

Many individuals with mild to moderate tics express minimal to no distress or functional impairment and may even be unaware of their tics. Even individuals with moderate to severe tics can experience minimal functional impairment, but psychological distress may occur. Infrequently, the presence of tics can lead to social isolation, social victimization, inability to work or attend school, or impaired quality of life.

Screening

Pediatricians should routinely screen for unusual movements and vocalizations. As an adjunct to a verbal screen, commonly used broad-band symptom rating scales such as the Child Behavior Checklist (CBCL) and the Swanson, Nolan, and Pelham (SNAP) include specific tic questions. Often families are unaware that frequent sniffing, coughing, or blinking may be indicative of tics, attributing these behaviors to medical problems (e.g., allergies, visual problems). A careful assessment of the timing, triggers, and specific characteristics may differentiate tics from other medical problems. If differentiation is difficult, a referral to a pediatric specialist in the affected system is warranted.

Assessment

If the screening suggests the presence of a tic disorder, a more comprehensive evaluation should ensue, including the age of onset, types of tics, tic frequency, alleviating and aggravating factors, and a family history of tics. Symptom rating scales specific for tics (e.g., the Motor Tic, Obsessions and Compulsions, Vocal Tic Evaluation Survey [MOVES], Tic Self Report Scale, Tourette's Disorder Scale, Parent Tic Questionnaire [PTQ], and Child Tourette's Disorder Impairment Scale–Parent Version) can supplement the assessment. For clinician-rated tic severity, the most commonly used instruments are the Yale Global Tic Severity Scale (YGTSS), Tourette Syndrome Severity Scale (TSSS), and Tourette Syndrome Global Scale (TSGS).

A medical workup should be considered for new-onset tics, particularly for presentations characterized by sudden onset, atypicality, or mental status abnormalities. Basic laboratory measures (hemogram, renal/hepatic function
panel, thyroid panel, and ferritin, along with urine drug screen for adolescents) should be considered. For new, sudden onset or severe symptom exacerbation, pediatric practitioners may assess for concurrent acute infection (e.g., culture, rapid viral tests). Electroencephalography and brain imaging are not routinely recommended and should be reserved for patients with other neurologic findings that might suggest an autoimmune encephalitis syndrome (limbic encephalitis). Comorbid psychiatric disorders (e.g., OCD, ADHD, ASD) should be investigated.

**Treatment**

The decision to treat tics is made with the child and family based on the level of impairment and distress caused by the tics. If tics are mild in severity, there may be no need for intervention after psychoeducation is provided.

**Psychoeducation** should include common symptom presentations, implications of concurrent conditions, course and prognosis, and treatment options (including no treatment). The youth's typical exacerbating and alleviating factors should be reviewed. The clinician can direct the family and youth to informational websites, including the Tourette Association of America (www.tourette.org).

Almost 75% of children with TD/PTD receive some form of classroom accommodation (most often ignoring the tics and permission to leave the room as needed). The accommodations may need to be formalized in an individualized education plan (IEP) if a child needs special education services or a 504 plan if the child just needs accommodations in the regular classroom.

Referral to a behavioral treatment specialist should be considered when tics are distressing or functionally impairing. The behavioral interventions with the strongest empirical support are **habit reversal therapy (HRT)** and **comprehensive behavioral intervention for tics (CBIT)**. The basic components of HRT include premonitory urge awareness training and building a competing response to the urge to tic (*Table 37.3*). Based on HRT, CBIT also includes relaxation training and a functional intervention designed to mitigate against tic-generating situations. A course of HRT/CBIT treatment typically takes several months or 8-10 sessions. In children and adolescents with TD, CBIT has been found to reduce significantly the severity of tics compared to education and supportive therapy. This finding has been supported by a meta-analysis of behavior therapy (HRT/CBIT) for TD, in which a medium to large
Effect size has been shown for behavioral therapy relative to comparison conditions.

### Table 37.3

**Components of Habit Reversal Procedure**

#### Increase Individual's Awareness of Habit

- **Response description**—have individual describe behavior to therapist in detail while reenacting the behavior and looking in a mirror.
- **Response detection**—inform individual of each occurrence of the behavior until each occurrence is detected without assistance.
- **Early warning**—have individual practice identifying earliest signs of the target behavior.
- **Situation awareness**—have individual describe all situations in which the target behavior is likely to occur.

#### Teach Competing Response to Habit

The competing response must result in isometric contraction of muscles involved in the habit, be capable of being maintained for 3 min, and be socially inconspicuous and compatible with normal ongoing activities but incompatible with the habit (e.g., clenching one's fist, grasping and clenching an object). For vocal tics and stuttering, deep relaxed breathing with a slight exhale before speech has been used as the competing response.

#### Sustain Compliance

- **Habit inconvenience review**—have individual review in detail all problems associated with target behavior.
- **Social support procedure**—family members and friends provide high levels of praise when a habit-free period is noted.
- **Public display**—individual demonstrates to others that he or she can control the target behavior in situations in which the behavior occurred in the past.
Facilitate Generalization—Symbolic Rehearsal Procedure

For each situation identified in situation awareness procedure, individual imagines himself or herself beginning the target behavior but stopping and engaging in the competing response.

Medications should be considered when the tics are causing severe impairment in the quality of life, or when psychiatric comorbidities are present. The only U.S. Food and Drug Administration (FDA)—approved medications to treat TD in children and adolescents are 2 first-generation (typical) antipsychotics (haloperidol, pimozide) and 1 second-generation (atypical) antipsychotic (aripiprazole). Alpha-agonists (clonidine, guanfacine) are also a consideration as first-line agents because of their more favorable side effect profile than the first- or second-generation antipsychotics (see Chapter 33).

Both antipsychotic and α-adrenergic medications have significant benefit compared with placebo for the pharmacologic treatment of youth with tic disorders. There have been no significant differences between the first- and second-generation antipsychotic agents tested.

Children with tic disorders may benefit from SSRI for the treatment of comorbid OCD, anxiety, or depressive disorders. Augmentation of SSRIs with an atypical antipsychotic has been a consideration in patients with concurrent tic disorders and OCD responding poorly to an SSRI alone. The presence of tics does not preclude the use of stimulants to address comorbid ADHD. However, close clinical monitoring is required for possible exacerbation of tics during stimulant treatment. Anger and rage outbursts are not uncommon among youth with tics (up to 80% in clinically referred samples). Behavioral therapies (CBT, parent management training) that address anger management may be useful. There are no controlled pharmacologic studies in youth with tic disorders with anger outbursts. There also is no rigorous scientific evidence to support the use of deep brain stimulation, repetitive magnetic stimulation, or dietary supplements in the treatment of TD or PTD.
Stereotypic Movement Disorder

Colleen A. Ryan, Heather J. Walter, David R. DeMaso

In DSM-5, stereotypic movement disorder (SMD) is defined as a neurodevelopmental disorder characterized by repetitive, seemingly driven, and apparently purposeless motor behavior (stereotypy) that interferes with social, academic, or other activities and may result in self-injury. The onset of SMD is the early developmental period (often before age 3 yr), and the symptoms are not attributable to the physiologic effects of a substance or neurologic condition and are not better explained by another neurodevelopmental or mental disorder. The disorder is considered mild if symptoms are easily suppressed by sensory stimulus or distraction, and severe if continuous monitoring and protective measures are required to prevent serious injury, with moderate falling between mild and severe.

Description

Examples of stereotypic movements include hand shaking or waving, body rocking, head banging, self-biting, and hitting one's own body. The presentation depends on the nature of the stereotypic movement and level of the child's awareness of the behavior. Among typically developing children, the repetitive movements may be stopped when attention is directed to the movements or when the child is distracted from performing them. Among children with intellectual disability, the behaviors may be less responsive to such efforts. Each individual presents with his or her own uniquely patterned behavior. Stereotypic movements may occur many times during a day, lasting a few seconds to several minutes or longer. The behaviors may occur in multiple contexts, including when the individual is excited, stressed, fatigued, or bored.
Clinical Course

Stereotypic movements typically begin within the 1st 3 yr of life. In children who develop complex motor stereotypies, the great majority exhibit symptoms before 24 mo of age. In most typically developing children, these movements resolve over time. Among individuals with intellectual disability, the stereotyped behaviors may persist for years, although the pattern may change over time.

Epidemiology

Simple stereotypic movements are common in typically developing young children. Some children may bang their head on their mattress as they are falling asleep or may sit and rock when bored or overstimulated. Self-injurious habits, such as self-biting or head banging, can occur in up to 25% of typically developing toddlers (often during tantrums), but they are almost invariably associated with developmental delay in children older than age 5 yr. Complex stereotypic movements are much less common (occurring in approximately 3–4% of children). Between 4% and 16% of individuals with intellectual disability engage in stereotypic movements.

Comorbidity

Stereotypic movements are a common manifestation of a variety of neurogenetic disorders, such as Lesch-Nyhan, Rett, fragile X, Cornelia de Lange, and Smith-Magenis syndromes.

Differential Diagnosis

According to DSM-5, stereotypic movements must be differentiated from normal development, ASDs, tic disorders, OCDs, and other neurologic and medical conditions. Simple stereotypic movements occurring in the context of typical development usually resolve with age. Stereotypic movements may be a presenting symptom of ASD, but SMD does not include the deficits in social communication characteristic of ASD. When ASD is present, SMD is diagnosed only when there is self-injury or when the stereotypic behaviors are sufficiently severe to become a focus of treatment. Typically, SMD has an earlier age of
onset than the tic disorders, and the movements are fixed in their pattern. SMD is distinguished from OCD by the absence of obsessions as well as the nature of the repetitive behaviors, which in OCD are purposeful (e.g., in response to obsessions). The diagnosis of stereotypic movements requires the exclusion of habits, mannerisms, paroxysmal dyskinesias, and benign hereditary chorea. A neurologic history and examination are required to assess features suggestive of other disorders, such as myoclonus, dystonia, and chorea.

**Etiology**

There is a possible evolutionary link between repetitive abnormal grooming-like behaviors and early human experience with adversity. Brain regions implicated in this model (e.g., amygdala, hippocampus) are those involved in navigating human experience through unpredictable, anxiety-provoked emotional states, as well as regions (e.g., nucleus accumbens) related to pleasure and reward seeking. The latter involves the hypothesis that individuals experience some level of gratification from performing the habit behavior.

Social isolation with insufficient stimulation (e.g., severe neglect) is a risk factor for self-stimulation that may progress into stereotypies, particularly repetitive rocking or spinning. Environmental stress may trigger stereotypic behaviors. Repetitive self-injurious behavior may be a behavioral phenotype in neurogenetic syndromes (e.g., Lesch-Nyhan, Rett, and Cornelia de Lange syndromes). Lower cognitive functioning is also linked to greater risk of stereotypic behaviors.

**Treatment**

The initial approach to helping children with mild stereotypy is for parents to ignore the undesired behavior, encourage substitute behavior, and not convey worry to their child. These behaviors may disappear with time and elimination of attention in young children. However, in children with intellectual disability or ASDs, stereotypies may be more refractory to treatment than in typically developing children and may necessitate referral to a behavioral psychologist, developmental-behavioral pediatrician, or child and adolescent psychiatrist for behavioral and psychopharmacologic management. The pediatrician should consider and rule out neglect of the child, which can be associated with
repetitive rocking, spinning, or other stereotypic movements. Behavior therapy is the mainstay of treatment, using a variety of strategies, including habit reversal, relaxation training, self-monitoring, contingency management, competing responses, and negative practice. The environment should also be modified to reduce risk of injury to those engaging in self-injurious behavior.

Atypical antipsychotic medications appear to be helpful in reducing stereotypic movements in youth with ASD. Patients with anxiety and obsessive-compulsive behaviors treated with SSRIs may show improvement in their stereotypic movements.

Habits

Habits involve an action or pattern of behavior that is repeated often. Habits are common in childhood and range from usually benign and transient behaviors (e.g., thumb sucking, nail biting) to more problematic (e.g., trichotillomania, bruxism). In DSM-5, habits are not included as a diagnostic category because they are not viewed as disorders causing clinically significant distress or impairment in functioning. Treatment with HRT has been effective as a first-line approach (see Table 37.3).

Thumb Sucking

Thumb sucking is common in infancy and in as many as 25% of children age 2 yr and 15% of children age 5 yr. Thumb sucking beyond 5 yr may be associated with sequelae (e.g., paronychia, anterior open bite). As with other rhythmic patterns of behavior, thumb sucking is self-soothing. Basic behavioral management, including encouraging parents to ignore thumb sucking and instead focus on praising the child for substitute behaviors, is often effective treatment. Simple reminders and reinforcers can also be considered, such as giving the child a sticker (or other reward) for each block of time that he or she does not suck the thumb. In rare cases, mechanical devices placed on the thumb or in the mouth to prevent thumb sucking or noxious agents (bitter salves) placed on the thumb may be part of the treatment plan.

Bruxism
Bruxism or teeth grinding is common (5–30% of children), can begin in the first 5 yr of life, and may be associated with daytime anxiety. Persistent bruxism can manifest as muscular or temporomandibular joint pain. Untreated bruxism can cause problems with dental occlusion. Helping the child find ways to reduce anxiety might relieve the problem; bedtime can be made more relaxing by reading or talking with the child and allowing the child to discuss fears. Praise and other emotional support are useful. Persistent bruxism requires referral to a dentist given the risk for dental occlusion.

Bibliography

Whittington C, Pennant M, Kendall T, et al. Practitioner review:

Anxiety, defined as dread or apprehension, is not considered pathologic, is seen across the life span, and can be adaptive (e.g., the anxiety one might feel during an automobile crash). Anxiety has both a cognitive-behavioral component, expressed in worrying and wariness, and a physiologic component, mediated by the autonomic nervous system. Anxiety disorders are characterized by pathologic anxiety, in which anxiety becomes disabling, interfering with social interactions, development, and achievement of goals or quality of life, and can lead to low self-esteem, social withdrawal, and academic underachievement. The average age of onset of anxiety disorder is 11 yr. Diagnosis of a particular anxiety disorder in a child requires significant interference in the child's psychosocial and academic or occupational functioning, which can occur even with subthreshold symptoms that do not meet criteria in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). Anxiety may have physical manifestations such as weight loss, pallor, tachycardia, tremors, muscle cramps, paresthesias, hyperhidrosis, flushing, hyperreflexia, and abdominal tenderness.

Separation anxiety disorder (SAD), childhood-onset social phobia or social anxiety disorder, generalized anxiety disorder (GAD), obsessive-compulsive disorder (OCD), phobias, posttraumatic stress disorder (PTSD), and panic disorder (PD) are all defined by the occurrence of either diffuse or specific anxiety, often related to predictable situations or cues. Anxiety disorders are the most common psychiatric disorders of childhood, occurring in 5–18% of all children and adolescents, prevalence rates comparable to physical disorders such as asthma and diabetes. Anxiety disorders are often comorbid with other psychiatric and medical disorders (including a second anxiety disorder); significant impairment in day-to-day functioning is common. High levels of fear
in adolescence are also a significant risk factor for experiencing later episodes of major depression in adulthood. Anxiety and depressive disorder in adolescence predict increased risk of anxiety and depressive symptoms (including suicide attempts) in adulthood, underscoring the need to diagnose and treat these underreported, yet prevalent, conditions early.

Because anxiety is both a normal phenomenon and, when highly activated, strongly associated with impairment, the pediatrician must be able to differentiate normal anxiety from abnormal anxiety across development (Fig. 38.1 and Table 38.1 ). Anxiety has an identifiable developmental progression for most children; most infants exhibit stranger wariness or anxiety beginning at 7-9 mo of age. Behavioral inhibition to the unfamiliar (withdrawal or fearfulness to novel stimuli associated with physiologic arousal) is evident in approximately 10–15% of the population at 12 mo of age and is moderately stable. Most children who show behavioral inhibition do not develop impairing levels of anxiety. A family history of anxiety disorders and maternal overinvolvement or enmeshment predicts later clinically significant anxiety in behaviorally inhibited infants. The infant who is excessively clingy and difficult to calm during pediatric visits should be followed for signs of increasing levels of anxiety.

![Normative fears throughout childhood and adolescence](From Craske MG, Stein MB: Anxiety. Lancet 388:3048–3058, 2016.)

**Table 38.1**

<table>
<thead>
<tr>
<th>Differential Diagnosis of Anxiety Disorders</th>
</tr>
</thead>
</table>
Preschoolers typically have specific fears related to the dark, animals, and imaginary situations, in addition to normative separation anxiety. Preoccupation with orderliness and routines (just right phenomena) often takes on a quality of anxiety for preschool children. Parents' reassurance is usually sufficient to help the child through this period. Although most school-age children abandon the imaginary fears of early childhood, some replace them with fears of bodily harm or other worries (Table 38.2). In adolescence, general worrying about school performance and worrying about social competence are common and remit as the teen matures.

**Table 38.2**

**DSM-5 Diagnostic Criteria for Specific Phobia**

A. Marked fear or anxiety about a specific object or situation (e.g., flying, heights, animals, receiving an injection, seeing blood).

*Note: In children, the fear or anxiety may be expressed by crying, tantrums,*
freezing, or clinging.

B. The phobic object or situation almost always provokes immediate fear or anxiety.

C. The phobic object or situation is actively avoided or endured with intense fear or anxiety.

D. The fear or anxiety is out of proportion to the actual danger posed by the specific object or situation and to the sociocultural context.

E. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.

F. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

G. The disturbance is not better explained by the symptoms of another mental disorder, including fear, anxiety and avoidance or situations associated with panic-like symptoms or other incapacitating symptoms (as in agoraphobia); objects or situations related to obsessions (as in obsessive-compulsive disorder); remainders of traumatic events (as in posttraumatic stress disorder); separation from home or attachment figures (as in separation anxiety disorder); or social situations (as in social anxiety disorder).

Specify if:

Code based on the phobic stimulus:

- **Animal** (e.g., spiders, insects, dogs).
- **Natural environment** (e.g., heights, storms, water).
- **Blood-injection-injury** (e.g., needles, invasive medical procedures).
- **Situational** (e.g., airplanes, elevators, enclosed places).
- **Other** (e.g., situations that may lead to choking or vomiting; in children, e.g., loud sounds or costumed characters).

Genetic or temperamental factors contribute more to the development of some anxiety disorders, whereas environmental factors are closely linked to the cause of others. Specifically, behavioral inhibition appears to be a heritable tendency and is linked with social phobia, generalized anxiety, and selective mutism. OCD
and other disorders associated with OCD-like behaviors, such as Tourette syndrome and other tic disorders, tend to have high genetic risk as well (see Chapter 37.1). Environmental factors, such as parent–infant attachment and exposure to trauma, contribute more to SAD and PTSD. Parental anxiety disorder is associated with an increased risk of anxiety disorder in offspring. Differences in the size of the amygdala and hippocampus are noted in patients with anxiety symptoms.

**Separation anxiety disorder** is one of the most common childhood anxiety disorders, with a prevalence of 3.5–5.4%. Approximately 30% of children presenting to an outpatient anxiety disorder clinic have SAD as a primary diagnosis. Separation anxiety is developmentally normal when it begins about 10 mo of age and tapers off by 18 mo. By 3 yr of age, most children can accept the temporary absence of their mother or primary caregiver.

SAD is more common in prepubertal children, with an average age of onset of 7.5 yr. Girls are more frequently affected than boys. SAD is characterized by unrealistic and persistent worries about separation from the home or a major attachment figure. Concerns include possible harm befalling the affected child or the child's primary caregivers, reluctance to go to school or to sleep without being near the parents, persistent avoidance of being alone, nightmares involving themes of separation, numerous somatic symptoms, and complaints of subjective distress. The first clinical sign might not appear until 3rd or 4th grade, typically after a holiday or a period where the child has been home because of illness, or when the stability of the family structure has been threatened by illness, divorce, or other psychosocial stressors.

Symptoms vary depending on the child's age: Children <8 yr often have associated school refusal and excessive fear that harm will come to a parent; children 9-12 yr have excessive distress when separated from a parent; and those 13-16 yr often have school refusal and physical complaints. SAD may be more likely to develop in children with lower levels of psychosocial maturity. Parents are often unable to be assertive in returning the child to school. Mothers of children with SAD often have a history of an anxiety disorder. In these cases the pediatrician should screen for parental depression or anxiety. Often, referral for parental treatment or family therapy is necessary before SAD and concomitant school refusal can be successfully treated.

Comorbidity is common in SAD. In children with comorbid tic disorders and anxiety, SAD is especially associated with tic severity. SAD is a predictor for early onset of PD. Children with SAD compared to those without SAD are 3
times more likely to develop PD in adolescence.

When a child reports recurring acute severe anxiety, antidepressant or anxiolytic medication is often necessary. Controlled studies of tricyclic antidepressants (TCAs, imipramine) and benzodiazepines (clonazepam) show that these agents are not generally effective. Data support the use of cognitive-behavioral therapy (CBT) and selective serotonin reuptake inhibitors (SSRIs) (see Chapter 33, Table 33.4). Adverse events with SSRI treatment, including suicidal and homicidal ideation, are uncommon. CBT alone is associated with less insomnia, fatigue, sedation, and restlessness than SSRIs. Combining SSRIs with CBT may be the best approach to achieving a positive response; long-term SSRI treatment can provide additional benefit.

**Childhood-onset social phobia (social anxiety disorder)** is characterized by excessive anxiety in social settings (including the presence of unfamiliar peers, or unfamiliar adults) or performance situations, leading to social isolation, and is associated with social scrutiny and fear of doing something embarrassing (Table 38.3). Fear of social settings can also occur in other disorders, such as GAD. Avoidance or escape from the situation usually dissipates anxiety in social phobia (SP), unlike GAD, where worry persists.

### Table 38.3

**DSM-5 Diagnostic Criteria for Social Anxiety Disorder (Social Phobia)**

A. Marked fear or anxiety about 1 or more social situations in which the individual is exposed to possible scrutiny by others. Examples include social interactions (e.g., having a conversation, meeting unfamiliar people), being observed (e.g., eating or drinking), and performing in front of others (e.g., giving a speech).

B. The individual fears that he or she will act in a way or show anxiety symptoms that will be negatively evaluated (i.e., will be humiliating or embarrassing; will lead to rejection or offend others).

C. The social situations almost always provoke fear or anxiety.

*Note:* In children, the fear or anxiety may be expressed by crying, tantrums, freezing, clinging, shrinking, or failing to speak in social situations.

D. The social situations are avoided or endured with intense fear or anxiety.

E. The fear or anxiety is out of proportion to the actual threat posed by the
social situation and to the sociocultural context.

F. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.

G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

H. The fear, anxiety, or avoidance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

I. The fear, anxiety, or avoidance is not better explained by the symptoms of another mental disorder, such as panic disorder, body dysmorphic disorder, or autism spectrum disorder.

J. If another medical condition (e.g., Parkinson disease, obesity, disfigurement from burns or injury) is present, the anxiety or avoidance is clearly unrelated or is excessive.

Specify if:

**Performance only:** If the fear is restricted to speaking or performing in public.

Children and adolescents with SP often maintain the desire for involvement with family and familiar peers. When severe, the anxiety can manifest as a panic attack. SP is associated with a decreased quality of life, with increased likelihood of having failed at least 1 grade, and a 38% likelihood of not graduating from high school. Its onset is typically during or before adolescence and is more common in girls. A family history of SP or extreme shyness is common. Approximately 70–80% of patients with SP have at least 1 comorbid psychiatric disorder. Most shy patients do not have SP.

**Social effectiveness therapy for children (SET-C),** alone or with SSRIs, is considered the treatment of choice for SP (see Table 33.4). SSRI and SET-C are superior to placebo in reducing social distress and behavioral avoidance and increasing general functioning. SET-C may be better than SSRI in reducing these symptoms. SET-C, but not SSRI, may be superior to placebo in improving social skills, decreasing anxiety in specific social interactions, and enhancing social
competence. SSRIs have a maximum effect by 8 wk; SET-C provides continued improvement through 12 wk. A combination of SSRI and CBT is superior to either treatment alone in reducing severity of anxiety in children with SP and other anxiety disorders. β-Adrenergic blocking agents are used to treat SP, particularly the subtype with performance anxiety and stage fright. β-Blockers are not approved by the U.S. Food and Drug Administration (FDA) for SP.

**School refusal**, which occurs in approximately 1–2% of children, is associated with anxiety in 40–50% of cases, depression in 50–60% of cases, and oppositional behavior in 50% of cases. Younger anxious children who refuse to attend school are more likely to have SAD, whereas older anxious children usually refuse to attend school because of SP. Somatic symptoms, especially abdominal pain and headaches, are common. There may be increasing tension in the parent–child relationship or other indicators of family disruption (domestic violence, divorce, or other major stressors) contributing to school refusal.

Management of school refusal typically requires parent management training and family therapy. Working with school personnel is always indicated; anxious children often require special attention from teachers, counselors, or school nurses. Parents who are coached to calmly send the child to school and to reward the child for each completed day of school are usually successful. In cases of ongoing school refusal, referral to a child and adolescent psychiatrist and psychologist is indicated. SSRI treatment may be helpful. Young children with affective symptoms have a good prognosis, whereas adolescents with more insidious onset or with significant somatic complaints have a more guarded prognosis.

**Selective mutism** is conceptualized as a disorder that overlaps with SP. Children with selective mutism talk almost exclusively at home, although they are reticent in other settings, such as school, daycare, or even relatives' homes. The mutism must be present for ≥1 mo. Often, one or more stressors, such as a new classroom or conflicts with parents or siblings, drive an already shy child to become reluctant to speak. It may be helpful to obtain history of normal language use in at least one situation to rule out any communication disorder (fluency disorder), neurologic disorder, or pervasive developmental disorder (autism, schizophrenia) as a cause of mutism. Fluoxetine in combination with behavioral therapy is effective for children whose school performance is severely limited by their symptoms (see Chapter 52). Other SSRIs may also be effective.

**Panic disorder** is a syndrome of recurrent, discrete episodes of marked fear
or discomfort in which patients experience abrupt onset of physical and psychological symptoms called panic attacks (Table 38.4). Physical symptoms can include palpitations, sweating, shaking, shortness of breath, dizziness, chest pain, and nausea. Children can present with acute respiratory distress but without fever, wheezing, or stridor, ruling out organic causes of the distress. The associated psychological symptoms include fear of death, impending doom, loss of control, persistent concerns about having future attacks, and avoidance of settings where attacks have occurred (agoraphobia, Table 38.5).

### Table 38.4

**DSM-5 Diagnostic Criteria for Panic Disorder**

A. Recurrent unexpected panic attacks. A panic attack is an abrupt surge of intense fear or intense discomfort that reaches a peak within minutes, and during which time 4 (or more) of the following symptoms occur:

*Note:* The abrupt surge can occur from a calm state or an anxious state.

1. Palpitations, pounding heart, or accelerated heart rate.
2. Sweating.
3. Trembling or shaking.
4. Sensations of shortness of breath or smothering.
5. Feelings of choking.
6. Chest pain or discomfort.
7. Nausea or abdominal distress.
9. Chills or heart sensations.
10. Paresthesias (numbness or tingling sensations).
11. Derealizations (feeling or unreality) or depersonalization (being detached from one-self).
12. Fear of losing control or “going crazy.”

*Note:* Culture-specific symptoms (e.g., tinnitus, neck soreness, headache, uncontrollable screaming or crying) may be seen. Such symptoms should not count as 1 of the 4 required symptoms.

B. At least 1 of the attacks has been followed by 1 mo (or more) of 1 or both of the following:

1. Persistent concern or worry about additional panic attacks or their
consequences (e.g., losing control, having a heart attack, “going crazy”).

2. A significant maladaptive change in behavior related to the attacks (e.g., behaviors designed to avoid having panic attacks, such as avoidance of exercise or unfamiliar situations).

C. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hyperthyroidism, cardiopulmonary disorders).

D. The disturbance is not better explained by another mental disorder (e.g., the panic attacks do not occur only in response to feared social situations, as in social anxiety disorder; in response to circumscribed phobic objects or situations, as in specific phobia; in response to obsessions, as in obsessive-compulsive disorder; or in response to reminders of traumatic events, as in posttraumatic stress disorder; or in response to separation from attachment figures, as in separation anxiety disorder).

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 208–209.

**Table 38.5**

**DSM-5 Diagnostic Criteria for Agoraphobia**

A. Marked fear or anxiety about 2 (or more) if the following 5 situations:
   1. Using public transportation (e.g., automobiles, buses, trains, ships, planes).
   2. Being in open spaces (e.g., parking lots, marketplaces, bridges).
   3. Being in enclosed places (e.g., shops, theaters, cinemas).
   4. Standing in line or being in a crowd.
   5. Being outside of the home alone.

B. The individual fears or avoids these situations because of thoughts that escape might be difficult or help might not be available in the event of a developing panic-like symptoms or other incapacitating or embarrassing symptoms (e.g., fear or falling in the elderly, fear of incontinence).

C. The agoraphobic situations almost always provoke fear or anxiety.

D. The agoraphobic situations are actively avoided, require the presence of a companion, or are endured with intense fear or anxiety.
E. The fear or anxiety is out of proportion to the actual danger posed by the agoraphobic situations and to the sociocultural context.

F. The fear, anxiety, or avoidance is persistent, typically lasting for 6 mo or more.

G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important area of functioning.

H. If another medical condition (e.g., inflammatory bowel disease, Parkinson disease) is present, the fear, anxiety, or avoidance is clearly excessive.

I. The fear, anxiety, or avoidance is not better explained by the symptoms or another mental disorder—for example, the symptoms are not confined to specific phobia, situational type; do not involve only social situations (as in social anxiety disorder); and are not related exclusively to obsessions (as in obsessive-compulsive disorder), reminders or traumatic events (as in posttraumatic stress disorder), or fear of separation (as in separation anxiety disorder).

Note: Agoraphobia is diagnosed irrespective of the presence of panic disorder. If an individual's presentation meets criteria for panic disorder and agoraphobia, both diagnoses should be assigned.

From the *Diagnosis and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013), American Psychiatric Association, pp 217–218.

PD is uncommon before adolescence, with the peak age of onset at 15-19 yr, occurring more often in girls. The postadolescence prevalence of PD is 1–2%. Early-onset PD and adult-onset PD do not differ in symptom severity or social functioning. *Early-onset* PD is associated with greater comorbidity, which can result from greater familial loading for anxiety disorders in the early-onset subtype. Children of parents with PD are much more likely to develop PD. A predisposition to react to autonomic arousal with anxiety may be a specific risk factor leading to PD. Twin studies suggest that 30–40% of the variance is attributed to genetics. The increasing rates of panic attack are also directly related to earlier sexual maturity. Cued panic attacks can be present in other anxiety disorders and differ from the uncued “out-of-the-blue” attacks in PD.

No randomized controlled trials (RCTs) have evaluated the effectiveness of antidepressant medication in youth with PD. Open-label studies with SSRIs appear to show effectiveness in the treatment of adolescents (see Table 33.4 ).
CBT may also be helpful. The recovery rate is approximately 70%.

**Generalized anxiety disorder** occurs in children who often experience unrealistic worries about different events or activities for at least 6 mo with at least 1 somatic complaint (Table 38.6). The diffuse nature of the anxiety symptoms differentiates it from other anxiety disorders. Worries in children with GAD usually center around concerns about competence and performance in school and athletics. GAD often manifests with somatic symptoms, including restlessness, fatigue, problems concentrating, irritability, muscle tension, and sleep disturbance. Given the somatic symptoms characteristic of GAD, the differential diagnosis must consider other medical causes. Excessive use of caffeine or other stimulants in adolescence is common and should be determined with a careful history. When the history or physical examination is suggestive, the pediatrician should rule out hyperthyroidism, hypoglycemia, lupus, pheochromocytoma, and other disorders (see Table 38.1; Fig. 38.2).

### Table 38.6

**DSM-5 Diagnostic Criteria for Generalized Anxiety Disorder**

A. Excessive anxiety and worry (apprehensive expectation), occurring more days than not for at least 6 mo, about a number of events or activities (such as work or school performance).

B. The individual finds it difficult to control the worry.

C. The anxiety and worry are associated with 3 (or more) of the following 6 symptoms (with at least some symptoms having been present for more days than not for the past 6 mo):

   - Restlessness or feeling keyed up or on edge.
   - Being easily fatigued.
   - Difficulty concentrating or mind going blank.
   - Irritability.
   - Muscle tension.
   - Sleep disturbance (difficulty falling or staying asleep, or restless, unsatisfying sleep).

*Note:* Only 1 item is required in children.

D. The anxiety, worry, or physical symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of
E. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or other medical condition (e.g., hyperthyroidism).

F. The disturbance is not better explained by another mental disorder (e.g., anxiety or worry about having panic attacks in panic disorder, negative evaluation in social anxiety disorder [social phobia], contamination or other obsessions in obsessive-compulsive disorder, separation from attachment figures in separation anxiety disorder, remainders of traumatic events in posttraumatic stress disorder, gaining weight in anorexia nervosa, physical complaints in somatic symptom disorder, perceived appearance flaws in body dysmorphic disorder, having a serious illness in illness anxiety disorder, or the content of delusional beliefs in schizophrenia or delusional disorder).

Children with GAD are extremely self-conscious and perfectionistic and
struggle with more intense distress than is evident to parents or others around them. They often have other anxiety disorders, such as simple phobia and PD. Onset may be gradual or sudden, although GAD seldom manifests until puberty. Boys and girls are equally affected before puberty, when GAD becomes more prevalent in girls. The prevalence of GAD ranges from 2.5–6% of children. Hypermetabolism in frontal precortical area and increased blood flow in the right dorsolateral prefrontal cortex may be present.

Children with GAD are good candidates for CBT, an SSRI, or their combination (see Table 33.4). Buspirone may be used as an adjunct to SSRI therapy. The combination of CBT and SSRI often results in a superior response in pediatric patients with anxiety disorders, including GAD. The recovery rate is approximately 80%.

It is important to distinguish children with GAD from those who present with specific repetitive thoughts that invade consciousness (obsessions) or repetitive rituals or movements that are driven by anxiety (compulsions). The most common obsessions are concerned with bodily wastes and secretions, the fear that something calamitous will happen, or the need for sameness. The most common compulsions are handwashing, continual checking of locks, and touching. At times of stress (bedtime, preparing for school), some children touch certain objects, say certain words, or wash their hands repeatedly.

**Obsessive-compulsive disorder** is diagnosed when the thoughts or rituals cause distress, consume time, or interfere with occupational or social functioning (Table 38.7). In the DSM-5, OCD and related disorders, such as trichotillomania, excoriation, body dysmorphic disorder, and hoarding, are listed separately and are no longer included under anxiety disorders.

**Table 38.7**

**DSM-5 Diagnostic Criteria for Obsessive-Compulsive Disorder**

<table>
<thead>
<tr>
<th>A. Presence of obsessions, compulsions, or both:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obsessions are defined by (1) and (2):</td>
</tr>
<tr>
<td>1. Recurrent and persistent thoughts, urges, or images that are experienced, at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress.</td>
</tr>
</tbody>
</table>
2. The individual attempts to ignore or suppress such thoughts, urges, or images, or to neutralize them with some other thought or action (i.e., by performing a compulsion).

Compulsions are defined by (1) and (2):

1. Repetitive behaviors (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly.
2. The behaviors or mental acts are aimed at preventing or reducing anxiety or distress, or preventing some dreaded event or situation; however, these behaviors or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent, or are clearly excessive.

B. The obsessions or compulsions are time-consuming (e.g., take more than 1 hr per day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

C. The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

D. The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder; preoccupation with appearance, as in body dysmorphic disorder; difficulty discarding or parting with possessions, as in hoarding disorder; hair pulling, as in trichotillomania [hair-pulling disorder]; skin picking, as in excoriation [skin-picking] disorder; stereotypies, as in stereotypic movement disorder; ritualized eating disorder, as in eating disorders; preoccupation with substances or gambling, as in substance-related and addictive disorders; preoccupation with having an illness, as in illness anxiety disorder; sexual urges or fantasies, as in paraphilic disorders; impulses, as in disruptive, impulse-control, and conduct disorders; guilty ruminations, as in schizophrenia spectrum and other psychotic disorders; or repetitive patterns of behavior, as in autism spectrum disorder).

Specify if:

**With good or fair insight:** The individual recognizes that obsessive-compulsive disorder beliefs are definitely or probably not true or that they may or may not be true.
**With poor insight:** The individual thinks obsessive-compulsive disorder beliefs are probably true.

**With absent insight/delusional beliefs:** The individual is completely convinced that obsessive-compulsive disorder beliefs are true.

Specify if:

**Tic-related:** The individual has a current or past history of a tic disorder.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 237.

OCD is a chronically disabling illness characterized by repetitive, ritualistic behaviors over which the patient has little or no control. OCD has a lifetime prevalence of 1–3% worldwide, and as many as 80% of all cases have their onset in childhood and adolescence. Common obsessions include contamination (35%) and thoughts of harming loved ones or oneself (30%). Washing and cleaning compulsions are common in children (75%), as are checking (40%) and straightening (35%). Many children are observed to have visuospatial irregularities, memory problems, and attention deficits, causing academic problems not explained by OCD symptoms alone.

The *Children's Yale-Brown Obsessive-Compulsive Scale* (C-YBOCS) and the *Anxiety Disorders Interview Schedule for Children* (ADIS-C) are reliable and valid methods for identifying children with OCD. The C-YBOCS is helpful in following the progression of symptoms with treatment. The *Leyton Obsessional Inventory* (LOI) is a self-report measure of OCD symptoms that is quite sensitive. Patients with OCD have consistently identified abnormalities in the frontostriatal-thalamic circuitry associated with severity of illness and treatment response. Comorbidity is common in OCD, with 30% of patients having comorbid tic disorders, 26% comorbid major depression, and 24% comorbid developmental disorders.

Consensus guidelines recommend that children and adolescents with OCD begin treatment with either CBT alone or CBT in combination with SSRI, when symptoms are moderate to severe (YBOCS >21). In OCD patients with comorbid tics, SSRIs are no more effective than placebo, and the combination of CBT and SSRI is superior to CBT; CBT alone is superior to placebo. Pediatric OCD patients with comorbid tics should begin treatment with CBT alone or combined CBT and SSRI. Pediatric patients with OCD who have a family
history of OCD may be significantly less responsive to CBT alone than patients without a family history.

There are 4 FDA-approved medications for pediatric OCD: fluoxetine, sertraline, fluvoxamine, and clomipramine. *Clomipramine*, a heterocyclic antidepressant and nonselective serotonin and norepinephrine reuptake inhibitor, is only indicated when a patient has failed 2 or more SSRI trials. There may be a role for glutamate-modulating medications in the treatment of OCD. The glutamate inhibitor *riluzole* (Rilutek) is FDA approved for amyotrophic lateral sclerosis (see Chapter 630.3) and has a good safety record. The most common adverse event with riluzole is transient increase in liver transaminases. Riluzole in children with treatment-resistant OCD may be beneficial and is well tolerated. Other glutamate-modulating agents, such as memantine, *N*-acetylcysteine, and *D*-cycloserine, have been used with some success in patients with OCD. Referral of patients with OCD to a mental health professional is always indicated.

In 10% of children with OCD, symptoms are triggered or exacerbated by group A β-hemolytic streptococcal infection (see Chapter 210). Group A β-hemolytic streptococci trigger antineuronal antibodies that cross-react with basal ganglia neural tissue in genetically susceptible hosts, leading to swelling of this region and resultant obsessions and compulsions. This subtype of OCD, called *pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS)*, is characterized by sudden and dramatic onset or exacerbation of OCD or tic symptoms, associated neurologic findings, and a recent streptococcal infection. Increased antibody titers of antistreptolysin O and antideoxyribonuclease B correlates with increased basal ganglia volumes. Plasmapheresis is effective in reducing OCD symptoms in some patients with PANDAS and also decreasing enlarged basal ganglia volume. OCD has also followed episodes of acute disseminated encephalomyelitis (see Chapter 618.4). The pediatrician should be aware of the infectious cause of some cases of tic disorders, and OCD and follow management guidelines (see Chapter 37).

Children with *phobias* avoid specific objects or situations that reliably trigger physiologic arousal (e.g., dogs, spiders) (see Table 38.2). The fear is excessive and unreasonable and can be cued by the presence or anticipation of the feared trigger, with anxiety symptoms occurring immediately. Neither obsessions nor compulsions are associated with the fear response; phobias only rarely interfere with social, educational, or interpersonal functioning. Assault by a relative and verbal aggression between parents can influence the onset of specific phobias. The parents of phobic children should remain calm in the face of the child's
anxiety or panic. Parents who become anxious themselves may reinforce their children's anxiety, and the pediatrician can usefully interrupt this cycle by calmly noting that phobias are not unusual and rarely cause impairment. The prevalence of specific phobias in childhood is 0.5–2%.

**Systematic desensitization** is a form of behavior therapy that gradually exposes the patient to the fear-inducing situation or object, while simultaneously teaching relaxation techniques for anxiety management. Successful repeated exposure leads to extinguishing anxiety for that stimulus. When phobias are particularly severe, SSRIs can be used with behavioral intervention. Low-dose SSRI treatment may be especially effective for some children with severe, refractory choking phobia.

**Posttraumatic stress disorder** is typically precipitated by an extreme stressor (see Chapter 14). PTSD is an anxiety disorder resulting from the long- and short-term effects of trauma that cause behavioral and physiologic sequelae in toddlers, children, and adolescents (Table 38.8). Another diagnostic category, **acute stress disorder**, reflects that traumatic events often cause acute symptoms that may or may not resolve. Previous trauma exposure, a history of other psychopathology, and symptoms of PTSD in parents predict childhood-onset PTSD. Many adolescent and adult psychopathologic conditions, such as conduct disorder, depression, and some personality disorders, might relate to previous trauma. PTSD is also linked to mood disorders and disruptive behavior. Separation anxiety is common in children with PTSD. The lifetime prevalence of PTSD by age 18 yr is approximately 6%. Up to 40% show symptoms, but do not fulfill the diagnostic criteria.

**Table 38.8**

**DSM-5 Diagnostic Criteria for Posttraumatic Stress Disorder**

*Posttraumatic Stress Disorder*

*Note:* The following criteria apply to adults, adolescents, and children older than 6 yr. For children 6 yr and younger, see corresponding criteria below.

A. Exposure to actual or threatened death, serious injury, or sexual violence in 1 (or more) of the following ways:
   1. Directly experiencing the traumatic event(s).
   2. Witnessing, in person, the event(s) as it occurred to others.
3. Learning that the traumatic event(s) occurred to a close family member or close friend. In cases of actual or threatened death of a family member or friend, the event(s) must have been violent or accidental.

4. Experiencing repeated or extreme exposure to aversive details of the traumatic event(s) (e.g., 1st responders collecting human remains; police officers repeatedly exposed to details of child abuse).

Note: Criterion A4 does not apply to exposure through electronic media, television, movies, or pictures, unless this exposure is work related.

B. Presence of 1 (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:
   1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).

   Note: In children older than 6 yr, repetitive play may occur in which themes or aspects of the traumatic event(s) are expressed.

   2. Recurrent distressing dreams in which the content and/or effect of the dream are related to the traumatic event(s).

   Note: In children, there may be frightening dreams without recognizable content.

   3. Dissociative reactions (e.g., flashbacks) in which the individual feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the more extreme expression being a complete loss or awareness of present surroundings.)

   Note: In children, trauma-specific reenactment may occur in play.

   4. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

   5. Marked physiologic reactions to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

C. Persistent avoidance of stimuli associated with the traumatic event(s), beginning after the traumatic event(s) occurred, as evidenced by 1 or both of the following:

   1. Avoidance of or efforts to avoid distressing memories, thoughts, or feelings about or closely associated with the traumatic
event(s).
2. Avoidance of or efforts to avoid external reminders (people, places, conversations, activities, objects, situations) that arouse distressing memories, thoughts, or feelings about or closely associated with the traumatic event(s).

D. Negative alterations in cognitions and mood associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Inability to remember an important aspect of the traumatic event(s) (typically due to dissociative amnesia and not to other factors such as head injury, alcohol, or drugs).
   2. Persistent and exaggerated negative beliefs or expectations about oneself, others, or the world (e.g., “I am bad,” “No one can be trusted,” “The world is completely dangerous,” “My whole nervous system is permanently ruined”).
   3. Persistent, distorted cognitions about the cause or consequences of the traumatic event(s) that lead the individual to blame himself/herself or others.
   4. Persistent negative emotional state (e.g., fear, horror, anger, guilt, or shame).
   5. Markedly diminished interest or participation in significant activities.
   6. Feelings of detachment or estrangement from others.
   7. Persistent inability to experience positive emotions (e.g., inability to experience happiness, satisfaction, or loving feelings).

E. Marked alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Irritable behavior and angry outbursts (with little or no provocation) typically expressed by verbal or physical aggression toward people or objects.
   2. Reckless or self-destructive behavior.
   3. Hypervigilance.
   4. Exaggerated startle response.
   5. Problems with concentration.
   6. Sleep disturbance (e.g., difficulty falling or staying asleep or restless sleep).
F. Duration of the disturbance (Criteria B, C, D, and E) is more than 1 mo.  
G. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.  
H. The disturbance is not attributable to the physiologic effects of a substance (e.g., medication, alcohol) or another medical condition.  

Specify whether:  

**With dissociative symptoms:** The individual’s symptoms meet the criteria for posttraumatic stress disorder, and in addition, in response to the stressor, the individual experiences persistent or recurrent symptoms of either of the following:  

1. **Depersonalization:** Persistent or recurrent experiences of feeling detached from, and as if one were an outside observer of, one’s mental processes or body (e.g., feeling as though one were in a dream; feeling a sense of unreality of self or body or of time moving slowly).  
2. **Derealization:** Persistent or recurrent experiences of unreality of surroundings (e.g., the world around the individual is experienced as unreal, dreamlike, distant, or distorted).  

*Note:* To use this subtype, the dissociative symptoms must not be attributable to the physiologic effects of a substance (e.g., blackouts, behavior during alcohol intoxication) or another medical condition (e.g., complex partial seizures).  

Specify if:  

**With delayed expression:** If the full diagnostic criteria are not met until at least 6 mo after the event (although the onset and expression of some symptoms may be immediate).  

---  

**Posttraumatic Stress Disorder for Children 6 Yr and Younger**  

A. In children 6 yr and younger, exposure to actual or threatened death, serious injury, or sexual violence in 1 (or more) of the following ways:  
1. Directly experiencing the traumatic event(s).  
2. Witnessing, in person, the event(s) as it occurred to others, especially primary caregivers.  

*Note:* Witnessing does not include events that are only in electronic media,
television, movies, or pictures.

3. Learning that the traumatic event(s) occurred to a parent or caregiving figure.

B. Presence of 1 (or more) of the following intrusion symptoms associated with the traumatic event(s), beginning after the traumatic event(s) occurred:

1. Recurrent, involuntary, and intrusive distressing memories of the traumatic event(s).

*Note:* Spontaneous and intrusive memories may not necessarily appear distressing and may be expressed as play reenactment.

2. Recurrent distressing dreams in which the content and/or effect of the dream is related to the traumatic event(s).

*Note:* It may not be possible to ascertain that the frightening content is related to the traumatic event.

3. Dissociative reactions (e.g., flashbacks) in which the child feels or acts as if the traumatic event(s) were recurring. (Such reactions may occur on a continuum, with the most extreme expression being a complete loss of awareness of present surroundings.) Such trauma-specific reenactment may occur in play.

4. Intense or prolonged psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event(s).

C. One (or more) of the following symptoms, representing either persistent avoidance of stimuli associated with the traumatic event(s) or negative alterations in cognitions and mood associated with the traumatic event(s), must be present, beginning after the event(s) or worsening after the event(s):

**Persistent Avoidance of Stimuli**

1. Avoidance of or efforts to avoid activities, places, or physical reminders that arouse recollections or the traumatic event(s).

2. Avoidance of or efforts to avoid people, conversations, or interpersonal situations that around recollections of the traumatic event(s).

**Negative Alterations in Cognitions**

3. Substantially increased frequency of negative emotional states (e.g., fear, guilt, sadness, shame, confusion).

4. Markedly diminished interest or participation in significant
activities, including constriction of play.
5. Socially withdrawn behavior.
6. Persistent reduction in expression of positive emotions.

D. Alterations in arousal and reactivity associated with the traumatic event(s), beginning or worsening after the traumatic event(s) occurred, as evidenced by 2 (or more) of the following:
   1. Irritable behavior and angry outbursts (with little or no provocation), typically expressed as verbal and physical aggression toward people or objects (including extreme temper tantrums).
   2. Hypervigilance.
   3. Exaggerated startle response.
   4. Problems with concentration.
   5. Sleep disturbance (e.g., difficulty falling asleep or staying asleep or restless sleep).

E. The duration of the disturbance is more than 1 mo.

F. The disturbance causes clinically significant distress or impairment in relationships with parents, siblings, peers, or other caregivers or with school behavior.

G. The disturbance is not attributable to the physiologic effects of a substance (e.g., medication or alcohol) or another medical condition.

Specify whether:

With dissociative symptoms: The individual's symptoms meet the criteria for posttraumatic stress disorder, and the individual experiences persistent or recurrent symptoms of either of the following:

   1. Depersonalization: Persistent or recurrent experiences of feeling detached from, and as if one were an outside observer of, one's mental processes or body (e.g., feeling as though one were in a dream; feeling a sense of unreality of self or body or of time moving slowly).
   2. Derealization: Persistent or recurrent experiences of unreality of surroundings (e.g., the world around the individual is experienced as unreal, dreamlike, distant, or distorted).

Note: To use this subtype, the dissociative symptoms must not be attributable to the physiologic effects of a substance (e.g., blackouts, behavior during alcohol intoxication) or another medical condition (e.g., complex partial
Events that pose actual or threatened physical injury, harm, or death to the child, child's caregiver, or others close to the child, and that produce considerable stress, fear, or helplessness, are required to make the diagnosis of PTSD. Three clusters of symptoms are also essential for diagnosis: reexperiencing, avoidance, and hyperarousal. Persistent **reexperiencing** of the stressor through intrusive recollections, nightmares, and reenactment in play are typical responses in children. Persistent **avoidance** of reminders and numbing of emotional responsiveness, such as isolation, amnesia, and avoidance, constitute the 2nd cluster of behaviors. Symptoms of **hyperarousal**, such as hypervigilance, poor concentration, extreme startle responses, agitation, and sleep problems, complete the symptom profile of PTSD. Occasionally, children regress in some of their developmental milestones after a traumatic event. Avoidance symptoms are usually observable in younger children, whereas older children may better describe reexperiencing and hyperarousal symptoms. Repetitive play involving the event, psychosomatic symptoms, and nightmares may also be observed.

Initial interventions after a trauma should focus on reunification with a parent and attending to the child's physical needs in a safe place. Aggressive treatment of pain, and facilitating a return to comforting routines, including regular sleep, is indicated. Long-term treatment may include individual, group, school-based, or family therapy, as well as pharmacotherapy, in selected cases. **Individual** treatment involves transforming the child's concept of himself or herself as victim to that of survivor and can occur through play therapy, psychodynamic therapy, or CBT. **Group** work is also helpful for identifying which children might need more intensive assistance. Goals of **family** work include helping the child establish a sense of security, validating the child's emotions, and anticipating situations when the child will need more support from the family.
Clonidine or guanfacine may be helpful for sleep disturbance, persistent arousal, and exaggerated startle response. Recent RCTs in children and adolescents with PTSD found no significant difference between SSRI and placebo. SSRIs may be considered in pediatric patients with PTSD who have comorbid conditions responsive to SSRIs, including depression, affective numbing, and anxiety (see Table 33.4). As for many other anxiety disorders, CBT is the psychotherapeutic intervention with the most empirical support.

Anxiety Associated With Medical Conditions

It is prudent to rule out organic conditions such as hyperthyroidism, caffeineism (carbonated beverages), hypoglycemia, central nervous system disorders (delirium, encephalopathy, brain tumors), migraine, asthma, lead poisoning, cardiac arrhythmias, and rarely, pulmonary embolism, hyperparathyroidism, systemic lupus erythematosus, anaphylaxis, porphyria, or pheochromocytoma, before making a diagnosis of an anxiety disorder (see Table 38.1). Some prescription drugs with side effects that can mimic anxiety include antiasthmatic agents, corticosteroids, sympathomimetics, SSRIs (initiation), anticholinergic agents, and antipsychotics. Nonprescription drugs causing anxiety include diet pills, antihistamines, stimulant drugs of abuse, drug withdrawal, and cold medicines.

Chronic illness is also an underlying cause of anxiety. Children are not often emotionally and cognitively competent to understand the implications of a serious and prolonged illness. In addition to the physiologic implications of illness, they must also attend to the hospitalizations, procedures, and medications that permeate their everyday schedule. This experience affects their schooling, friendships, activities, and dynamics of the nuclear family, including the experiences of their well siblings.

School issues surrounding both prolonged absences and school reentry following a medical condition can cause or reinforce and escalate existing anxiety. School is a foundation not only for learning, but it is central to children's social experiences and feelings of normalcy. It is often impeded and stunted by illness. Academic struggles can result from missing classes, medication use, and emotional status. Children with chronic conditions are also socially disadvantaged, with friendship networks hampered by unstable attendance or
social rejection for being different. Consulting with the school psychologist can be beneficial in preparing teachers and classmates before the child returns to school. An agreement between the student and school staff should be implemented, outlining a plan for taking medication, needing rest, or consulting on other needs. If the child and family agree, an informational meeting with students and teachers can normalize the situation. Explaining the condition makes it less scary for children who catastrophize or worry about contagion. Classmates and teachers are a natural accessible resource and can be a valuable support community. Medication may also be warranted to supplement social supports.

The experiences of the siblings of children with chronic illness are often forgotten, with familial resources focused on medical-financial consequences and the emotional and physical functioning of the ill child. It is not uncommon for the siblings of ill children to experience depression and anxiety as well. Assessing their social support systems, communication opportunities with parents and emotional outlets are critical to maintaining healthy functioning. Maintaining a redefined schedule of after-school activities and social engagements are helpful in allowing siblings to continue in school.

**Safety and Efficacy Concerns About SSRIs**

No empirical evidence suggests the superiority of one SSRI over another. Data are limited on combining medications. SSRIs are usually well tolerated by most children and adolescents. The FDA issued a “black box” warning of increased agitation and suicidality among adolescents and children taking SSRIs. This warning was based on review of studies in children and adolescents with major depression and not anxiety disorders. Close monitoring is always warranted.

**Bibliography**

Garcia AM, Sapyta JJ, Moore PS, et al. Predictors and moderators of treatment outcome in the Pediatric Obsessive

Mood disorders are interrelated sets of psychiatric symptoms characterized by a core deficit in emotional self-regulation. Classically, the mood disorders have been divided into depressive and bipolar disorders, representing the two emotional polarities, dysphoric (“low”) and euphoric (“high”) mood.

The depressive disorders include major depressive, persistent depressive, disruptive mood dysregulation, other specified/unspecified depressive, premenstrual dysphoric, and substance/medication-induced disorders, as well as depressive disorder caused by another medical condition (Fig. 39.1).
Description

**Major depressive disorder (MDD)** is characterized by a distinct period of at least 2 wk (an *episode*) in which there is a depressed or irritable mood and/or loss of interest or pleasure in almost all activities that is present for most of the day, nearly every day (*Table 39.1*). Major depression is associated with characteristic vegetative and cognitive symptoms, including disturbances in appetite, sleep, energy, and activity level; impaired concentration; thoughts of worthlessness or guilt; and suicidal thoughts or actions. Major depression is considered *mild* if few or no symptoms in excess of those required to make the diagnosis are present, and the symptoms are mildly distressing and manageable and result in minor functional impairment. Major depression is considered *severe* if symptoms substantially in excess of those required to make the diagnosis are present, and the symptoms are highly distressing and unmanageable and markedly impair function. *Moderate* major depression is intermediate in severity between mild and severe.

**Table 39.1**

<table>
<thead>
<tr>
<th>DSM-5 Diagnostic Criteria for Major Depressive Episode</th>
</tr>
</thead>
</table>
A. Five (or more) of the following symptoms have been present during the same 2 wk period and represent a change from previous functioning; at least 1 of the symptoms is either (1) depressed mood or (2) loss of interest or pleasure.

1. Depressed most of the day, nearly every day, as indicated by either subjective report (e.g., feels sad, empty, hopeless) or observation made by others (e.g., appears tearful).

Note: In children and adolescents, can be irritable mood.

2. Markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day (as indicated by either subjective account or observation).

3. Significant weight loss when not dieting or weight gain (e.g., a change of more than 5% of body weight in a month), or decrease or increase in appetite nearly every day.

Note: In children, consider failure to make expected weight gain.

4. Insomnia or hypersomnia nearly every day.

5. Psychomotor agitation or retardation nearly every day (observable by others, not merely subjective feelings of restlessness or being slowed down).

6. Fatigue or loss of energy nearly every day.

7. Feelings of worthlessness or excessive or inappropriate guilt (which may be delusional) nearly every day (not merely self-reproach or guilt about being sick).

8. Diminished ability to think or concentrate, or indecisiveness, nearly every day (either by subjective account or as observed by others).

9. Recurrent thoughts of death (not just fear of dying), recurrent suicidal ideation without a specific plan, or a suicide attempt or a specific plan for committing suicide.

B. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

C. The episode is not attributable to the physiologic effects of a substance or to another medical condition.

Note: Criteria A-C represent a major depressive episode.

D. The occurrence of the major depressive episode is not better explained by schizoaffective disorder, schizophrenia, schizophreniform disorder,
Persistent depressive disorder is characterized by depressed or irritable mood for more days than not, for at least 1 yr (in children and adolescents). As with major depression, this chronic form of depression is associated with characteristic vegetative and cognitive symptoms; however, the cognitive symptoms of persistent depression are less severe (e.g., low self-esteem rather than worthlessness, hopelessness rather than suicidality). As with major depression, persistent depressive disorder is characterized as mild, moderate, or severe (Table 39.2).

**Table 39.2**

**DSM-5 Diagnostic Criteria for Persistent Depressive Disorder**

A. Depressed mood for most of the day, for more days than not, as indicated either by subjective account or observation by others, for at least 2 yr.  
*Note:* In children and adolescents, mood can be irritable and duration must be at least 1 yr.

B. Presence, while depressed, of 2 (or more) of the following:
   1. Poor appetite or overeating.
   2. Insomnia or hypersomnia.
   3. Low energy or fatigue.
   4. Low self-esteem.
   5. Poor concentration or difficulty making decisions.
   6. Feelings of hopelessness.

C. During the 2 yr period (1 yr for children or adolescents) of the disturbance, the individual has never been without the symptoms in Criteria A and B for more than 2 mo at a time.

D. Criteria for a major depressive disorder may be continuously present for 2
E. There has never been a manic episode or a hypomanic episode, and criteria have never been met for cyclothymic disorder.

F. The disturbance is not better explained by a persistent schizoaffective disorder, schizophrenia, delusional disorder, or other specified or unspecified schizophrenia spectrum and other psychotic disorder.

G. The symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition (e.g., hypothyroidism).

H. The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Note: Because the criteria for a major depressive episode include 4 symptoms that are absent from the symptom list for persistent depressive disorder (dysthymia), a very limited number of individuals will have depressive symptoms that have persisted longer than 2 yr but will not meet criteria for persistent depressive disorder. If full criteria for a major depressive episode have been met at some point during the current episode of illness, they should be given a diagnosis of major depressive disorder. Otherwise, a diagnosis of other specified depressive disorder or unspecified depressive disorder is warranted.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 168–169.

Overall, the clinical presentation of major and persistent depressive disorders in children and adolescents is similar to that in adults. The prominence of the symptoms can change with age: irritability and somatic complaints may be more common in children, and energy, activity level, appetite, and sleep disturbances may be more common in adolescents. Because of the cognitive and linguistic immaturity of young children, symptoms of depression in that age-group may be more likely to be observed than self-reported.

The core feature of **disruptive mood dysregulation disorder (DMDD)** is severe, persistent irritability evident most of the day, nearly every day, for at least 12 mo in multiple settings (at home, at school, with peers). The irritable mood is interspersed with frequent (≥3 times/wk) and severe (verbal rages, physical aggression) temper outbursts (*Table 39.3*). This diagnosis is intended to
characterize more accurately the extreme irritability that some investigators had considered a developmental presentation of bipolar disorder, and to distinguish extreme irritability from the milder presentations characteristic of oppositional defiant disorder (ODD) and intermittent explosive disorder.

Table 39.3

**DSM-5 Diagnostic Criteria for Disruptive Mood Dysregulation Disorder**

A. Severe recurrent temper outbursts manifested verbally (e.g., verbal rages) and/or behaviorally (e.g., physical aggression toward people or property) that are grossly out of proportion in intensity or duration to the situation or provocation.

B. The temper outbursts are inconsistent with developmental level.

C. The temper outbursts occur, on average, 3 or more times per week.

D. The mood between temper outbursts is persistently irritable or angry most of the day, nearly every day, and is observable by others (e.g., parents, teachers, peers).

E. Criteria A-D have been present for 12 or more months. Throughout that time, the individual has not had a period lasting 3 or more consecutive months without all of the symptoms in Criteria A-D.

F. Criteria A and D are present in at least 2 of 3 settings (i.e., at home, at school, with peers) and are severe in at least 1 of these.

G. The diagnosis should not be made for the first time before age 6 yr or after age 18 yr.

H. By history or observation, the age at onset of Criteria A-E is before 10 yr.

I. There has never been a distinct period lasting more than 1 day during which the full symptom criteria, except duration, for a manic or hypomanic episode have been met.

*Note:* Developmentally appropriate mood elevation, such as occurs in the context of a highly positive event or its anticipation, should not be considered as a symptom of mania or hypomania.

J. The behaviors do not occur exclusively during an episode of major depressive disorder and are not better explained by another mental disorder (e.g., autism spectrum disorder, posttraumatic stress disorder, separation...
anxiety disorder, persistent depressive disorder [dysthymia]).

Note: The diagnosis cannot coexist with oppositional defiant disorder, intermittent explosive disorder, or bipolar disorder, though it can coexist with others, including major depressive disorder, attention-deficit/hyperactivity disorder, conduct disorder, and substance use disorders. Individuals whose symptoms meet criteria for both disruptive mood dysregulation disorder and oppositional defiant disorder should only be given the diagnosis of disruptive mood dysregulation disorder. If an individual has ever experienced a manic or hypomanic episode, the diagnosis of disruptive mood dysregulation disorder should not be assigned.

K. The symptoms are not attributable to the physiologic effects of a substance or to another medical or neurologic condition.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p. 156.

**Other specified/unspecified depressive disorder** (subsyndromal depressive disorder) applies to presentations in which symptoms characteristic of a depressive disorder are present and cause clinically significant distress or functional impairment, but do not meet the full criteria for any of the disorders in this diagnostic class.

**Epidemiology**

The overall prevalence of parent-reported diagnosis of depressive disorder in the United States (excluding DMDD) among 3-17 yr old children is approximately 2.1% (current) and 3.9% (ever); the prevalence rate increases to 12.8% (lifetime) for 12-17 yr olds. The male:female ratio (excluding DMDD) is approximately 1:1 during childhood and beginning in early adolescence rises to 1:1.5-3.0 in adulthood.

Based on rates of chronic and severe persistent irritability, which is the core feature of DMDD, the overall 6 mo to 1 yr prevalence has been estimated in the 2–5% range. In 3 community samples, the 3 mo prevalence rate of DMDD ranged from 0.8–3.3%, with the highest rates occurring in preschoolers (although DSM-5 does not permit this diagnosis until age 6 yr). Approximately
5–10% of children and adolescents are estimated to have subsyndromal (unspecified) depression.

**Clinical Course**

Major depression may first appear at any age, but the likelihood of onset greatly increases with puberty. Incidence appears to peak in the 20s. The median duration of a major depressive episode is about 5-8 mo for clinically referred youth and 3-6 mo for community samples. The course is quite variable in that some individuals rarely or never experience remission, whereas others experience many years with few or no symptoms between episodes. Persistent depressive disorder often has an early and insidious onset and by definition, a chronic course (average untreated duration in both clinical and community samples: 3.5 yr).

Prepubertal depressive disorders exhibit more heterotypic than homotypic continuity; depressed children appear to be more likely to develop nondepressive psychiatric disorders in adulthood than depressive disorders. Adolescents exhibit greater homotypic continuity, with the probability of recurrence of depression reaching 50–70% after 5 yr. The persistence of even mild depressive symptoms during remission is a powerful predictor of recurrence; other negative prognostic factors include more severe symptoms, longer time to remission, history of maltreatment, and comorbid psychiatric disorders. Up to 20% of depressed adolescents develop a bipolar disorder; the risk is higher among adolescents who have a high family loading for bipolar disorder, who have psychotic depression, or who have had pharmacologically induced mania.

**Differential Diagnosis**

A number of psychiatric disorders, general medical conditions, and medications can generate symptoms of depression or irritability and must be distinguished from the depressive disorders. The psychiatric disorders include autism spectrum disorder (ASD), attention-deficit/hyperactivity disorder (ADHD), and bipolar, anxiety, trauma- and stressor-related, disruptive/impulse control/conduct, and substance-related disorders. Medical conditions include neurologic disorders (including autoimmune encephalitis), endocrine disorders (including hypothyroidism and Addison disease), infectious diseases, tumors, anemia,
uremia, failure to thrive, chronic fatigue disorder, and pain disorder. Medications include narcotics, chemotherapy agents, β-blockers, corticosteroids, and contraceptives. The diagnosis of a depressive disorder should be made after these and other potential explanations for the observed symptoms have been ruled out.

**Comorbidity**

Major and persistent depressive disorders often co-occur with other psychiatric disorders. Depending on the setting and source of referral, 40–90% of youths with a depressive disorder have other psychiatric disorders, and up to 50% have ≥2 comorbid diagnoses. The most common comorbid diagnosis is an anxiety disorder and as such may reflect a common diathesis; other common comorbidities include ADHD and disruptive behavior, eating, and substance use disorders. The development of depressive disorders can both lead to and follow the development of the comorbid disorders.

Preliminary data suggest that DMDD occurs with other psychiatric disorders, including other depressive disorders, ADHD, conduct disorder, and substance use disorders, from 60–90% of the time. Because the symptoms of DMDD overlap in part with symptoms of bipolar disorder, ODD, and intermittent explosive disorder, by Diagnostic Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) convention, hierarchical diagnostic rules apply. Thus, bipolar disorder takes precedence over DMDD if a manic/hypomanic episode has ever occurred, and DMDD takes precedence over ODD and intermittent explosive disorder if full criteria for DMDD are met.

**Sequelae**

Approximately 60% of youths with MDD report thinking about suicide, and 30% attempt suicide. Youths with depressive disorders are also at high risk of substance abuse, impaired family and peer relationships, early pregnancy, legal problems, educational and occupational underachievement, and poor adjustment to life stressors, including physical illness.

Children with DMDD have displayed elevated rates of social impairments, school suspension, and service use. Irritability in adolescence has predicted the development of major depressive and dysthymic disorders and generalized
anxiety disorder (but not bipolar disorder) 20 yr later, as well as lower educational attainment and income.

Etiology and Risk Factors

Current models of vulnerability to depressive disorders are grounded in gene and environment pathways. Genetic studies have demonstrated the heritability of depressive disorders, with monozygotic twin studies finding concordance rates of 40–65%. In families, both bottom-up (children to parents) and top-down (parents to children) studies have shown a 2-4-fold bidirectional increase in depression among first-degree relatives. The exact nature of genetic expression remains unclear. Cerebral variations in structure and function (particularly serotonergic), the function of the hypothalamic-pituitary-adrenal axis, difficult temperament/personality (i.e., negative affectivity), and ruminative, self-devaluing cognitive style have been implicated as components of biologic vulnerability. The great majority of depressive disorders arise in youths with long-standing psychosocial difficulties, among the most predictive of which are physical/sexual abuse, neglect, chronic illness, school difficulties (bullying, academic failure), social isolation, family or marital disharmony, divorce/separation, parental psychopathology, and domestic violence. Longitudinal studies demonstrate the greater importance of environmental influences in children who become depressed than in adults who become depressed. Factors shown to be protective against the development of depression include a positive relationship with a parent; better family function; closer parental supervision, monitoring, and involvement; a prosocial peer group; higher IQ; and greater educational aspirations.

Prevention

Numerous experimental trials have sought to demonstrate the effectiveness of psychological or educational strategies in preventing the onset of depressive disorders in children and adolescents. These programs generally have provided information about the link between depressed mood and depressogenic thoughts and behaviors, as well as training in skills intended to modify these thoughts and behaviors. A Cochrane review found small effects of these programs on depression symptoms when implemented universally vs no intervention, with
selective programs (targeted at high-risk groups) performing better than universal programs; however, the effect of prevention programs was null compared with attention controls.

Screening/Case Finding

Adolescents presenting in the primary care setting should be queried, along with their parent(s), about depressed mood as part of the routine clinical interview. A typical screening question would be, “Everyone feels sad or angry some of the time, how about you (or your teen)?” The parents of younger children can be queried about overt signs of depression, such as tearfulness, irritability, boredom, or social isolation. A number of standardized screening instruments widely used in the primary care setting (e.g., Pediatric Symptom Checklist, Strengths and Difficulties Questionnaire, Vanderbilt ADHD Diagnostic Rating Scales) have items specific to sad mood, and as such can be used to focus the interview.

The role of universal depression screening using standardized depression-specific instruments is unclear. A Cochrane review found that the use of depression screening in primary care has little or no impact on the recognition, management, or outcome of depression. Nonetheless, the U.S. Preventive Services Task Force (PSTF) recommends the universal use of depression screening instruments, but only among adolescents and only when systems are in place to ensure adequate follow-up. Targeted screening of known high-risk groups (e.g., youth who are homeless, refugees, attracted to the same sex, involved with child welfare or juvenile justice), or youth experiencing known psychosocial adversities (see Etiology and Risk Factors earlier) or self-reporting a dysphoric mood, may be a higher-yield case-finding strategy than universal screening.

Early Intervention

Youth (and/or their parents) presenting in the primary care setting who self-report, or respond affirmatively to queries about, a distressing life experience or a depressed or irritable mood should be offered the opportunity to talk about the situation with the pediatric practitioner (separately with the older youth as indicated). By engaging in active listening (e.g., “I hear how upset you have been feeling, tell me more about what happened to make you feel that way”), the
pediatric practitioner can begin to assess the onset, duration, context, and severity of the symptoms and associated dangerousness, distress, and functional impairment. In the absence of acute dangerousness (e.g., suicidality, psychosis, substance abuse) and significant distress or functional impairment, the pediatric practitioner (or co-located behavioral health therapist) can schedule a follow-up appointment within 1-2 wk to conduct a depression assessment. At this follow-up visit, to assist with decision-making about appropriate level of care, a depression-specific screening standardized rating scale can be administered to assess symptom severity (Table 39.4), and additional risk factors can be explored (see Etiology and Risk Factors earlier).

Treatment decisions should be guided by the understanding that depression in youth is highly responsive to placebo (50–60%) or brief nonspecific intervention (15–30%). The goal of treatment is **remission**, defined as a period of at least 2 wk with no or very few depressive symptoms, and ultimately **recovery**, defined as a period of at least 2 mo with no or very few depressive symptoms. Assessment of remission and recovery can be aided using the depression-specific standardized rating scales, in which remission is defined as scores below the
scale-specific clinical cutpoint.

For mild symptoms (manageable and not functionally impairing) and in the absence of major risk factors (e.g., suicidality; psychosis; substance use; history of depression, mania, or traumatic exposures; parental psychopathology, particularly depression; severe family dysfunction), guided self-help (anticipatory guidance) with watchful waiting and scheduled follow-up may suffice. Guided self-help can include provision of educational materials (e.g., pamphlets, books, workbooks, apps, internet sites) that provide information to the youth about coping adaptively with depressogenic situations, as well as advice to parents about strengthening the parent–child relationship and modifying depressogenic exposures (e.g., taking action against bullying, increasing opportunities for social interaction and support, protecting child from exposure to marital discord). Additional self-help activities that have shown promise in improving mild depressive symptoms include physical exercise, relaxation therapy (e.g., yoga, mindfulness), and a regular sleep schedule.

For youths who continue to have mild depression after a few weeks of guided self-help, supportive therapy by a mental health professional (ideally co-located in the primary care, school, or community setting) may be an appropriate subsequent step. Supportive psychotherapy, which can be delivered in individual or group formats, focuses on teaching thoughts (e.g., positive self-talk) and behaviors (e.g., pleasurable activities, relaxation, problem solving, effective communication) known to ameliorate depressive symptoms, as well as providing concrete social or material problem-solving assistance to the youth or family as needed.

**Treatment**

For youths who have not responded to approximately 4-8 wk of supportive psychotherapy, or who from the outset exhibit moderate to severe, comorbid, or recurrent depression or suicidality, or who have a history of mania, traumatic exposures, or severe family dysfunction or psychopathology, assessment and treatment in the specialty mental health setting by a child-trained mental health clinician should be considered.

For moderate to severe depression, specific manualized psychotherapies, antidepressant medication, or a combination of both should be considered. At present, there is insufficient evidence on which to base definitive conclusions about the relative effectiveness of these treatments.
Clinical trials of acute treatments have generated support for the efficacy of cognitive-behavioral therapy (CBT)/behavioral activation therapy and interpersonal therapy as monotherapies in depressed youth, but overall effect sizes are modest (0.35 and 0.26, respectively). For children age 12 and younger, meta-analyses suggest no benefit of CBT over no treatment. CBT focuses on identifying and correcting cognitive distortions that may lead to depressed mood and teaches problem-solving, behavior activation, social communication, and emotional regulation skills to combat depression. Interpersonal therapy focuses on enhancing interpersonal problem solving and social communication to decrease interpersonal conflicts. Each of these therapies typically involves 8-12 weekly visits. Limited evidence suggests that family therapy may be more effective than no treatment in decreasing depression and improving family functioning.

Two selective serotonin reuptake inhibitors (SSRIs), fluoxetine and escitalopram, are the only antidepressants approved by the U.S. Food and Drug Administration (FDA) for the treatment of depression in youth, and fluoxetine alone is approved for preadolescents. Randomized controlled trials (RCTs) of the effectiveness of antidepressants are mixed, but meta-analyses of RCTs have been fairly consistent in their disappointing findings.

Based on a 2007 meta-analysis, approximately 60% of youths with MDD responded to antidepressants from multiple medication classes (vs 50% for placebo), but only about 30% of medicated depressed youths experienced symptom remission. Fluoxetine consistently demonstrated greater efficacy and was the only SSRI separating from placebo in studies of depressed preadolescents. The absolute risk for suicidal thoughts in youths treated with antidepressant medication was approximately 3%, vs 2% of those given placebo.

In another Cochrane review, antidepressants from multiple classes decreased symptom severity in children and adolescents with depressive disorders and increased remission/response in adolescents, but the effects were small and may not have been clinically significant. Fluoxetine and escitalopram possibly outperformed other antidepressants for safety and effectiveness.

In a 2016 meta-analysis of all classes of antidepressants prescribed for MDD in children and adolescents, only fluoxetine was statistically significantly more effective than placebo. Duloxetine and venlafaxine had adverse tolerability profiles, and youths taking venlafaxine were suggested to have a significantly increased risk for suicidality.

These findings converge in the suggestion that fluoxetine should be
considered first-line therapy among antidepressants unless other factors (e.g., comorbidities, side effect profiles, personal/family history of response to a specific medication) favor an alternative antidepressant. Considering both efficacy and tolerability findings, next-best choices may be escitalopram (for adolescents) and sertraline (for children and adolescents). In light of the accumulated findings, antidepressants should be used cautiously in youth and likely should limited to patients (especially adolescents) with moderate to severe depression for whom psychosocial interventions are either ineffective or not feasible.

Clinical severity, comorbidity, family conflict, low drug concentration, nonadherence, anhedonia, sleep difficulties, subsyndromal manic symptoms, and child maltreatment have all been related to treatment resistance. Approximately 50% of depressed youth failing to respond to the 1st SSRI respond after switching to a 2nd antidepressant plus CBT, vs approximately 40% who respond to a 2nd medication alone. For youth with psychotic depression, augmenting the antidepressant with an atypical antipsychotic medication should be considered, while monitoring closely for side effects.

Before initiating antidepressant medication, baseline symptom severity should be assessed using a standardized rating scale (see Table 39.4). The initial dose of fluoxetine for moderate to severe major depressive disorder generally would be 10 mg for children age 6-12 yr and 20 mg for adolescents age ≥13. Clinical response, tolerability, and emergence of behavioral activation, mania, or suicidal thoughts should be assessed weekly (per FDA recommendation) for the 1st 4 wk. If the youth has safely tolerated the antidepressant, the baseline standardized symptom rating scale should be readministered to assess response to treatment. Because the findings from a recent meta-analysis suggest that treatment gains in response to SSRI medications are greatest early in treatment and minimal after 4 wk, if substantial improvement in the rating scale score has not occurred at 4 wk despite confirmation of adherence to the medication regimen, consultation from a child and adolescent psychiatrist should be considered.

Because of the high rate of recurrence, successful treatment should continue for 6-12 mo. The findings from one RCT suggested that the addition of relapse-prevention CBT to ongoing medication management reduces the risk of relapse more than medication management alone, even after the end of treatment. When treatment concludes, all antidepressants (except possibly fluoxetine because of long half-life) should be discontinued gradually to avoid withdrawal symptoms (gastrointestinal upset, disequilibrium, sleep disruption, flulike symptoms,
sensory disturbances). Patients with recurrent (≥2 episodes), chronic, or severe major depression may require treatment beyond 12 mo.

To date, there are no rigorous studies evaluating the effectiveness of pharmacologic or psychosocial treatment approaches to persistent depressive disorder or DMDD. The aforementioned treatments for MDD may prove helpful in persistent depressive disorder. In suspected cases of DMDD, child and adolescent psychiatry consultation may be helpful to clarify diagnosis and suggest treatment approaches.

**Level of Care**

Most children and adolescents with mild to moderate depressive disorders can be safely and effectively treated as outpatients, provided that a clinically appropriate schedule of visits can be maintained through the phases of treatment. Inpatient treatment should be considered for youth who present with a high risk of suicide, serious self-harm, or self-neglect, or when the family is not able to provide an appropriate level of supervision or follow-up with outpatient treatment recommendations, or when comprehensive assessment for diagnostic clarity is needed. When considering inpatient admission for a young person with depression, the benefits of inpatient treatment needs to be balanced against potential detrimental effects, such as the loss of family and community support.

39.2
Bipolar and Related Disorders

Heather J. Walter, David R. DeMaso

Description

The bipolar and related disorders include bipolar I, bipolar II, cyclothymic, and other specified/unspecified bipolar and related disorders, as well as bipolar and related disorder caused by another medical condition.

A manic episode is characterized by a distinct period of at least 1 wk in which there is an abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy that is present for most of the day, nearly every day (or any duration if hospitalization is necessary). The episode is associated with characteristic cognitive and behavioral symptoms, including disturbances in self-regard, speech, attention, thought, activity, impulsivity, and sleep (Table 39.5). To diagnose bipolar I disorder, criteria must be met for at least 1 manic episode, and the episode must not be better explained by a psychotic disorder. The manic episode may have been preceded and may be followed by hypomanic or major depressive episodes. Bipolar I disorder is rated as mild, moderate, or severe in the same way as the depressive disorders (see Description section of Chapter 39.1).

Table 39.5

DSM-5 Diagnostic Criteria for a Manic Episode

A. A distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting at least 1 wk and present most of the day, nearly every day (or any duration if hospitalization is necessary).

B. During the period of mood disturbance and increased energy or activity, 3
(or more) of the following symptoms (4 if the mood is only irritable) are present to a significant degree and represent a noticeable change from usual behavior:

1. Inflated self-esteem or grandiosity.
2. Decreased need for sleep (e.g., feels rested after only 3 hr of sleep).
3. More talkative than usual or pressure to keep talking.
4. Flight of ideas or subjective experience that thoughts are racing.
5. Distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed.
6. Increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation (i.e., purposeless non-goal-directed activity).
7. Excessive involvement in activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments).

C. The mood disturbance is sufficiently severe to cause marked impairment in social or occupational functioning or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features.

D. The episode is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, other treatment) or to another medical condition.

Note: A full manic episode that emerges during antidepressant treatment (e.g., medication, electroconvulsive therapy) but persists at a fully syndromal level beyond the physiologic effect of that treatment is sufficient evidence for a manic episode and, therefore, a bipolar I diagnosis.

Note: Criteria A-D constitute a manic episode. At least 1 lifetime manic episode is required for the diagnosis of bipolar I disorder.

To diagnose bipolar II disorder, criteria must be met for at least 1 hypomanic episode and at least 1 major depressive episode. A hypomanic episode is similar to a manic episode but is briefer (at least 4 days) and less severe (causes less impairment in functioning, is not associated with psychosis,
and would not require hospitalization) (Table 39.6). In bipolar II disorder, there must never have been a manic disorder, the episodes must not be better explained by a psychotic disorder, and the symptoms of depression or the unpredictability caused by frequent alternation between periods of depression and hypomania must cause clinically significant distress or functional impairment. Bipolar II disorder is also rated as mild, moderate, or severe.

Table 39.6

**DSM-5 Diagnostic Criteria for a Hypomanic Episode**

A. A distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting at least 4 consecutive days and present most of the day, nearly every day.

B. During the period of mood disturbance and increased energy or activity, 3 (or more) of the following symptoms (4 if the mood is only irritable) have persisted, represent a noticeable change from usual behavior, and have been present to a significant degree:
   1. Inflated self-esteem or grandiosity.
   2. Decreased need for sleep (e.g., feels rested after only 3 hr of sleep).
   3. More talkative than usual or pressure to keep talking.
   4. Flight of ideas or subjective experience that thoughts are racing.
   5. Distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed.
   6. Increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation (i.e., purposeless non-goal-directed activity).
   7. Excessive involvement in activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments).

C. The episode is associated with an unequivocal change in functioning that is uncharacteristic of the individual when not symptomatic.

D. The disturbance in mood and the change in functioning are observable by others.
E. The disturbance is not severe enough to cause marked impairment in social or occupational functioning or to necessitate hospitalization. If there are psychotic features, the episode is, by definition, manic.

F. The episode is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, other treatment) or to another medical condition.

Note: A full hypomanic episode that emerges during antidepressant treatment (e.g., medication, electroconvulsive therapy) but persists at a fully syndromal level beyond the physiologic effect of that treatment is sufficient evidence for a hypomanic episode diagnosis. However, caution is indicated so that 1 or 2 symptoms (particularly increased irritability, edginess, or agitation following antidepressant use) are not taken as sufficient for diagnosis of a hypomanic episode, nor necessarily indicative of a bipolar diathesis.

Note: Criteria A-F constitute a hypomanic episode. Hypomanic episodes are common in bipolar I disorder but are not required for the diagnosis of bipolar I disorder.

**Cyclothymic disorder** is characterized by a period of at least 1 yr (in children and adolescents) in which there are numerous periods with hypomanic and depressive symptoms that do not meet criteria for a hypomanic episode or a major depressive episode, respectively.

Other specified/unspecified bipolar and related disorders (**subsyndromal bipolar disorder**) applies to presentations in which symptoms characteristic of a bipolar and related disorder are present and cause distress or functional impairment, but do not meet the full criteria for any of the disorders in this diagnostic class. Although this diagnosis (formerly known as “bipolar disorder, not otherwise specified”) had frequently been applied to children with severe and chronic mood and behavioral dysregulation who did not precisely fit other diagnostic categories, the empirical support for the validity of this practice has been sparse. Children who formerly received this diagnosis may meet criteria for DMDD (see Chapter 39.1).

In adolescents, the clinical manifestations of mania are similar to those in
adults, and psychosis (delusions, hallucinations) often is an associated symptom. Mood in a manic episode is often described as euphoric, excessively cheerful, high, or “feeling on top of the world.” During the episode, the adolescent may engage in multiple new projects that are initiated with little knowledge of the topic and often at unusual hours (middle of the night). Inflated self-esteem is usually present, ranging from uncritical self-confidence to marked grandiosity, and may reach delusional proportions. The adolescent may sleep little if at all for days and still feel rested and full of energy. Speech can be rapid, pressured, and loud and characterized by jokes, puns, amusing irrelevancies, and theatricality. Frequently there is a “flight of ideas,” evidenced by an almost continuous flow of accelerated speech, with abrupt shifts from one topic to another. Distractibility is evidenced by an inability to censor irrelevant extraneous stimuli, which often prevents an individual with mania from engaging in a rational conversation. The expansive mood, grandiosity, and poor judgment often lead to reckless involvement in activities with high potential for personal harm.

Controversy surrounds the applicability of the diagnostic criteria for mania to prepubertal children. It may be developmentally normal for children to be elated, expansive, grandiose, or talkative, reducing the specificity of these symptoms to this disorder. In addition, the distractibility, overactivity, impulsivity, and irritability formerly ascribed to bipolar disorder by some investigators may be better explained by a diagnosis of ADHD, with or without comorbid ODD. The presentation of severe and pervasive irritability formerly diagnosed as “bipolar disorder” may be better captured by the diagnosis of DMDD.

Epidemiology

The lifetime prevalence of bipolar disorder I among adults worldwide is approximately 0.6% for bipolar I disorder, 0.4% for bipolar II disorder, and 1.4% for subsyndromal bipolar disorder. Bipolar I disorder affects men and women equally, whereas bipolar II disorder is more common in women. Lifetime rates of mania among youth have ranged from 0.1% to 1.7%. Since the 1990s, there has been a significant increase in the diagnosis of bipolar disorder in the United States that was not mirrored in the United Kingdom. The estimated annual number of U.S. office-based visits of youth with a diagnosis of bipolar disorder increased from 25 per 100,000 population in 1994–1995 to 1,003/100,000 in 2002–2003. U.S. hospital discharge diagnoses increased from 1.4 to 7.3/10,000
in 9-13 yr old children and from 5.1 to 20.4/10,000 in 14-19 yr olds. These increases were not found in U.K. hospital discharges, questioning whether bipolar disorder was being overdiagnosed in the United States, with resultant increases in prescribing of antipsychotic and mood-stabilizing medications.

Clinical Course

The mean age of onset of the 1st manic episode is approximately 18 yr for bipolar I disorder. Premorbid problems are common in bipolar disorder, especially temperamental difficulties with mood and behavioral regulation. Premorbid anxiety also is common. The early course of adolescent-onset bipolar I disorder appears to be more chronic and refractory to treatment than adult-onset bipolar disorder. Comorbidity predicts functional impairment, and age at onset predicts duration of episodes. Sleep impairment and family conflict are inversely related to favorable treatment response, suggesting important targets for treatment. The bipolar disorders are highly recurrent, and 70–80% of bipolar I patients will have additional mood episodes. Recurrent episodes can approximate 4 in 10 years, with the interepisode interval shortening as the patient ages. Although the majority of patients with bipolar I return to a fully functional level between episodes, approximately one-third continue to be symptomatic and functionally impaired between episodes.

The initial presentation of bipolar I disorder is often an MDD. Switching from a depressive episode to a manic episode by adulthood may occur in 10–20% of youth, both spontaneously and during depression treatment. Factors that predict the eventual development of mania in depressed youth include a depressive episode characterized by rapid onset, psychomotor retardation, and psychotic features; a family history of affective disorders, especially bipolar disorder; and a history of mania or hypomania after antidepressant therapy.

The mean age of onset of bipolar II disorder is 20 yr. The illness most often begins with a depressive episode and is not recognized as bipolar II disorder until a hypomanic episode occurs, in about 12% of individuals with the initial diagnosis of major depression. Many individuals experience several episodes of major depression before experiencing the first recognized hypomanic episode. Anxiety, substance misuse, or eating disorders may also precede the onset of bipolar II, complicating its detection. About 5–15% of individuals with bipolar II disorder will ultimately develop a manic episode, which changes the diagnosis to bipolar I disorder.
Depression in bipolar I or II usually has an earlier age of onset, more frequent episodes of shorter duration, an abrupt onset and offset, is linked to comorbid substance misuse, and is triggered by stressors. Atypical symptoms such as hypersomnia, lability, and weight instability are also common in bipolar depression, reported in up to 90% of cases vs 50% in unipolar depression. Psychosis, psychomotor retardation, and catatonia are also more characteristic of bipolar depression, whereas somatic complaints are more frequent in unipolar depression. A family history of mania is also a relevant discriminating factor.

Provision of clinical services is poor for youth with bipolar disorder. In one healthcare system study spanning 2 yr follow-up after diagnosis, despite complex drug regimens, medication appointments were infrequent, averaging 1 visit every 2 mo. More than half of patients needed 1 or more hospitalizations, and almost half had psychiatric emergency department visits. In a national study, 38% of youths diagnosed with bipolar disorder had received no treatment at all.

**Differential Diagnosis**

Numerous psychiatric disorders, general medical conditions, and medications can generate manic-like symptoms and must be distinguished from the bipolar and related disorders. The psychiatric disorders include ADHD, ODD, and intermittent explosive, posttraumatic stress, depressive, anxiety, substance abuse, and borderline personality disorders. Medical conditions include neurologic disorders, endocrine disorders, infectious diseases, tumors, anemia, uremia, and vitamin deficiencies. Medications include androgens, bronchodilators, cardiovascular medications, corticosteroids, chemotherapy agents, thyroid preparations, and certain psychiatric medications (benzodiazepines, antidepressants, stimulants). The diagnosis of a bipolar disorder should be made after these other explanations for the observed symptoms have been ruled out.

For bipolar II disorder, the main differential is unipolar depression (MDD) or cyclothymic disorder.

**Comorbidity**

The most common simultaneous comorbidities (ADHD, ODD, conduct disorder, anxiety) may be difficult to distinguish from mania because of considerable symptom overlap. Substance use also is a common comorbidity in adolescents,
and presentations that appear to be manic may remit when the substances of abuse are discontinued.

**Sequelae**

The lifetime risk of suicide in individuals with bipolar disorder is estimated to be at least 15 times that of the general population. Factors associated with suicide attempts include female gender, young age at illness onset, depressive polarity of first illness episode or of current or most recent episode, comorbid anxiety disorder, any comorbid substance use disorder, borderline personality disorder, and first-degree family history of suicide. By contrast, completed suicides are associated with male sex and a first-degree family history of suicide. Despite patients with bipolar disorder having normal or even superior cognition before diagnosis, bipolar disorder has been associated with decrements in executive function and verbal memory. Youths with bipolar disorder are also at high risk for substance abuse, antisocial behavior, impaired academic performance, impaired family and peer relationships, and poor adjustment to life stressors.

**Etiology and Risk Factors**

Twin studies of adults suggest the heritability of bipolar disorder may be 60–90%, while shared and unique environmental factors may account for 30–40% and 10–20%, respectively. Offspring of parents with bipolar disorders are at high risk for early-onset bipolar disorders as well as anxiety and behavioral disorders and mood dysregulation. There is an average 10-fold increased risk among adult relatives of individuals with bipolar disorder, with the magnitude of risk increasing with the degree of kinship. Bipolar disorder and schizophrenia likely share a genetic origin, reflected in familial co-aggregation of the two disorders.

Studies to date suggest key roles for the amygdala, anterior paralimbic cortices, and their connections in the emotional dysregulation of bipolar disorder. Some of these abnormalities are apparent by adolescence, whereas others appear to progress over adolescence into young adulthood.

*Dysthymic* (sad), *cyclothymic* (labile), or *hyperthymic* (irritable) temperaments may presage eventual bipolar disorder. Premorbid anxiety and dysphoria also are common. Environmental factors such as irritable and negative parenting styles,
physical and sexual abuse, poor social support, and prenatal alcohol exposure may interact with genetic vulnerability to produce early onset of bipolar illness as well as negative prognostic indicators. *Affective lability* in particular has been associated with high levels of childhood trauma, and gradual sensitization to stressors has been linked to episode recurrence.

**Prevention**

Although empirical support is sparse, one study demonstrated the effectiveness of family-focused treatment vs an educational control in hastening and sustaining recovery from mood symptoms in a high-familial-risk cohort of youths with subsyndromal symptoms of mania. Family-focused treatment is a manualized psychoeducational intervention designed to reduce family stress, conflict, and affective arousal by enhancing communication and problem solving between youths and their caregivers. Pharmacologic interventions for subsyndromal mania have produced equivocal results.

**Case Finding**

Cardinal manic symptoms of elation, increased energy, and grandiosity occurring in adolescents as a discrete episode representing an unequivocal and uncharacteristic change in functioning should alert pediatric practitioners to the possibility of bipolar disorder. High scores on parent-completed versions of mania-specific rating scales (e.g., *General Behavior Inventory, Child Mania Rating Scale, Young Mania Rating Scale*) have been associated with increased likelihood of a bipolar diagnosis. However, in general, screening tools for bipolar disorder have suboptimal psychometric properties when applied to young people. Because of the complexity of diagnosing and treating bipolar disorders, any suspected cases should be referred to the specialty mental health setting for comprehensive assessment and treatment.

**Treatment**

For mania in bipolar I disorder, medication is the primary treatment. Studies have demonstrated the superiority of antipsychotics over mood stabilizers in the treatment of mania, with haloperidol, risperidone, and olanzapine ranked as the
most efficacious agents and quetiapine, risperidone, and olanzapine ranked as the most tolerable agents. Taken together, risperidone and olanzapine may have the best overall efficacy and tolerability. Asenapine has also been found to be effective and well tolerated. The FDA has approved aripiprazole, risperidone, quetiapine, and asenapine for the treatment of bipolar disorder from age 10 yr, and olanzapine from age 13 years. The choice of antipsychotic medication is based on factors such as side effect profiles, comorbidities, adherence, and positive response of a family member.

Among traditional mood stabilizers, only lithium is FDA approved for the treatment of bipolar disorder from age 12 yr, and its efficacy and tolerability compared to placebo has been demonstrated in RCTs. There also is meta-analytic evidence that lithium reduces the risk of suicide and total deaths in patients with both unipolar and bipolar depressive disorder.

No published RCT evidence supports the efficacy of other mood stabilizers (e.g., divalproex sodium, topiramate, carbamazepine, oxcarbazepine, lamotrigine) in the treatment of youth with bipolar disorder, and retrospective cohort studies suggest that those who receive antipsychotics are less likely to discontinue treatment and less likely to receive treatment augmentation than youth who receive mood stabilizers. None of the mood-stabilizing medications (other than lithium) have FDA approval for the treatment of bipolar disorder in youth, and as such, likely should not be first-line treatments.

Medication trials should be systematic and their duration sufficient (generally 6-8 wk) to determine the agent’s effectiveness. Care should be taken to avoid unnecessary polypharmacy, in part by discontinuing agents that have not demonstrated significant benefit. Because these medications are associated with significant side effects, careful monitoring of baseline and follow-up indices is imperative.

The regimen needed to stabilize acute mania should be maintained for 12-24 mo. Maintenance therapy is often needed for adolescents with bipolar I disorder, and some patients need lifelong medication. Any attempts to discontinue prophylactic medication should be done gradually while closely monitoring the patient for relapse.

Antidepressants alone should not be prescribed for depressive symptoms in bipolar I disorder because of the risk of manic switch. However, in an RCT, olanzapine/fluoxetine combination was superior to placebo in youth with depression in bipolar I and has been FDA approved for this indication in patients age 10-17 yr. For treatment of depression in bipolar II, antidepressant medication
(preferably SSRIs or bupropion) may be used cautiously. Comorbid ADHD can be treated with a stimulant once a mood-stabilizer has been initiated.

**Psychotherapy** is a potentially important adjunctive treatment for the bipolar disorders. Therapies with some evidence of efficacy, primarily as adjunctive to pharmacotherapy, include multifamily psychoeducational psychotherapy and family-focused treatment (probably efficacious), child and family-focused CBT (possibly efficacious), dialectical behavioral therapy, and interpersonal and social rhythm therapy (experimental). Active components of these therapies include family involvement and psychoeducation, along with self-regulation, cognitive restructuring, communication, problem-solving, and emotion regulation skills. Factors that adversely influence response to therapy include high-conflict families and sleep impairment, suggesting the importance of targeting these factors in treatment.

**Level of Care**

Most youths with bipolar disorders can be safely and effectively treated as outpatients, provided that an appropriate schedule of visits and laboratory monitoring can be maintained through the course of treatment. Youths who are suicidal or psychotic typically require inpatient care.

**Bibliography**

Goldstein TR, Ha W, Axelson DA, et al. Predictors of

Vande Voort JL, Singh A, Bernardi J, et al. Treatments and

Youth suicide is a major public health problem. In 2014 for all youth between ages 10 and 19 yr in the United States, suicide was the 2nd leading cause of death, with approximately 5,500 lives lost each year. The suicide rate for youth age 15-19 yr was 9.8 per 100,000 persons (14.2 for males, 5.1 for females), while the rate for youth age 10-14 yr was 2.0/100,000 (2.4 for males, 1.6 for females). There are numerous psychiatric, social, cultural, and environmental risk factors for suicidal behavior, and knowledge of these risk factors can facilitate identification of youths at highest risk (Fig. 40.1).
Epidemiology

Suicidal Ideation and Attempts

Based on the 2015 Youth Risk Behavior Survey, almost one third of 9th through 12th grade students in the United States felt so sad or hopeless almost every day for ≥2 wk in a row during the previous year that they stopped doing usual activities. During that same period, 18% of the students reported that they had seriously considered attempting suicide, and 9% reported that they had actually attempted suicide one or more times. A suicide attempt in the previous year that resulted in an injury, poisoning, or overdose that had to be treated by a physician.
or nurse was reported by 3% of students.

It is estimated that for every completed youth suicide, as many as 200 suicide attempts are made. Poisoning, suffocation, and firearms are the most common causes of suicide, whereas ingestion of medication is the most common method of attempted suicide (Fig. 40.2). The 15-19 yr old age-group is the most likely to intentionally harm themselves by ingestion, receive treatment in the emergency department (ED), and survive. Attempts are more common in adolescent females than males (approximately 3 : 1-4 : 1) and in Hispanic females than their non-Hispanic counterparts. Gay, lesbian, bisexual, transgender, and bullied youths also have disproportionately high rates of suicide attempts. Attempters who have made prior suicide attempts, who used a method other than ingestion, who have a plan (nonimpulsive), who have no regret, and who still want to die are at increased risk for completed suicide.
Suicide Completions

In the United States, completed suicide is very rare before age 10. Rates of completed suicide increase steadily across adolescence into young adulthood, peaking in the early 20s. The male:female ratio for completed suicide rises with age from 3 : 1 in children to approximately 4 : 1 in 15-24 yr olds, and to >6 : 1 among 20-24 yr olds.

In 2015 among 10-19 yr olds, the highest suicide rates, 21.8 and 16.6 per 100,000, were among Native American males and females, respectively, followed by white males (10.6/100,000). The groups with the lowest rates were Asian/Pacific Islander females, Hispanic females, and black females (2.4, 2.3, and 1.9/100,000, respectively). **Firearms** are the most common method used to complete suicide in the United States, accounting for 50% of all suicide deaths in 2015 (Fig. 40.2). The next most prevalent methods are **suffocation** (27%) and **poisoning** (15%). Firearms are the most lethal method of suicide completion; the death rate with respect to firearms is approximately 80–90%, whereas the death rate is only 1.5–4% for overdoses. Among males, firearms are the most frequently used method of suicide (55%); among females, poisoning is the most common method (34%).

From 1999 through 2014, the age-adjusted suicide rate in the United States increased 24%, from 10.5 to 13.0/100,000, with the pace of increase greater after 2006. Rates increased for both males and females and for all ages 10-74; the percent increase among females was greatest for those age 10-14, and for males, those age 45-64.

Risk Factors

In addition to age, race/ethnicity, and a history of a previous suicide attempt, multiple risk factors predispose youths to suicide (see Fig. 40.1).

Preexisting Mental Disorder

Approximately 90% of youths who complete suicide have a preexisting psychiatric illness, most often major depression. Among females, chronic anxiety, especially panic disorder, also is associated with suicide attempts and completion. Among males, conduct disorder and substance use convey increased risk. Comorbidity of a substance use disorder, a depressive disorder, and conduct
disorder are linked to suicide by firearm. Schizophrenia spectrum disorders are linked to suicide attempts and completions.

**Cognitive Distortions**

Negative self-attributions can contribute to the hopelessness typically associated with suicidality; hopelessness may contribute to approximately 55% of the explained variance in continued suicidal ideation. Many youth who are suicidal hold negative views of their own competence, have poor self-esteem, engage in catastrophic thinking, and have difficulty identifying sources of support or reasons to live. Many young people lack the coping strategies necessary to manage strong emotions and instead tend to *catastrophize* and engage in *all-or-nothing* thinking.

**Biologic Factors**

Postmortem studies show observable differences between the brains of individuals who have completed suicide and those who died from other causes. The brain systems that may be related to suicide completion are the serotonergic system, adrenergic system, and the hypothalamic-pituitary axis. Family history of mental disorders also is linked to completed suicide.

**Social, Environmental, and Cultural Factors**

Of youths who attempt suicide, 65% can name a precipitating event for their action. Most adolescent suicide attempts are precipitated by *stressful life events* (e.g., academic or social problems; being bullied; trouble with the law; questioning one's sexual orientation or gender identify; newly diagnosed medical condition; recent or anticipated loss).

Suicide attempts may also be precipitated by exposure to news of another person's suicide or by reading about or viewing a suicide portrayed in a romantic light in the media. Media coverage of suicide is linked to fluctuating incidence rates of suicides, particularly among adolescents. Glorification or sensationalization of suicide in the media has found to be associated with an increase in suicides. When media coverage includes a detailed description of specific means used, the use of that particular method may increase in the overall population.
For some immigrants, suicidal ideation can be associated with high levels of acculturative stress, especially in the context of family separation and limited access to supportive resources. Physical and sexual abuse can also increase one's risk of suicide, with 15–20% of female suicide attempters having had a history of abuse. The general association between family conflict and suicide attempts is strongest in children and early adolescents. Family psychopathology and a family history of suicidal behavior also convey excess risk. The lack of supportive social relations with peers, parents, and school personnel interacts in increasing the risk of suicide among youth.

**Protective Factors**

Protective factors can provide a counterbalance for those contemplating suicide. These may include a sense of family responsibility, life satisfaction, future orientation, social support, coping and problem-solving skills, religious faith, intact reality testing, and solid therapeutic relationships (e.g., pediatrician, teacher, therapist).

**Assessment and Intervention**

The U.S. Preventive Services Task Force has concluded that there is insufficient evidence to recommend universal suicide screening in the primary care setting for children and adolescents. Pediatric practitioners should consider suicide potential and the need for mental health assessment in the context of concerning information elicited in child/parent psychosocial histories (e.g., HEADSS Psychosocial Risk Assessment; see Chapter 32, Table 32.2), general screening measure scores out of the normal range (e.g., Pediatric Symptom Checklist Internalizing Sub-Scale; see Chapter 28), or self-reported statements or behaviors from patients and parents.

All suicidal ideation and attempts should be taken seriously and require a thorough assessment by a child-trained mental health clinician to evaluate the youth's current state of mind, underlying psychiatric conditions, and ongoing risk of harm. **Emergency** mental health assessment is needed for immediate threat to self (i.e., suicidal intent and plan); **urgent** mental health assessment (48-72 hr) is needed for severe psychiatric symptoms, significant change in overall functioning, and suicidal ideation without intent or plan. **Routine** mental health assessment is appropriate for mild to moderate psychiatric symptoms without
suicidal ideation.

Pediatric practitioners should expect the mental health clinician to evaluate the presence and degree of suicidality and underlying risk factors. The reliability and validity of child interviewing are affected by children's level of cognitive development as well as their understanding of the relationship between their emotions and behavior. Confirmation of the youth’s suicidal behavior can be obtained from information gathered by interviewing others who know the child or adolescent. A discrepancy between patient and parent reports is not unusual, with both children and adolescents being more likely to disclose suicidal ideation and suicidal actions than their parents.

In the mental health assessment, suicidal ideation can be assessed by explicit questions posed in a nonjudgmental, noncondescending, matter-of-fact approach. The *Ask Suicide-Screening Questionnaire* (ASQ) is a validated 4-item measure shown in the ED setting to have high sensitivity and negative predictive value in identifying youth at risk for suicide ideation and behavior: (1) “In the past few weeks, have you felt that you or your family would be better off if you were dead?” (2) “In the past few weeks, have you wished you were dead?” (3) “In the past few weeks, have you been having thoughts about killing yourself?” and (4) “Have you ever tried to kill yourself?” If a “yes” response is given to any of these 4 questions, the patient is asked, (5) “Are you having thoughts of killing yourself right now?” Another common screening test is the *Columbia Suicide Severity Rating Scale* (C-SSRS) Screener (Table 40.1).

Response Protocol to Screening (based on last item answered “Yes”)

Item 1— Mental Health Referral at discharge
Item 2— Mental Health Referral at discharge
Item 3— Care Team Consultation (Psychiatric Nurse) and Patient Safety Monitor/Procedures
Item 4— Psychiatric Consultation and Patient Safety Monitor/Procedures
Item 5— Psychiatric Consultation and Patient Safety Monitor/Procedures
Item 6— If over 3 months ago, Mental Health Referral at discharge
   If 3 months ago or less, Psychiatric Consultation and Patient Safety Monitor

The assessment of a suicidal attempt should include a detailed exploration of the hours immediately preceding the attempt to identify precipitants as well as the circumstances of the attempt itself, to understand fully the patient's intent and potential lethality. The calculation of the level of suicide concern is complex, requiring a determination across a spectrum of risk. At the low end of the risk spectrum are youth with thoughts of death or wanting to die, but without suicidal thoughts, intent, or plan. Those with highly specific suicide plans, preparatory acts or suicide rehearsals, and clearly articulated intent are at the high end. A suicidal history, presently impaired judgment (as seen in altered mental states including depression, mania, anxiety, intoxication, substance abuse, psychosis, trauma-reactive, hopelessness, rage, humiliation, impulsivity), as well as poor social support, further exacerbates the heightened risk. Among adolescents who consider self-harm, those who carry out (enactors) self-injury are more likely to have family or friends (or think that their peers) engaged in self-harm, and are more impulsive than those who only have thoughts of self-harm (ideators).

For youth who are an imminent danger to themselves (i.e., have active [“I want
inpatient level of psychiatric care is necessary to ensure safety, clarify diagnoses, and comprehensively plan treatment. These patients can be hospitalized voluntarily or involuntarily. It is helpful for the pediatric practitioner to have an office protocol to follow in these situations. This protocol should take into consideration state laws regarding involuntary hospitalization, transportation options, nearest emergency assessment site, necessary forms for hospitalization, and available emergency mental health consultants.

For those youth suitable for treatment in the outpatient setting (e.g., suicidal ideation without intent, intact mental status, few or no other risk factors for suicidality, willing and able to participate in outpatient treatment; has caregivers able to provide emotional support, supervision, safeguarding, and adherence to follow-up), an appointment should be scheduled within a few days with a mental health clinician. Ideally, this appointment should be scheduled before leaving the assessment venue, because almost 50% of those who attempt suicide fail to follow through with the mental health referral. A procedure should be in place to contact the family if the family fails to complete the referral.

Through follow-up office visits, pediatric practitioners can help support and facilitate the implementation of psychotherapies (e.g., cognitive-behavioral therapy, dialectical behavioral therapy, mentalization-based treatment, family therapy) that target the specific psychiatric disorders and the emotional dysphoria or behavioral dysregulation that accompany suicidal ideation or behavior. In conjunction with a child and adolescent child psychiatrist, psychotropic medications may be used as indicated to treat underlying psychiatric disorders. Pediatric practitioners also can encourage social connectedness to peers and to community organizations (e.g., school or church), as well as promote help-seeking (e.g., talking to a trusted adult when distressed) and wellness (e.g., sleep, exercise, relaxation, nutrition) behaviors. In the event of a completed suicide, pediatricians can offer support to the family, particularly by monitoring for adverse bereavement responses in siblings and parents.

**Prevention**

The aforementioned risk factors associated with suicide are relatively common and individually not strong predictors of suicide. The assessment is complicated by patients who may attempt to conceal their suicide thoughts and by those who express suicidal thoughts without serious intent. Suicide screening has been
challenging because most screening instruments have variable sensitivity and specificity. In addition, the burden of follow-up mental health evaluations for those who screen positive has been daunting. Although primary care–feasible screening tools may be help to identify some adults at increased risk for suicide, they have, to date, demonstrated limited ability to detect suicide risk in adolescents.

Prevention strategies in the pediatric medical home include training staff to recognize and respond to the warning signs of suicide (Table 40.2), screening for and treating depression, educating patients/parents about warning signs for suicide, and restricting access to modes of lethal self-harm. Young people have increased rates of suicide attempts and completions if they live in homes where firearms are present and available. When recommended by their primary care providers, most parents restrict access of their children to guns and medications. Pediatric practitioners should consider counseling parents to remove firearms from the home entirely or securely lock guns and ammunition in separate locations. Anecdotal evidence suggests youths frequently know where guns and keys to gun cabinets are kept, even though parents may think they do not. The same recommendation applies to restricting access to potentially lethal prescription and nonprescription medications (e.g., containers of >25 acetaminophen tablets) and alcohol. These approaches emphasize the importance of restriction of access to means for suicide to prevent self-harm.

### Table 40.2

**Warning Signs of Suicide**

Seek help as soon as possible by contacting a mental health professional or by calling the National Suicide Prevention Lifeline at **1-800-273-TALK** if you or someone you know exhibits any of the following signs:

- Threatening to hurt or kill oneself or talking about wanting to hurt or kill oneself.
- Looking for ways to kill oneself by seeking access to firearms, available pills, or other means.
- Talking or writing about death, dying, or suicide when these actions are out of the ordinary for the person.
- Feeling hopeless.
- Feeling rage or uncontrolled anger or seeking revenge.
• Acting reckless or engaging in risky activities, seemingly without thinking.
• Feeling trapped, “like there's no way out.”
• Increasing alcohol or drug use.
• Withdrawing from friends, family, and society.
• Feeling anxious, agitated, or unable to sleep, or sleeping all the time.
• Experiencing dramatic mood changes.
• Seeing no reason for living, or having no sense of purpose in life.

Screening for suicide in schools is also fraught with problems related to low specificity of the screening instrument and paucity of referral sites, as well as poor acceptability among school administrators. **Gatekeeper** (e.g., student support personnel) training appears effective in improving skills among school personnel and is highly acceptable to administrators but has not been shown to prevent suicide. School curricula (e.g., Signs of Suicide) have shown some preventive potential by teaching students to recognize the signs of depression and suicide in themselves and others and providing them with specific action steps necessary for responding to these signs. Peer helpers have not generally been shown to be efficacious.

CHAPTER 41

Eating Disorders

Richard E. Kreipe, Taylor B. Starr

Eating disorders (EDs) are characterized by body dissatisfaction related to overvaluation of a thin body ideal, associated with dysfunctional patterns of cognition and weight control behaviors that result in significant biologic, psychological, and social complications. Although usually affecting white, adolescent females, EDs also affect males and cross all racial, ethnic, and cultural boundaries. Early intervention in EDs improves outcome.

Definitions

Anorexia nervosa (AN) involves significant overestimation of body size and shape, with a relentless pursuit of thinness that, in the restrictive subtype, typically combines excessive dieting and compulsive exercising. In the binge-purge subtype, patients might intermittently overeat and then attempt to rid themselves of calories by vomiting or taking laxatives, still with a strong drive for thinness (Table 41.1).

Table 41.1

**DSM-5 Diagnostic Criteria for Anorexia Nervosa**

A. Restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as a weight that is less than minimally normal or, for children and adolescents, less than that minimally expected.
B. Intense fear of gaining weight or of becoming fat, or persistent behavior that interferes with weight gain, even though at a significantly low weight.

C. Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of the current low body weight.

Specify whether:

**Restricting type** (ICD-10-CM code F50.01): During the last 3 mo, the individual has not engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas). This subtype describes presentations in which weight loss is accomplished primarily through dieting, fasting, and/or excessive exercise.

**Binge-eating/purging type** (ICD-10-CM code F50.02): During the last 3 mo, the individual has engaged in recurrent episodes of binge eating or purging behavior (i.e., self-induced vomiting or the misuse of laxatives, diuretics, or enemas).

Specify if:

**In partial remission**: After full criteria for anorexia nervosa were previously met, Criterion A (low body weight) has not been met for a sustained period, but either Criterion B (intense fear of gaining weight or becoming fat or behavior that interferes with weight gain) or Criterion C (disturbances in self-perception of weight and shape) is still met.

**In full remission**: After full criteria for anorexia nervosa were previously met, none of the criteria has been met for a sustained period of time.

Specify current severity:

The minimum level of severity is based, for adults, on current body mass index (BMI) (see below) or, for children and adolescents, on BMI percentile. The ranges below are derived from World Health Organization categories for thinness in adults; for children and adolescents, corresponding BMI percentiles should be used. The level of severity may be increased to reflect clinical symptoms, the degree of functional disability, and the need for supervision.
**Mild**: BMI ≥ 17 kg/m²  
**Moderate**: BMI 16-16.99 kg/m²  
**Severe**: BMI 15-15.99 kg/m²  
**Extreme**: BMI < 15 kg/m²

**Bulimia nervosa (BN)** is characterized by episodes of eating large amounts of food in a brief period, followed by compensatory vomiting, laxative use, exercise, or fasting to rid the body of the effects of overeating in an effort to avoid obesity *(Table 41.2)*.

**Table 41.2**

**DSM-5 Diagnostic Criteria for Bulimia Nervosa**

A. Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
   1. Eating, in a discrete period of time (e.g., within any 2 hr period), an amount of food that is definitely larger than what most individuals would eat in a similar period of time under similar circumstances.
   2. A sense of lack of control over eating during the episode (e.g., a feeling that one cannot stop eating or control what or how much one is eating).

B. Recurrent inappropriate compensatory behaviors in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, or other medications; fasting; or excessive exercise.

C. The binge eating and inappropriate compensatory behaviors both occur, on average, at least once a week for 3 mo.

D. Self-evaluation is unduly influenced by body shape and weight.

E. The disturbance does not occur exclusively during episodes of anorexia nervosa.
Specify if:

**In partial remission**: After full criteria for bulimia nervosa were previously met, some, but not all, of the criteria have been met for a sustained period of time.

**In full remission**: After full criteria for bulimia nervosa were previously met, none of the criteria has been met for a sustained period of time.

Specify current severity:

The minimum level of severity is based on the frequency of inappropriate compensatory behaviors (see below). The level of severity may be increased to reflect other symptoms and the degree of functional disability.

- **Mild**: An average of 1-3 episodes of inappropriate compensatory behaviors per week.
- **Moderate**: An average of 4-7 episodes of inappropriate compensatory behaviors per week.
- **Severe**: An average of 8-13 episodes of inappropriate compensatory behaviors per week.
- **Extreme**: An average of 14 or more episodes of inappropriate compensatory behaviors per week.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (Copyright 2013). American Psychiatric Association, p 345.

Children and adolescents with EDs may not fulfill criteria for AN or BN in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) and may fall into a subcategory of **atypical anorexia nervosa**, or a more appropriately defined category of **avoidant/restrictive food intake disorder** (**ARFID**). In these conditions, food intake is restricted or avoided because of adverse feeding or eating experiences or the sensory qualities of food, resulting in significant unintended weight loss or nutritional deficiencies and problems with social interactions (Table 41.3).

**Table 41.3**

**DSM-5 Diagnostic Criteria for Avoidant/Restrictive Food Intake Disorder**
A. An eating or feeding disturbance (e.g., apparent lack of interest in eating or food; avoidance based on the sensory characteristics of food; concern about aversive consequences of eating) as manifested by persistent failure to meet appropriate nutritional and/or energy needs associated with one (or more) of the following:
   1. Significant weight loss (or failure to achieve expected weight gain or faltering growth in children).
   2. Significant nutritional deficiency.
   3. Dependence on enteral feeding or oral nutritional supplements.
   4. Marked interference with psychosocial functioning.
B. The disturbance is not better explained by lack of available food or by an associated culturally sanctioned practice.
C. The eating disturbance does not occur exclusively during the course of anorexia nervosa or bulimia nervosa, and there is no evidence of a disturbance in the way in which one's body weight or shape is experienced.
D. The eating disturbance is not attributable to a concurrent medical condition or not better explained by another mental disorder. When the eating disturbance occurs in the context of another condition or disorder, the severity of the eating disturbance exceeds that routinely associated with the condition or disorder and warrants additional clinical attention.

Specify if:

**In remission**: After full criteria for avoidant/restrictive food intake disorder were previously met, the criteria have not been met for a sustained period of time.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 334.

**Binge eating disorder (BED)**, in which binge eating is not followed regularly by any compensatory behaviors (vomiting, laxatives), is a stand-alone category in DSM-5 but shares many features with obesity (see Chapter 60). **Eating disorder–not otherwise specified (ED-NOS)**, often called “disordered eating,” can worsen into full syndrome EDs.
Epidemiology

The classic presentation of AN is an early to middle adolescent female of above-average intelligence and socioeconomic status who is a conflict-avoidant, risk-aversive perfectionist and is struggling with disturbances of anxiety and/or mood. BN tends to emerge in later adolescence, sometimes evolving from AN, and is typified by impulsivity and features of borderline personality disorder associated with depression and mood swings. The 0.5–1% and 3–5% incidence rates among younger and older adolescent females for AN and BN, respectively, probably reflect ascertainment bias in sampling and underdiagnosis in cases not fitting the common profile. The same may be true of the significant gender disparity, in which female patients account for approximately 85% of patients with diagnosed EDs. In some adolescent female populations, ≥10% have ED-NOS.

No single factor causes the development of an ED; sociocultural studies indicate a complex interplay of culture, ethnicity, gender, peers, and family. The gender dimorphism is presumably related to females having a stronger relationship between body image and self-evaluation, as well as the influence of the Western culture’s thin body ideal. Race and ethnicity appear to moderate the association between risk factors and disordered eating, with African American and Caribbean females reporting lower body dissatisfaction and less dieting than Hispanic and non-Hispanic white females. Because peer acceptance is central to healthy adolescent growth and development, especially in early adolescence, when AN tends to have its initial prevalence peak, the potential influence of peers on EDs is significant, as are the relationships among peers, body image, and eating. Teasing by peers or by family members (especially males) may be a contributing factor for overweight females.

Family influence in the development of EDs is even more complex because of the interplay of environmental and genetic factors; shared elements of the family environment and immutable genetic factors account for approximately equal amounts of the variance in disordered eating. There are associations between parents' and children's eating behaviors; dieting and physical activity levels suggest parental reinforcement of body-related societal messages. The influence of inherited genetic factors on the emergence of EDs during adolescence is also significant, but not directly. Rather, the risk for developing an ED appears to be mediated through a genetic predisposition to anxiety (see Chapter 38), depression (see Chapter 39), or obsessive-compulsive traits that may be
modulated through the internal milieu of puberty. There is no evidence to support the outdated notion that parents or family dynamics cause an ED. Rather, the family dynamics may represent responses to having a family member with a potentially life-threatening condition. The supportive influence on recovery of parents as nurturing caregivers cannot be overestimated.

Pathology and Pathogenesis

The emergence of EDs coinciding with the processes of adolescence (e.g., puberty, identity, autonomy, cognition) indicates the central role of development. A history of sexual trauma is not significantly more common in EDs than in the population at large, but when present makes recovery more difficult and is more common in BN. EDs may be viewed as a final common pathway, with a number of predisposing factors that increase the risk of developing an ED, precipitating factors often related to developmental processes of adolescence triggering the emergence of the ED, and perpetuating factors that cause an ED to persist. EDs often begin with dieting but gradually progress to unhealthy habits that lessen the negative impact of associated psychosocial problems to which the affected person is vulnerable because of premorbid biologic and psychological characteristics, family interactions, and social climate. When persistent, the biologic effects of starvation and malnutrition (e.g., true loss of appetite, hypothermia, gastric atony, amenorrhea, sleep disturbance, fatigue, weakness, depression), combined with the psychological rewards of increased sense of mastery and reduced emotional reactivity, actually maintain and reward pathologic ED behaviors.

This positive reinforcement of behaviors and consequences, generally viewed by parents and others as negative, helps to explain why persons with an ED characteristically deny that a problem exists and resist treatment. Although noxious, purging can be reinforcing because of a reduction in anxiety triggered by overeating; purging also can result in short-term, but reinforcing, improvement in mood related to changes in neurotransmitters. In addition to an imbalance in neurotransmitters, most notably serotonin and dopamine, alterations in functional anatomy also support the concept of EDs as brain disorders. The cause-and-effect relationship in central nervous system (CNS) alterations in EDs is not clear, nor is their reversibility.
Clinical Manifestations

Except for ARFID, in which weight loss is *unintentional*, a central feature of EDs is the overestimation of body size, shape, or parts (e.g., abdomen, thighs) leading to intentional weight control practices to reduce weight (AN) or prevent weight gain (BN). Associated practices include severe restriction of caloric intake and behaviors intended to reduce the effect of calories ingested, such as compulsive exercising or purging by inducing vomiting or taking laxatives. Eating and weight loss habits commonly found in EDs can result in a wide range of energy intake and output, the balance of which leads to a wide range in weight, from extreme loss of weight in AN to fluctuation around a normal to moderately high weight in BN. Reported eating and weight control habits thus inform the initial primary care approach (Table 41.4).

### Table 41.4
Eating and Weight Control Habits Commonly Found in Children and Adolescents With an Eating Disorder (ED)

<tr>
<th>Beverages</th>
<th>Water or other low- or no-calorie drinks; nonfat milk</th>
<th>Variable, diet soda common; may drink alcohol to excess</th>
<th>Fluids often restricted to avoid weight gain</th>
<th>Fluids ingested to aid vomiting or replace losses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Meals</td>
<td>Consistent schedule and structure to meal plan. Reduced or eliminated caloric content, often starting with breakfast, then lunch, then dinner. Volume can increase with fresh fruits, vegetables, and salads as primary food sources.</td>
<td>Meals less regimented and planned than in AN; more likely impulsive and unregulated, often eliminated following a binge-purge episode.</td>
<td>Rigid adherence to “rules” governing eating leads to sense of control, confidence, and mastery.</td>
<td>Elimination of a meal following a binge-purge only reinforces the drive for binge later in the day.</td>
</tr>
<tr>
<td>Snacks</td>
<td>Reduced or eliminated from meal plan.</td>
<td>Often avoided in meal plans, but then impulsively eaten.</td>
<td>Snack foods removed early because “unhealthy”.</td>
<td>Snack “comfort foods” can trigger a binge.</td>
</tr>
<tr>
<td>Dieting</td>
<td>Initial dieting gives way to chaotic eating, often interpreted by the patient as evidence of being “weak” or “lazy”.</td>
<td>Initial dieting gives way to chaotic eating, often interpreted by the patient as evidence of being “weak” or “lazy”.</td>
<td>Distinguishing between healthy meal planning with reduced calories and dieting in ED may be difficult.</td>
<td>Dieting tends to be impulsive and short-lived, with “diets” often resulting in unintended weight gain.</td>
</tr>
<tr>
<td>Binge eating</td>
<td>None in restrictive subtype, but an essential feature in binge-purge subtype.</td>
<td>Essential feature, often secretive. Shame and guilt prominent afterward.</td>
<td>Often “subjective” (more than planned but not large).</td>
<td>Relieves emotional distress, may be planned.</td>
</tr>
<tr>
<td>Exercise</td>
<td>Characteristically obsessive-compulsive, ritualistic, and progressive. May excel in dance, long-distance running.</td>
<td>Less predictable. May be athletic, or may avoid exercise entirely.</td>
<td>May be difficult to distinguish active thin vs ED.</td>
<td>Males often use exercise as means of “purging”.</td>
</tr>
<tr>
<td>Vomiting</td>
<td>Characteristic of binge-purge subtype. May chew, then spit out, rather than.</td>
<td>Most common habit intended to reduce effects of.</td>
<td>Physiologic and emotional instability prominent.</td>
<td>Strongly “addictive” and self-punishing, but does not eliminate calories.</td>
</tr>
</tbody>
</table>
Swallowing food as a variant of overeating can occur after a meal as well as a binge, many still ingested—many still absorbed.

Laxatives
- If used, generally to relieve constipation in restrictive subtype, but as a cathartic in binge-purge subtype
- Second most common habit used to reduce or avoid weight gain, often used in increasing doses for cathartic effect
- Physiologic and emotional instability prominent
- Strongly “addictive,” self-punishing, but ineffective means to reduce weight (calories are absorbed in small intestine, but laxatives work in colon)

Diet pills
- Very rare, if used; more common in binge-purge subtype
- Used to either reduce appetite or increase metabolism
- Use of diet pills implies inability to control eating
- Control over eating may be sought by any means

AN, Anorexia nervosa; BN, bulimia nervosa.

Although weight control patterns guide the initial pediatric approach, an assessment of common symptoms and findings on physical examination is essential to identify targets for intervention. When reported symptoms of excessive weight loss (feeling tired and cold; lacking energy; orthostasis; difficulty concentrating) are explicitly linked by the clinician to their associated physical signs (hypothermia with acrocyanosis and slow capillary refill; loss of muscle mass; bradycardia with orthostasis), it becomes more difficult for the patient to deny that a problem exists. Furthermore, awareness that bothersome symptoms can be eliminated by healthier eating and activity patterns can increase a patient's motivation to engage in treatment. Tables 41.5 and 41.6 detail common symptoms and signs that should be addressed in a pediatric assessment of a suspected ED.

Table 41.5
Symptoms Commonly Reported by Patients With an Eating Disorder (ED)

<td>Early fullness and discomfort with eating.</td>
<td>Discomfort after a binge.</td>
</tr>
</tbody>
</table>

Constipation
Perceives contour as “fat,” often preferring well-defined abdominal musculature

Cramps and diarrhea with laxative abuse
tone of GI tract musculature, especially the stomach
Laxatives may be used to relieve constipation or as a cathartic
Symptom reduction with healthy eating can take weeks to occur

Extremities and musculoskeletal
Cold, blue hands and feet
No characteristic symptoms
Self-cutting or burning on wrists or arms
Energy-conserving low body temperature with slow blood flow most notable peripherally
Quickly reversed with healthy eating

Nervous system
No characteristic symptom
No characteristic symptom
Neurologic symptoms suggest diagnosis other than ED

Mental status
Depression, anxiety, obsessive-compulsive symptoms, alone or in combination
Depression; PTSD; borderline personality disorder traits
Underlying mood disturbances can worsen with dysfunctional weight control practices and can improve with healthy eating
AN patients might report emotional "numbness" with starvation preferable to emotionality associated with healthy eating

AN, Anorexia nervosa; BN, bulimia nervosa; ED, eating disorder; GI, gastrointestinal; PTSD, posttraumatic stress disorder.

AN, Anorexia nervosa; BN, bulimia nervosa; PTSD, posttraumatic stress disorder; SG, specific gravity; SSRIs, selective serotonin reuptake inhibitors.

### Differential Diagnosis

In addition to identifying symptoms and signs that deserve targeted intervention for patients who have an ED, a comprehensive history and physical examination are required to rule out other conditions in the differential diagnosis. Weight loss can occur in any condition with increased catabolism (e.g., hyperthyroidism, malignancy, occult chronic infection) or malabsorption (e.g., inflammatory bowel disease, celiac disease) or in other disorders (Addison disease, type 1 diabetes mellitus, stimulant abuse), but these illnesses are generally associated with other findings and are not usually associated with decreased caloric intake.

Patients with inflammatory bowel disease can reduce intake to minimize abdominal cramping; eating can cause abdominal discomfort and early satiety in AN because of gastric atony associated with significant weight loss, not malabsorption. Likewise, signs of weight loss in AN might include hypothermia, acrocyanosis with slow capillary refill, and neutropenia similar to some features of sepsis, but the overall picture in EDs is one of relative cardiovascular stability compared with sepsis. Endocrinopathies are also in the differential of EDs. With BN, voracious appetite in the face of weight loss might suggest diabetes mellitus, but blood glucose levels are normal or low in EDs. Adrenal insufficiency mimics many physical symptoms and signs found in restrictive AN but is associated with elevated potassium levels and hyperpigmentation. Thyroid disorders may be considered, because of changes in weight, but the overall presentation of AN includes symptoms of both underactive and overactive...
thyroid, such as hypothermia, bradycardia, and constipation, as well as weight loss and excessive physical activity, respectively.

In the CNS, craniopharyngiomas and Rathke pouch tumors can mimic some of the findings of AN, such as weight loss and growth failure, and even some body image disturbances, but the latter are less fixed than in typical EDs and are associated with other findings, including evidence of increased intracranial pressure. **Mitochondrial neurogastrointestinal encephalomyopathy**, caused by a mutation in the *TYMP* gene, presents with gastrointestinal dysmotility, cachexia, ptosis, peripheral neuropathy, ophthalmoplegia, and leukoencephalopathy. Symptoms begin during the 2nd decade of life and are often initially diagnosed as AN. Early satiety, vomiting, cramps, constipation, and pseudoobstruction result in weight loss often before the neurologic features are noticed (see Chapter 616.2). Acute or chronic oromotor dysfunction and obsessive-compulsive disorder may mimic an eating disorder. Fear of choking may lead to **avoidance-restrictive food intake disorder**.

Any patient with an atypical presentation of an ED, based on age, sex, or other factors not typical for AN or BN, deserves a scrupulous search for an alternative explanation. In ARFID, disturbance in the neurosensory processes associated with eating, not weight loss, is the central concern and must be recognized for appropriate treatment. Patients can have both an underlying illness and an ED. The core features of dysfunctional eating habits—body image disturbance and change in weight—can coexist with conditions such as diabetes mellitus, where patients might manipulate their insulin dosing to lose weight.

**Laboratory Findings**

Because the diagnosis of an ED is made clinically, there is no confirmatory laboratory test. Laboratory abnormalities, when found, are the result of malnutrition, weight control habits, or medical complications; studies should be chosen based on history and physical examination. A routine screening battery typically includes complete blood count, erythrocyte sedimentation rate (should be normal), and biochemical profile. Common abnormalities in ED include low white blood cell count with normal hemoglobin and differential; hypokalemic, hypochloremic metabolic alkalosis from severe vomiting; mildly elevated liver enzymes, cholesterol, and cortisol levels; low gonadotropins and blood glucose with marked weight loss; and generally normal total protein, albumin, and renal function. An electrocardiogram may be useful when profound bradycardia or
arrhythmia is detected; the ECG usually has low voltage, with nonspecific ST or T-wave changes. Although prolonged QTc has been reported, prospective studies have not found an increased risk for this. Nonetheless, when a prolonged QTc is present in a patient with ED, it may increase the risk for ventricular dysrhythmias.

Complications

No organ is spared the harmful effects of dysfunctional weight control habits, but the most concerning targets of medical complications are the heart, brain, gonads, and bones. Some cardiac findings in EDs (e.g., sinus bradycardia, hypotension) are physiologic adaptations to starvation that conserve calories and reduce afterload. Cold, blue hands and feet with slow capillary refill that can result in tissue perfusion insufficient to meet demands also represent energy-conserving responses associated with inadequate intake. All these acute changes are reversible with restoration of nutrition and weight. Significant orthostatic pulse changes, ventricular dysrhythmias, or reduced myocardial contractility reflect myocardial impairment that can be lethal. In addition, with extremely low weight, refeeding syndrome (a result of the rapid drop in serum phosphorus, magnesium, and potassium with excessive reintroduction of calories, especially carbohydrates), is associated with acute tachycardia and heart failure and neurologic symptoms. With long-term malnutrition, the myocardium appears to be more prone to tachyarrhythmias, the second most common cause of death in these patients after suicide. In BN, dysrhythmias can also be related to electrolyte imbalance.

Clinically, the primary CNS area affected acutely in EDs, especially with weight loss, is the hypothalamus. Hypothalamic dysfunction is reflected in problems with thermoregulation (warming and cooling), satiety, sleep, autonomic cardioregulatory imbalance (orthostasis), and endocrine function (reduced gonadal and excessive adrenal cortex stimulation), all of which are reversible. Anatomic studies of the brain in ED have focused on AN, with the most common finding being increased ventricular and sulcal volumes that normalize with weight restoration. Persistent gray matter deficits following recovery, related to the degree of weight loss, have been reported. Elevated medial temporal lobe cerebral blood flow on positron emission tomography, similar to that found in psychotic patients, suggests that these changes may be related to body image distortion. Also, visualizing high-calorie foods is
associated with exaggerated responses in the visual association cortex that are similar to those seen in patients with specific phobias. Patients with AN might have an imbalance between serotonin and dopamine pathways related to neurocircuits in which dietary restraint reduces anxiety.

Reduced gonadal function occurs in male and female patients; it is clinically manifested in AN as amenorrhea in female patients and erectile dysfunction in males. It is related to understimulation from the hypothalamus as well as cortical suppression related to physical and emotional stress. Amenorrhea precedes significant dieting and weight loss in up to 30% of females with AN, and most adolescents with EDs perceive the absence of menses positively. The primary health concern is the negative effect of decreased ovarian function and estrogen on bones. Decreased bone mineral density (BMD) with osteopenia or the more severe osteoporosis is a significant complication of EDs (more pronounced in AN than BN). Data do not support the use of sex hormone replacement therapy because this alone does not improve other causes of low BMD (low body weight, lean body mass, low insulin-like growth factor-1, high cortisol).

**Treatment**

**Principles Guiding Primary Care Treatment**

The approach in primary care should facilitate the acceptance by the ED patient (and parents) of the diagnosis and initial treatment recommendations. A nurturant-authoritative approach using the biopsychosocial model is useful. A pediatrician who explicitly acknowledges that the patient may disagree with the diagnosis and treatment recommendations and may be ambivalent about changing eating habits, while also acknowledging that recovery requires strength, courage, willpower, and determination, demonstrates nurturance. Parents also find it easier to be nurturing once they learn that the development of an ED is neither a willful decision by the patient nor a reflection of poor parenting. Framing the ED as a “coping mechanism” for a complex variety of issues with both positive and negative aspects avoids blame or guilt and can prepare the family for professional help that will focus on strengths and restoring health, rather than on the deficits in the adolescent or the family.

The authoritative aspect of a physician's role comes from expertise in health, growth, and physical development. A goal of primary care treatment should be attaining and maintaining health—not merely weight gain—although weight
gain is a means to the goal of wellness. Providers who frame themselves as consultants to the patient with authoritative knowledge about health can avoid a countertherapeutic authoritarian stance. Primary care health-focused activities include monitoring the patient's physical status, setting limits on behaviors that threaten the patient's health, involving specialists with expertise in EDs on the treatment team, and continuing to provide primary care for health maintenance, acute illness, or injury.

The biopsychosocial model uses a broad ecologic framework, starting with the biologic impairments of physical health related to dysfunctional weight control practices, evidenced by symptoms and signs. Explicitly linking ED behaviors to symptoms and signs can increase motivation to change. In addition, there are usually unresolved psychosocial conflicts in both the intrapersonal (self-esteem, self-efficacy) and the interpersonal (family, peers, school) domains. Weight control practices initiated as coping mechanisms become reinforced because of positive feedback. That is, external rewards (e.g., compliments about improved physical appearance) and internal rewards (e.g., perceived mastery over what is eaten or what is done to minimize the effects of overeating through exercise or purging) are more powerful to maintain behavior than negative feedback (e.g., conflict with parents, peers, and others about eating) is to change it. Thus, when definitive treatment is initiated, more productive alternative means of coping must be developed.

**Nutrition and Physical Activity**

The primary care provider generally begins the process of prescribing nutrition, although a dietitian should be involved eventually in the meal planning and nutritional education of patients with AN or BN. Framing food as fuel for the body and the source of energy for daily activities emphasizes the health goal of increasing the patient's energy level, endurance, and strength. For patients with AN and low weight, the nutrition prescription should work toward gradually increasing weight at the rate of about 0.5-1 lb/wk, by increasing energy intake by 100-200 kcal increments every few days, toward a target of approximately 90% of average body weight for sex, height, and age. Weight gain will not occur until intake exceeds output, and eventual intake for continued weight gain can exceed 4,000 kcal/day, especially for patients who are anxious and have high levels of thermogenesis from nonexercise activity. Stabilizing intake is the goal for patients with BN, with a gradual introduction of “forbidden” foods while also
limiting foods that might trigger a binge.

When initiating treatment of an ED in a primary care setting, the clinician should be aware of common cognitive patterns. Patients with AN typically have all-or-none thinking (related to perfectionism) with a tendency to overgeneralize and jump to catastrophic conclusions, while assuming that their body is governed by rules that do not apply to others. These tendencies lead to the dichotomization of foods into good or bad categories, having a day ruined because of one unexpected event, or choosing foods based on rigid self-imposed restrictions. These thoughts may be related to neurocircuitry and neurotransmitter abnormalities associated with executive function and rewards. Weight loss in the absence of body shape, size, or weight concerns should raise suspicion about ARFID, because the emotional distress associated with “forced” eating is not associated with gaining weight, but with the neurosensory experience of eating.

A standard nutritional balance of 15–20% calories from protein, 50–55% from carbohydrate, and 25–30% from fat is appropriate. The fat content may need to be lowered to 15–20% early in the treatment of AN because of continued fat phobia. With the risk of low BMD in patients with AN, calcium and vitamin D supplements are often needed to attain the recommended 1,300 mg/day intake of calcium. Refeeding can be accomplished with frequent small meals and snacks consisting of a variety of foods and beverages (with minimal diet or fat-free products), rather than fewer high-volume high-calorie meals. Some patients find it easier to take in part of the additional nutrition as canned supplements (medicine) rather than food. Regardless of the source of energy intake, the risk for refeeding syndrome (see Complications earlier) increases with the degree of weight loss and the rapidity of caloric increases. Therefore, if the weight has fallen below 80% of expected weight for height, refeeding should proceed carefully (not necessarily slowly) and possibly in the hospital (Table 41.7).

Preoccupation with ego-syntonic thoughts
Coexisting psychiatric disorders

Miscellaneous

Requires supervision after meals and while using the restroom
Failed day treatment

Patients with AN tend to have a highly structured day with restrictive intake, in contrast to BN, which is characterized by a lack of structure, resulting in chaotic eating patterns and binge-purge episodes. All patients with AN, BN, or ED-NOS benefit from a daily structure for healthy eating that includes 3 meals and at least 1 snack a day, distributed evenly over the day, based on balanced meal planning. Breakfast deserves special emphasis because it is often the first meal eliminated in AN and is often avoided the morning after a binge-purge episode in BN. In addition to structuring meals and snacks, patients should plan structure in their activities. Although overexercising is common in AN, completely prohibiting exercise can lead to further restriction of intake or to surreptitious exercise; inactivity should be limited to situations in which weight loss is dramatic or there is physiologic instability. Also, healthy exercise (once a
Primary Care Treatment

Follow-up primary care visits are essential in the management of EDs. Close monitoring of the response of the patient and the family to suggested interventions is required to determine which patients can remain in primary care treatment (patients with early, mildly disordered eating), which patients need to be referred to individual specialists for co-management (mildly progressive disordered eating), and which patients need to be referred for interdisciplinary team management (EDs). Between the initial and subsequent visits, the patient can record daily caloric intake (food, drink, amount, time, location), physical activity (type, duration, intensity), and emotional state (e.g., angry, sad, worried) in a journal that is reviewed jointly with the patient in follow-up. Focusing on the recorded data helps the clinician to identify dietary and activity deficiencies and excesses, as well as behavioral and mental health patterns, and helps the patient to become objectively aware of the relevant issues to address in recovery.

Given the tendency of patients with AN to overestimate their caloric intake and underestimate their activity level, before reviewing the journal record it is important at each visit to measure weight, without underwear, in a hospital gown after voiding; urine specific gravity; temperature; and blood pressure and pulse in supine, sitting, and standing positions as objective data. In addition, a targeted physical examination focused on hypometabolism, cardiovascular stability, and mental status, as well as any related symptoms, should occur at each visit to monitor progress (or regression).

Referral to Mental Health Services

In addition to referral to a registered dietitian, mental health and other services are important elements of treatment of ED patients. Depending on availability and experience, these services can be provided by a psychiatric social worker, psychologist, or psychiatrist, who should team with the primary care provider. ARFID presents the challenge of working with patients' negative experience of
eating, or fear of trauma such as vomiting or choking, while also addressing inadequate nutritional needs. Although patients with AN often are prescribed a selective serotonin reuptake inhibitor (SSRI) because of depressive symptoms, there is no evidence of efficacy for patients at low weight; food remains the initial treatment of choice to treat depression in AN. **SSRIs**, very effective in reducing binge-purge behaviors regardless of depression, are considered a standard element of therapy in BN. SSRI dosage in BN, however, may need to increase to an equivalent of >60 mg of fluoxetine to maintain effectiveness.

Cognitive-behavioral therapy, which focuses on restructuring “thinking errors” and establishing adaptive patterns of behavior, is more effective than interpersonal or psychoanalytic approaches in ED patients. **Dialectical behavioral therapy**, in which distorted thoughts and emotional responses are challenged, analyzed, and replaced with healthier ones, with an emphasis on “mindfulness,” requires adult thinking skills and is useful for older patients with BN. **Group therapy** can provide much needed support, but it requires a skilled clinician. Combining patients at various levels of recovery who experience variable reinforcement from dysfunctional coping behaviors can be challenging if group therapy patients compete with each other to be “thinner” or take up new behaviors such as vomiting.

The younger the patient, the more intimately the parents need to be involved in therapy. The only treatment approach with evidence-based effectiveness in the treatment of AN in children and adolescents is **family-based treatment**, exemplified by the Maudsley approach. This 3-phase intensive outpatient model helps parents play a positive role in restoring their child's eating and weight to normal, then returns control of eating to the child, who has demonstrated the ability to maintain healthy weight, and then encourages healthy progression in the other domains of adolescent development. Features of effective family treatment include (1) an agnostic approach in which the cause of the disease is unknown and irrelevant to weight gain, emphasizing that parents are not to blame for EDs; (2) parents being actively nurturing and supportive of their child's healthy eating while reinforcing limits on dysfunctional habits, rather than an authoritarian “food police” or complete hands-off approach; and (3) reinforcement of parents as the best resource for recovery for almost all patients, with professionals serving as consultants and advisors to help parents address challenges.
Referral to an Interdisciplinary Eating Disorder Team

The treatment of a child or adolescent diagnosed with an ED is ideally provided by an interdisciplinary team (physician, nurse, dietitian, mental health provider) with expertise treating pediatric patients. Because such teams, often led by specialists in adolescent medicine at medical centers, are not widely available, the primary care provider might need to convene such a team. Adolescent medicine–based programs report encouraging treatment outcomes, possibly related to patients entering earlier into care and the stigma that some patients and parents may associate with psychiatry-based programs. Specialty centers focused on treating EDs are generally based in psychiatry and often have separate tracks for younger and adult patients. The elements of treatment noted earlier (cognitive-behavioral, dialectical behavioral, family-based), as well as individual and group treatment, should all be available as part of interdisciplinary team treatment. Comprehensive services ideally include intensive outpatient and partial hospitalization as well as inpatient treatment. Regardless of the intensity, type, or location of the treatment services, the patient, parents, and primary care provider are essential members of the treatment team. A recurring theme in effective treatment is helping patients and families reestablish connections that are disrupted by the ED.

**Inpatient** medical treatment of EDs is generally limited to patients with AN, to stabilize and treat life-threatening starvation and to provide supportive mental health services. Inpatient medical care may be required to avoid refeeding syndrome in severely malnourished patients, provide nasogastric tube feeding for patients unable or unwilling to eat, or initiate mental health services, especially family-based treatment, if this has not occurred on an outpatient basis (see Table 41.7). Admission to a general pediatric unit is advised only for short-term stabilization in preparation for transfer to a medical unit with expertise in treating pediatric EDs. Inpatient psychiatric care of EDs should be provided on a unit with expertise in managing the often challenging behaviors (e.g., hiding or discarding food, vomiting, surreptitious exercise) and emotional problems (e.g., depression, anxiety). Suicidal risk is small, but patients with AN might threaten suicide if made to eat or gain weight in an effort to “get their parents to back off.”

An ED **partial hospital program** offers outpatient services that are less intensive than round-the-clock inpatient care. Generally held 4-5 days/wk for 6
to 9 hr each session, partial hospital program services typically are group-based and include eating at least 2 meals as well as opportunities to address issues in a setting that more closely approximates “real life” than inpatient treatment. That is, patients sleep at home and are free-living on weekends, exposing them to challenges that can be processed during the 25-40 hr each week in program, as well as sharing group and family experiences.

Supportive Care

In relation to pediatric EDs, support groups are primarily designed for parents. Because their daughter or son with an ED often resists the diagnosis and treatment, parents often feel helpless and hopeless. Because of the historical precedent of blaming parents for causing EDs, parents often express feelings of shame and isolation ([www.maudsleyparents.org](http://www.maudsleyparents.org)). Support groups and multifamily therapy sessions bring parents together with other parents whose families are at various stages of recovery from an ED in ways that are educational and encouraging. Patients often benefit from support groups after intensive treatment or at the end of treatment because of residual body image or other issues after eating and weight have normalized.

Prognosis

With early diagnosis and effective treatment, ≥80% of youth with AN recover: They develop normal eating and weight control habits, resume menses, maintain average weight for height, and function in school, work, and relationships, although some still have poor body image. With weight restoration, fertility returns as well, although the weight for resumption of menses (approximately 92% of average body weight for height) may be lower than the weight for ovulation. The prognosis for BN is less well established, but outcome improves with multidimensional treatment that includes SSRIs and attention to mood, past trauma, impulsivity, and any existing psychopathology. Since the diagnosis of ARFID was only established in 2013, little is known about its long-term prognosis, although anecdotal evidence suggests that weight restoration is not actively resisted as it is in AN. Atypical AN and ED-NOS may still have significant morbidity.
Prevention

Given the complexity of the pathogenesis of EDs, prevention is difficult. Targeted preventive interventions can reduce risk factors in older adolescents and college-age women. Universal prevention efforts to promote healthy weight regulation and discourage unhealthy dieting have not shown effectiveness in middle school students. Programs that include recovered patients or focus on the problems associated with EDs can inadvertently normalize or even glamorize EDs and should be discouraged.

Bibliography

CHAPTER 42

Disruptive, Impulse-Control, and Conduct Disorders

Heather J. Walter, David R. DeMaso

The disruptive, impulse-control, and conduct disorders are interrelated sets of psychiatric symptoms characterized by a core deficit in self-regulation of anger, aggression, defiance, and antisocial behaviors. The disruptive, impulse-control, and conduct disorders include oppositional defiant, intermittent explosive, conduct, other specified/unspecified disruptive/impulse control/conduct, and antisocial personality disorders, as well as pyromania and kleptomania.

Description

Oppositional defiant disorder (ODD) is characterized by a pattern lasting at least 6 mo of angry, irritable mood, argumentative/defiant behavior, or vindictiveness exhibited during interaction with at least 1 individual who is not a sibling (Table 42.1). For preschool children, the behavior must occur on most days, whereas in school-age children, the behavior must occur at least once a week. The severity of the disorder is considered mild if symptoms are confined to only 1 setting (e.g., at home, at school, at work, with peers), moderate if symptoms are present in at least 2 settings, and severe if symptoms are present in ≥4 settings.

Table 42.1

DSM-5 Diagnostic Criteria for Oppositional Defiant Disorder

A. A pattern of angry/irritable mood, argumentative/defiant behavior, or
vindictiveness lasting at least 6 mo as evidenced by at least 4 symptoms from any of the following categories, and exhibited during interaction with at least 1 individual who is not a sibling:

**Angry/Irritable Mood**
1. Often loses temper.
2. Is often touchy or easily annoyed.
3. Is often angry and resentful.

**Argumentative/Defiant Behavior**
4. Often argues with authority figures or, for children and adolescents, with adults.
5. Often actively defies or refuses to comply with requests from authority figures or with rules.
6. Often deliberately annoys others.
7. Often blames others for his or her mistakes or misbehavior.

**Vindictiveness**
8. Has been spiteful or vindictive at least twice within the past 6 mo.

*Note:* The persistence and frequency of these behaviors should be used to distinguish a behavior that is within normal limits from a behavior that is symptomatic. For children younger than 5 yr, the behavior should occur on most days for a period of at least 6 mo unless otherwise noted (Criterion A8). For individuals 5 yr or older, the behavior should occur at least once per week for at least 6 mo, unless otherwise noted (Criterion A8). While these frequency criteria provide guidance on a minimal level of frequency to define symptoms, other factors should be considered, such as whether the frequency and intensity of the behaviors are outside a range that is normative for the individual's developmental level, gender, and culture.

B. The disturbance in behavior is associated with distress in the individual or others in his or her immediate social context (e.g., family, peer group, work colleagues), or it impacts negatively on social, educational, occupational, or other important areas of functioning.
C. The behaviors do not occur exclusively during the course of a psychotic, substance use, depressive, or bipolar disorder. Also, the criteria are not met for disruptive mood dysregulation disorder.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 462–463.

**Intermittent explosive disorder (IED)** is characterized by recurrent verbal or physical aggression that is grossly disproportionate to the provocation or to any precipitating psychosocial stressors (Table 42.2). The outbursts, which are impulsive and/or anger-based rather than premeditated and/or instrumental, typically last <30 min and frequently occur in response to a minor provocation by a close intimate.

**Table 42.2**

**DSM-5 Diagnostic Criteria for Intermittent Explosive Disorder**

A. Recurrent behavioral outbursts representing a failure to control aggressive impulses as manifested by either of the following:
   1. Verbal aggression (e.g., temper tantrums, tirades, verbal arguments or fights) or physical aggression toward property, animals, or other individuals, occurring twice weekly, on average, for a period of 3 mo. The physical aggression does not result in damage or destruction of property and does not result in physical injury to animals or other individuals.
   2. Three behavioral outbursts involving damage or destruction of property and/or physical assault involving physical injury against animals or other individuals occurring with a 12 mo period.

B. The magnitude of aggressiveness expressed during the recurrent outbursts is grossly out of proportion to the provocation or to any precipitating psychosocial stressors.

C. The recurrent aggressive outbursts are not premeditated (i.e., they are impulsive and/or anger-based) and are not committed to achieve some tangible objective (e.g., money, power, intimidation).

D. The recurrent aggressive outbursts cause either marked distress in the
individual or impairment in occupational or interpersonal functioning, or as associated with financial or legal consequences.

E. Chronological age is at least 6 yr (or equivalent developmental level).

F. The recurrent aggressive outbursts are not better explained by another mental disorder (e.g., major depressive disorder, bipolar disorder, disruptive mood dysregulation disorder, a psychotic disorder, antisocial personality disorder, borderline personality disorder) and are not attributable to another medical condition (e.g., head trauma, Alzheimer disease) or to the physiologic effects of a substance (e.g., a drug of abuse, a medication). For children ages 6-18 yr, aggressive behavior that occurs as part of an adjustment disorder should not be considered for this diagnosis.

Note: This diagnosis can be made in addition to the diagnosis of attention-deficit/hyperactivity disorder, conduct disorder, oppositional defiant disorder, or autism spectrum disorder when recurrent impulsive aggressive outbursts are in excess of those usually seen in these disorders and warrant clinical attention.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 466.

**Conduct disorder (CD)** is characterized by a repetitive and persistent pattern over at least 12 mo of serious rule-violating behavior in which the basic rights of others or major societal norms or rules are violated (Table 42.3). The symptoms of CD are divided into 4 major categories: aggression to people and animals, destruction of property, deceitfulness or theft, and serious rule violations (e.g., truancy, running away). Three subtypes of CD (which have different prognostic significance) are based on the age of onset: childhood-onset type, adolescent-onset type, and unspecified. A small proportion of individuals with CD exhibit characteristics (lack of remorse/guilt, callous/lack of empathy, unconcerned about performance, shallow/deficient affect) that qualify for the “with limited prosocial emotions” specifier. CD is classified as *mild* when few if any symptoms over those required for the diagnosis are present, and the symptoms cause relatively minor harm to others. CD is classified as *severe* if many symptoms over those required for the diagnosis are present, and the symptoms cause considerable harm to others. *Moderate* severity is intermediate between mild and severe.
Table 42.3

DSM-5 Diagnostic Criteria for Conduct Disorder

A. A repetitive and persistent pattern of behavior in which the basic rights of others or major age-appropriate societal norms or rules are violated, as manifested by the presence of at least 3 of the following 15 criteria in the past 12 mo from any of the categories below, with at least 1 criterion present in the past 6 mo:

**Aggression to People and Animals**
1. Often bullies, threatens, or intimidates others.
2. Often initiates physical fights.
3. Has used a weapon that can cause serious physical harm to others (e.g., a bat, brick, broken bottle, knife, gun).
4. Has been physically cruel to people.
5. Has been physically cruel to animals.
6. Has stolen while confronting a victim (e.g., mugging, purse snatching, extortion, armed robbery).
7. Has forced someone into sexual activity.

**Destruction of Property**
8. Has deliberately engaged in fire setting with the intention of causing serious damage.
9. Has deliberately destroyed others' property (other than by fire setting).

**Deceitfulness or Theft**
10. Has broken into someone else's house, building, or car.
11. Often lies to obtain good or favors or to avoid obligations (i.e., “cons” others).
12. Has stolen items of nontrivial value without confronting a victim (e.g., shoplifting, but without breaking and entering; forgery).

**Serious Violations of Rules**
13. Often stays out at night despite parental prohibitions, beginning before age 13 yr.
14. Has run away from home overnight at least twice while living in the parental or parental surrogate home, or once without returning for a lengthy period.

15. Is often truant from school, beginning before age 13 yr.

B. The disturbance in behavior causes clinically significant impairment in social, academic, or occupational functioning.

C. If the individual is age 18 yr or older, criteria are not met for antisocial personality disorder.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 469–471.

**Other specified/unspecified disruptive/impulse-control/CD (sub-syndromal disorder)** applies to presentations in which symptoms characteristic of the disorders in this class are present and cause clinically significant distress or functional impairment, but do not meet full diagnostic criteria for any of the disorders in this class.

**Epidemiology**

The prevalence of ODD is approximately 3%, and in preadolescents is more common in males than females (1.4 : 1). One-year prevalence rates for IED and CD approximate 3% and 5%, respectively. For CD, prevalence rates rise from childhood to adolescence and are higher among males than females. The prevalence of these disorders has been shown to be higher in lower socioeconomic classes. This class of disorders constitutes the most frequent referral problem for youth, accounting for one third to one half of all cases seen in mental health clinics. Racial/ethnic minority youth with these disorders utilize specialty mental health services at lower rates than their white peers.

**Clinical Course**

Oppositional behavior can occur in all children and adolescents at times, particularly during the toddler and early teenage periods when establishing autonomy and independence are normative developmental tasks. Oppositional
behavior becomes a concern when it is intense, persistent, and pervasive and when it affects the child's social, family, and academic life.

Some of the earliest manifestations of oppositionality are stubbornness (3 yr), defiance and temper tantrums (4-5 yr), and argumentativeness (6 yr). Approximately 65% of children with ODD exit from the diagnosis after a 3 yr follow-up; earlier age at onset of oppositional symptoms conveys a poorer prognosis. ODD often precedes the development of CD (approximately 30% higher likelihood with comorbid attention-deficit/hyperactivity disorder [ADHD]), but also increases the risk for the development of depressive and anxiety disorders. The defiant and vindictive symptoms carry most of the risk for CD, whereas the angry, irritable mood symptoms carry most of the risk for anxiety and depression.

IED usually begins in late childhood or adolescence and appears to follow a chronic and persistent course over many years.

The onset of CD may occur as early as the preschool years, but the first significant symptoms usually emerge during the period from middle childhood through middle adolescence; onset is rare after age 16 yr. Symptoms of CD vary with age as the individual develops increased physical strength, cognitive abilities, and sexual maturity. Symptoms that emerge first tend to be less serious (e.g., lying), while those emerging later tend to be more severe (e.g., sexual or physical assault). Severe behaviors emerging at an early age convey a poor prognosis. In the majority of individuals, the disorder remits by adulthood; in a substantial fraction, antisocial personality disorder develops. Individuals with CD also are at risk for the later development of mood, anxiety, posttraumatic stress, impulse control, psychotic, somatic symptom, and substance-related disorders.

**Differential Diagnosis**

The disorders in this diagnostic class share a number of characteristics with each other as well as with disorders from other classes, and as such must be carefully differentiated. ODD can be distinguished from CD by the absence of physical aggression and destructiveness and by the presence of angry, irritable mood. ODD can be distinguished from IED by the lack of serious aggression (physical assault). IED can be distinguished from CD by the lack of predatory aggression and other, nonaggressive symptoms of CD.

The oppositionality seen in ODD must be distinguished from that seen in
ADHD, depressive and bipolar disorders (including disruptive mood dysregulation disorder), language disorders, intellectual disability, and social anxiety disorder. ODD should not be diagnosed if the behaviors occur exclusively during the course of a psychotic, substance use, depressive, or bipolar disorder, or if criteria are met for disruptive mood dysregulation disorder. IED should not be diagnosed if the behavior can be better explained by a depressive, bipolar, disruptive mood dysregulation, psychotic, antisocial personality, or borderline personality disorder. The aggression seen in CD must be distinguished from that seen in ADHD and intermittent explosive, depressive, bipolar, and adjustment disorders.

**Comorbidity**

Rates of ODD are much higher in children with ADHD, which suggests shared temperamental risk factors. Depressive, anxiety, and substance use disorders are most often comorbid with IED. ADHD and ODD are both common in individuals with CD, and this comorbid presentation predicts worse outcomes. CD also may occur with anxiety, depressive, bipolar, learning, language, and substance-related disorders.

**Sequela**

The disruptive, impulse-control, and conduct disorders are associated with a wide range of psychiatric disorders in adulthood and with many other adverse outcomes, such as suicidal behavior, physical injury, delinquency and criminality, legal problems, substance use, unplanned pregnancy, social instability, marital failure, and academic and occupational underachievement.

**Etiology and Risk Factors**

At the individual level, a number of neurobiologic markers (lower heart rate and skin conductance reactivity, reduced basal cortisol reactivity, abnormalities in the prefrontal cortex and amygdala, serotonergic abnormalities) have been variously associated with aggressive behavior disorders. Other biologic risk factors include pre-, peri-, and postnatal insults; cognitive and linguistic impairment, particularly language-based learning deficits; difficult temperamental
characteristics, particularly negative affectivity, poor frustration tolerance, and impulsivity; certain personality characteristics (novelty seeking, reduced harm avoidance, and reward dependence); and certain cognitive characteristics (cognitive rigidity, hostile attributions for ambiguous social cues).

At the family level, a consistently demonstrated risk factor is ineffective parenting. Parents of behaviorally disordered children are more inconsistent in their use of rules; issue more and unclear commands; are more likely to respond to their child based on their own mood rather than the child's behavior; are less likely to monitor their children's whereabouts; and are relatively unresponsive to their children's prosocial behavior. Complicating this association is the consistent finding that temperamentally difficult children are more likely to elicit negative parenting responses, including physical punishment, which can exacerbate anger and oppositionality in the child. Other important family-level influences include impaired parent–child attachment, child maltreatment (physical and sexual abuse), exposure to marital conflict and domestic violence, family poverty and crime, and family genetic liability (family history of the disorders in this class along with substance use, depressive, bipolar, schizophrenic, somatization, and personality disorders, as well as ADHD, have all been shown to be associated with the development of behavior disorders).

Peer-level influence on the development of behavior problems include peer rejection in childhood and antisocial peer groups. Neighborhood influences include social processes such as collective efficacy and social control.

Prevention

A useful conduct problem prevention program is the Fast Track (http://fasttrackproject.org), a multicomponent school-based intervention comprising a classroom curriculum targeted at conflict resolution and interpersonal skills, parent training, and interventions targeted at the school environment. Implemented in 1st through 10th grade, former program participants at age 25 had a lower prevalence of any externalizing, internalizing, or substance abuse problem than program nonparticipants. Program participants also had lower violent and drug crime conviction scores, lower risky sexual behavior scores, and higher well-being scores. Another useful prevention program, the Seattle Social Development Project (http://ssdp-tip.org/SSDP/index.html), is also a multicomponent school-based intervention of teacher, parent, and student components targeting classroom management,
interpersonal problem-solving, child behavior management, and academic support skills. Implemented in 1st through 6th grades, outcomes at age 19 yr demonstrated that the intervention decreased lifetime drug use and delinquency for participant males compared with males in comparator communities, but had no significant effects on females.

**Screening/Case Finding**

The parents of children presenting in the primary care setting should be queried about angry mood or aggressive, defiant, or antisocial behavior as part of the routine clinical interview. A typical screening question would be, “Does [name] have a lot of trouble controlling [his/her] anger or behavior?” A number of standardized broad-band screening instruments widely used in the primary care setting (*Pediatric Symptom Checklist*, *Strengths and Difficulties Questionnaire*, *Vanderbilt ADHD Diagnostic Rating Scales*) have items specific to angry mood and aggressive behavior, and as such can be used to focus the interview.

**Early Intervention**

Youth (and/or their parents) presenting in the primary care setting who self-report or respond affirmatively to queries about difficulties managing angry mood or aggressive or antisocial behavior should be afforded the opportunity to talk about the situation with the pediatric practitioner (separately with the older youth as indicated). By engaging in active listening (e.g., “I hear how you have been feeling. Tell me more about what happened to make you feel that way”), the pediatric practitioner can establish a therapeutic rapport and begin to assess the onset, duration, context, and severity of the symptoms, and associated dangerousness, distress, and functional impairment. In the absence of acute dangerousness (e.g., homicidality, assaultiveness, psychosis, substance abuse) and significant distress or functional impairment, the pediatric practitioner can schedule a follow-up appointment within 1-2 wk to conduct a behavior assessment. At this follow-up visit, to assist with decision-making about appropriate level of care, a behavior screening instrument can be administered (*Table 42.4*) and additional risk factors explored (see *Etiology and Risk Factors* earlier).
For mild symptoms (manageable by the parent and not functionally impairing) and in the absence of major risk factors (homicidality, assaultiveness, psychosis, substance use, child maltreatment, parental psychopathology, or severe family dysfunction), **guided self-help** (anticipatory guidance) with watchful waiting and scheduled follow-up may suffice. Guided self-help can include provision of educational materials (pamphlets, books, videos, workbooks, internet sites) that provide information to the youth about dealing with anger-provoking situations, and advice to parents about strengthening the parent–child relationship, effective parenting strategies, and the effects of adverse environmental exposures on the development of behavior problems. In a Cochrane review, media-based parenting interventions had a moderate positive effect on child behavior problems, either alone or as an adjunct to medication. An example of a self-help program for parents is the **Positive Parenting Program** (Triple P; [www.triplep.net](http://www.triplep.net)), online version, in which parents can purchase 4 modules of instruction addressing techniques for positive parenting and strategies for encouraging good behavior, teaching new emotional and behavioral skills, and managing misbehavior (see Chapter 19).

If the problematic behavior is occurring predominantly at school, the parent can be advised about the role of a special education evaluation in the assessment and management of the child’s misbehavior, including the development of a behavioral intervention plan to prevent disciplinary actions that is formalized in an individualized educational plan (IEP) or 504 plan.

If a mental health clinician has been co-located or integrated into the primary care setting, all parents of young children (universal prevention), as well as the parents of youth with mild behavior problems (indicated prevention), can be provided with a brief version of **parent training**. Programs targeted at toddlers through 12 yr olds have been found to be effective in improving parenting skills, parental mental health, and child emotional and behavior problems. For example, *Incredible Years* ([http://www.incredibleyears.com](http://www.incredibleyears.com)) has a 6-8 session
universal prevention version to help parents promote their 2-6 yr old children's emotional regulation, social competence, problem solving, and reading readiness. A 12-20 session version is designed to strengthen parent–child interactions, reduce harsh discipline, and foster parents' ability to promote children's social, emotional, and language development in their toddler to school-age children. A randomized trial in pediatric practices found that Incredible Years significantly improved parenting practices and 2-4 yr olds' disruptive behaviors compared to a wait-list control. Similarly, for children with behavior problems, the Triple P program has seminar (three 90 min sessions), brief (15-30 min consultations), and primary care (four 20-30 min consultations) versions for the parents of youth from birth to the teenage years, specifically designed for implementation in the primary care setting. The Triple P interventions, supported by an extensive evidence base, focus on strengthening the parent–child relationship, identifying and monitoring the frequency of a problem behavior, and implementing and reviewing the effects of a targeted behavior plan.

**Treatment**

For youth who continue to have mild to moderate behavior problems after several weeks of guided self-help or a brief course of parent training, or who from the outset exhibit moderate to severe or comorbid aggression, homicidality, assaultiveness, psychosis, or substance use, or who have a history of child maltreatment or severe family dysfunction or psychopathology, assessment and treatment in the specialty mental health setting by a child-trained mental health clinician should be provided.

The youth's problem behavior may predominantly occur at home, at school, with peers, or in the community, or it may be pervasive. If possible, interventions need to address each context specifically, rather than assuming generalizability of treatment. Thus, for behaviors mostly manifested in the home setting, parent training would be the treatment of choice, whereas for behaviors manifested mostly at school, consultation with the teacher and recommendation of a special education evaluation for service eligibility can be useful. When there are pervasive problems, including aggression toward peers, cognitive-behavioral therapy with the child/teen can be employed in addition to the other interventions.

Parent training has been extensively studied for the treatment of youth
problem behavior. These programs, typically 10-15 wk in duration, focus on some combination of the following components: understanding social learning principles, developing a warm supportive relationship with the child, encouraging child-directed interaction and play, providing a predictable structured household environment, setting clear simple household rules, consistently praising and materially rewarding positive behavior, consistently ignoring annoying behavior (followed by praise when the annoying behavior ceases), and consistently giving consequences (e.g., time-out, loss of privileges) for dangerous or destructive behavior. Other important targets for parenting training include understanding developmentally appropriate moods and behavior, managing difficult temperamental characteristics, fostering the child's social and emotional development, and protecting the child from traumatic exposures.

Specific parent training programs include Parent–Child Interaction Therapy, Triple P, Helping the Noncompliant Child, Incredible Years, and Parent Management Training Oregon. Predictors of nonresponse to these interventions have included greater initial symptom severity as well as involvement of the parent with child protection services.

Adherence to the complete treatment regimen has limited the effectiveness of parent training programs. Estimates of premature termination are as high as 50–60%, and termination within 5 treatment sessions is not uncommon. Predictors of premature termination of parent training programs have included single-parent status, low family income, low parental education levels, young maternal age, minority group status, and life stresses.

Cognitive behavioral therapy (CBT) for youth with disruptive behavior also has been extensively studied. Common CBT techniques for disruptive behavior include identifying the antecedents and consequences of disruptive or aggressive behavior, learning strategies for recognizing and regulating anger expression, problem-solving and cognitive restructuring (perspective-taking) techniques, and modeling and rehearsing social appropriate behaviors that could replace angry or aggressive reactions. Programs typically are delivered in 16-20 weekly sessions.

Multicomponent treatments for serious behavior disorders such as CD target the broader social context. Multidimensional Treatment Foster Care, delivered in a foster care setting for 6-9 mo, typically includes foster parent training and support; family therapy for biologic parents; youth anger management, social skills, and problem-solving training; school-based behavioral interventions and academic support; and psychiatric consultation and medication management, when needed. Multisystemic Therapy, typically
lasting 3-5 mo, generally includes social competence training, parent and family skills training, medications, academic engagement and skills building, school interventions and peer mediation, mentoring and after-school programs, and involvement of child-serving agencies. These multicomponent programs have been designated “probably efficacious” because of the limited rigorous supporting evidence. Predictors of nonresponse to multicomponent treatments have included higher frequency of rule-breaking behavior and predatory aggression, higher psychopathy scores, and comorbid mood disorders.

Two classes of medication, **stimulants** and **atypical antipsychotics**, have strong evidence for the management of impulsive, anger-driven aggressive behavior, although neither is approved by the U.S. Food and Drug Administration (FDA) for this indication. Resource limitations may necessitate provision of pharmacotherapy in the primary care setting; the safety and efficacy of this practice can be enhanced by regular consultation with a child and adolescent psychiatrist. Several studies have shown favorable effects of stimulants on oppositional behavior and aggression in youths with ADHD. The doses of stimulants used for aggression are similar to those used for ADHD (average dose for methylphenidate, approximately 1 mg/kg/day). There is evidence for efficacy of risperidone in reducing aggression and conduct problems in children age 5-18 yr. The suggested usual daily dose of risperidone for severe aggression is 1.5-2 mg for children and 2-4 mg for adolescents. The initial starting doses are 0.25 mg for children and 0.5 mg for adolescents, titrating upward to the usual daily dose, as indicated and tolerated.

Medication trials should be systematic, and the duration of trials should be sufficient (generally 6-8 wk for atypical antipsychotics) to determine the agent's effectiveness. The short-term goal of treatment is to achieve at least a 50% reduction in aggressive symptoms, as assessed by a standardized rating scale (see Table 42.4); the ultimate goal is to achieve symptom remission (below clinical cutpoint on rating scale). A 2nd medication of the same class can be considered if there is insufficient evidence of response to the maximal tolerated dose by 8 weeks. Care should be taken to avoid unnecessary polypharmacy, in part by discontinuing agents that have not demonstrated significant benefit. Discontinuation of the medication should be considered after a symptom-free interval.

**Level of Care**
Most children and adolescents with a behavior disorder can be safely and effectively treated in the outpatient setting. Youths with intractable CD may benefit from residential or specialized foster care treatment, where more intensive treatments can be provided.

Kendler KS, Aggen SH, Patrick CJ. Familial influences on conduct disorder reflect 2 genetic factors and 1 shared environmental factor. *JAMA Psychiatry*. 2013;70:78–86.

Temper tantrums are common during the first few years of life. They are typically developmentally normative expressions of children's frustration with their own limitations or anger about not being able to get their way. It is important for parents to recognize the differences between tantrum types and precipitants in order to determine the best course of action to manage the ensuing behavior. Dealing with tantrum behavior can become very frustrating for parents, but many tantrums can be averted by a parent’s awareness or attunement to certain cues given by their child, particularly in the early years. In particular, parents should be aware that when a child is tired, hungry, or feeling ill or has to make a transition, it can be expected that the child will be more likely to have a tantrum because children are more easily overwhelmed. In this case, it is advised that parents plan ahead and take a preventive stance by being aware of triggers and minimizing the potential for a tantrum. For example, parents should not make a tired or hungry child accompany them on an extended outing unless absolutely necessary. Additionally, depending on the child's developmental level, it is helpful to have a clear discussion ahead of time about the expectations in certain scenarios. When children are able to demonstrate good control, their behavior should be acknowledged and praised. This will increase the likelihood that they will engage in the desired response more often, even in frustrating situations.

In the case of children who engage in tantrum behavior to get their way, parents may feel more inclined to respond to such defiance with yelling or threats, which can reinforce and even escalate the oppositional behavior. Parents should attempt to avert defiance by giving the child choices; once the child has begun a tantrum, he or she can be placed in time-out. If the tantrum was to avoid
a task, the child should be required to complete the task once time-out is over. Parents should state the reason the child is being placed in time-out, but they should not discuss the reasons before or during time-out. Once the time-out is over and the child is calm, it may be helpful for parents to discuss with the child the reasons for the child's frustration and their expectations for how the child will respond in the future.

**Breath-holding spells** occasionally occur during a tantrum and can be frightening to parents. These are reflexive events in which the crying child becomes apneic, pale, or cyanotic, may lose consciousness, and occasionally will have a brief seizure. Parents are best advised to ignore breath holding once it has started. Without reinforcement, breath holding generally disappears.

Subtypes of breath-holding spells include cyanotic, pallid, or mixed episodes. *Cyanotic spells* are the dominant type. *Pallid spells* may be similar to vasovagal-related syncopal events in older children and may be initiated by similar stimuli. *Iron deficiency* with or without anemia may be present, and some children with breath-holding spells respond to iron therapy. There is no increased risk of seizure disorders in children who have had a short seizure during a breath-holding spell. Medical conditions to rule-out in breath-holding spells (usually pallid) include seizures, Chiari crisis, dysautonomia, cardiac arrhythmias, and central nervous system lesions.

The first key to the office management of temper tantrums and breath-holding spells is to help parents intervene before the child is highly distressed. The parent can be instructed to calmly remind the child of the expected behavior and the potential consequence if the expected behavior does not occur. If the child does not comply, he or she should be placed in time-out for a period approximating 1 min for each year of age. Time-out can be effectively used in children up to age 10 yr. Parents should also be advised to be mindful of their own reactions to their child's tantrum behavior, to avoid an escalation of the child's behavior caused by an angry parental response.

If behavioral measures such as time-out fail, pediatricians must assess other aspects of parent–child interactions, such as the frequency of positive interactions, the consistency of parental responses to child behavior, and the way that parents handle anger, before making further recommendations. In the absence of frequent positive parent–child interactions, time-out may not be effective, and inconsistent responding to problem behavior increases the likelihood of the behavior continuing. Children can be frightened by the intensity of their own angry feelings and by angry feelings they arouse in their parents.
Parents should model the anger control that they want their children to exhibit. Some parents are unable to see that if they lose control themselves, their own angry behavior does not help their children to internalize appropriate behavior. Advising parents to calmly provide simple choices will help the child to feel more in control and to develop a sense of autonomy. Providing the child with options also typically helps reduce the child's feelings of anger and shame, which can later have adverse effects on social and emotional development. Providing choice also reduces power struggles between the parent and child and can aid in enhancing the parent–child relationship and building problem-solving skills.

When tantrum behavior, including breath holding, does not respond to parent coaching or is accompanied by head banging or high levels of aggression, referral for a mental health evaluation is indicated. Further evaluation is also recommended if tantrum behavior persists into the latency period and preteen years.

Bibliography

Lying, Stealing, and Truancy

Lying

There are various reasons why a child might lie. For children between ages 2 and 4 yr, lying can be used as a method of playing with language. By observing the reactions of parents, preschoolers learn about expectations for honesty in communication. Lying can also be a form of fantasy for children, who describe things as they wish them to be rather than as they are. To avoid an unpleasant confrontation, a child who has not done something that a parent wanted may say that it has been done. The child's sense of time and reason does not permit the realization that this only postpones a confrontation. It is important for the parent to keep in mind that lying behavior in this age-group is rarely malicious or premeditated.

In older children, lying is generally an effort to cover up something that they do not want to accept in their own behavior. The lie is invented to achieve a temporary good feeling and to protect the child against a loss of self-esteem. Lying in this age-group is also an attempt to avoid a negative consequence for misbehavior. Older children are also more likely to intentionally leave out critical parts of a story in an attempt to deceive or avoid a negative consequence. Habitual lying can also be promoted by poor adult modeling. Many adolescents lie to avoid adults' disapproval. Alternatively, lying may be used as a method of rebellion. Chronic lying can occur in combination with several other antisocial behaviors and is a sign of underlying psychopathology or family dysfunction.

Parents should address lying by giving the child a clear message of what is acceptable. Sensitivity and support combined with limit setting are necessary for a successful intervention. While habitual lying can become frustrating for
parents, they should be discouraged from making accusations or focusing on
catching their child in a lie and instead should work toward creating an
atmosphere that makes it easier for their child to tell the truth. Parents should let
the child know that telling the truth about a difficult situation will allow the
parents to help them better problem-solve the issue at hand. Should a situation
arise where the parents are aware of the details, the lie should be confronted
while providing the facts of what is known and also stating the desired or
expected behavior. If a parent is aware that a child took a cookie without
permission and the child denies it, the parent can state, “I am disappointed that
you took the cookie without permission. I need you to ask me first.” The child is
then reminded of how he can get things that he desires in an acceptable way; an
appropriate consequence can then be given. Parents should be encouraged to
address the expectations for their home and children in a family meeting or in
regular discussions with their child outside the context of the child's lying.

Regardless of age or developmental level, when lying becomes a common
way of managing conflict, intervention is warranted. If this behavior cannot be
resolved through the parents' understanding of the situation and the child's
understanding that lying is not a reasonable alternative, a mental health
evaluation is indicated.

Stealing

Many children steal something at some point in their lives. Often, when very
young children steal, the behavior is an impulsive action to acquire something
they want. A common example is the child who takes candy or a toy from the
store shelf. If a parent notices this behavior, the situation is a teaching
opportunity and should be used to talk with the child about having to pay for
things at the store and not taking things without permission. It should not be
expected that a very young child will be aware of all the rules around shopping
or stealing. It may also be difficult for a child who has been used to being able to
freely take whatever she wants to be aware of all the expected behaviors across
different settings. When preschoolers and school-age children begin to steal
frequently even after they have been told not to, the behavior may be a response
to stressful environmental circumstances and requires further exploration and
evaluation.

For some older children, stealing can be an expression of anger or revenge
for perceived frustrations with parents or other authority figures. In such
instances, stealing becomes one way the child and adolescent can manipulate and attempt to control their world. Stealing can also be learned from adults. Some children will report that the behavior is “exciting” for them, and they may also engage in the behavior for peer approval. In some cases, youth living in poverty may engage in the behavior as a survival mechanism.

It is important for parents to help the child undo the theft through some form of restitution. The child should be made to return the stolen articles or render their equivalent either in money that the child can earn or in services. When stealing is part of a pattern of broader conduct problems, referral for a mental health evaluation is warranted.

**Truancy**

Truancy and running away are never developmentally appropriate. **Truancy** may represent disorganization within the home, caretaking needs of younger siblings, developing conduct problems, or emotional problems including depression or anxiety. When truancy occurs in **younger children**, there are usually psychosocial concerns with the parents or adult caretakers in the home that prevent them from following through with the regular demands for their children. It is important to consider whether parents are struggling with housing and food insecurity, making school attendance less of a priority. Parents with intellectual disability or their own mental health or substance abuse problems may become overwhelmed with managing the home and caring for their children, and thus might not consistently ensure their child gets to school. Also, children might decide to remain at home to take care of parents who are impaired.

Truancy is more common in **older children** and can be a function of multiple factors, including but not limited to learning difficulties, social anxiety, depression, traumatic exposure, bullying, peer pressure, and substance use. In any of these cases, the child should be referred for further evaluation to assess the barriers to returning to school. Best practices for dealing with truancy resulting from school avoidance and anxiety include addressing the underlying psychological symptoms causing the school avoidance and empowering parents, children, and school staff to work on a consistent plan for a return to school.

Younger children may threaten **running away** out of frustration or a desire to “get back at” parents. Older children who run away are almost always expressing a serious underlying problem within themselves or their family,
including violence, abuse, and neglect. Adolescent runaways are at high risk for substance abuse, unsafe sexual activity (e.g., sexual exploitation), and other risk-taking behaviors.

Youth exhibiting truancy or running away should be referred for a mental health evaluation.

Bibliography

Aggression is a serious symptom associated with significant morbidity and mortality. Early intervention is indicated for persistent aggressive behavior, because children may not simply “grow out of it.” Aggressive tendencies are heritable, although environmental factors can promote aggression in susceptible children. Both enduring and temporary stressors affecting a family can increase aggressive behavior in children. Aggression in childhood is correlated with both poverty and chaotic family situations, including chronic unemployment, family discord, and exposure to community and domestic violence, criminality, and psychiatric disorders. Children born to teenage mothers and parents with limited resources and support are also at risk. Boys are almost universally reported to be more aggressive than girls. A difficult temperament and later aggressiveness are related. When children with temperament difficulties elicit punitive caregiving within the family environment, it can set up a cycle of increasing aggression. Aggressive children often misinterpret social cues in such a way that they perceive hostile intent in ambiguous or benign interactions, and then may react with verbal or physical aggression toward peers and parents.

It is important to differentiate the causes and motives for childhood aggression. Intentional aggression may be primarily instrumental, i.e. to achieve an end, primarily hostile, i.e. to inflict physical or psychological pain, or primarily angry and impulsive. Children who are callous, not empathetic, and often aggressive require mental health intervention. These children are at high risk for suspension from school and eventual school failure. Because learning disorders are common in this population, aggressive children should be referred for screening. Aggressive behavior is often present in a variety of other psychological conditions, including attention-deficit/hyperactivity, oppositional
defiant, intermittent explosive, conduct, and disruptive mood dysregulation disorders (see Chapters 39 and 42).

Aggressive behavior in boys is relatively consistent from the preschool period through adolescence. Without effective intervention, a boy with a high level of aggressive behavior between 3 and 6 yr of age has a high probability of carrying this behavior into adolescence. The developmental progression of aggression among girls is less well studied. Fewer girls show physically aggressive behavior in early childhood. However, interpersonal coercive behavior, especially in peer relationships, is seen in girls. This behavior may be related to the development of physical aggression for girls in adolescence (e.g., fighting) or other conduct problems (e.g., stealing).

Children exposed to aggressive models on television, in video games, or in play have more aggressive behavior compared with children not exposed to these models. Parents' anger and aggressive or harsh punishment can model behavior that children may imitate when they are physically or psychologically hurt. Parents' abuse may be transmitted to the next generation by several modes: children imitate aggression that they have witnessed; abuse can cause brain injury, which itself predisposes the child to violence; and internalized rage often results from abuse.

Aggressive behavior in youth is often oriented toward peers through bullying (see Chapter 14.1). While it is developmentally normative for children to engage in some teasing behavior, bullying has a more serious tone. Bullying is defined as unwanted aggressive behavior in which there is a real or perceived imbalance of power or strength between the bully and the victim. Typically, it involves a pattern of behavior repeated over time. Although most often perceived as physical aggression, bullying can take on a variety of forms, including relational bullying, the most common form engaged in by girls.

Cyberbullying is a particular risk during the middle and high school years because of increased exposure and access to multiple social media platforms at this developmental stage. Parents should be advised to closely monitor their child's social media exposure through both smartphone- and internet-based platforms and maintain open communication with their children. Children may bully others because of impulse control and social skills deficits, strong need for power and negative dominance, satisfaction in causing harm to others, or psychological or material rewards. Children who bully are at risk for a variety of negative school and psychological outcomes.

Victims of bullying are particularly at risk for negative outcomes, especially if
the behavior is not addressed by adults. Victimization experiences are associated with school avoidance and school dropout, social isolation, somatic symptoms, and increased psychological problems such as depression and anxiety. There have been numerous cases of suicide in children who reported a prior history of being bullied. Should a concern arise around bullying in the school setting, parents should be advised to reach out to their child's teacher, school counselor, and school administrative staff to have the bullying behavior addressed. Many schools also have a bullying intervention protocol that can be implemented, and state departments of education have antibullying policies with formal protocols to address concerns. Given the significant psychological risks for victims of bullying, it is essential that victims be referred for mental health evaluation.

Bibliography

Self-injurious behavior can be defined as intentional self-inflicted damage to the surface of an individual's body of a type likely to induce bleeding, bruising, or pain, with the expectation that the injury will lead to only minor or moderate physical harm.

Self-injurious behaviors and cutting in particular have been documented in children as young as 7 yr, with increasing rates among preteens, adolescents, and young adults. Rates of self-injury are generally higher in females than in males, but cutting and other self-injurious behaviors occur in both sexes. It is estimated that in the United States, approximately 20% or more of adolescents have engaged in some form of self-injury at some point in their lives. There are no significant race, ethnicity, or class differences among youth who engage in self-injurious behavior. Youth identified as those with the highest risk include females age 15-19 and males 20-24, with cutting being the most common form of self-injury. For those youth who engage in self-injurious behavior for the first time, approximately 20% will repeat the behavior within the same year, with cutting being the most likely repeated self-injurious behavior.

Common types of self-injury include cutting, scratching, burning, carving, piercing, hitting or punching, biting, picking at wounds, and digging nails into the skin. The most common areas of injury are the arms, legs, and torso. Females with significant psychiatric symptomatology have been found to cut on parts of their body other than their arms (breasts, genitals, groin, neck). Objects used in cutting include razors, scissors, broken glass, hard plastic, knives, staples, paperclips, or any other object sharp enough to cause injury.

Usually, self-injurious behavior does not occur with the intention of suicide but can unintentionally result in significant harm or even death. Although self-
injury and suicide are often seen as distinct behaviors, research exploring the attitudes of youth who have engaged in self-injury indicates that there is a strong identification with suicide and death for this population, making self-injurious behavior a significant clinical issue that cannot be ignored or minimized. Some youth engage in repeated self-injury without ever attempting suicide, but studies suggest that 50–75% of adolescents who have a history of self-injurious behavior will make a suicide attempt at some point.

Youth have reported many avenues of exposure before engaging in self-injurious behavior. They often report that they have friends who cut to attempt to alleviate negative emotions, so they try it as well. Youth may also share their stories of self-injury on websites and social media, possibly contributing to experimentation in those who view the postings. Impressionable youth have also reported learning about cutting for the first time from hearing reports of celebrities who have engaged in the behavior.

Self-injurious behavior is associated with depression, anxiety, peer victimization, social isolation, low self-esteem, substance abuse, eating disorders, impulsivity, poor school performance, delinquency, and neglectful or highly punitive parenting practices, as well as a history of physical or sexual abuse. The behavior may begin as an impulsive response to internal distress for younger adolescents, but for those who are older, the behavior can take on a self-reinforcing function. Youth may feel a sense of relief or mastery over negative emotions once the behavior has been completed. Some youth report that they engage in self-injurious behavior when feeling overwhelmed or in a state of panic, in order to feel that they can “breathe again,” or when they are feeling numb, the self-injury pain allows them to “feel something” again. Cutting may also serve as a distraction from emotional pain, provide a sense of control over the body, or be used as a form of self-punishment for a perceived wrongdoing. Youth often report that they are unable to resist the urge to engage in the behavior and will continue to feel increasing levels of distress until they have completed the self-injury; they view it as a way to regulate affect. Others also look forward to and enjoy the behavior and tend to plan and think about when they will be able to do it again. Youth who view the cutting behavior as an enjoyable, private, and positive coping strategy tend to have more dependence on the behavior and more resistance to stopping it.

Some adolescents and young adults have engaged in repeated acts of self-injury for years without sharing this behavior with others or without the behavior being known. They will often go to great lengths to keep the behavior a secret.
Some individuals wear bracelets to cover scars on their arms or wear long sleeves in summer to hide the scarring. They report feeling ashamed of the behavior and fear rejection or disappointment from family and friends should they find out. At times, fear of being rejected or a disappointment to others can increase feelings of depression and anxiety and can serve to perpetuate the behavior. There is also a cohort of adolescents who are more open about showing their scars and sharing their behavior with others; their discussion about the behavior can tend to seem provocative. In either case, the behavior is a way to communicate or manage some level of distress. Many youth who engage in self-injurious behavior may never be seen in a hospital emergency department or by a mental health professional.

Parents should be advised to monitor their child's and adolescent's media access and be aware of their peer group. Maintaining open communication can assist parents in recognizing an increase in concerning behaviors and patterns of behaviors. Parents should also be encouraged to talk with their child about their use of and exposure to drugs and alcohol, because substance use can accompany involvement in self-injurious behavior. Learning that their child has been engaging in self-injury can be frightening for parents because they are unsure of what to do or why their child is engaging in this behavior. It is important that they seek mental health services for their child. It is also recommended that the adolescent receive a full assessment for risk of suicide when self-injury is a concern.

The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) has classified nonsuicidal self-injury (NSSI) as a condition requiring further study before consideration for possible placement in forthcoming editions of DSM. Proposed diagnostic criteria include self-inflicted injury without suicidal intent occurring on 5 or more days in the past year, with lack of suicidal intent either stated by the individual or inferred by the individual's repeated engagement in a behavior that he knows is not likely to result in death. The individual expects that the self-injurious behavior will relieve a negative feeling or thought, resolve an interpersonal difficulty, or induce a positive feeling state. The self-injurious behavior is associated with interpersonal difficulties or negative feelings or thoughts, preoccupation with the intended behavior that is difficult to control, or frequent thoughts about the intended behavior. The proposed criteria also specify that the behavior is not socially sanctioned (e.g., body piercing, tattooing) and is not restricted to skin picking or nail biting. Finally, the behavior must be associated with significant distress or functional
impairment.

Self-injurious behavior in individuals with developmental disabilities often occurs in association with stereotypic movement disorder (see Chapter 37.2).

Bibliography

Psychosis is a severe disruption of thought, perception, and behavior resulting in **loss of reality testing.** Psychosis can occur as part of a mood disorder, such as major depressive disorder or bipolar I disorder; between mood disorder episodes, as in schizoaffective disorder; or without mood disorder episodes, as in schizophrenia. Transient psychotic episodes can arise during times of psychological or physiologic stress in patients who are vulnerable because of personality, developmental, or genetic disorders. Delusions, hallucinations, disorganized thinking, and grossly disorganized behavior (positive symptoms) are key features that define psychoses across disorders, likely because of shared pathophysiologic mechanisms. Negative symptoms, on the other hand, are most typical of schizophrenia.

**Delusions** are fixed, unchangeable, false beliefs held despite conflicting evidence. They may include a variety of themes (persecutory, referential, somatic, religious, grandiose). Delusions are considered bizarre if they are clearly implausible. **Hallucinations** are vivid, clear, perceptual-like experiences that occur without external stimulus and have the full force and impact of normal perceptions. They may occur in any sensory modality; auditory hallucinations are the most common. **Disorganized thinking** is typically inferred from an individual's speech (loose associations, tangentiality, or incoherence). **Grossly disorganized behavior** may range from childlike silliness to catatonic behavior. **Negative symptoms** include diminished emotional expression, avolition, alogia (lack of speech), anhedonia (inability to experience pleasure), and asociality. Negative symptoms generally account for a substantial portion of the long-term morbidity associated with schizophrenia.

Given the centrality of hallucinations and delusions in making a diagnosis of a psychotic illness, their differentiation from developmentally normal **fantasy** is
essential. When children are *imagining*, they control the fantasy and do not have the perceptual experience of seeing and hearing. When children are *hallucinating*, they do not control the hallucination. Almost two thirds of children will endorse at least 1 psychotic-like experience, most often a hallucination, and when not persistent or accompanied by distress, these experiences are not usually a cause for concern. The largest population-based study to date evaluating psychotic symptoms and neurocognition in youth 11-21 yr old found that those who endorsed more psychotic-like experiences than is typical for their age had reduced accuracy across neurocognitive domains, reduced global functioning, and increased risk of depression, anxiety, behavioral disorders, substance use, and suicidal ideation. Thus, psychotic-like symptoms that are frequent, distressing, and cause impairment signal a need for further evaluation and monitoring; however, only a small minority of these children will develop full-blown psychotic illnesses.

### 47.1

**Schizophrenia Spectrum and Other Psychotic Disorders**

*Joseph Gonzalez-Heydrich, Heather J. Walter, David R. DeMaso*

Schizophrenia spectrum and other psychotic disorders as described in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) include brief psychotic disorder, schizophreniform disorder, schizophrenia, schizoaffective disorder, substance/medication-induced psychotic disorder, psychotic disorder caused by another medical condition, catatonia associated with another mental disorder, catatonic disorder due to another medical condition, unspecified catatonia, delusional disorder, schizotypal personality disorder, and other specified/unspecified schizophrenia spectrum and other psychotic disorders.
Description

The schizophrenia spectrum and other psychotic disorders are primarily characterized by the active (or positive) symptoms of psychosis, specifically delusions, hallucinations, disorganized speech, or grossly disorganized or catatonic behavior. Brief psychotic disorder is characterized by the duration of 1 or more of these symptoms for at least 1 day but <1 mo followed by complete resolution. Emergence of symptoms may or may not be preceded by an identifiable stressor (Table 47.1 ). Although brief, the level of impairment in this disorder may be severe enough that supervision is required to ensure that basic needs are met and the individual is protected from the consequences of poor judgment and cognitive impairment.

Table 47.1

DSM-5 Diagnostic Criteria for Brief Psychotic Disorder

A. Presence of 1 (or more) of the following symptoms. At least 1 of these must be (1), (2), or (3):
   1. Delusions.
   2. Hallucinations.
   3. Disorganized speech (e.g., frequent derailment or incoherence).
   4. Grossly disorganized or catatonic behavior.

Note: Do not include a symptom if it is a culturally sanctioned response.

B. Duration of an episode of the disturbance is at least 1 day but less than 1 mo, with eventual full return to premorbid level of functioning.

C. The disturbance is not better explained by major depressive or bipolar disorder with psychotic features or another psychotic disorder such as schizophrenia or catatonia, and is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

Specify if:

With marked stressor(s) (brief reactive psychosis): If symptoms occur in response to events that, singly or together, would be markedly stressful to almost anyone in similar circumstances in the individual's culture.
Without marked stressor(s): If the symptoms do not occur in response to events that, singly or together, would be would be markedly stressful to almost anyone in similar circumstances in the individual's culture.

With postpartum onset: If onset is during pregnancy or within 4 wk postpartum.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, p 94.

If 2 or more psychotic symptoms persist from 1 mo up to 6 mo, the condition is called *schizophreniform disorder* (Table 47.2). To meet DSM-5 criteria for *schizophrenia*, 2 or more psychotic symptoms must have been present for a significant time during 1 mo (unless suppressed by treatment), and the level of psychosocial functioning must be markedly below the level achieved before the onset (or there is failure in children to achieve the expected level of functioning). In addition, there must be continuous signs of the disturbance (prodromal, active, or residual symptoms) for at least 6 mo (Table 47.3).

**Table 47.2**

**DSM-5 Diagnostic Criteria for Schizophreniform Disorder**

A. Two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least 1 of these must be (1), (2), or (3):
   1. Delusions.
   2. Hallucinations.
   3. Disorganized speech (e.g., frequent derailment or incoherence).
   4. Grossly disorganized or catatonic behavior.
   5. Negative symptoms (i.e., diminished emotional expression or avolition).

B. An episode of the disorder lasts at least 1 mo but less than 6 mo. When the diagnosis must be made without waiting for recovery, it should qualified as “provisional.”

C. Schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or
manic episodes have occurred concurrently with the active-phase symptoms; or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.

D. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

Specify if:

**With good prognostic features** : This specifier requires the presence of at least 2 of the following features: onset of prominent psychotic symptoms within 4 wk of the first noticeable change in usual behavior or functioning; confusion or perplexity; good premorbid social and occupational functioning; and absence of blunted or flat affect.

**Without good prognostic features** : This specifier is applied if 2 or more of the above features have not been present.

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 96–97.

**Table 47.3**

**DSM-5 Diagnostic Criteria for Schizophrenia**

A. Two (or more) of the following, each present for a significant portion of time during a 1 mo period (or less if successfully treated). At least 1 of these must be (1), (2), or (3):

1. Delusions.
2. Hallucinations.
3. Disorganized speech (e.g., frequent derailment or incoherence).
4. Grossly disorganized or catatonic behavior.
5. Negative symptoms (i.e., diminished emotional expression or avolition).

B. For a significant portion of the time since the onset of the disturbance, level of functioning in 1 or more major areas, such as work, interpersonal relations, or self-care, is markedly below the level achieved prior to the onset (or when the onset is in childhood or adolescence, there is failure to achieve expected level of interpersonal, academic, or occupational functioning).
C. Continuous signs of the disturbance persist for at least 6 mo. This 6 mo period must include at least 1 mo of symptoms (or less if successfully treated) that meet Criterion A (i.e., active-phase symptoms) and may include periods of prodromal or residual symptoms. During these prodromal or residual periods, the signs of the disturbance may be manifested by only negative symptoms or by 2 or more symptoms listed in Criterion A present in an attenuated form (e.g., odd beliefs, unusual perceptual experiences).

D. Schizoaffective disorder and depressive or bipolar disorder with psychotic features have been ruled out because either (1) no major depressive or manic episodes have occurred concurrently with the active-phase symptoms; or (2) if mood episodes have occurred during active-phase symptoms, they have been present for a minority of the total duration of the active and residual periods of the illness.

E. The disturbance is not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication) or another medical condition.

F. If there is a history of autism spectrum disorder or a communication disorder of childhood onset, the additional diagnosis of schizophrenia is made only if prominent delusions or hallucinations, in addition to the other required symptoms of schizophrenia, are also present for at least a month (or less if successfully treated).

From the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, (Copyright 2013). American Psychiatric Association, pp 99–100.

Individuals with schizophrenia can display inappropriate affect, dysphoric mood, disturbed sleep patterns, and lack of interest in eating, or food refusal. Depersonalization, derealization, somatic concerns, and anxiety and phobias are common. Cognitive deficits are observed, including decrements in declarative memory, working memory, language function, and other executive functions, as well as slower processing speed. These individuals may have no insight or awareness of their disorder, which is a predictor of nonadherence to treatment, higher relapse rates, and poorer illness course. Hostility and aggression can be associated with schizophrenia, although spontaneous or random assault is uncommon. Aggression is more frequent for younger males and for individuals with a past history of violence, non-adherence with treatment, substance abuse,
and impulsivity.

The essential features of schizophrenia are the same in childhood as in adulthood, but it is more difficult to make the diagnosis. In children, delusions and hallucinations may be less elaborate, visual hallucinations may be more common, and disorganized speech may be better attributed to an autism spectrum or communication disorder. In a review of 35 studies of youth with schizophrenia, the most frequent psychotic symptoms were auditory hallucinations (82%), delusions (78%), thought disorder (66%), disorganized or bizarre behavior (53%), and negative symptoms (50%).

Epidemiology

Brief psychotic disorders have been reported to account for 9% of first-onset psychosis in the United States, with a 2 : 1 ratio in favor of females. The incidence of schizophreniform disorders in the United States appears as much as 5-fold less than that of schizophrenia. The lifetime prevalence of schizophrenia is approximately 0.3–0.7%, although variations are reported by race/ethnicity, across countries, and by geographic origin for immigrants. The male:female ratio is approximately 1.4 : 1. Males generally have worse premorbid adjustment, lower educational achievement, more prominent negative symptoms, and more cognitive impairment than females.

Clinical Course

Brief psychotic disorder most often appears in adolescence or early adulthood, with the average age of onset in the mid-30s, but can occur throughout the life span. A diagnosis of brief psychotic disorder requires full remission within 1 mo of onset and gradual return to premorbid level of function. The age of onset of schizophreniform disorder is similar to that of schizophrenia. Recovery from an episode of the disorder is within 6 mo; however, about two thirds of patients relapse and eventually receive a diagnosis of schizophrenia or schizoaffective disorder. Abrupt onset, confusion, absence of blunted affect, and good premorbid functioning predict a better outcome in schizophreniform disorder.

Schizophrenia typically develops between the late teens and the mid-30s; onset before adolescence is rare. The peak age at onset for the first psychotic episode is in the early to mid-20s for males and in the late 20s for females. The
onset may be abrupt or insidious, but the majority of individuals manifest a slow and gradual development of symptoms, with about half of individuals complaining of depressive symptoms. The predictors of course and outcome are largely unexplained. The course appears to be favorable in approximately 20% of cases, and a small number of individuals are reported to recover completely. However, many remain chronically ill, with exacerbations and remissions of active symptoms, whereas others experience progressive deterioration. Most individuals diagnosed with schizophrenia require daily living supports. Positive symptoms tend to diminish over time, and negative symptoms are the most persistent, along with cognitive deficits.

**Differential Diagnosis**

The differential diagnosis for the psychotic disorders is broad and includes reactions to substances/medications (dextromethorphan, LSD, hallucinogenic mushrooms, psilocybin, peyote, cannabis, stimulants, inhalants; corticosteroids, anesthetics, anticholinergics, antihistamines, amphetamines); medical conditions causing psychotic-like symptoms (Table 47.4); and other psychiatric disorders (depressive, bipolar, obsessive-compulsive, factitious, body dysmorphic, posttraumatic stress, autism spectrum, communication, personality). The differential diagnosis can be difficult because many conditions that can be mistaken for psychosis also increase the risk for it.

ROHHAD. Rapid-onset obesity with hypothalamic dysfunction, hypoventilation, autonomic dysregulation.

**Autoimmune encephalitis** caused by anti–N-methyl-D-aspartate (NMDA) receptor or other autoantibodies may manifest with psychosis, anxiety, depression, agitation, aggression, delusions, catatonia, visual or auditory hallucinations, disorientation, and paranoia in combination with sleep disturbances, autonomic dysfunction (hypoventilation), dyskinesias, movement disorders, seizures, memory loss, and a depressed level of consciousness (Fig. 47.1). The electroencephalogram (EEG), cerebrospinal fluid (CSF), and MRI are usually, but not always, abnormal. The constellation of psychosis and encephalitic features should suggest the diagnosis, although at presentation,
behavioral problems may be the dominant feature (see Chapter 616.4).

![FIG. 47.1 Clinical characteristics of patients with anti–NMDA receptor encephalitis.](Modified from Wandinger KP, Saschenbrecker S, Stoecker W, Dalmau J: Anti-NMDA-receptor encephalitis: a severe multistage, treatable disorder presenting with psychosis, J Neuroimmunol 231:86-91, 2011, Fig 2.)

Determining when identifiable medical conditions are causing delirium with prominent psychotic symptoms may be difficult (Table 47.5 and Table 47.6). In general, delirium due to medical causes is often associated with abnormalities in vital signs and the neurologic examination (including level of consciousness). A positive family or prior personal history of serious psychiatric illness is less likely. When psychotic symptoms are caused by identifiable medical conditions, there are often impairments in attention, orientation, recent memory, and intellectual function. Hallucinations may be caused by medical illness, but are often tactile, visual, or olfactory, whereas auditory hallucinations are more common in primary psychotic disorders. Patients whose hallucinations are caused by medical illness are more likely than patients with primary psychotic disorders to be aware that the hallucinations do not represent reality.

**Table 47.6**

**Features Suggesting Neurologic Disease in Patients With Psychiatric Symptoms**

**Atypical Psychiatric Features**

- Late or very early age of onset
- Acute or subacute onset
- Lack of significant psychosocial stressors
- Catatonia
Diminished comportment
Cognitive decline
Intractability despite adequate therapy
Progressive symptoms

**History of Present Illness**

- New or worsening headache
- Inattention
- Somnolence
- Incontinence
- Focal neurologic complaints such as weakness, sensory changes, incoordination, or gait difficulty
- Neuroendocrine changes
- Anorexia/weight loss

**Patient Medical History**

- Risk factors for cerebrovascular disease or central nervous system infections
- Malignancy
- Immunocompromised status
- Significant head trauma
- Seizures
- Movement disorder
- Hepatobiliary disorders
- Abdominal crises of unknown cause
- Biologic relatives with similar diseases or complaints

**Unexplained Diagnostic Abnormalities**

- Screening laboratory tests
- Neuroimaging studies or possibly imaging of other systems
- Electroencephalogram
- Cerebrospinal fluid
The diagnosis of a psychotic disorder should be made only after other explanations for the observed symptoms have been thoroughly considered. Mistakenly diagnosing psychosis when it is not present can lead to inappropriate use of antipsychotics with all their attendant risks, and mistakenly dismissing psychotic symptoms as nonpsychotic manifestations of, for example, autism or trauma can lead to long delays in treatment of the psychosis. The persistence, frequency, and form of possible psychotic symptoms, as well as the degree of accompanying distress and functional regression, need to be considered in determining the likelihood of an underlying psychotic pathophysiology.

**Comorbidity**

In a review of 35 studies of youth with schizophrenia, rates of comorbidity approximated 34% for posttraumatic stress disorder, 34% for attention-deficit/hyperactivity and/or disruptive behavior disorders, and 32% for substance abuse/dependence.

**Sequelae**

Follow-up studies of early-onset schizophrenia suggest moderate to severe impairment across the life span. Poor outcome is predicted by low premorbid functioning, insidious onset, higher rates of negative symptoms, childhood onset, and low intellectual functioning. When followed into adulthood, youth with schizophrenia demonstrated greater social deficits, lower levels of employment, and were less likely to live independently, relative to those with other childhood psychotic disorders. Approximately 5–6% of individuals with schizophrenia die by suicide, approximately 20% attempt suicide on one or more occasions, and many more have suicidal ideation. Life expectancy is reduced in individuals with schizophrenia because of associated medical conditions; a shared vulnerability for psychosis and medical disorders may explain some of the medical comorbidity of schizophrenia.
Etiology and Risk Factors

Etiologic evidence for schizophrenia supports a neurodevelopmental and neurodegenerative model, with multiple genetic and environmental exposures playing important roles. It has been hypothesized that although psychotic disorders likely have their origins in early development, it is not until youth are in their mid-teens that the underlying neural structures manifest the disabling functional deficits and resultant psychotic symptoms.

Genetic Factors

The lifetime risk of developing schizophrenia is 5-20 times higher in first-degree relatives of affected probands than the general population. Concordance rates of 40–60% and 5–15% have been reported, respectively, in monozygotic and dizygotic twins. Genome-wide association studies have implicated variants in >100 different genes as leading to statistically significant but small increases in the risk for schizophrenia (odds ratios of about 1.4). The risk for schizophrenia increases with increasing burden of these common risk alleles, and approximately 30% of the risk of schizophrenia is attributable to common genetic variants. Rare variants of larger effect have also been implicated as increasing risk. Some rare copy number variants where stretches of the genome encompassing many genes are either duplicated or deleted have been shown to increase the risk of schizophrenia more markedly, with odds ratios of 2-25. Although these copy number variants, including such “hot spots” as 1q21.1, 15q13.3, and 22q11.2, may be responsible for 0.5–1.0% of typical adolescent/adult-onset schizophrenia, data indicate that they are responsible for about 12% of schizophrenia cases with onset before age 13 yr. There is increasing evidence that the same genetic risk alleles impart risk for multiple disorders (e.g., depression).

Environmental Factors

In utero exposure to maternal famine, advanced paternal age, prenatal infections, obstetric complications, marijuana use, and immigration have been hypothesized to contribute to the development of schizophrenia. Environmental exposures may mediate disease risk through direct neurologic damage, gene-environment interactions, epigenetic effects, or de novo mutations. There is no evidence that
psychological or social factors alone cause schizophrenia. Rather, environmental factors potentially interact with biologic risk factors to mediate the timing of onset, course, and severity of the disorder. Expressed emotion within the family setting can influence the onset and exacerbation of acute episodes and relapse rates.

**Neuroanatomic Abnormalities**

Increased lateral ventricle volumes, along with reductions in hippocampus, thalamus, and frontal lobe volumes, have been reported in schizophrenia. Youth in particular have reductions in gray matter volumes and reduced cortical folding. Neurotransmitter systems, particularly central nervous system dopamine circuits, are hypothesized to have a key role in the pathophysiology of schizophrenia. The dopamine hypothesis is derived in part from the identification of $D_2$ receptor blockade as the mechanism for the action of antipsychotic medications.

**Prevention**

There has been significant interest in prospectively identifying youth at risk for schizophrenia spectrum and other psychotic disorders in an effort to provide early intervention before the development of a full-blown psychotic disorder. Various names, including attenuated psychosis syndrome (APS), clinical high risk (CHR), psychosis risk syndrome, ultrahigh risk, at-risk mental state, and prodromal stage, have been used to describe patients who present with troubling symptoms suggestive of early psychosis.

APS or CHR is characterized by the presence of delusions, hallucinations, or disorganized speech in attenuated forms. Affected individuals may express a variety of unusual or odd beliefs or may have unusual perceptual experiences, including frank hallucinations, but retain insight into their unreality; their speech may be generally understandable but vague; and their behavior may be unusual but not grossly disorganized. Individuals who had been socially active may become withdrawn. The symptoms are described as present at least once per week for the past month and have begun or worsened over the past year. Although the symptoms are less severe and more transient than in a psychotic disorder, 20–40% with these attenuated symptoms appear to go on to a psychotic
disorder within several years of symptom presentation. There is evidence that
premorbid lower cognitive and social skills as well as a history of substance
abuse contribute to the risk of developing a full-blown psychotic disorder in
individuals with APS/CHR.

Some evidence indicates that antipsychotic medication may delay conversion
of attenuated to full-blown psychosis and ameliorate attenuated symptoms in
active treatment, yet there appear to be no lasting effects after the medication is
withdrawn. Additionally, the known adverse effects of antipsychotics argue
against their being used broadly to prevent psychosis in patients with APS/CHR,
given that about two thirds of them do not go on to develop a psychotic disorder.

Antidepressants have been associated with symptomatic improvement in
adolescents with APS/CHR. Psychological interventions, including social skills,
cognitive, and interaction training programs, as well as educational family
interventions and cognitive-behavioral therapy (CBT), are reported to improve
symptoms and psychosocial functioning in youth with early symptoms and
decrease the rate of conversion to psychosis.

Despite improvements in diagnostic predictive validity, significant concern
remains regarding a high false-positive rate (identifying an individual as
prodromal who does not go on to develop psychosis) that may cause individuals
to be stigmatized or exposed to unnecessary treatment. In this context, youth
with early symptoms suggestive of psychosis should be referred to a child and
adolescent psychiatrist or other qualified mental health specialist, and/or a
specialized research program.

**Screening/Case Finding**

Pediatric practitioners can make general inquiries of youth and their parents
regarding problems with thinking or perceptions. For the older youth, such
questions as “Does your mind ever play tricks on you?,” “Do you hear voices
talking to you when no one is there?,” and “Does your mind ever feel
confused?” can help elicit symptoms. For younger children, the clinician must
ensure that the child understands the questions. True psychotic symptoms are
generally confusing to the individual. Highly descriptive, detailed, organized,
and situation-specific reports are less likely to represent true psychosis. Overt
evidence of psychosis is not always present on mental status examination, but in
the absence of this, the validity of symptom reports should be scrutinized. Youth
presenting with possible psychosis warrant assessment and treatment by a child
and adolescent psychiatrist or other qualified mental health specialist.

**Assessment**

The diagnostic assessment of schizophrenia in youth is uniquely complicated, and misdiagnosis is common. Most children who report hallucinations do not meet criteria for schizophrenia, and many do not have a psychotic illness. The persistence, frequency, and form of possible psychotic symptoms; the presence of distress; functional impairment; and insight need to be considered in arriving at a diagnosis. Expertise in childhood psychopathology and experience in assessing reports of psychotic symptoms in youth are important prerequisite skills for clinicians evaluating youth for possible psychosis. Comprehensive diagnostic assessments, which reconcile mental status findings with the rigorous application of diagnostic criteria, help improve accuracy.

There are no neuroimaging, psychological, or laboratory tests that establish a diagnosis of schizophrenic spectrum disorders. The medical evaluation focuses on ruling out nonpsychiatric causes of psychosis, while also establishing baseline laboratory parameters for monitoring medication therapy. Routine laboratory testing typically includes blood counts, basic metabolic panel, and liver, renal, and thyroid function. More extensive evaluation is indicated for atypical presentations, such as a gross deterioration in cognitive and motor abilities, focal neurologic symptoms, or delirium. Neuroimaging may be indicated when neurologic symptoms are present, or an EEG may be indicated for a clinical history suggestive of seizures. Toxicology screens are indicated for acute onset or exacerbations of psychosis, when exposure to drugs of abuse cannot be ruled out. Genetic testing is indicated if there are associated dysmorphic or syndromic features. Tests to rule out specific syndromes or diseases are indicated for clinical presentations suggestive of a specific syndrome (e.g., amino acid screens for inborn errors of metabolism, ceruloplasmin for Wilson disease, porphobilinogen for acute intermittent porphyria, NMDA receptor antibodies for autoimmune encephalitis).

Neuropsychological testing cannot establish the diagnosis but may be important for documenting cognitive deficits for academic planning.

**Treatment**
It is important to recognize hallmark phases in the assessment and management of schizophrenia. In the **prodrome phase**, most patients experience functional deterioration (i.e., social withdrawal, idiosyncratic preoccupations, unusual behaviors, academic failure, deteriorating self-care skills, and/or dysphoria) before the onset of psychotic symptoms. The **acute phase** is characterized by prominent positive symptoms and deterioration in functioning. The **re recuperative/recovery phase** is marked by a several-month period of impairment and predominantly negative symptoms. The **residual phase** (if reached) has no positive symptoms, although negative symptoms may cause continued impairment.

Treatment goals include decreasing psychotic symptomatology, directing the child toward a developmentally typical trajectory, and reintegrating the child into the home and community. Children and families facing schizophrenia spectrum disorders require an array of mental health services to address their psychological, social, educational, and cultural needs. Given the insidious onset and chronic course of these disorders, the patient must be followed longitudinally, with periodic reassessment to hone diagnostic accuracy and tailor services to meet the patient's and family's needs. Integrated psychopharmacologic, psychotherapeutic, psychoeducational, and case management services are often necessary.

**Psychoeducation** about the illness with an assessment of the potential role of stigma in treatment participation is critical for improving adherence with treatment recommendations. Assessing a child's strengths and vulnerabilities as well as available environmental resources is critical in devising an effective treatment plan. School and community liaison work to develop and maintain a day-to-day schedule for the patient is important. Specialized educational programs should be considered within the school system. Cognitive remediation has led to some promising gains in planning ability and cognitive flexibility. Effective and collaborative communication among the family, the pediatrician, a child and adolescent psychiatrist, and other mental health providers increases the potential for the patient's optimal functioning.

**Pharmacotherapy**

First-generation (typical) and second-generation (atypical) antipsychotic medications have been shown to be effective in reducing psychotic symptoms. These antipsychotics appear to outperform placebo and to have approximately
equal effectiveness, except for ziprasidone and clozapine, which may be less and more effective than the others, respectively. Risperidone, aripiprazole, quetiapine, olanzapine, and lurasidone are FDA-approved second-generation antipsychotics for treating schizophrenia in patients 13 yr and older, and paliperidone for those 12 yr and older. Several of the first-generation antipsychotics are also FDA approved for children and adolescents. The choice of which agent to use first is typically based on U.S. Food and Drug Administration approval status, side effect profile, patient and family preference, clinician familiarity, and cost. Depot antipsychotics have not been studied in pediatric age groups and have inherent risks with long-term exposure to side effects. Although clozapine is effective in treating both positive and negative symptoms, its risk for agranulocytosis and seizures limits its use to those patients with treatment-resistant disorders. Ziprasidone and paliperidone are associated with QT prolongation; this finding along with the inferior effectiveness of ziprasidone limits its use with children and adolescents.

Most patients require long-term treatment and are at significant risk for relapse if their medication is discontinued, and more than three quarters of youth with schizophrenia discontinue their medication within 180 days. As such, the goal is to maintain the medication at the lowest effective dose to minimize potential adverse events. Many patients will continue to experience some degree of positive or negative symptoms, requiring ongoing treatment. Patients should maintain regular physician contact to monitor symptom course, side effects, and adherence.

Electroconvulsive therapy (ECT) may be used with severely impaired adolescents if medications are either not helpful or cannot be tolerated. It has not been systematically studied in children.

Psychosis Associated With Epilepsy

Joseph Gonzalez-Heydrich, Heather J. Walter, David R. DeMaso

Schizophrenia spectrum and other psychotic disorders include psychotic disorder due to another medical condition (Table 47.7). Psychosis associated with epilepsy has been reported in children and adults. Also called schizophrenic-like psychosis of epilepsy, the disorder manifests with delusions or hallucinations associated with poor insight. The characterization is complicated by the fact that anticonvulsant drugs can cause psychosis and antipsychotic drugs can lower the seizure threshold, producing seizures.

Table 47.7

**DSM-5 Diagnostic Criteria for Psychotic Disorder Due to Another Medical Condition**

A. Prominent hallucinations or delusions.
B. There is evidence from the history, physical examination, or laboratory findings that the disturbance is the direct pathophysiologic consequence of another medical condition.
C. The disturbance is not better explained by another mental disorder.
D. The disturbance does not occur exclusively during the course of a delirium.
E. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.

Specify whether:
- **With delusions**: If delusions are the predominant symptom.
- **With hallucinations**: If hallucinations are the predominant symptom.

Psychosis associated with epilepsy can be further differentiated into ictal, interictal, and postictal psychosis. Ictal-induced psychosis is a form of nonconvulsive status epilepticus, usually complex partial status that can last for hours to days and is associated with periods of impaired consciousness. Brief interictal psychosis can last days to weeks and is associated with paranoia, delusions, and auditory hallucinations. Chronic interictal psychosis resembles schizophrenia and manifests with paranoia, visual hallucinations, and catatonia. Postictal psychosis is the most common type (observed in 2–7% of patients with epilepsy) and lasts up to 1 wk and then spontaneously remits.

The diagnosis requires a strong index of suspicion and EEG monitoring. Treatment requires appropriate anticonvulsant drugs and, if the psychosis persists, initiating low-dose antipsychotic medication.

Catatonia in Children and Adolescents

Joseph Gonzalez-Heydrich, Heather J. Walter, David R. DeMaso

**Catatonia** is a poorly defined state presenting as an unusual manifestation of decreased or increased muscle tone and decreased responsiveness (although agitation may be present) occurring in association with a broad array of conditions affecting children, adolescents, and adults. These conditions include psychosis, autism spectrum disorder, developmental disorders, drug-induced conditions, mood disorders, and a wide range of medical disorders (Table 47.8). Not surprising given its ill-defined nature, the prevalence of catatonia in children and adolescents is unknown, although it is generally believed to be significantly underdiagnosed. Recognition of catatonia by a clinician is important because the disorder is generally very responsive to treatment with benzodiazepines and/or ECT.

Overdose: LSD, phencyclidine (PCP), cocaine, MDMA (Ecstasy), disulfiram, levetiracetam

**Diagnosis and Treatment**

Catatonia is defined as 3 or more of the 12 symptoms listed in Table 47.9. An important next step is the evaluation (and possible elimination) of medications being administered to the child for their potential to induce catatonic symptoms, a not-infrequent side effect of many medical and psychiatric medications. Of particular importance, antipsychotics should be discontinued because they have been associated with an increased incidence of malignant catatonia or neuroleptic malignant syndrome.

**Table 47.9**

**DSM-5 Diagnostic Criteria for Catatonic Disorder Due to Another Medical Condition**

A. The clinical picture is dominated by 3 (or more) of the following symptoms:

1. Stupor (i.e., no psychomotor activity; not actively relating to environment).
2. Catalepsy (i.e., passive induction of a posture held against gravity).
3. Waxy flexibility (i.e., slight, even resistance to positioning by examiner).
4. Mutism (i.e., no, or very little, verbal response [Note: not applicable if there is an established aphasia]).
5. Negativism (i.e., opposing or not responding to instructions or external stimuli).
6. Posturing (i.e., spontaneous and active maintenance of a posture...
against gravity).
7. Mannerism (i.e., odd, circumstantial caricature of normal actions).
8. Stereotypy (i.e., repetitive, abnormally frequent, non-goal-directed movements).
9. Agitation, not influenced by external stimuli.
11. Echolalia (i.e., mimicking another's speech).
12. Echopraxia (i.e., mimicking another's movements).

B. There is evidence from the history, physical examination, or laboratory findings that the disturbance is the direct pathophysiologic consequence of another medical condition.

C. The disturbance is not better explained by another mental disorder (e.g., a manic episode).

D. The disturbance does not occur exclusively during the course of a delirium.

E. The disturbance causes clinically significant distress or impairment in social, occupational, or other areas of functioning.

Coding note: Include the name of the medical condition in the name of the mental disorder (e.g., F06.1 catatonic disorder due to hepatic encephalopathy). The other medical condition should be coded and listed separately immediately before the catatonic disorder due to the medical condition (e.g., K71.90 hepatic encephalopathy; F06.1 catatonic disorder due to hepatic encephalopathy).

Benzodiazepines (typically lorazepam) and ECT are effective in adults and appear to be effective in children. Fig. 47.2 shows a treatment algorithm using a lorazepam challenge test (oral, intravenous, or intramuscular lorazepam, 1-2 mg). If the challenge test does reverse symptoms, increasing doses of lorazepam are indicated, with careful monitoring to avoid side effects. ECT may be indicated alone (if no improvement with lorazepam) or in combination with lorazepam if some but incomplete improvement is noted.
The outlook for catatonia is greatly impacted by that of the associated condition(s). The long-term outcome for patients treated with ECT is unknown, but mortality rates in catatonic patients declined after the introduction of ECT in treatment.

**Bibliography**

Cornic F, Consoli A, Cohen D. Catatonic syndrome in children
Among adults, hallucinations are viewed as synonymous with “psychosis” and as harbingers of serious psychopathology. In children, hallucinations can be part of normal development and more often than in adults can be associated with nonpsychotic psychopathology, psychosocial stressors, drug intoxication, or physical illness. The first clinical task in evaluating youth who report
Hallucinations is to sort out those associated with severe mental illness from those derived from other causes (Fig. 47.3).

**Clinical Manifestations**

**Hallucinations** are perceptions (typically auditory, visual, tactile, or olfactory) that occur in the absence of identifiable external stimuli. Hallucinations can be further categorized as *nondiagnostic* (hearing footsteps, knocking, or one's name) and *diagnostic* (hearing one or more voices saying words other than one's own name).

In children with nonpsychotic hallucinations, the other symptoms of psychosis are absent. *Nonpsychotic* hallucinations typically occur in the context of severe traumatic stress, developmental difficulties, social and emotional deprivation, parents whose own psychopathology promotes a breakdown in the child's sense of reality, cultural beliefs in mysticism, and unresolved mourning. *Auditory* hallucinations of voices telling the child to do “bad things” may be more often associated with disruptive behavior disorders than psychotic diagnoses. Hearing a voice invoking suicide is often associated with depression. Trauma-related auditory hallucinations are commonly associated with posttraumatic stress disorder or a brief psychotic disorder with marked stressors. The content of the
hallucinations may be relevant in understanding the underlying psychopathology and developmental issues.

**Diagnosis and Differential Diagnosis**

**Acute phobic hallucinations** are benign and common and occur in previously healthy preschool children. The hallucinations are often visual or tactile, last 10-60 min, and occur at any time but most often at night. The child is quite frightened and might complain that bugs or snakes are crawling over him or her and attempt to remove them. The cause is unknown. The differential diagnosis includes drug overdose or poisoning, high fever, encephalitis, and psychosis. The child's fear is not alleviated by reassurance by the parents or physician, and the child is not amenable to reason. Findings on physical and mental status examinations are otherwise normal. Symptoms can persist for 1-3 days, slowly abating over 1-2 wk.

The differential diagnosis of hallucinations comprises a broad range of mental disorders, including diagnoses in which hallucinations are not the hallmark feature, but may be viewed as associated symptoms (posttraumatic stress disorder, nonpsychotic mood disorders, and disruptive, impulse-control, and conduct disorders); diagnoses that are defined by psychotic features (brief psychotic disorder, schizophrenia, major depressive or bipolar disorder with psychotic features); and at-risk clinical states (poor reality testing). In addition, other medical conditions can manifest with hallucinations, including drug intoxications (cannabis, LSD, cocaine, amphetamines, barbiturates), medication side effects (e.g., corticosteroids, anticholinergics, stimulants), and physical illnesses (e.g., thyroid, parathyroid, and adrenal disorders; Wilson disease; electrolyte imbalances; infections; migraines; seizures; neoplasms).

**Treatment**

The evaluation of the underlying condition directs the type of treatment needed. Nonpsychotic hallucinations suggest the need for disorder-specific psychotherapy (e.g., trauma-focused CBT for posttraumatic stress disorder) and perhaps adjunctive medication (e.g., antidepressant for depression or anxiety, brief trial of antipsychotic for agitation). CBT focused on helping the youth understand the origin of the hallucinations and on developing coping strategies.
for stressful situations may be helpful for older children and adolescents. True psychotic hallucinations suggest the need for antipsychotic medication.

Chapter 48 Neurodevelopmental and Executive Function and Dysfunction
Chapter 49 Attention-Deficit/Hyperactivity Disorder
Chapter 50 Dyslexia
Chapter 51 Math and Writing Disabilities
Chapter 52 Language Development and Communication Disorders
Chapter 53 Developmental Delay and Intellectual Disability
Chapter 54 Autism Spectrum Disorder
Terminology and Epidemiology

A neurodevelopmental function is a basic brain process needed for learning and productivity. Executive function (EF) is an umbrella term used to describe specific neurocognitive processes involved in the regulating, guiding, organizing, and monitoring of thoughts and actions to achieve a specific goal. Processes considered to be “executive” in nature include inhibition/impulse control, cognitive/mental flexibility, emotional control, initiation skills, planning, organization, working memory, and self-monitoring. Neurodevelopmental and/or executive dysfunctions reflect any disruptions or weaknesses in these processes, which may result from neuroanatomic or psychophysiologic malfunctioning. Neurodevelopmental variation refers to differences in neurodevelopmental functioning. Wide variations in these functions exist within and between individuals. These differences can change over time and need not represent pathology or abnormality.

Neurodevelopmental and/or executive dysfunction places a child at risk for developmental, cognitive, emotional, behavioral, psychosocial, and adaptive challenges. Preschool-age children with neurodevelopmental or executive dysfunction may manifest delays in developmental domains such as language, motor, self-help, or social-emotional development and self-regulation. For the school-age child, an area of particular focus is academic skill development. The Diagnostic and Statistical Manual of Mental Disorder, Fifth Edition (DSM-5) classifies academic disorder within the group of neurodevelopmental disorders as specific learning disorder (SLD), with broadened diagnostic criteria recognizing impairments in reading, written expression, and mathematics. In the
International Classification of Diseases, Tenth Edition (ICD-10), neurodevelopmental disorders include specific developmental disorders of scholastic skills with specific reading disorder, mathematics disorder, and disorder of written expression. Dyslexia is categorized separately in ICD-10 under “Symptoms and Signs Not Elsewhere Classified.” Frontal lobe and executive function deficit is also included in this category. Disorders of executive function have traditionally been viewed as a component of attention-deficit/hyperactivity disorder (ADHD), which is also classified in DSM-5 as a neurodevelopmental disorder.

There are no prevalence estimates specifically for neurodevelopmental dysfunction, but overall estimates for learning disorders range from 3–10% with a similar range reported for ADHD. These disorders frequently co-occur. The range in prevalence is likely related to differences in definitions and criteria used for classification and diagnosis, as well as differences in methods of assessment.

Etiology and Pathogenesis

Neurodevelopmental and executive dysfunction may result from a broad range of etiologic factors, including genetic, medical, psychological, environmental, and sociocultural influences.

There is a high degree of heritability reported in learning and attention disorders, with estimates ranging from 45–80%. Specific genes have been identified that are associated with reading disorders, including the DYX2 locus on chromosome 6p22 and the DYX3 locus on 2p12. Neuroimaging studies have confirmed links between gene variations and variations in cortical thickness in areas of the brain known to be associated with learning and academic performance, such as the temporal regions. Chromosomal abnormalities can lead to unique patterns of dysfunction, such as visual-spatial deficits in girls diagnosed with Turner syndrome (see Chapter 98.4) or executive and language deficits in children with fragile X syndrome (Chapter 98.5). Chromosome 22q11.2 deletion syndrome (velocardiofacial-DiGeorge syndrome; Chapter 98.3) has been associated with predictable patterns of neurodevelopmental and executive dysfunction that can be progressive, including a higher prevalence of intellectual disability, as well as deficits in visual-spatial processing, attention, working memory, verbal learning, arithmetic, and language.

Genetic vulnerabilities may be further influenced by perinatal factors, including very low birthweight, severe intrauterine growth restriction, perinatal
hypoxic-ischemic encephalopathy, and prenatal exposure to substances such as alcohol and drugs. Increased risk of neurodevelopmental and executive dysfunction has also been associated with environmental toxins, including lead (see Chapter 739); drugs such as cocaine; infections such as meningitis, HIV, and Zika; and brain injury secondary to intraventricular hemorrhage, periventricular leukomalacia, or head trauma. The academic effects of concussion in children and adolescents, although usually temporary, have been well characterized, including impaired concentration and slowed processing speed. Repeated injuries have a much higher likelihood of long-term negative neurocognitive effects.

Early psychological trauma may result in both structural and neurochemical changes in the developing brain, which may contribute to neurodevelopmental and executive dysfunction. Findings suggest that the effects of exposure to trauma or abuse early in the developmental course can induce disruption of the brain's regulatory system and may influence right hemisphere function with associated risk for problems with information processing, memory, focus, and self-regulation. Environmental and sociocultural deprivation can lead to, or potentiate, neurodevelopmental and executive dysfunction, and numerous studies have indicated that parent/caregiver executive functioning impacts the development of EFs in offspring.

With regard to pathogenesis, investigations of neuroanatomic substrates have yielded important information about the underlying mechanisms in neurodevelopmental and executive dysfunction. Multiple neurobiologic investigations have identified differences in the left parietotemporal and left occipitotemporal brain regions of individuals with dyslexia compared to those without reading difficulties (see Chapter 50). Studies have also described the neural circuitry, primarily in the parietal cortex, underlying mathematical competencies such as the processing of numerical magnitude and mental arithmetic. The associations between executive dysfunction and the prefrontal/frontal cortex have been well established, and insults to the frontal lobe regions often result in dysfunction of executive abilities (e.g., poor inhibitory control). Although the prefrontal/frontal cortex may be the primary control region for EFs, there is considerable interconnectivity between the brain's frontal regions and other areas, such as arousal systems (reticular activating system), motivational and emotional systems (limbic system), cortical association systems (posterior/anterior; left/right hemispheres), and input/output systems (frontal motor/posterior sensory areas).
Core Neurodevelopmental Functions

The neurodevelopmental processes that are critical to a child's successful functioning may best be understood as falling within core neurodevelopmental domains. Notwithstanding such classification of domains, the clinical distinctions often made regarding “cognitive” processes (e.g., intelligence, EF, attention, language, memory) are relatively artificial because these brain functions are highly integrated.

Sensory and Motor Function

Sensory development (e.g., auditory, visual, tactile, proprioceptive) begins well before birth. This neurodevelopmental process is crucial in helping children experience, understand, and manipulate their environments. Sensory development progresses in association with environmental exposure and with the development of other cognitive processes, such as motor development. Through sensory experiences, children's brains mature as new neuronal pathways are created and existing pathways are strengthened.
